we also get that $I^\flat$ *has the global system invertibility in* $\mathcal{I}$ *and, therefore, we conclude that* $I^\flat$ *has the global system algebraizability in* $\mathcal{I}$*.*

On the other hand, $1 \in \{1,2\}$ *and* $\sigma^\flat_\Sigma[1,0] \leq \{\{1,2\}\}$*, but* $0 \notin \{1,2\}$*. Therefore,* $I^\flat$ *does not have the global family modus ponens in* $\mathcal{I}$ *and, hence, a fortiori, it does not have the global family syntactic algebraizability in* $\mathcal{I}$*.*

Note that the preceding example also shows that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic algebraizability but not the LF syntactic algebraizability in $\mathcal{I}$. We present also an additional example depicting a π-institution $\mathcal{I}$ with a set of natural transformations $I^\flat$, with two distinguished arguments, that has the GS syntactic algebraizability but not the LS syntactic algebraizability in $\mathcal{I}$.

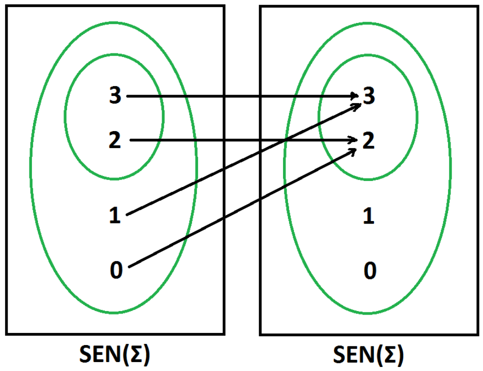
Example 741 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3\} \to \{0,1,2,3\}$ *given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
- $N^\flat$ *is the category of natural transformations generated by*
  - *a unary natural transformation* $\lambda^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\lambda^\flat_\Sigma : \{0,1,2,3\} \to \{0,1,2,3\}$ *be given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
  - *a ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2,3\}^3 \to \{0,1,2,3\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \textit{if } x = y \textit{ or } (x,y) = (0,1) \textit{ or } z = 2 \textit{ or } z = 3 \\ 0, & \textit{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{0,1,2,3\}\}.$$



Note that both theory families, $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems. So* $\mathcal{I}$ *is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global (family or system) syntactic algebraizability in* $\mathcal{I}$*, but it does not have the local (family or system) syntactic algebraizability in* $\mathcal{I}$*.*

Concerning global equivalence, the defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that the relation of global equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *is the identity relation. Therefore,* $I^\flat$ *has the global system equivalence in* $\mathcal{I}$*. Because of that, the global compatibility and the global modus ponens are trivially satisfied.*

Finally, consider the set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of natural transformations in* $N^\flat$*, given by* $\tau = \{\iota \approx \lambda^\flat\}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity natural transformation. Since, for every* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*, we have*

$$\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad \overleftrightarrow{I}_\Sigma[\phi, \lambda^\flat_\Sigma(\phi)] \le \mathrm{Thm}(\mathcal{I}),$$

we also get that $I^\flat$ *has the global system invertibility in* $\mathcal{I}$ *and, therefore, we conclude that* $I^\flat$ *has the global system algebraizability in* $\mathcal{I}$*.*

On the other hand, $\sigma^\flat_\Sigma(0,1,\xi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*, but* $\sigma^\flat_\Sigma(1,0,0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*, whence* $I^\flat$ *does not have the local symmetry in* $\mathcal{I}$ *and, therefore, a fortiori, fails to satisfy the local syntactic algebraizability in* $\mathcal{I}$*.*

We close with a transfer property for the syntactic algebraizability properties that we have focused on in this section.

Corollary 742 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has a (uniform) syntactic algebraizability property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* I *has the corresponding syntactic algebraizability property in* $\mathcal{A}$*.*

Proof: This follows directly from Corollary 730 and Proposition 736. ■

10.14 Regularity

We turn now to the study of various versions of the regularity property, based on the local versus global and the theory family versus theory system dualities.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local family regularity in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \text{ imply } I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$
- $I^\flat$ has the **local system regularity in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \text{ imply } I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$
- $I^\flat$ has the **global family regularity in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \text{ imply } I^\flat_\Sigma[\phi, \psi] \leq T;$$
- $I^\flat$ has the **global system regularity in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \text{ imply } I^\flat_\Sigma[\phi, \psi] \leq T.$$

We give now the hierarchy of regularity properties.

Proposition 743 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments.*

(a) If $I^\flat$ has the global family regularity, then it has the local family regularity in $\mathcal{I}$;

(b) If $I^\flat$ has the local family regularity, then it has the local system regularity in $\mathcal{I}$;

(c) $I^\flat$ has the global system regularity if and only if it has the local system regularity in $\mathcal{I}$.

Proof:

(a) Suppose that $I^\flat$ has the global family regularity in $\mathcal{I}$. Consider $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, we have, by hypothesis, $I^\flat_\Sigma[\phi, \psi] \leq T$. But this implies that $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $I^\flat$ has the local family regularity in $\mathcal{I}$.

(b) The conclusion follows directly from the fact that every theory system is a theory family of $\mathcal{I}$.

(c) For the "only if" direction, we repeat the argument used in the proof of Part (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families.

Suppose, conversely, that $I^\flat$ has the local system regularity in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi) \in T_{\Sigma'}.$$

Thus, by the local system regularity, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Since this holds for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$, we get that $I^\flat_\Sigma[\phi, \psi] \leq T$, Therefore, $I^\flat$ has the global system regularity in $\mathcal{I}$.

■

Proposition 743 has established the following hierarchy of regularity properties:

Global Family Regular

$\downarrow$

Local Family Regular

$\downarrow$

System Regular

We also note the following regarding natural sufficient conditions under which some of these properties coincide.

Proposition 744 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. If* $\mathcal{I}$ *is systemic, then all three regularity properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then the (global) system regularity property coincides with the family regularity property and this causes the collapsing of the hierarchy. ■

So in the case of a systemic π-institution $\mathcal{I}$, there is only one possible regularity property.

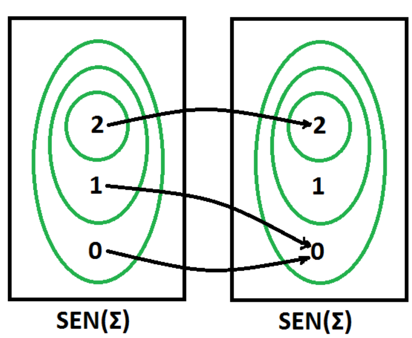
We provide some examples to show that the implications of Proposition 743 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding regularity properties are proper inclusions.

We first present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the local family regularity but not the global family regularity in $\mathcal{I}$.

Example 745 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } (x,y) = (1,1) \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments.*

$\mathcal{I}$ has three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* SEN *are theory systems. We show that $I^\flat$ has the local family regularity in $\mathcal{I}$, but it does not have the global family regularity in $\mathcal{I}$.*

For the local family regularity note, first, that $\sigma^\flat_\Sigma(2,2) = 2$, which takes care of $\mathrm{Thm}(\mathcal{I})$ *and that the case of* $\mathrm{SEN}^\flat$ *is trivial. So we only need to check the case with $T = \{\{1,2\}\}$. Since $\sigma^\flat_\Sigma(2,2) = \sigma^\flat_\Sigma(1,2) = \sigma^\flat_\Sigma(2,1) = 2$ and $\sigma^\flat_\Sigma(1,1) = 1$, the defining condition for local family regularity is also satisfied for $T = \{\{1,2\}\}$. Therefore, $I^\flat$ has the local family regularity in $\mathcal{I}$.*

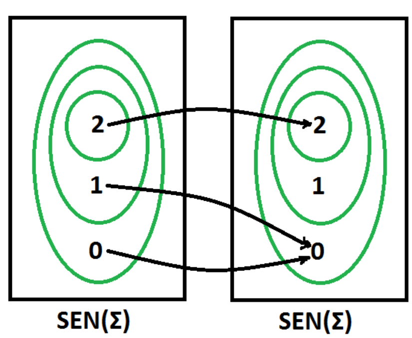
On the other hand, we have $1 \in \{1,2\}$ but $\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(1), \mathrm{SEN}^\flat(f)(1)) = \sigma^\flat_\Sigma(0,0) = 0 \notin \{1,2\}$. Thus, $1 \in T$, but $\sigma^\flat_\Sigma[1,1] \nleq T$, which shows that $I^\flat$ does not have the global family regularity in $\mathcal{I}$.

Next we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the system regularity but not the local family regularity in $\mathcal{I}$.

Example 746 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ and $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;*
- *$N^\flat$ is the category of natural transformations generated by the single binary natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by letting $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ be given, for all $a, b \in \mathrm{SEN}^\flat(\Sigma)$, by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$. Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat$ having two distinguished arguments.

$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$*, but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*. We show that $I^\flat$ has the (local) system regularity in $\mathcal{I}$, but it does not have the local family regularity in $\mathcal{I}$.*

For the local system regularity note that $\sigma^\flat_\Sigma(2,2) = 2$, which takes care of $\mathrm{Thm}(\mathcal{I})$*, and that the case of* $\mathrm{SEN}^\flat$ *is trivial.*

On the other hand, for the local family regularity, note that $1 \in T_\Sigma = \{1,2\}$, but $\sigma^\flat_\Sigma(1,1) = 0 \notin T_\Sigma$. Therefore $I^\flat$ does not have the local family regularity in $\mathcal{I}$.

We now prove a transfer property for regularity.

Proposition 747 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $I^\flat$ a collection of natural transformations $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $I^\flat$ has a regularity property in $\mathcal{I}$ if and only if, for every algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, I has the corresponding regularity property in $\mathcal{A}$.*

Proof: If I has a regularity property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same regularity property in $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$. Since $\langle \mathbf{F}, C^{\mathcal{F}}\rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding regularity property in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has a regularity property in $\mathcal{I}$. We look at each of the three properties in turn.

(a) Suppose $I^\flat$ has the global family regularity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get by global family regularity, $I^\flat_\Sigma[\phi,\psi] \le \alpha^{-1}(T)$. Thus, by Lemma 95, $I_{F(\Sigma)}[\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)] \le T$. We conclude that I has the global family regularity in $\mathcal{A}$.

(b) Suppose $I^\flat$ has the local family regularity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi \in \alpha^{-1}(T_{F(\Sigma)})$ and $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get by local family regularity, that

$$I^\flat_\Sigma(\phi,\psi,\vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}), \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma).$$

Thus, $\alpha_\Sigma(I^\flat_\Sigma(\phi,\psi,\vec{\xi})) \subseteq T_{F(\Sigma)}$ or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi),\alpha_\Sigma(\psi),\alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma).$$

It follows, taking into account the surjectivity of $\langle F,\alpha\rangle$, that I has the local family regularity in $\mathcal{A}$.

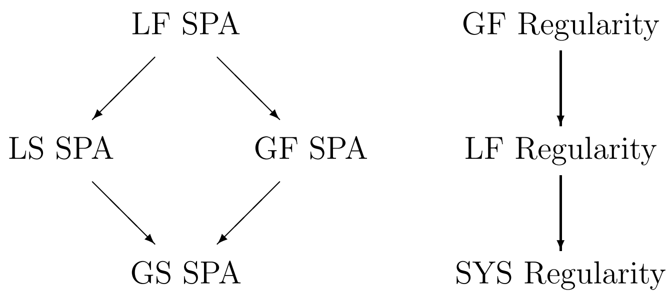
(c) The system regularity follows analogously, taking into account the fact that if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

■

10.15 Syntactic Regularity

In this section we focus on the four uniform syntactic protoalgebraicity properties, LF SPA, LS SPA, GF SPA and GS SPA, and we add to those versions of the regularity property to obtain several versions of the syntactic regularity property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown on the left below.



Moreover, by our study of regularity, we know that the various versions of regularity fall into the linear hierarchy shown on the right of the diagram.

By combining syntactic protoalgebraicity with regularity properties, we obtain twelve syntactic regularity properties as follows. Let $X \in \{\mathrm{LF}, \mathrm{LS}, \mathrm{GF}, \mathrm{GS}\}$ and $Y \in \{\mathrm{LF}, \mathrm{GF}, \mathrm{SYS}\}$, where LF stands for "Local Family", LS stands for "Local System", GF stands for "Global Family", GS stands for "Global System" and SYS stands for "SYStem", abbreviating both the local and the global system properties, in case they are identical.

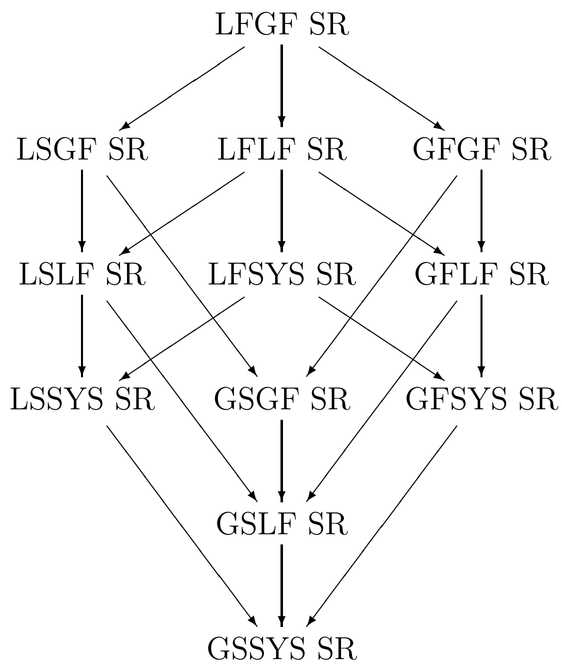
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments. We say that $I^\flat$ has the **XY syntactic regularity in** $\mathcal{I}$ (**XY SR in** $\mathcal{I}$) if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y regularity in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and regularity properties, we obtain the following hierarchical structure for the various flavors of the syntactic regularity property.

Corollary 748 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. The twelve syntactic regularity properties form the hierarchy shown on the accompanying diagram.*

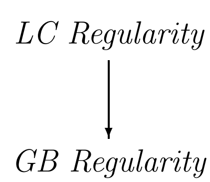
Proof: This follows directly from Corollary 726 and Proposition 743. ■



Based on the analysis performed on SPA and regularity, we have the following result regarding sufficient conditions under which some of the twelve syntactic regularity properties coincide.

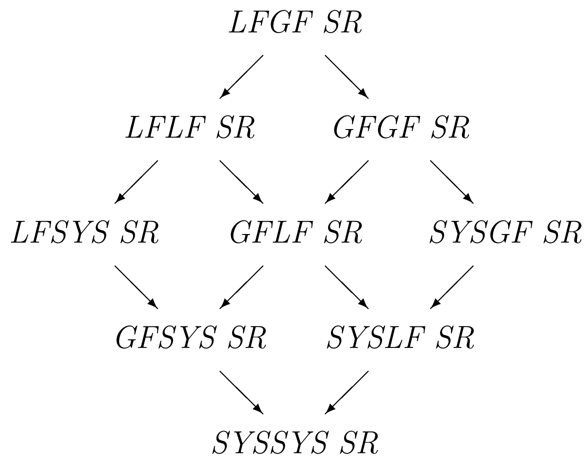
Corollary 749 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the syntactic regularity hierarchy collapses to the one depicted below;*



(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the syntactic regularity hierarchy collapses to the one depicted below, where the System versions of both the SPA and the invertibility properties are*

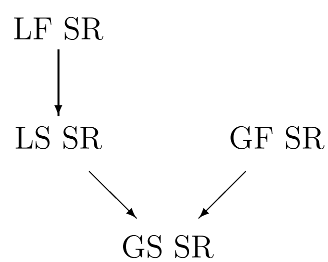
grouped together under the label SYS.



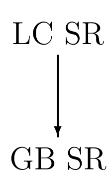
Proof: The statement follows from Corollary 727 and Proposition 743. ■

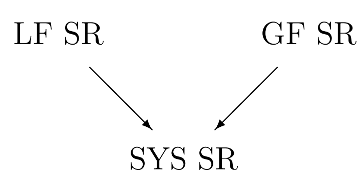
For a systemic π-institution with a parameter-free set of natural transformations, there is only one syntactic regularity property, since all versions of syntactic protoalgebraicity and all versions of regularity collapse to a single property.

Instead of studying this entire hierarchy in detail, we concentrate again on the uniformly defined classes. So we define **LF SR**, **LS SR**, **GF SR** and **GS SR** to mean, respectively, LFLF syntactic, LSLS syntactic, GFGF syntactic and GSGS syntactic regularity. These classes form, according to Corollary 748, the sub hierarchy depicted below.



Moreover, according to Corollary 749, this reduces to the hierarchy depicted on the left below for a systemic π-institution and to the one depicted on the right below for a parameter free set of natural transformations.





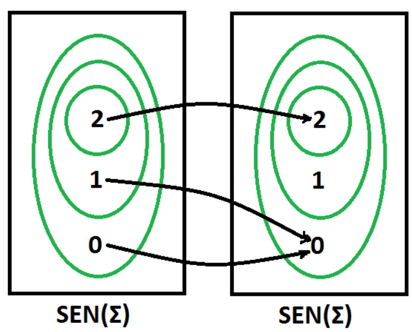
We provide examples to show that the inclusions between these four uniform classes of the syntactic regularity hierarchy are proper in general.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic regularity, but not the LF syntactic regularity in $\mathcal{I}$.

Example 750 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by a binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 1, & \text{if } \{x,y\} = \{1,2\} \\ 0, & \text{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

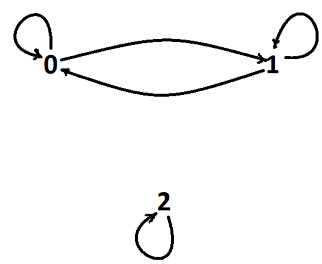
$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. So* $\mathcal{I}$ *is not systemic.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system syntactic regularity in* $\mathcal{I}$*, but it does not have the local family syntactic regularity in* $\mathcal{I}$*.*

First, we look at local system equivalence. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that the elements of* $\mathrm{SEN}^\flat(\Sigma)$ *are related in local system equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *as shown in the diagram. Therefore,* $I^\flat$ *has the local system equivalence in* $\mathcal{I}$*.*

Next, observe that, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$*, the pairs* $(\sigma^\flat_\Sigma(\phi,0), \sigma^\flat_\Sigma(\phi,1))$ *and* $(\sigma^\flat_\Sigma(0,\phi), \sigma^\flat_\Sigma(1,\phi))$ *are related via* $I^\flat$ *modulo* $\mathrm{Thm}(\mathcal{I})$*. Thus,* $I^\flat$ *has the local system congruence in* $\mathcal{I}$*.*



Next, note that, since the only pairs (ϕ,ψ)*, with* $\phi\neq\psi$*, such that* $\sigma^\flat_\Sigma(\phi,\psi)\in \mathrm{Thm}_\Sigma(\mathcal{I})$ *are* $(0,1)$ *and* $(1,0)$ *and for neither of these is* $\phi\in\mathrm{Thm}_\Sigma(\mathcal{I})$*,* $I^\flat$ *has the local system modus ponens in* $\mathcal{I}$*.*

Finally, for local system regularity, note that the defining condition is trivially satisfied for $\mathrm{SEN}^\flat$*, whereas, for* $\mathrm{Thm}(\mathcal{I})$*, we clearly have that, if* $\phi,\psi\in\mathrm{Thm}_\Sigma(\mathcal{I})$*, then* $\phi=\psi=2$*, whence* $\sigma^\flat_\Sigma(\phi,\psi)=2\in\mathrm{Thm}_\Sigma(\mathcal{I})$*. Therefore* $I^\flat$ *has the local system regularity in* $\mathcal{I}$ *and, therefore, we conclude that* $I^\flat$ *has the local system syntactic regularity in* $\mathcal{I}$*.*

On the other hand, $1\in\{1,2\}$ *and* $\sigma^\flat_\Sigma(1,0)=2\in\{1,2\}$*, but* $0\notin\{1,2\}$*. Therefore,* $I^\flat$ *does not have the local family modus ponens in* $\mathcal{I}$ *and, hence, a fortiori, it does not have the local family syntactic regularity in* $\mathcal{I}$*.*

Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic regularity but not the GF syntactic regularity in $\mathcal{I}$.

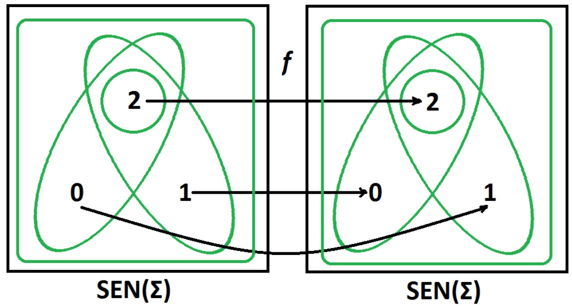
Example 751 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f:\Sigma\to\Sigma$*, such that* $f\circ f=i_\Sigma$*;*
- $\mathrm{SEN}^\flat:\mathbf{Sign}^\flat\to\mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma)=\{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f):\{0,1,2\}\to\{0,1,2\}$ *given by* $0\mapsto1$*,* $1\mapsto0$ *and* $2\mapsto2$*;*
- $N^\flat$ *is the category of natural transformations generated by a single binary natural transformation* $\sigma^\flat:(\mathrm{SEN}^\flat)^2\to\mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma:\{0,1,2\}^2\to\{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y)=\begin{cases}2, & \text{if } x=y \text{ or } \{x,y\}=\{0,1\}\\ 1, & \text{if } \{x,y\}=\{0,2\}\\ 0, & \text{if } \{x,y\}=\{1,2\}\end{cases}$$

Let $\mathcal{I}=\langle\mathbf{F},C\rangle$ *be the* π*-institution determined by*

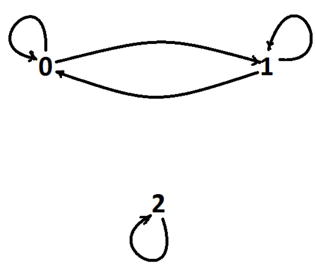
$$\mathcal{C}_\Sigma=\{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$



$\mathcal{I}$ has four theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{0,2\}\}$, $T' = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. In particular, $\mathcal{I}$ is not systemic.*

Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat$ having both arguments distinguished. We show that $I^\flat$ has the global system syntactic regularity in $\mathcal{I}$, but it does not have the global family syntactic regularity in $\mathcal{I}$.

First, we look at global system equivalence. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ in $\mathcal{I}$ are all trivially satisfied for $\mathrm{SEN}^\flat$. *For the theory system* $\mathrm{Thm}(\mathcal{I})$, *it suffices to observe that the elements of* $\mathrm{SEN}^\flat(\Sigma)$ *are related in global system equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *as shown in the diagram. Therefore, $I^\flat$ has the global system equivalence in $\mathcal{I}$.*



Next, observe that, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the pairs $(\sigma^\flat_\Sigma(\phi,0), \sigma^\flat_\Sigma(\phi,1))$ and $(\sigma^\flat_\Sigma(0,\phi), \sigma^\flat_\Sigma(1,\phi))$ are related via $I^\flat$ modulo $\mathrm{Thm}(\mathcal{I})$. *Thus, $I^\flat$ has the global system congruence in $\mathcal{I}$.*

Now note that, since the only pairs (ϕ,ψ), with $\phi \neq \psi$, such that $\sigma^\flat_\Sigma[\phi,\psi] \leq$ $\mathrm{Thm}(\mathcal{I})$ *are* $(0,1)$ *and* $(1,0)$ *and for neither of these is $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $I^\flat$ has the global system modus ponens in $\mathcal{I}$.*

For the global system regularity, note that the defining condition is satisfied trivially for $\mathrm{SEN}^\flat$, *whereas for* $\mathrm{Thm}(\mathcal{I})$, *if $\phi,\psi \in \mathrm{Thm}_\Sigma(\mathcal{I})$, then $\phi,\psi = 2$, whence we get $\sigma^\flat_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I})$. Therefore, we conclude that $I^\flat$ has the global system syntactic regularity in $\mathcal{I}$.*

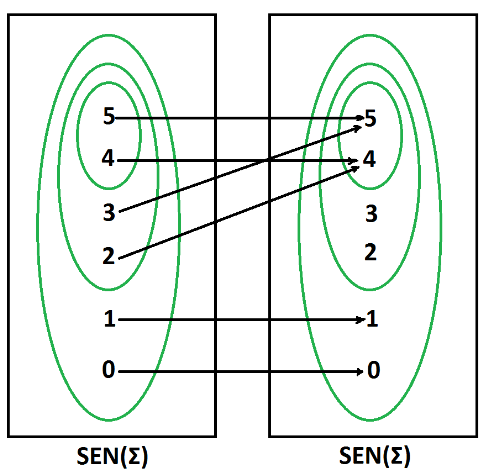
On the other hand, $1 \in \{1,2\}$ and $\sigma^\flat_\Sigma[1,0] \leq \{\{1,2\}\}$, but $0 \notin \{1,2\}$. Therefore, $I^\flat$ does not have the global family modus ponens in $\mathcal{I}$ and, hence, a fortiori, it does not have the global family syntactic regularity in $\mathcal{I}$.

Finally, we present an example of a π-institution $\mathcal{I}$ with a set of natural transformations $I^\flat$, with two distinguished arguments, that has the GS syntactic regularity but not the LS syntactic regularity in $\mathcal{I}$.

Example 752 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4,5\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3,4,5\} \to \{0,1,2,3,4,5\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 1$*,* $2 \mapsto 4$*,* $3 \mapsto 5$*,* $4 \mapsto 4$ *and* $5 \mapsto 5$*;*
- $N^\flat$ *is the category of natural transformations generated by a ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2,3,4,5\}^3 \to \{0,1,2,3,4,5\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 4, & \text{if } x = y \text{ or } \{x,y\} = \{4,5\} \\ & \quad \text{or } ((x,y) = (1,4) \text{ and } z = 0,1,4,5) \\ & \quad \text{or } ((x,y) = (1,5) \text{ and } z = 0,1,4,5) \\ 2, & \text{else if } \{x,y\} \subseteq \{2,3,4,5\} \\ & \qquad \text{or } (x,y) = (1,2) \text{ or } (x,y) = (1,3) \\ 0, & \text{otherwise} \end{cases}.$$



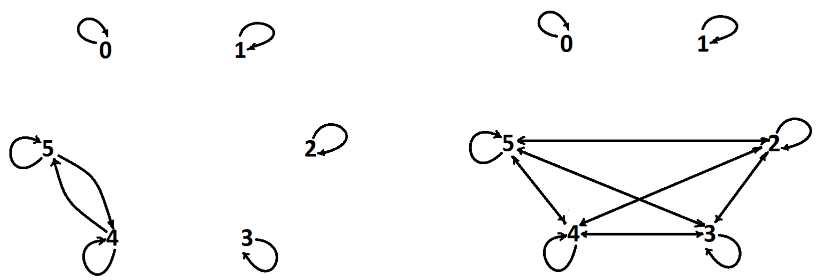
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{4,5\},\{2,3,4,5\},\{0,1,2,3,4,5\}\}.$$

Note that all three theory families, $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{2,3,4,5\}\}$ *and* $\mathrm{SEN}^\flat$*, are also theory systems. So* $\mathcal{I}$ *is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global (family or system) syntactic regularity in* $\mathcal{I}$*, but it does not have the local (family or system) syntactic regularity in* $\mathcal{I}$*.*

Concerning global equivalence, the defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that the relation of global equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *is the binary relation on* $\mathrm{SEN}^\flat(\Sigma)$ *depicted on the left graph in the figure. Moreover, the relation of global equivalence modulo*



T *is the binary relation on* $\mathrm{SEN}^\flat(\Sigma)$ *depicted on the right graph in the figure. Therefore,* $I^\flat$ *has the global system equivalence in* $\mathcal{I}$*.*

Looking at these two graphs and taking into account the definition of $\sigma^\flat$*, we can see that the defining conditions of the global compatibility and the global modus ponens are also satisfied for all three theory systems.*

For global regularity, note again that the defining condition is trivially satisfied for $\mathrm{SEN}^\flat$*, that* $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$*, if* $\phi,\psi \in \{4,5\}$*, and that* $\sigma^\flat_\Sigma[\phi,\psi] \leq T$*, if* $\phi,\psi \in \{2,3,4,5\}$*. Thus, we conclude that* $I^\flat$ *has the global regularity in* $\mathcal{I}$ *and, therefore,* $I^\flat$ *has the global system syntactic regularity in* $\mathcal{I}$*.*

On the other hand, $\sigma^\flat_\Sigma(1,2,\xi) = 2 \in T_\Sigma$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*, whereas* $\sigma^\flat_\Sigma(2,1,0) = 0 \notin T_\Sigma$*, whence* $I^\flat$ *does not have the local system symmetry in* $\mathcal{I}$ *and, therefore, a fortiori, fails to satisfy the local system syntactic regularity in* $\mathcal{I}$*.*

We close with a transfer property for the (uniform) syntactic regularity properties that we have studied in this section.

Corollary 753 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has a (uniform) syntactic regularity property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* I *has the corresponding syntactic regularity property in* $\mathcal{A}$*.*

Proof: This follows directly from Corollary 730 and Proposition 747. ∎

10.16 Modus Fortis

We conclude with the study of versions of the modus fortis (also known as the Wójcicki or the Rasiowa) property. In the next setion, we call Rasiowa property the combination of syntactic protoalgebraicity with the modus fortis.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments. We say that:

- $I^\flat$ has the **local family modus fortis** (**local family MF**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\psi \in T_\Sigma \text{ implies } I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$
- $I^\flat$ has the **local system modus fortis** (**local system MF**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\psi \in T_\Sigma \text{ implies } I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$
- $I^\flat$ has the **global family modus fortis** (**global family MF**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\psi \in T_\Sigma \text{ implies } I^\flat_\Sigma[\phi, \psi] \le T;$$
- $I^\flat$ has the **global system modus fortis** (**global system MF**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\psi \in T_\Sigma \text{ implies } I^\flat_\Sigma[\phi, \psi] \le T.$$

We give now the hierarchy of modus fortis properties.

Proposition 754 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $I^\flat$ *has the global family MF, then it has the local family MF in* $\mathcal{I}$*;*

(b) If $I^\flat$ *has the local family MF, then it has the local system MF in* $\mathcal{I}$*;*

(c) $I^\flat$ *has the global system MF if and only if it has the local system MF in* $\mathcal{I}$*.*

Proof:

(a) Suppose that $I^\flat$ has the global family MF in $\mathcal{I}$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\psi \in T_\Sigma$. Then, we have, by hypothesis, $I^\flat_\Sigma[\phi, \psi] \leq T$. This implies that $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $I^\flat$ has the local family MF in $\mathcal{I}$.

(b) The conclusion follows directly from the fact that every theory system is a theory family of $\mathcal{I}$.

(c) For the "only if" direction, we repeat the argument used in the proof of Part (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families.

Suppose, conversely, that $I^\flat$ has the local system MF in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\psi \in T_\Sigma$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\mathrm{SEN}^\flat(f)(\psi) \in T_{\Sigma'}$. Thus, by the local system MF, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Since this holds, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$, we get that $I^\flat_\Sigma[\phi, \psi] \leq T$, Therefore, $I^\flat$ has the global system MF in $\mathcal{I}$.

■

Proposition 754 has established the following hierarchy of Modus Fortis properties:

Global Family MF

↓

Local Family MF

↓

System MF

We also note the following regarding natural sufficient conditions under which some of these properties coincide.

Proposition 755 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. If* $\mathcal{I}$ *is systemic, then all three modus fortis properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then the (global) system MF coincides with the family MF property and this causes the collapsing of the hierarchy. ■

So in the case of a systemic π-institution $\mathcal{I}$, there is only one possible modus fortis property.

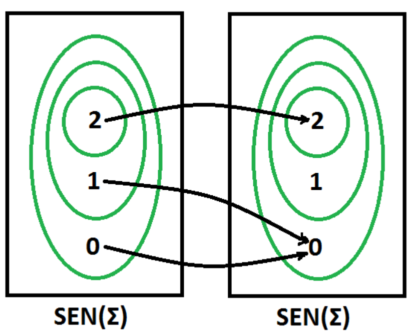
We provide some examples to show that the implications of Proposition 754 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding modus fortis properties are proper inclusions.

We first present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the local family MF but not the global family MF in $\mathcal{I}$.

Example 756 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } x \neq 2 \text{ and } y = 1 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$C_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\}.$$

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments.*

$\mathcal{I}$ *has three theory families, but only* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. We show that* $I^\flat$ *has the local family modus fortis, but it does not have the global family modus fortis in* $\mathcal{I}$.

For the local family MF note, first, that, for all $x \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(x,2) = 2$, *which takes care of* $\mathrm{Thm}(\mathcal{I})$, *and that the case of* $\mathrm{SEN}^\flat$ *is trivial. So we only need to check the case with* $T = \{\{1,2\}\}$. *Since, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(x,2) = 2$ *and, also,* $\sigma^\flat_\Sigma(0,1) = \sigma^\flat_\Sigma(1,1) = 1$ *and* $\sigma^\flat_\Sigma(2,1) = 2$, *the defining condition for local family MF is also satisfied for* $T = \{\{1,2\}\}$. *Therefore,* $I^\flat$ *has the local family MF in* $\mathcal{I}$.

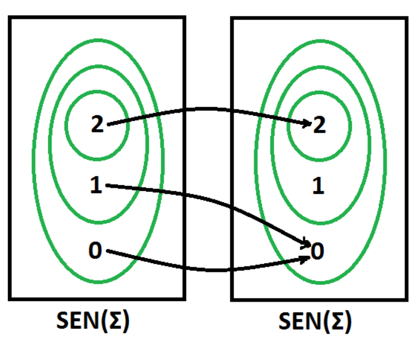
On the other hand, we have $1 \in \{1,2\}$ *but* $\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(0), \mathrm{SEN}^\flat(f)(1)) = \sigma^\flat_\Sigma(0,0) = 0 \notin \{1,2\}$. *Thus,* $1 \in T$, *but* $\sigma^\flat_\Sigma[0,1] \nsubseteq T$, *which shows that* $I^\flat$ *does not have the global family MF in* $\mathcal{I}$.

Next we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the system modus fortis but not the local family modus fortis in $\mathcal{I}$.

Example 757 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given, for all* $a, b \in \mathrm{SEN}^\flat(\Sigma)$, *by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat$ *having two distinguished arguments.*

$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$. *We show that* $I^\flat$ *has the (local) system MF in* $\mathcal{I}$, *but it does not have the local family MF in* $\mathcal{I}$.

For the local system MF note that, for all $x \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(x,2) = 2$, *which takes care of* $\mathrm{Thm}(\mathcal{I})$, *and that the case of* $\mathrm{SEN}^\flat$ *is trivial.*

On the other hand, for the local family MF, note that $1 \in T_\Sigma = \{1,2\}$, *but* $\sigma^\flat_\Sigma(0,1) = 0 \notin T_\Sigma$. *Therefore,* $I^\flat$ *does not have the local family MF in* $\mathcal{I}$.

We finally prove a transfer property for modus fortis.

Proposition 758 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $I^\flat$ *has an MF property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, I *has the corresponding MF property in* $\mathcal{A}$.

Proof: If I has an MF property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same property in $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}}\rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding MF property in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has an MF property in $\mathcal{I}$. We look at each of the three properties in turn.

(a) Suppose $I^\flat$ has the global family MF in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\psi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. Since, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get by global family MF, $I^\flat_\Sigma[\phi,\psi] \leq \alpha^{-1}(T)$. Thus, by Lemma 95,

$$I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.$$

We conclude that I has the global family MF in $\mathcal{A}$.

(b) Suppose $I^\flat$ has the local family MF in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\psi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. Since $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get by local family MF, that

$$I^\flat_\Sigma(\phi,\psi,\vec{\xi}) \subseteq \alpha^{-1}_\Sigma(T_{F(\Sigma)}), \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma).$$

Thus, $\alpha_\Sigma(I^\flat_\Sigma(\phi,\psi,\vec{\xi})) \subseteq T_{F(\Sigma)}$ or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma).$$

It follows, taking into account the surjectivity of $\langle F,\alpha\rangle$, that I has the local family MF in $\mathcal{A}$.

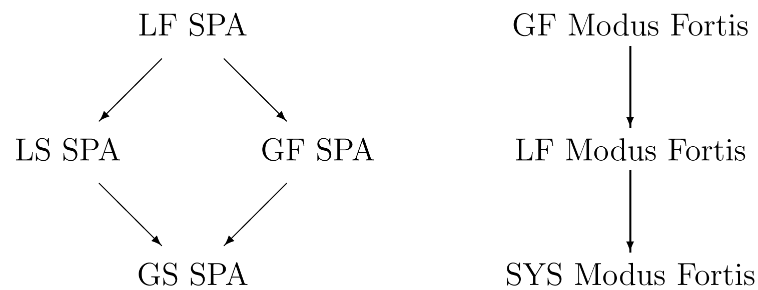
(c) The system MF follows analogously, taking into account the fact that if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

■

10.17 The Rasiowa Property

In this section we focus again on the four uniform syntactic protoalgebraicity properties, LF SPA, LS SPA, GF SPA and GS SPA, and we add to those versions of the modus fortis property to obtain several versions of the Rasiowa property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown on the left below.



Moreover, by our study of modus fortis, we know that the various versions of modus fortis (MF) fall into the linear hierarchy shown on the right of the diagram.

By combining syntactic protoalgebraicity with MF properties, we obtain twelve Rasiowa properties as follows. Let $X \in \{\mathrm{LF}, \mathrm{LS}, \mathrm{GF}, \mathrm{GS}\}$ and $Y \in \{\mathrm{LF}, \mathrm{GF}, \mathrm{SYS}\}$, where LF stands for "Local Family", LS stands for "Local System", GF stands for "Global Family", GS stands for "Global System" and SYS stands for "SYStem", abbreviating both the local and the global system properties, when they are identical.

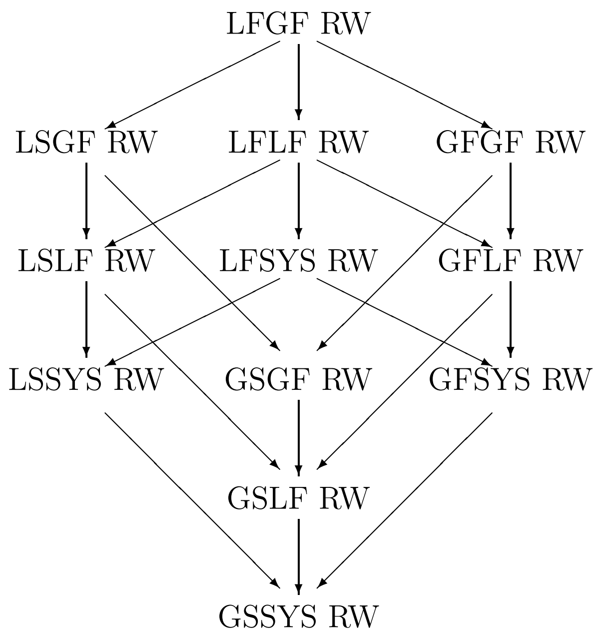
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments. We say that $I^\flat$ has the **XY Rasiowa property in $\mathcal{I}$** (**XY RW in $\mathcal{I}$**), or that $I^\flat$ is **XY Rasiowan in $\mathcal{I}$**, if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y modus fortis in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and MF properties, we obtain the following a priori hierarchical structure for the various flavors of the Rasiowa property.

Corollary 759 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments. The twelve Rasiowa properties form the hierarchy shown on the accompanying diagram.*

Proof: This follows directly from Corollary 726 and Proposition 754. ∎



It turns out that all these classes collapse to a single class! Indeed, as we show next, the only π-institutions, with a set of natural transformations having two distinguished arguments, satisfying the global system syntactic protoalgebraicity and the system modus fortis are the inconsistent ones. As a consequence, they also satisfy the local family syntactic protoalgebraicity and the global family modus fortis.

Proposition 760 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. If* $I^\flat$ *has the GSSYS Rasiowa property in* $\mathcal{I}$*, then* $\mathcal{I}$ *is inconsistent.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$. Since $I^\flat$ is reflexive, $I^\flat_\Sigma(\phi, \phi, \vec{\xi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\phi, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $\mathrm{Thm}_\Sigma(\mathcal{I}) \neq \varnothing$. Fix $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we get, using the SYS Rasiowa property, $I^\flat_\Sigma[\phi, t] \leq \mathrm{Thm}(\mathcal{I})$. Then, by GS symmetry, $I^\flat_\Sigma[t, \phi] \leq \mathrm{Thm}(\mathcal{I})$. Thus, by GS modus ponens, we get $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Since this holds for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we conclude that $\mathrm{Thm}(\mathcal{I}) = \mathrm{SEN}^\flat$ and, therefore, $\mathcal{I}$ is inconsistent. ∎

So the hierarchy of Corollary 759 consists actually of a single property, which we call the **Rasiowa property**, and the only π-institutions satisfying that property are the inconsistent ones.

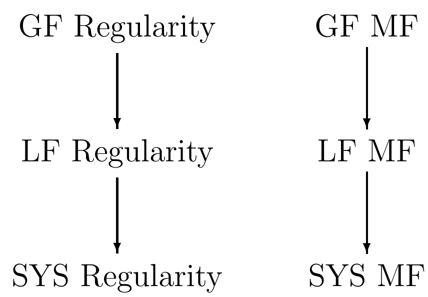
The Rasiowa property also transfers.

Corollary 761 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two* *distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $I^\flat$ *has the Rasiowa property in* $\mathcal{I}$ *if and only if, for every algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, I *has the Rasiowa property in* $\mathcal{A}$.

Proof: This follows directly from Corollary 730 and Proposition 758. ∎

10.18 Modus Fortis and Regularity

Recall the hierarchies of the regularity and modus fortis properties that we have introduced previously. These are depicted again below.



The various versions of these three properties are not independent. In fact the modus fortis properties imply the corresponding regularity properties. We prove these straightforward dependencies in the following two propositions.

Proposition 762 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

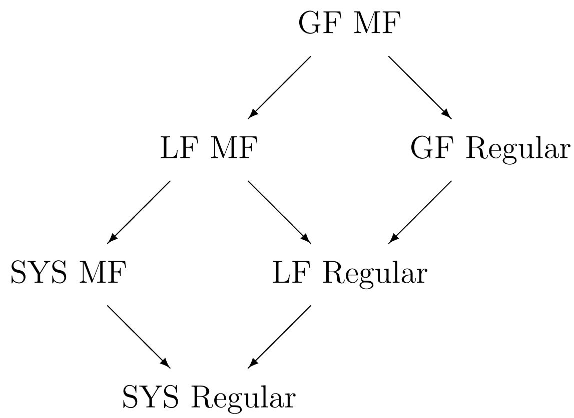
(a) If $I^\flat$ *has the global family MF, then it has the global family regularity in* $\mathcal{I}$*;*

(b) If $I^\flat$ *has the local family MF, then it has the local family regularity in* $\mathcal{I}$*;*

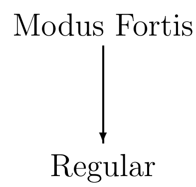
(c) If $I^\flat$ *has the system MF, then it has the system regularity in* $\mathcal{I}$.

Proof: We only provide a proof for Part (a), since Parts (b) and (c) can be proved in essentially the same way. So suppose that $I^\flat$ has the global family modus fortis in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $\psi \in T_\Sigma$ and $I^\flat$ has the global family modus fortis in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \psi] \leq T$. This show that $I^\flat$ has the global family regularity in $\mathcal{I}$. ∎

Proposition 762 together with the previously established hierarchies of regularity and modus fortis properties, establish the following combined hierarchy of these properties.



Recall, now that, if $\mathcal{I}$ is systemic, all three versions of regularity and modus fortis are identified. Therefore, in the case of a systemic π-institution $\mathcal{I}$ with a set $I^\flat$ of natural transformations having two distinguished arguments, the hierarchy above reduces to simply



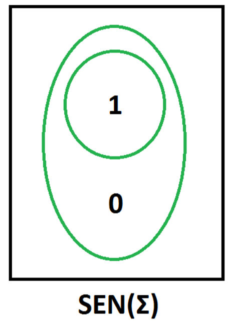
On the other hand, since the property of being parameter-free does not affect either the regularity or the Modus Fortis hierarchies, it has no effect on the mixed hierarchy either.

We present an example of a π-institution $\mathcal{I}$, with a set $I^\flat$ of natural transformations, having two distinguished variables, that has the global family regularity property in $\mathcal{I}$, but does not have the system modus fortis property in $\mathcal{I}$.

Example 763 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given, for all* $x,y \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\}$. *Consider the set* $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat$ *having two distinguished arguments.*

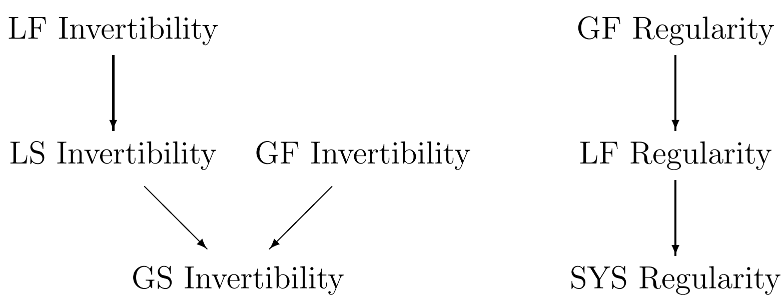
$\mathcal{I}$ *has two theory families* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$, *both of which are theory systems. So it is a systemic* π*-institution. We show that* $I^\flat$ *has the global family regularity in* $\mathcal{I}$, *but it does not have the system modus fortis in* $\mathcal{I}$.

For the global family regularity, note that the condition is trivial when $T = \mathrm{SEN}^\flat$, *whereas for* $T = \mathrm{Thm}(\mathcal{I})$, *if* $\phi = \psi = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *we have* $\sigma^\flat_\Sigma(1,1) = 1$, *which gives* $\sigma^\flat_\Sigma[1,1] \leq \mathrm{Thm}(\mathcal{I})$. *Thus,* $I^\flat$ *is indeed global family regular in* $\mathcal{I}$.

On the other hand, note that $1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *but* $\sigma^\flat_\Sigma(0,1) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$. *Therefore,* $I^\flat$ *does not have the system MF in* $\mathcal{I}$.

10.19 Regularity and Invertibility

Recall the hierarchies that we have introduced previously based on invertibility and regularity. These are depicted again below.



Connecting the regularity with the invertibility conditions requires additional hypotheses. Namely, we will suppose that the π-institution under consideration has natural theorems and satisfies some form of the modus ponens property.

Proposition 764 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$, *having natural theorems, and* $I^\flat$:

$(\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $I^\flat$ *has the global family modus ponens and the global family regularity, then it has the global family invertibility in* $\mathcal{I}$*;*

(b) If $I^\flat$ *has the local family modus ponens and the local family regularity, then it has the local family invertibility in* $\mathcal{I}$*;*

(c) If $I^\flat$ *has the local system modus ponens and the system regularity, then it has the local system invertibility in* $\mathcal{I}$*;*

(d) If $I^\flat$ *has the global system modus ponens and the system regularity, then it has the global system invertibility in* $\mathcal{I}$*.*

Proof: We only provide a proof for Part (a), since Parts (b)-(d) can be proved in essentially the same way. Let $\top^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ be a natural theorem and suppose that $I^\flat$ has the global family modus ponens and the global family regularity in $\mathcal{I}$. Consider the singleton $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, given by

$$\tau^\flat = \{\top^\flat \approx \iota\},$$

where $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ is the identity natural transformation. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$.

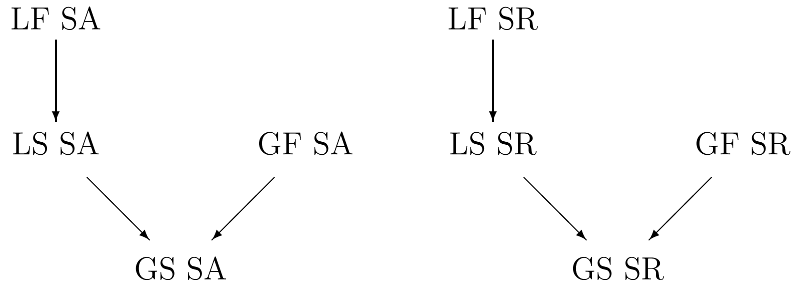
- If $\phi \in T_\Sigma$, then, since $\top^\flat_\Sigma(\phi) \in \mathrm{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by global family regularity, $I^\flat_\Sigma[\top^\flat_\Sigma(\phi), \phi] \leq T$, i.e., $I^\flat_\Sigma[\tau^\flat_\Sigma(\phi)] \leq T$.

- Suppose, conversely, that $I^\flat_\Sigma[\tau^\flat_\Sigma(\phi)] \leq T$. Then $I^\flat_\Sigma[\top^\flat_\Sigma(\phi), \phi] \leq T$. Since $\top^\flat_\Sigma(\phi) \in T_\Sigma$, we get, by global family modus ponens, $\phi \in T_\Sigma$.

We conclude that $\phi \in T_\Sigma$ if and only if $I^\flat_\Sigma[\tau^\flat_\Sigma(\phi)] \leq T$. Thus, $I^\flat$ has the global family invertibility in $\mathcal{I}$, with witnessing set of natural transformations $\tau^\flat$. ■

10.20 The Algebraic Hierarchy

Recall the three hierarchies that we have introduced previously based on uniform combinations of the syntactic protoalgebraizability properties and the invertibility, regularity and modus fortis properties. These formed the hierarchies of syntactically algebraizable (SA), syntactically regular (SR) and Rasiowa properties, respectively. The first two are depicted again below, whereas the last consists of a single property, which, as we saw in Proposition 760, is characteristic of inconsistent π-institutions.



The various versions of these three properties are not independent. Since, as was shown in Proposition 762, the modus fortis properties imply the corresponding regularity properties and, as was shown in Proposition 764, regularity properties, fortified with some form of the modus ponens, imply the corresponding invertibility properties, we obtain ensuing relationships between the Rasiowa, syntactic regularity and syntactic algebraizability properties.

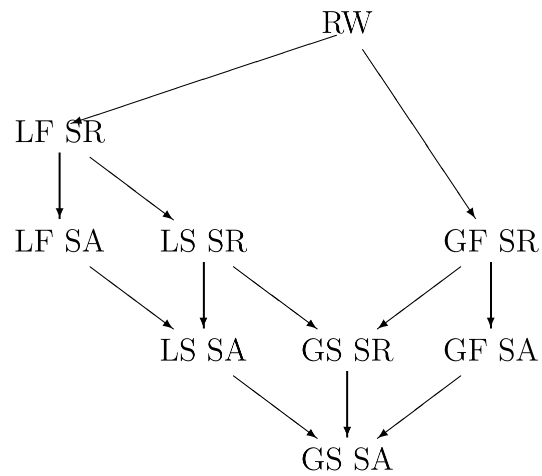
Corollary 765 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. If* $I^\flat$ *has the Rasiowa property, then it has all four syntactic regularity properties.*

Proof: Directly from the definitions and Proposition 762. ∎

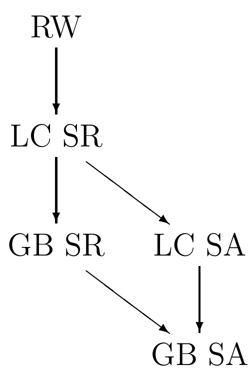
Corollary 766 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. If* $I^\flat$ *has a syntactic regularity property, then it has the corresponding syntactic algebraizability property in* $\mathcal{I}$*.*

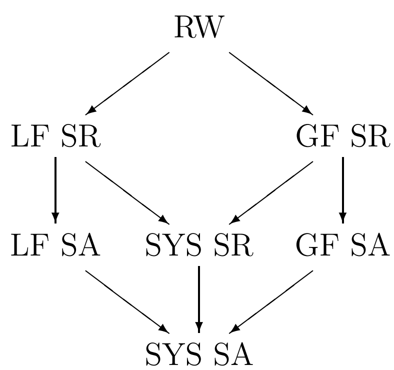
Proof: We present in detail the reasoning for the global family versions. Suppose that $I^\flat$ is a set of natural transformations, with two distinguished arguments, having the global family syntactic regularity in $\mathcal{I}$. Note that, by global family syntactic protoalgebraicity, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I})$. Thus, $\mathcal{I}$ has natural theorems. Moreover, by the definition of global family syntactic regularity, $I^\flat$ has both the global family modus ponens and the global family regularity in $\mathcal{I}$. It follows now, by Proposition 764, that $I^\flat$ has the global family invertibility in $\mathcal{I}$. Thus, it also has the global family syntactic algebraizability in $\mathcal{I}$. ∎

Corollaries 765 and 766 together with the previously established hierarchies of syntactic algebraizability, syntactic regularity and Rasiowa properties, establish the following combined hierarchy of these properties.



Recall, now that, if $\mathcal{I}$ is systemic, then the two local versions and the two global versions of syntactic algebraizability become identified and that the same holds for syntactic regularity. Therefore, in the case of a systemic π-institution $\mathcal{I}$ with a set $I^\flat$ of natural transformations having two distinguished arguments, the hierarchy above reduces to the simpler hierarchy shown on the left below.





Furthermore, the property of being parameter-free has the effect of collapsing the two versions of system syntactic algebraizability and the two versions of system syntactic regularity properties. Thus, the hierarchy of the three properties for parameter-free sets of natural transformations $I^\flat$ in $\mathcal{I}$ is given by the diagram shown on the right above.

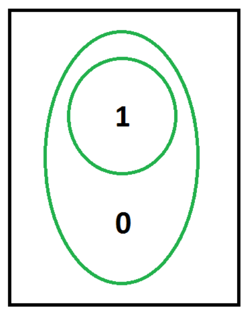
We present some examples to show that all inclusions in the diagram of the hierarchy of Rasiowa, syntactic regularity and syntactic algebraizablity properties are proper in general.

We first present an example of a π-institution $\mathcal{I}$, with a set $I^\flat$ of natural transformations, with two distinguished arguments, that has the local and global family syntactic regularity properties in $\mathcal{I}$, but does not have the Rasiowa property in $\mathcal{I}$.

Example 767 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given, for all* $x, y \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\}$*.* $\mathcal{I}$ *has two theory families* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, both of which are theory systems. So it is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has (all kinds of) the syntactic regularity in* $\mathcal{I}$*, but it does not have the Rasiowa property in* $\mathcal{I}$*.*

First, we look at the equivalence property. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *coincides with the identity relation on* $\mathrm{SEN}^\flat(\Sigma)$*. Therefore,* $I^\flat$ *has the local system equivalence in* $\mathcal{I}$*.*

The fact that equivalence modulo $\mathrm{Thm}(\mathcal{I})$ *is the identity relation immediately implies that* $I^\flat$ *also has the compatibility property and the modus ponens in* $\mathcal{I}$*.*

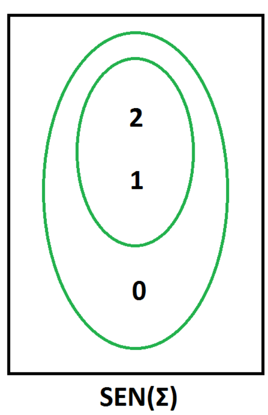
Finally, for regularity, note that the defining condition is trivially satisfied for $\mathrm{SEN}^\flat$*, whereas, for* $\mathrm{Thm}(\mathcal{I})$*, we clearly have that, if* $\phi, \psi \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, then* $\phi = \psi = 1$*, whence* $\sigma^\flat_\Sigma(\phi,\psi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. Therefore* $I^\flat$ *has the regularity property in* $\mathcal{I}$ *and, therefore, we conclude that* $I^\flat$ *has the syntactic regularity in* $\mathcal{I}$*.*

On the other hand, since $\mathcal{I}$ is not an inconsistent π-institution, $I^\flat$ does not have the Rasiowa property in $\mathcal{I}$.

Next, we look at an example of a π-institution $\mathcal{I}$, with a set $I^\flat$ of natural transformations, with two distinguished arguments, that has the local and global family syntactic algebraizability properties in $\mathcal{I}$, but does not possess the global system syntactic regularity in $\mathcal{I}$.

Example 768 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by*
  - *a unary natural transformation* $\lambda^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\lambda^\flat_\Sigma : \{0,1,2\} \to \{0,1,2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*
  $$\lambda^\flat_\Sigma(x) = \begin{cases} 2, & \text{if } x = 2 \\ 1, & \text{otherwise} \end{cases};$$
  - *a binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given, for all* $x, y \in \mathrm{SEN}^\flat(\Sigma)$*, by*
  $$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1,2\},\{0,1,2\}\}$*.* $\mathcal{I}$ *has two theory families* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, both of which are theory systems. So it is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has (all kinds of) the syntactic algebraizability in* $\mathcal{I}$*, but it does not have (any kind of) the syntactic regularity in* $\mathcal{I}$*.*

First, we look at the equivalence property. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *coincides with the identity relation on* $\mathrm{SEN}^\flat(\Sigma)$*. Therefore,* $I^\flat$ *has the local system equivalence in* $\mathcal{I}$*.*

The fact that equivalence modulo $\mathrm{Thm}(\mathcal{I})$ *is the identity relation immediately implies that* $I^\flat$ *also has the compatibility property and the modus ponens in* $\mathcal{I}$*.*

Finally, for invertibility, consider the set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of natural transformations in* $N^\flat$*, defined by* $\tau = \{\iota \approx \lambda^\flat\}$*. Note that the defining condition is trivially satisfied for* $\mathrm{SEN}^\flat$*, whereas, for* $\mathrm{Thm}(\mathcal{I})$*, we clearly have that,*

$$\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad \sigma^\flat_\Sigma(\phi, \lambda^\flat_\Sigma(\phi)) \in \mathrm{Thm}_\Sigma(\mathcal{I}).$$

Therefore, $I^\flat$ *has the invertibility and, hence, the syntactic algebraizability property in* $\mathcal{I}$*.*

On the other hand, we have $1, 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, but* $\sigma^\flat_\Sigma(1,2) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*. Therefore,* $I^\flat$ *fails to have the regularity property and, hence, a fortiori, does not have the syntactic regularity property in* $\mathcal{I}$*.*

Chapter 11

The Syntactic Leibniz Hierarchy: Foundations

11.1 Syntactic Prealgebraicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **prealgebraic** if, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

We say that $\mathcal{I}$ is **syntactically prealgebraic** if there exists $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that $I^\flat$ has:

- reflexivity;
- global system transitivity;
- global system compatibility; and
- global system modus ponens.

In that case, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic prealgebraicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically prealgebraic π-institution, with witnessing transformations $I^\flat$, then $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T, for all $T \in \mathrm{ThSys}(\mathcal{I})$. As a consequence, using Corollary 98, we may conclude that, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\overleftrightarrow{I^\flat}(T) = \Omega(T).$$

Proposition 769 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations $I^\flat$, then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T.*

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$.

Since $I^\flat$ is reflexive in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I}) \leq T$. Therefore, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \phi] \leq T$, which shows that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Suppose, next, that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Thus, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \leq T$. By the definition of $\overleftrightarrow{I^\flat}$, we get $\overleftrightarrow{I^\flat}_\Sigma[\psi, \phi] \leq T$ and, hence, $\langle \psi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Next, assume that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Then we get $\langle \phi, \psi \rangle$, $\langle \psi, \chi \rangle$, $\langle \psi, \phi \rangle$, $\langle \chi, \psi \rangle \in I^\flat_\Sigma(T)$. Since $I^\flat$ is globally system transitive in $\mathcal{I}$, we conclude that $\langle \phi, \chi \rangle$, $\langle \chi, \phi \rangle \in I^\flat_\Sigma(T)$ and, therefore, $\langle \phi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

To show the congruence property, assume that $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is a natural transformation in $N^\flat$ and that $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, for all $i < k$. Thus, since $I^\flat$ has the global system compatibility in $\mathcal{I}$, we get that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle \in I^\flat_\Sigma(T)$. By symmetry, we also get $\langle\sigma^\flat_\Sigma(\vec{\psi}),\sigma^\flat_\Sigma(\vec{\phi})\rangle \in I^\flat_\Sigma(T)$ and, hence, that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Finally, since by Lemma 93, $\overleftrightarrow{I^\flat}(T)$ is a relation system on $\mathbf{F}$, we conclude that $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$.

To conclude the proof, note that, if $\phi \in T_\Sigma$ and $\langle\phi,\psi\rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, then $\psi \in T_\Sigma$ by the global system modus ponens of $I^\flat$ in $\mathcal{I}$ and the fact that $I^\flat \subseteq \overleftrightarrow{I^\flat}$. ■

Based on Proposition 769, we can conclude that $\overleftrightarrow{I^\flat}$ defines the Leibniz congruence systems of the theory systems of $\mathcal{I}$.

Corollary 770 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically prealgebraic, with witnessing transformations* $I^\flat$*, if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\overleftrightarrow{I^\flat}(T) = \Omega(T).$$

Proof: The only if is by Proposition 769 and Corollary 98. The if is obvious, since the displayed equations immediately implies the four properties of $\overleftrightarrow{I^\flat}$ defining syntactic prealgebraicity. ■

Corollary 770 has as an immediate consequence the important fact that syntactic prealgebraicity implies (semantic) prealgebraicity.

Theorem 771 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is syntactically prealgebraic, then it is prealgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $I^\flat$. Let $T,T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \le T'$. Then

$$\begin{array}{rcll}\Omega(T) & = & \overleftrightarrow{I^\flat}(T) & \text{(by Corollary 770)}\\ & \le & \overleftrightarrow{I^\flat}(T') & \text{(by Lemma 94)}\\ & = & \Omega(T'). & \text{(by Corollary 770)}\end{array}$$

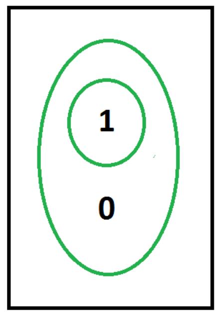
Thus, $\mathcal{I}$ is prealgebraic. ■

The following example shows that the inclusion of Theorem 771 is proper.

Example 772 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*

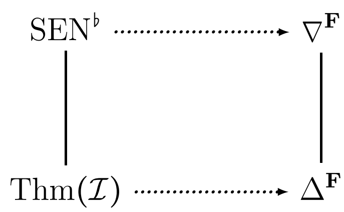
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*
$$\sigma^\flat_\Sigma(x,y) = 1, \quad \textit{for all } x,y \in \{0,1\}.$$



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$*.*

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, which are also theory systems. Clearly,* $\mathrm{Thm}(\mathcal{I}) \le \mathrm{SEN}^\flat$*. Moreover,* $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ *and* $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$*. Since* $\Omega(\mathrm{Thm}(\mathcal{I})) \le \Omega(\mathrm{SEN}^\flat)$*,* $\mathcal{I}$ *is prealgebraic.*



On the other hand, there does not exist $I^\flat \subseteq N^\flat$*, such that* $I^\flat$ *has the required properties to constitute a witnessing set of transformations in* $\mathcal{I}$*. Any set containing projections cannot satisfy reflexivity and the set consisting only of* $\sigma^\flat$ *does not satisfy the modus ponens property. We conclude that* $\mathcal{I}$ *is not syntactically prealgebraic.*

We provide, next, a characterization of syntactic prealgebraicity in terms of the global system modus ponens property of a subset of natural transformations intrinsically associated with the π-institution. Later, we use this characterization to provide an exact description of those prealgebraic π-institutions which are syntactically prealgebraic.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. We define the **reflexive core** of $\mathcal{I}$ to be the collection
$$R^{\mathcal{I}} = \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \le \mathrm{Thm}(\mathcal{I}))\}.$$

Note that the defining condition is equivalent to asserting that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\rho^\flat_\Sigma(\phi, \phi, \vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathcal{I}).$$

It is clear that $R^{\mathcal{I}}(T)$ is a reflexive relation system on $\mathbf{F}$, for every theory family T of $\mathcal{I}$.

Lemma 773 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $R^{\mathcal{I}}(T)$ *is a reflexive relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. That $R^{\mathcal{I}}(T)$ is a relation system follows from Lemma 93. For reflexivity, it is required that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\langle \phi, \phi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. But this is equivalent to $R^{\mathcal{I}}_\Sigma[\phi, \phi] \le T$, which certainly holds, since, by definition of $R^{\mathcal{I}}$, $R^{\mathcal{I}}_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I}) \le T$. ∎

Now, using Proposition 97, we draw a useful conclusion about the role of the reflexive core in determining the Leibniz congruence system associated with a given theory family.

Proposition 774 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) \le R^{\mathcal{I}}(T).$$

Proof: By Lemma 773 and Proposition 97. ∎

We next show that, for every theory family T of $\mathcal{I}$, $R^{\mathcal{I}}(T)$ is also a symmetric relation system on $\mathbf{F}$.

Lemma 775 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $R^{\mathcal{I}}(T)$ *is a symmetric relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. That $R^{\mathcal{I}}(T)$ is a relation system follows from Lemma 93. To show that it is symmetric, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. Equivalently, $R^{\mathcal{I}}_\Sigma[\phi, \psi] \le T$. Now consider any $\rho^\flat \in R^{\mathcal{I}}$. By the definition of $R^{\mathcal{I}}$, we get that $\overline{\rho^\flat} \in R^{\mathcal{I}}$. Therefore, by the hypothesis, $\overline{\rho^\flat}_\Sigma[\phi, \psi] \le T$. But this gives $\rho^\flat_\Sigma[\psi, \phi] \le T$. Since this holds for all $\rho^\flat \in R^{\mathcal{I}}$, we conclude that $R^{\mathcal{I}}_\Sigma[\psi, \phi] \le T$. Hence, $\langle \psi, \phi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. Therefore, $R^{\mathcal{I}}(T)$ is a symmetric relation system on $\mathbf{F}$. ∎

We turn, next, to the congruence compatibility property. More precisely, we show that, for all theory families T of $\mathcal{I}$, $R^{\mathcal{I}}(T)$ has the compatibility property in $\mathbf{F}$.

Lemma 776 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $R^{\mathcal{I}}(T)$ *has the compatibility property in* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Note that, because of Corollary 12, it suffices to show that, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$, and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in R^{\mathcal{I}}_\Sigma(T) \quad \text{implies} \quad \langle \sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi}) \rangle \in R^{\mathcal{I}}_\Sigma(T).$$

Suppose, $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in R^{\mathcal{I}}_\Sigma(T)$ or, equivalently, $R^{\mathcal{I}}_\Sigma[\phi, \psi] \le T$. Let $\rho^\flat : (\mathrm{SEN}^\flat)^n \to \mathrm{SEN}^\flat$ be arbitrary in $R^{\mathcal{I}}$. We consider the natural transformation $\rho'^\flat : (\mathrm{SEN}^\flat)^{n+k} \to \mathrm{SEN}^\flat$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\zeta, \eta, \vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, by

$$\rho'^\flat_\Sigma(\zeta, \eta, \vec{\chi}, \vec{\xi}) = \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta, \vec{\chi}), \sigma^\flat_\Sigma(\eta, \vec{\chi}), \vec{\xi}).$$

Now note that, since $\sigma^\flat \in N^\flat$, $\rho^\flat \in N^\flat$ and

$$\begin{aligned}\rho'^\flat \quad = \quad & \rho^\flat \circ \langle \sigma^\flat \circ \langle p^{n+k,0}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \sigma^\flat \circ \langle p^{n+k,1}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \\ & p^{n+k,k+1}, \dots, p^{n+k,n+k-1} \rangle,\end{aligned}$$

we get, by the definition of a category of natural transformations, that $\rho'^\flat \in N^\flat$.

Next, note that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\zeta, \vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}\rho'^\flat_\Sigma(\zeta, \zeta, \vec{\chi}, \vec{\xi}) \quad &= \quad \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta, \vec{\chi}), \sigma^\flat_\Sigma(\zeta, \vec{\chi}), \vec{\xi}) \quad \text{(by definition of } \rho'^\flat) \\ &\in \quad \mathrm{Thm}_\Sigma(\mathcal{I}). \quad \text{(since } \rho^\flat \in R^{\mathcal{I}}).\end{aligned}$$

Thus, by the definition of the reflexive core, we get that $\rho'^\flat \in R^{\mathcal{I}}$.

Now since $\rho'^\flat \in R^{\mathcal{I}}$ and, by hypothesis, $R^{\mathcal{I}}_\Sigma[\phi, \psi] \le T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \vec{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\phi, \vec{\chi})), \mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\psi, \vec{\chi})), \vec{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho^\flat_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \le T.$$

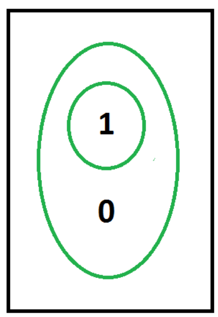
Since this holds for all $\rho^\flat \in R^{\mathcal{I}}$, we get that $R^{\mathcal{I}}_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \le T$ or, equivalently, $\langle \sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi}) \rangle \in R^{\mathcal{I}}_\Sigma(T)$. Therefore, $R^{\mathcal{I}}(T)$ has the congruence compatibility property in $\mathbf{F}$. ■

It is possible, but not necessary, that the reflexive core of a π-institution has the global system modus ponens. To see this, we present two examples. In the first example, we look at a π-institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does have the global system modus ponens in $\mathcal{I}$.

Example 777 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 0, & \text{if } (x,y) = (1,0) \\ 1, & \text{otherwise} \end{cases}.$$



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$*. The only theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems.*

Note that $\sigma^\flat \in R^{\mathcal{I}}$*, since, for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. On the other hand, no projection natural transformation can be in the reflexive core.*

To see that $R^{\mathcal{I}}$ *satisfies the global system modus ponens in* $\mathcal{I}$*, note that it does so trivially for the theory system* $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, it is possible that* $\sigma^\flat_\Sigma(\phi,\psi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $\phi = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *only if* $\psi = 1$*. Thus,* $R^{\mathcal{I}}$ *has the global system MP in* $\mathcal{I}$*, as claimed.*

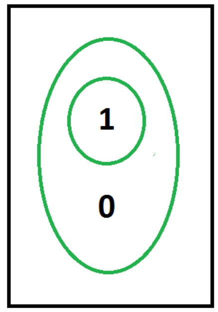
Next, we present an example of a π-institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does not have the global system modus ponens in $\mathcal{I}$.

Example 778 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*

- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = 1, \quad \textit{for all } x,y \in \{0,1\}.$$



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$*. So its two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems.*

Note that $\sigma^\flat \in R^{\mathcal{I}}$*, since, for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. On the other hand, no projection natural transformation can be in the reflexive core.*

To see that $R^{\mathcal{I}}$ *does not satisfy the global system modus ponens in* $\mathcal{I}$*, note that* $1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and that* $\sigma^\flat_\Sigma(1,0) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, but* $0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*. Thus,* $R^{\mathcal{I}}$ *does not have the global system MP in* $\mathcal{I}$*.*

It turns out that possession of the global system modus ponens by the reflexive core intrinsically characterizes syntactic prealgebraicity. We can show, at the outset, that the reflexive core having the global system modus ponens is necessary for syntactic prealgebraicity.

Theorem 779 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically prealgebraic, then* $R^{\mathcal{I}}$ *has the global system modus ponens.*

Proof: Suppose that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $I^\flat$. Thus, $I^\flat$ has reflexivity, global system transitivity, global system compatibility and the global system modus ponens in $\mathcal{I}$. Since $I^\flat$ is reflexive in $\mathcal{I}$, we get, by the definition of the reflexive core, that $I^\flat \subseteq R^{\mathcal{I}}$. But, then, since, by hypothesis, $I^\flat$ has the global system modus ponens, it follows that, a fortiori, $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$. ■

In proving the reverse implication, we now show that having the global system modus ponens implies the global system transitivity property of the reflexive core.

Proposition 780 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *has the global system modus ponens, then it also has the global system transitivity in* $\mathcal{I}$*.*

Proof: Suppose that $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$ and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. This means that $R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 776, we get that, for all $\rho^\flat \in R^{\mathcal{I}}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$R^{\mathcal{I}}_{\Sigma'}[\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}), \rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi})] \leq T.$$

Since $R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$, we get by the global system MP of $R^{\mathcal{I}}$ that, for all $\rho^\flat \in R^{\mathcal{I}}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Thus, $R^{\mathcal{I}}_\Sigma[\phi, \chi] \leq T$, whence $\langle \phi, \chi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. Therefore $R^{\mathcal{I}}$ has the global system transitivity in $\mathcal{I}$. ■

Proposition 780 closes a line of work that was started with the definition of a reflexive core and with Lemma 773.

Theorem 781 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *has the global system modus ponens, then* $\mathcal{I}$ *is syntactically prealgebraic, with witnessing transformations* $R^{\mathcal{I}}$*.*

Proof: By Lemma 773, $R^{\mathcal{I}}$ is reflexive in $\mathcal{I}$. By Lemma 775, $\mathcal{I}$ is globally family symmetric in $\mathcal{I}$. By hypothesis and Proposition 780, it is globally system transitive in $\mathcal{I}$. By Lemma 776 it has the global family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the global system modus ponens in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $R^{\mathcal{I}}$. ■

Theorems 779 and 781 provide the promised characterization of syntactic prealgebraicity in terms of the global system modus ponens of the reflexive core.

$$\mathcal{I} \text{ is Syntactically Prealgebraic} \longleftrightarrow R^{\mathcal{I}} \text{ has Global System MP.}$$

Theorem 782 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically prealgebraic if and only if* $R^{\mathcal{I}}$ *has the global system modus ponens in* $\mathcal{I}$*.*

Proof: Theorem 779 gives the "only if" and the "if" is by Theorem 781. ■

If $\mathcal{I}$ is syntactically prealgebraic, then $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 770, since $R^{\mathcal{I}}$ forms a set of witnessing transformations that, in addition, has the global family symmetry in $\mathcal{I}$.

Proposition 783 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *has the global system modus ponens, then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}}(T).$$

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$. If $R^{\mathcal{I}}$ has the global system modus ponens, then, by Lemma 773, Lemma 775, Lemma 776, the hypothesis and Proposition 780, $R^{\mathcal{I}}(T)$ is a congruence system that is compatible with T. Therefore, by Corollary 98, we get that $\Omega(T) = R^{\mathcal{I}}(T)$. ■

We also get another related characterization of syntactic prealgebraicity.

$$\begin{array}{l}\mathcal{I} \text{ is Syntactically Prealgebraic} \\ \qquad\qquad \longleftrightarrow R^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ \qquad\qquad\qquad\qquad \text{of Theory Systems in } \mathcal{I}.\end{array}$$

Theorem 784 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically prealgebraic if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}}(T).$$

Proof: If $\mathcal{I}$ is syntactically prealgebraic, then, by Theorem 782, $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$. Thus, by Proposition 783, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = R^{\mathcal{I}}(T)$.

Conversely, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $R^{\mathcal{I}}(T) = \Omega(T)$, then, $R^{\mathcal{I}}$ is reflexive, globally system transitive, has the global family compatibility and the global system modus ponens. Thus, $R^{\mathcal{I}}$ is a set of witnessing transformations and $\mathcal{I}$ is syntactically prealgebraic. ■

We finally show that the property that separates prealgebraicity from syntactic prealgebraicity is exactly the Leibniz compatibility property with respect to the theory system generated by the reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $R^{\mathcal{I}}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

We show that, if $R^{\mathcal{I}}$ has the global system modus ponens, then it is Leibniz.

Proposition 785 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *has the global system modus ponens, then it is Leibniz.*

Proof: Suppose $R^{\mathcal{I}}$ has the global system modus ponens. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. To show that $\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi]))$, we use the criterion for membership given in Theorem 19. To this end, let $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ be in $N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$, such that

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\xi}) \in C_{\Sigma'}(R^{\mathcal{I}}_\Sigma[\phi, \psi]).$$

By Lemma 776,

$$R^{\mathcal{I}}_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\xi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\xi})] \leq C(R^{\mathcal{I}}_\Sigma[\phi, \psi]).$$

Since, by hypothesis, $R^{\mathcal{I}}$ has the global system modus ponens, we obtain that $\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \in C_{\Sigma'}(R^{\mathcal{I}}_\Sigma[\phi, \psi])$. By symmetry, we now have that

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\xi}) \in C_{\Sigma'}(R^{\mathcal{I}}_\Sigma[\phi, \psi]) \\ \qquad\qquad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \in C_{\Sigma'}(R^{\mathcal{I}}_\Sigma[\phi, \psi]).\end{array}$$

Therefore, by Theorem 19, we conclude that $\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi]))$, and, hence, $R^{\mathcal{I}}$ is Leibniz. ■

Here is an example of a π-institution $\mathcal{I}$, with a Leibniz reflexive core not having the global system modus ponens.

Example 786 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

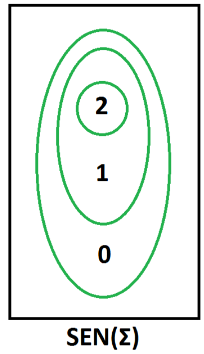
- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0, 1, 2\}^2 \to \{0, 1, 2\}$ *be given, for all* $x, y \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *has three theory families* $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{1, 2\}\}$ *and* $\mathrm{SEN}^\flat$*, all of which are theory systems.*



Note that $R^{\mathcal{I}} = \{\sigma^\flat\}$. *We show that* $R^{\mathcal{I}}$ *is Leibniz, but does not have the global system modus ponens.*

To verify the Leibniz property, note that, if $\phi = \psi$ *the conclusion is trivial. If* $\phi \neq \psi$*, then, if* $\{\phi,\psi\} \neq \{0,1\}$*, then* $R^{\mathcal{I}}_\Sigma[\phi,\psi] = \{\{0\}\}$*, whence* $C(R^{\mathcal{I}}_\Sigma[\phi,\psi]) = \mathrm{SEN}^\flat$ *and, therefore,*

$$\Omega(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) = \nabla^{\mathbf{F}}$$

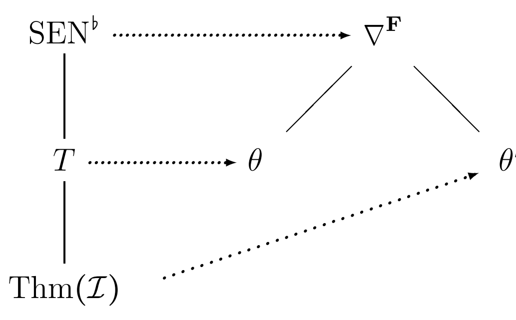
and the conclusion follows. Otherwise, if $\{\phi,\psi\} = \{0,1\}$*, then* $C(R^{\mathcal{I}}_\Sigma[\phi,\psi]) = \mathrm{Thm}(\mathcal{I})$*, whence*

$$\Omega(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) = \{\{0,1\},\{2\}\}$$

and the conclusion follows. Therefore, $R^{\mathcal{I}}$ *is Leibniz.*

On the other hand, we have $1 \in \{1,2\}$ *and* $R^{\mathcal{I}}_\Sigma[1,0] \leq \{\{1,2\}\}$*, whereas* $0 \notin \{1,2\}$*. Therefore,* $R^{\mathcal{I}}$ *fails to have the global system modus ponens in* $\mathcal{I}$*.*

We note, with a nod to what is to follow, that $\mathcal{I}$ *is not prealgebraic, since, as is clear by the poset diagrams of theory systems and associated Leibniz congruence systems, the Leibniz operator is not monotonic on theory systems (here* $\theta = \{\{0\},\{1,2\}\}$ *and* $\theta' = \{\{0,1\},\{2\}\}$*).*



In the opposite direction, and on the positive side, in a *prealgebraic* π-institution $\mathcal{I}$, if the reflexive core is Leibniz, then it does have the global system modus ponens in $\mathcal{I}$.

Proposition 787 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a prealgebraic* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *is Leibniz, then it has the global system modus ponens in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is prealgebraic and that $R^{\mathcal{I}}$ is Leibniz. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$. Now we have

$$\begin{array}{lll}\langle\phi,\psi\rangle & \in & \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) \quad \text{(since } R^{\mathcal{I}} \text{ is Leibniz)}\\ & \subseteq & \Omega_\Sigma(T). \quad \text{(since } R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T \text{ and } \mathcal{I} \text{ is prealgebraic)}\end{array}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T, that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$. ■

We now show that a π-institution is syntactically prealgebraic if and only if it is prealgebraic and it has a Leibniz reflexive core.

$$\begin{array}{rcl}\text{Syntactic Prealgebraicity} & = & R^{\mathcal{I}} \text{ has Global System MP}\\ & = & R^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems}\\ & & \quad \text{of Theorem Systems in } \mathcal{I}\\ & = & \text{Prealgebraicity} + R^{\mathcal{I}} \text{ is Leibniz}\end{array}$$

Theorem 788 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic if and only if it is prealgebraic and has a Leibniz reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically prealgebraic. Then it is prealgebraic by Theorem 771. Moreover, its reflexive core has the global family modus ponens by Theorem 782 and, hence, by Proposition 785, its reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is prealgebraic with a Leibniz reflexive core. Then, by Proposition 787, its reflexive core has the global system modus ponens and, therefore, by Theorem 782, $\mathcal{I}$ is syntactically prealgebraic. ■

It is not difficult to see that syntactic prealgebraicity transfers from a π-institution $\mathcal{I}$ to all its generalized matrix families.

Theorem 789 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations $I^\flat$, if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle\mathbf{A}, \langle F, \alpha\rangle\rangle$, the generalized matrix family $\langle\mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ is syntactically prealgebraic, with witnessing transformations $I^{\mathcal{A}}$.*

Proof: The "if" follows by considering the algebraic system $\mathcal{F} = \langle\mathbf{F}, \langle I, \iota\rangle\rangle$. For the "only if", assume that $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations $I^\flat$, and let $\mathcal{A} = \langle\mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{rll}\langle\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in T_{F(\Sigma)} & \text{iff} & \langle\phi,\psi\rangle \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})\\ & \text{iff} & I^\flat_\Sigma[\phi,\psi] \leq \alpha^{-1}(T)\\ & \text{iff} & I^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.\end{array}$$

Taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that $\langle\mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ is syntactically prealgebraic, with witnessing transformations $I^{\mathcal{A}}$. ■

11.2 Syntactic Protoalgebraicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **protoalgebraic** if, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \le T' \quad \text{implies} \quad \Omega(T) \le \Omega(T').$$

We say that $\mathcal{I}$ is **syntactically protoalgebraic** if there exists $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that $I^\flat$ has:

- reflexivity;
- global family transitivity;
- global family compatibility; and
- global family modus ponens.

In that case, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic protoalgebraicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically protoalgebraic π-institution, with witnessing transformations $I^\flat$, then $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T, for all $T \in \mathrm{ThFam}(\mathcal{I})$. As a consequence, using Corollary 98, we may conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\overleftrightarrow{I^\flat}(T) = \Omega(T).$$

Proposition 790 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations $I^\flat$, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$.

Since $I^\flat$ is reflexive in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I}) \le T$. Therefore, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \phi] \le T$, which shows that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Suppose, next, that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Thus, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \le T$. By the definition of $\overleftrightarrow{I^\flat}$, we then get $\overleftrightarrow{I^\flat}_\Sigma[\psi, \phi] \le T$ and, hence, $\langle \psi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Next, assume that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Then we get $\langle \phi, \psi \rangle$, $\langle \psi, \chi \rangle$, $\langle \psi, \phi \rangle$, $\langle \chi, \psi \rangle \in I^\flat_\Sigma(T)$. Since $I^\flat$ is transitive in $\mathcal{I}$, we conclude that $\langle \phi, \chi \rangle$, $\langle \chi, \phi \rangle \in I^\flat_\Sigma(T)$ and, therefore, $\langle \phi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

To show the congruence property, assume that $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is a natural transformation in $N^\flat$ and that $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, for all $i < k$. Thus, since $I^\flat$ has the compatibility property in $\mathcal{I}$, we get that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle\in I^\flat_\Sigma(T)$. By symmetry, we also get $\langle\sigma^\flat_\Sigma(\vec{\psi}),\sigma^\flat_\Sigma(\vec{\phi})\rangle\in I^\flat_\Sigma(T)$ and, hence, that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle\in\overleftrightarrow{I^\flat}_\Sigma(T)$.

Finally, since by Lemma 93, $\overleftrightarrow{I^\flat}(T)$ is a relation system on $\mathbf{F}$, we conclude that $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$.

To conclude the proof, note that, if $\phi\in T_\Sigma$ and $\langle\phi,\psi\rangle\in\overleftrightarrow{I^\flat}_\Sigma(T)$, then $\psi\in T_\Sigma$ by the global family modus ponens of $I^\flat$ in $\mathcal{I}$ and the fact that $I^\flat\subseteq\overleftrightarrow{I^\flat}$. ■

Based on Proposition 790, we can conclude that $\overleftrightarrow{I^\flat}$ defines the Leibniz congruence systems of the theory families of $\mathcal{I}$.

Corollary 791 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic, with witnessing transformations* $I^\flat$*, if and only if, for all* $T\in\mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftrightarrow{I^\flat}(T)=\Omega(T).$$

Proof: The "only if" is by Proposition 790 and Corollary 98. The "if" is again obvious, as in Corollary 770. ■

Corollary 791 has as an immediate consequence the important fact that syntactic protoalgebraicity implies (semantic) protoalgebraicity.

Theorem 792 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically protoalgebraic, then it is protoalgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. Let $T,T'\in\mathrm{ThFam}(\mathcal{I})$, such that $T\le T'$. Then

$$\begin{array}{rcll}\Omega(T)&=&\overleftrightarrow{I^\flat}(T)&\text{(by Corollary 791)}\\&\le&\overleftrightarrow{I^\flat}(T')&\text{(by Lemma 94)}\\&=&\Omega(T').&\text{(by Corollary 791)}\end{array}$$

Thus, $\mathcal{I}$ is protoalgebraic. ■

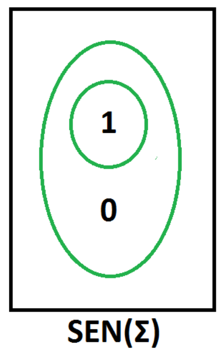
The following example shows that the inclusion of Theorem 792 is proper.

Example 793 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat:\mathbf{Sign}^\flat\to\mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma)=\{0,1\}$*;*

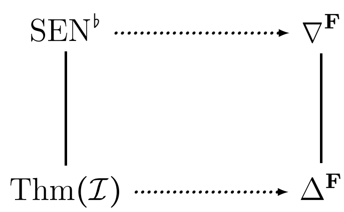
- *$N^\flat$ is the category of natural transformations generated by the single binary natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by letting: $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ be given by*

$$\sigma^\flat_\Sigma(x,y) = 1, \quad \textit{for all } x,y \in \{0,1\}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be the π-institution determined by $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$.

$\mathcal{I}$ has two theory families, $\mathrm{Thm}(\mathcal{I})$ and $\mathrm{SEN}^\flat$, such that $\mathrm{Thm}(\mathcal{I}) \le \mathrm{SEN}^\flat$. Moreover, $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$. Since $\Omega(\mathrm{Thm}(\mathcal{I})) \le \Omega(\mathrm{SEN}^\flat)$, $\mathcal{I}$ is protoalgebraic.



On the other hand, there does not exist $I^\flat \subseteq N^\flat$, such that $I^\flat$ has the required properties to constitute a witnessing set of transformations in $\mathcal{I}$. Any set containing projections cannot satisfy reflexivity and the set consisting only of $\sigma^\flat$ does nor satisfy the modus ponens property. We conclude that $\mathcal{I}$ is not syntactically protoalgebraic.

We now work towards a dual goal. We first provide a characterization of syntactic protoalgebraicity in terms of the global family modus ponens property of the reflexive core of the π-institution. Then, we use this characterization to provide an exact description of those protoalgebraic π-institutions which are syntactically protoalgebraic.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall that the **reflexive core** of $\mathcal{I}$ is the collection

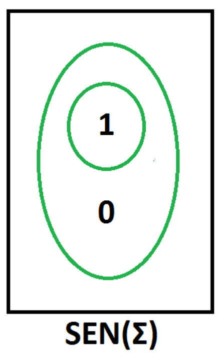
$$R^{\mathcal{I}} = \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \le \mathrm{Thm}(\mathcal{I}))\}.$$

It is possible, but not necessary, that the reflexive core of a π-institution has the global family modus ponens. To see this, we present two examples. In the first example, we look at a π-institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does have the global family modus ponens in $\mathcal{I}$.

Example 794 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 0, & \text{if } (x,y) = (1,0) \\ 1, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$.

Note that $\sigma^\flat \in R^{\mathcal{I}}$*, since, for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$. *On the other hand, no projection natural transformation can be in the reflexive core.*

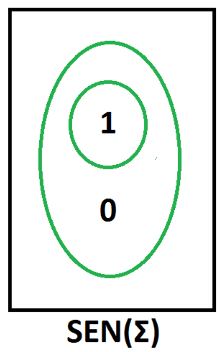
To see that $R^{\mathcal{I}}$ *satisfies the modus ponens in* $\mathcal{I}$*, note that it does so trivially for the theory family* $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, it is possible that* $\sigma^\flat_\Sigma(\phi,\psi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $\phi = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *only if* $\psi = 1$. *Thus,* $R^{\mathcal{I}}$ *has the global family MP in* $\mathcal{I}$*, as claimed.*

Next, we present an example of a π-institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does not have the global family modus ponens in $\mathcal{I}$.

Example 795 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1\}^2 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = 1, \quad \textit{for all } x,y \in \{0,1\}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$.

Note that $\sigma^\flat \in R^{\mathcal{I}}$*, since, for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. On the other hand, no projection natural transformation can be in the reflexive core.*

To see that $R^{\mathcal{I}}$ *does not satisfy the modus ponens in* $\mathcal{I}$*, note that* $1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and that* $\sigma^\flat_\Sigma(1,0) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, but* $0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*. Thus,* $R^{\mathcal{I}}$ *does not have the global family MP in* $\mathcal{I}$*.*

It turns out that possession of the global family modus ponens by the reflexive core intrinsically characterizes syntactic protoalgebraicity. We can show, at the outset, that the reflexive core having the global family modus ponens is necessary for syntactic protoalgebraicity. Thus, there is no point in exploring syntactic protoalgebraicity unless the π-institution $\mathcal{I}$ under scrutiny is such that $R^{\mathcal{I}}$ has the global family MP.

Theorem 796 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically protoalgebraic, then* $R^{\mathcal{I}}$ *has the global family modus ponens.*

Proof: Suppose that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. Thus, $I^\flat$ has reflexivity, global family transitivity, global family compatibility and the global family modus ponens in $\mathcal{I}$. Since $I^\flat$ is reflexive in $\mathcal{I}$, we get, by the definition of the reflexive core, that $I^\flat \subseteq R^{\mathcal{I}}$. But, then, since, by hypothesis, $I^\flat$ has the global family modus ponens, it follows that, a fortiori, $R^{\mathcal{I}}$ has the global family modus ponens in $\mathcal{I}$. ∎

To prove the reverse implication, we show, first, that having the global family modus ponens implies the global family transitivity property of the reflexive core.

Proposition 797 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global family modus ponens, then it also has the global family transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^{\mathcal{I}}$ has the global family modus ponens in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. This means that $R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 776, we get that, for all $\rho^\flat \in R^{\mathcal{I}}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$R^{\mathcal{I}}_{\Sigma'}[\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}), \rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi})] \leq T.$$

Since $R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$, we get by the global family MP of $R^{\mathcal{I}}$ that, for all $\rho^\flat \in R^{\mathcal{I}}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Thus, $R^{\mathcal{I}}_\Sigma[\phi, \chi] \leq T$, whence $\langle \phi, \chi \rangle \in R^{\mathcal{I}}_\Sigma(T)$. Therefore $R^{\mathcal{I}}$ is globally family transitive in $\mathcal{I}$. ∎

Proposition 797 closes a line of work that was started with the definition of a reflexive core and goes back to Lemma 773.

Theorem 798 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global family modus ponens, then $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations $R^{\mathcal{I}}$.*

Proof: By Lemma 773, $R^{\mathcal{I}}$ is reflexive in $\mathcal{I}$. By Lemma 775, $\mathcal{I}$ is globally family symmetric in $\mathcal{I}$. By hypothesis and Proposition 797, it is globally family transitive in $\mathcal{I}$. By Lemma 776 it has the global family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the global family modus ponens in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $R^{\mathcal{I}}$. ∎

Theorems 796 and 798 provide the promised characterization of syntactic protoalgebraicity in terms of the global family modus ponens of the reflexive core.

$\mathcal{I}$ is Syntactically Protoalgebraic $\longleftrightarrow$ $R^{\mathcal{I}}$ has Global Family MP.

Theorem 799 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic if and only if* $R^{\mathcal{I}}$ *has the global family modus ponens in* $\mathcal{I}$*.*

Proof: Theorem 796 gives the "only if" and the "if" is by Theorem 798. ■

If $\mathcal{I}$ is syntactically protoalgebraic, then $R^{\mathcal{I}}$ defines Leibniz congruence systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 791, since $R^{\mathcal{I}}$ forms a set of witnessing transformations that, in addition, has the global family symmetry in $\mathcal{I}$.

Proposition 800 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}}$ *has the global family modus ponens, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}}(T).$$

Proof: If $R^{\mathcal{I}}$ has the global family modus ponens, then, by Lemma 773, Lemma 775, Lemma 776, the hypothesis and Proposition 797, $R^{\mathcal{I}}(T)$ is a congruence system that is compatible with T. Therefore, by Corollary 98, we get that $\Omega(T) = R^{\mathcal{I}}(T)$. ■

We also get (almost) for free another related characterization of syntactic protoalgebraicity.

$$\begin{array}{l}\mathcal{I} \text{ is Syntactically Protoalgebraic} \\ \qquad\qquad \longleftrightarrow R^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems.}\end{array}$$

Theorem 801 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}}(T).$$

Proof: If $\mathcal{I}$ is syntactically protoalgebraic, then, by Theorem 799, $R^{\mathcal{I}}$ has the family modus ponens in $\mathcal{I}$. Thus, by Proposition 800, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = R^{\mathcal{I}}(T)$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $R^{\mathcal{I}}(T) = \Omega(T)$, then, $R^{\mathcal{I}}$ is reflexive, globally family transitive, has the global family compatibility and the global family modus ponens. Thus, $R^{\mathcal{I}}$ is a set of witnessing transformations and $\mathcal{I}$ is syntactically protoalgebraic. ■

We finally show that the property that separates protoalgebraicity from syntactic protoalgebraicity is exactly the Leibniz compatibility property with respect to the theory family generated by the reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $R^{\mathcal{I}}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

We have shown in Proposition 785 that, if $R^{\mathcal{I}}$ has the global system modus ponens, then it is Leibniz.

Corollary 802 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global family modus ponens, then it is Leibniz.*

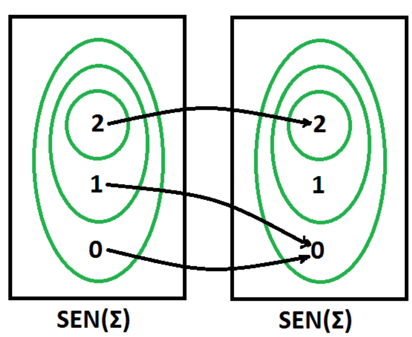
Proof: Directly from Proposition 785 ∎

Here is an example of a π-institution $\mathcal{I}$, with a Leibniz reflexive core not having the global family modus ponens.

Example 803 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given, for all* $a, b \in \mathrm{SEN}^\flat(\Sigma)$, *by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$.

Note that $R^{\mathcal{I}} = \{\sigma^\flat\}$. *We show that* $R^{\mathcal{I}}$ *is Leibniz, but does not have the global family modus ponens.*

To verify the Leibniz property, note that, if $\phi = \psi$ *the conclusion is trivial and, if* $\{\phi,\psi\} \neq \{0,1\}$, *then* $C_\Sigma(R^{\mathcal{I}}_\Sigma[\phi,\psi]) = \mathrm{SEN}^\flat(\Sigma)$, *whence*

$$\Omega(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) = \nabla^{\mathbf{F}}$$

and the conclusion follows. Finally, if $\{\phi,\psi\} = \{0,1\}$, *then* $C_\Sigma(R^{\mathcal{I}}_\Sigma[\phi,\psi]) = \{2\}$, *whence* $\Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) = \{\{0,1\},\{2\}\}$ *and, therefore,*

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])),$$

as required. We conclude that $R^{\mathcal{I}}$ *is Leibniz.*

On the other hand, we have $1 \in \{1,2\}$ *and* $R^{\mathcal{I}}_\Sigma[1,0] \leq \{\{1,2\}\}$, *whereas* $0 \notin \{1,2\}$. *Therefore,* $R^{\mathcal{I}}$ *fails to have the global family modus ponens in* $\mathcal{I}$.

In the opposite direction, and on the positive side, in a *protoalgebraic* π-institution $\mathcal{I}$, if the reflexive core is Leibniz, then it has the global family modus ponens in $\mathcal{I}$.

Proposition 804 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$. *If* $R^{\mathcal{I}}$ *is Leibniz, then it has the global family modus ponens in* $\mathcal{I}$.

Proof: Suppose that $\mathcal{I}$ is protoalgebraic and that $R^{\mathcal{I}}$ is Leibniz. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$. Now we have

$$\begin{array}{lll}\langle\phi,\psi\rangle & \in & \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) \quad \text{(since } R^{\mathcal{I}} \text{ is Leibniz)}\\ & \subseteq & \Omega_\Sigma(T). \quad \text{(since } R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T \text{ and } \mathcal{I} \text{ is protoalgebraic)}\end{array}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T, that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}}$ has the global family modus ponens in $\mathcal{I}$. ∎

We now show that a π-institution is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core.

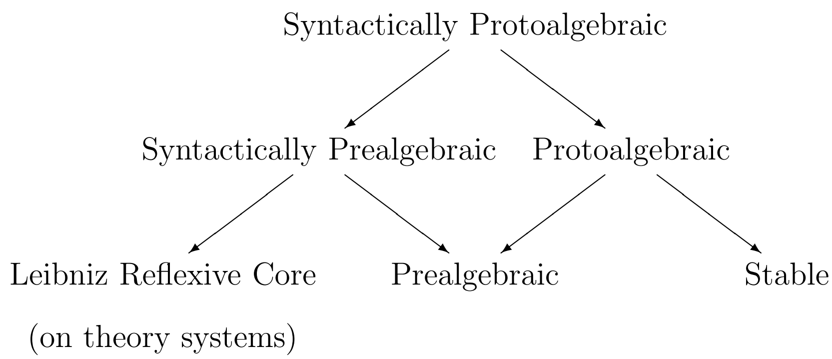
Syntactic Protoalgebraicity	=	$R^{\mathcal{I}}$ has Global Family MP
	=	$R^{\mathcal{I}}$ Defines Leibniz Congruence Systems
	=	Protoalgebraicity + $R^{\mathcal{I}}$ is Leibniz

Theorem 805 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically protoalgebraic. Then it is protoalgebraic by Theorem 792. Moreover, its reflexive core has the global family modus ponens by Theorem 799 and, hence, by Corollary 802, its reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is protoalgebraic with a Leibniz reflexive core. Then, by Proposition 804, its reflexive core has the global family modus ponens and, therefore, by Theorem 799, $\mathcal{I}$ is syntactically protoalgebraic. ∎

We have now established the following hierarchy of properties:



In fact, it turns out that many of the given characterizations of syntactic protoalgebraicity can be recast in terms of the corresponding ones concerning syntactic prealgebraicity by adding stability. The main result that allows this connection is the one corresponding to Theorem 175, but concerning syntactic protoalgebraicity and syntactic prealgebraicity rather than their respective semantic versions.

Theorem 806 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is syntactically prealgebraic and stable.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically protoalgebraic. Then, it is, a fortiori, syntactically prealgebraic. Moreover, by Theorem 792, it is protoalgebraic. Therefore, by Theorem 175, it is stable.

Suppose, conversely, that $\mathcal{I}$ is syntactically prealgebraic and stable. Consider $T \in \mathrm{ThFam}(\mathcal{I})$. Then we have

$$\begin{array}{rcll} \Omega(T) & = & \Omega(\overleftarrow{T}) & \text{(stability)} \\ & = & R^{\mathcal{I}}(\overleftarrow{T}) & \text{(syntactic prealgebraicity and Theorem 784)} \\ & = & R^{\mathcal{I}}(T). & \text{(Proposition 99)} \end{array}$$

By Theorem 801, we conclude that $\mathcal{I}$ is syntactically protoalgebraic. ∎

Now we obtain, almost for free, the following corollaries, which contain the promised characterizations involving stability.

Corollary 807 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is stable and* $R^{\mathcal{I}}$ *has the global system modus ponens.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 782, it is stable and $R^{\mathcal{I}}$ has the global system modus ponens. ■

Corollary 808 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is stable and* $R^{\mathcal{I}}$ *defines Leibniz congruence systems of theory systems of* $\mathcal{I}$*, i.e., for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $\Omega(T) = R^{\mathcal{I}}(T)$*.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 784, it is stable and $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. ■

Corollary 809 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is prealgebraic, stable and* $R^{\mathcal{I}}$ *is Leibniz.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 788, it is prealgebraic, stable and $R^{\mathcal{I}}$ is Leibniz. ■

Finally, it is not difficult to see, in this case as well, that syntactic protoalgebraicity transfers from a π-institution $\mathcal{I}$ to all its generalized matrix families.

Theorem 810 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically protoalgebraic, with witnessing transformations* $I^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the generalized matrix family* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ *is syntactically protoalgebraic, with witnessing transformations* $I^{\mathcal{A}}$*.*

Proof: The proof mimics the proof of Theorem 789. ■

11.3 Matrix Semantics

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that an $\mathcal{I}$**-matrix family** is a pair $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is an $\mathcal{I}$-filter family on $\mathcal{A}$. The class of all $\mathcal{I}$-matrix families is denoted by MatFam($\mathcal{I}$). $\mathcal{I}$-matrix families on $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$, i.e., pairs of the form $\langle \mathcal{F}, T\rangle$, where $T \in \mathrm{ThFam}(\mathcal{I})$, are called **Lindenbaum $\mathcal{I}$-matrix families**. The collection of all Lindenbaum $\mathcal{I}$-matrix families is denoted by LMatFam($\mathcal{I}$).

Four subclasses of MatFam($\mathcal{I}$) are distinguished and will be of particular interest to us in the upcoming sections. These are:

- The class $\mathrm{LMatFam}^*(\mathcal{I})$ of all **reduced Lindenbaum $\mathcal{I}$-matrix families**:
$$\mathrm{LMatFam}^*(\mathcal{I}) = \{\langle \mathcal{F}/\Omega(T), T/\Omega(T)\rangle : T \in \mathrm{ThFam}(\mathcal{I})\};$$
- The class $\mathrm{LMatFam}^{Su}(\mathcal{I})$ of all **Suszko reduced Lindenbaum $\mathcal{I}$-matrix families**:
$$\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I}) = \{\langle \mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T), T/\widetilde{\Omega}^{\mathcal{I}}(T)\rangle : T \in \mathrm{ThFam}(\mathcal{I})\};$$
- The class $\mathrm{MatFam}^*(\mathcal{I})$ of all **reduced $\mathcal{I}$-matrix families**:
$$\mathrm{LMatFam}^*(\mathcal{I}) = \{\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}(\mathcal{I}) : \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}\};$$
- The class $\mathrm{MatFam}^{Su}(\mathcal{I})$ of all **Suszko reduced $\mathcal{I}$-matrix families**:
$$\mathrm{MatFam}^{Su}(\mathcal{I}) = \{\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}(\mathcal{I}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}\}.$$

The following characterizations of the last two classes are well-known and very useful in practice.

Proposition 811 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$. *Then the following equalities hold (where the classes are perceived as being closed under isomorphism):*

(a) $\mathrm{MatFam}^*(\mathcal{I}) = \{\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$;

(b) $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I}) = \{\langle \mathcal{F}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T), T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$.

Proof: We prove Part (a). Part (b) can be proven similarly. First, if $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, then, since, by definition, $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$, we get that $\langle \mathcal{A}, T\rangle \cong \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle$. For the reverse inclusion, it suffices to observe that, given an $\mathbf{F}$-algebraic system $\mathcal{A}$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have, essentially due to the definition of the Leibniz congruence system, that
$$\Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}.$$
Therefore, $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle \in \mathrm{MatFam}^*(\mathcal{I})$. ■

It turns out that all four classes of $\mathcal{I}$-matrix families defined above form matrix family semantics for the π-institution $\mathcal{I}$. More precisely, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, a class M of $\mathcal{I}$-matrix families is called a **matrix (family) semantics for $\mathcal{I}$** if $C = C^{\mathrm{M}}$, i.e., for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, $\phi \in C_\Sigma(\Phi)$ if and only if, for all $\langle \mathcal{A}, T \rangle \in \mathrm{M}$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}.$$

Proposition 812 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathcal{I}$. The four classes*

$$\mathrm{LMatFam}^*(\mathcal{I}), \mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I}), \mathrm{MatFam}^*(\mathcal{I}) \text{ and } \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$$

are all matrix semantics for $\mathcal{I}$.

Proof: Let M be any of these four matrix family classes. Since M consists of $\mathcal{I}$-matrix families, we have that $C \leq C^{\mathrm{M}}$.

For the converse, note that the following inclusions hold:

$$\begin{array}{ccccc} & & \mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I}) & \searrow & \\ & & & & \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I}) \\ \mathrm{LMatFam}^*(\mathcal{I}) & \longrightarrow & \mathrm{MatFam}^*(\mathcal{I}) & \nearrow & \end{array}$$

Therefore, we have, by definition, the inclusions

$$\begin{array}{ccccc} & \nearrow & C^{\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})} & & \\ C^{\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})} & & & & \\ & \searrow & C^{\mathrm{MatFam}^*(\mathcal{I})} & \longrightarrow & C^{\mathrm{LMatFam}^*(\mathcal{I})} \end{array}$$

It follows that it suffices to show that the two reduced Lindenbaum matrix family classes satisfy $C^{\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})} \leq C$ and $C^{\mathrm{LMatFam}^*(\mathcal{I})} \leq C$. We show the first inclusion, since the second can be proven similarly.

Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that

$$\phi \in C_\Sigma^{\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})}(\Phi).$$

Let $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\Phi \subseteq T_\Sigma$. Then, $\Phi/\widetilde{\Omega}_\Sigma^{\mathcal{I}}(T) \subseteq T_\Sigma/\widetilde{\Omega}_\Sigma^{\mathcal{I}}(T)$. Since $\langle \mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T), T/\widetilde{\Omega}^{\mathcal{I}}(T) \rangle \in \mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})$, we get, by hypothesis, $\phi/\widetilde{\Omega}_\Sigma^{\mathcal{I}}(T) \in T_\Sigma/\widetilde{\Omega}_\Sigma^{\mathcal{I}}(T)$. Thus, using the compatibility of $\widetilde{\Omega}^{\mathcal{I}}(T)$ with T, we get that $\phi \in T_\Sigma$. Since $T \in \mathrm{ThFam}(\mathcal{I})$ was arbitrary, we conclude that $\phi \in C_\Sigma(\Phi)$. ∎

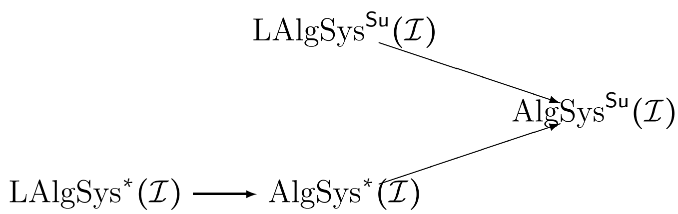
We denote the classes of the underlying $\mathbf{F}$-algebraic systems of the matrix families in $\mathrm{LMatFam}^*(\mathcal{I})$, $\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})$, $\mathrm{MatFam}^*(\mathcal{I})$ and $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$, respectively, by

$$\mathrm{LAlgSys}^*(\mathcal{I}), \mathrm{LAlgSys}^{\mathsf{Su}}(\mathcal{I}), \mathrm{AlgSys}^*(\mathcal{I}) \text{ and } \mathrm{AlgSys}^{\mathsf{Su}}(\mathcal{I}).$$

So we have

$$\begin{array}{rcl}
\mathrm{LAlgSys}^*(\mathcal{I}) & = & \{\mathcal{F}/\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I})\};\\
\mathrm{LAlgSys}^{\mathsf{Su}}(\mathcal{I}) & = & \{\mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T) : T \in \mathrm{ThFam}(\mathcal{I})\};\\
\mathrm{AlgSys}^*(\mathcal{I}) & = & \{\mathcal{A} : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\};\\
\mathrm{AlgSys}^{\mathsf{Su}}(\mathcal{I}) & = & \{\mathcal{A} : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}.
\end{array}$$

We clearly have the following inclusion relationships between those four classes of $\mathbf{F}$-algebraic systems:



11.4 Algebraic Semantics

In the study of logical systems formalized as π-institutions and, more specifically, as related to their algebraic properties, the notions of an algebraic semantics and that of equational definability of truth are paramount. We introduce and study these two notions in this section.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Consider a class K of $\mathbf{F}$-algebraic systems. We define the closure system $C^{\mathrm{K}} : \mathcal{P}(\mathrm{SEN}^\flat)^2 \to \mathcal{P}(\mathrm{SEN}^\flat)^2$, by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $C^{\mathrm{K}}_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)^2) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)^2)$ be given, for all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)^2$, by

$$\begin{array}{lll}
\phi \approx \psi \in C^{\mathrm{K}}_\Sigma(E) & \text{iff} & \text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathrm{K},\\
& & \alpha_\Sigma(E) \subseteq \Delta^{\mathcal{A}}_{F(\Sigma)} \text{ implies } \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).
\end{array}$$

Given a set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, with a single distinguished argument, we say that the class K of $\mathbf{F}$-algebraic systems is a **$\tau^\flat$-algebraic semantics for $\mathcal{I}$**, or, more simply, a **$\tau^\flat$-semantics for $\mathcal{I}$**, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq C^{\mathrm{K}}(\tau^\flat_\Sigma[\Phi]).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution, based on $\mathbf{F}$, and M a class of $\mathcal{I}$-matrix families. Given a set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, we say that

truth is $\tau^\flat$-equationally definable in M, or, more simply, that **truth is $\tau^\flat$-definable in** M if, for all $\langle\mathcal{A},T\rangle \in$ M, with $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ and $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Delta^{\mathcal{A}}.$$

It turns out that classes of algebraic systems forming $\tau^\flat$-semantics for a π-institution and classes of matrix families in which truth is $\tau^\flat$-definable are closely interrelated. To express this connection, we first formulate a technical lemma.

Lemma 813 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and let* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *be a set of natural transformations in* $N^\flat$. *Suppose* $\mathfrak{A} = \langle\mathcal{A},T\rangle$, *with* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *and* $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$, *is an* $\mathbf{F}$*-matrix family in which truth is* $\tau^\flat$*-definable. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C^{\mathfrak{A}}_\Sigma(\Phi) \quad \textit{iff} \quad \tau^\flat_\Sigma[\phi] \leq C^{\mathcal{A}}(\tau^\flat_\Sigma[\Phi]).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then we have the following sequence of equivalent statements:

$$\begin{array}{lll}
\phi \in C^{\mathfrak{A}}_\Sigma(\Phi) & \text{iff,} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\
& & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}\\
& & \qquad\qquad \text{implies } \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}\\
& \text{iff,} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\
& & \tau^{\mathcal{A}}_{F(\Sigma')}[\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))] \leq \Delta^{\mathcal{A}}\\
& & \qquad\qquad \text{implies } \tau^{\mathcal{A}}_{F(\Sigma')}[\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))] \leq \Delta^{\mathcal{A}}\\
& \text{iff,} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\
& & \tau^{\mathcal{A}}_{F(\Sigma')}[\mathrm{SEN}(F(f))(\alpha_\Sigma(\Phi))] \leq \Delta^{\mathcal{A}}\\
& & \qquad\qquad \text{implies } \tau^{\mathcal{A}}_{F(\Sigma')}[\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi))] \leq \Delta^{\mathcal{A}}\\
& \text{iff,} & \text{by Lemma 93,}\\
& & \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\Phi)] \leq \Delta^{\mathcal{A}} \text{ implies } \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}}\\
& \text{iff,} & \text{by surjectivity of } \langle F,\alpha\rangle,\\
& & \alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}} \text{ implies } \alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}\\
& \text{iff} & \tau^\flat_\Sigma[\phi] \leq C^{\mathcal{A}}(\tau^\flat_\Sigma[\Phi]).
\end{array}$$

■

Now we establish the promised relationship between algebraic semantics and matrix semantics.

Theorem 814 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *a set of natural transformation in* $N^\flat$. *A class* K *of* $\mathbf{F}$*-algebraic systems is a* $\tau^\flat$*-semantics for* $\mathcal{I}$ *if and only if it is the class of underlying algebraic systems of some matrix semantics* M *for* $\mathcal{I}$ *in which truth is* $\tau^\flat$*-definable.*

Proof: Suppose, first, that M is a matrix semantics for $\mathcal{I}$ in which truth is $\tau^\flat$-definable and let K be the class of its underlying algebraic systems. Then we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in C_\Sigma(\Phi) & \text{iff} & \phi \in C^{\mathrm{M}}_\Sigma(\Phi) \quad (\text{M a matrix semantics})\\ & \text{iff} & (\forall \mathfrak{A} \in \mathrm{M})(\phi \in C^{\mathfrak{A}}_\Sigma(\Phi)) \quad (\text{by definition})\\ & \text{iff} & (\forall \mathcal{A} \in \mathrm{K})(\tau^\flat_\Sigma[\phi] \leq C^{\mathcal{A}}(\tau^\flat_\Sigma[\Phi])) \quad (\text{by Lemma 813})\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq C^{\mathrm{K}}(\tau^\flat_\Sigma[\Phi]). \quad (\text{by definition})\end{array}$$

Thus, K is a $\tau^\flat$-semantics for $\mathcal{I}$.

Suppose, conversely, that K is a $\tau^\flat$-semantics for $\mathcal{I}$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in$ K, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$. Define, for all $\Sigma \in |\mathbf{Sign}|$,

$$T^{\mathcal{A},\tau}_\Sigma = \{\phi \in \mathrm{SEN}(\Sigma) : \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Delta^{\mathcal{A}}\},$$

and set $T^{\mathcal{A},\tau} = \{T^{\mathcal{A},\tau}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$. Then, let

$$\mathrm{M} = \{\langle \mathcal{A}, T^{\mathcal{A},\tau}\rangle : \mathcal{A} \in \mathrm{K}\}.$$

Note that K is the class of all underlying algebraic systems of the matrix systems in M and, also, that, for all $\mathcal{A} \in \mathrm{K}$, truth is $\tau^\flat$-definable in $\langle \mathcal{A}, T^{\mathcal{A},\tau}\rangle$ by the definition of $T^{\mathcal{A},\tau}$. Thus, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in C_\Sigma(\Phi) & \text{iff} & \tau^\flat_\Sigma[\phi] \leq C^{\mathrm{K}}(\tau^\flat_\Sigma[\Phi]) \quad (\text{K a } \tau^\flat\text{-semantics})\\ & \text{iff} & (\forall \mathcal{A} \in \mathrm{K})(\tau^\flat_\Sigma[\phi] \leq C^{\mathcal{A}}(\tau^\flat_\Sigma[\Phi])) \quad (\text{by definition})\\ & \text{iff} & (\forall \mathfrak{A} \in \mathrm{M})(\phi \in C^{\mathfrak{A}}_\Sigma(\Phi)) \quad (\text{by Lemma 813})\\ & \text{iff} & \phi \in C^{\mathrm{M}}_\Sigma(\Phi). \quad (\text{by definition})\end{array}$$

We conclude that M is a matrix semantics for $\mathcal{I}$. ■

Corollary 815 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution, based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a set of natural transformation in $N^\flat$. If truth is $\tau^\flat$-definable in any of the classes*

$$\mathrm{LMatFam}^*(\mathcal{I}), \mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I}), \mathrm{MatFam}^*(\mathcal{I}) \text{ or } \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I}),$$

then, the corresponding class

$$\mathrm{LAlgSys}^*(\mathcal{I}), \mathrm{LAlgSys}^{\mathsf{Su}}(\mathcal{I}), \mathrm{AlgSys}^*(\mathcal{I}) \text{ or } \mathrm{AlgSys}^{\mathsf{Su}}(\mathcal{I})$$

is a $\tau^\flat$-semantics for $\mathcal{I}$.

Proof: This follows from Theorem 814, since the four displayed classes of $\mathcal{I}$-matrix families are matrix semantics for $\mathcal{I}$ and the four displayed classes of algebraic systems are the respective classes of their underlying algebraic systems. ■

11.5 Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is:

- **Leibniz truth equational** if there exists $\tau^\flat \subseteq N^\flat$, with a single distinguished argument, such that truth is $\tau^\flat$-definable in $\mathrm{LMatFam}^*(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle \in \mathrm{LMatFam}^*(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)};$$
- **Universally Leibniz truth equational** if there exists $\tau^\flat \subseteq N^\flat$, with a single distinguished argument, such that truth is $\tau^\flat$-definable in the class $\mathrm{MatFam}^*(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}};$$
- **Suszko truth equational** if there exists $\tau^\flat \subseteq N^\flat$, with a single distinguished argument, such that truth is $\tau^\flat$-definable in $\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T), T/\widetilde{\Omega}^{\mathcal{I}}(T) \rangle \in \mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi/\widetilde{\Omega}^{\mathcal{I}}_\Sigma(T) \in T_\Sigma/\widetilde{\Omega}^{\mathcal{I}}_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T)}[\phi/\widetilde{\Omega}^{\mathcal{I}}_\Sigma(T)] \leq \Delta^{\mathcal{F}/\widetilde{\Omega}^{\mathcal{I}}(T)};$$
- **Universally Suszko truth equational** if there exists $\tau^\flat \subseteq N^\flat$, with a single distinguished argument, such that truth is $\tau^\flat$-definable in the class $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}}.$$

The set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ will be called a set of **witnessing equations** (of/for the corresponding truth equationality property).

The following proposition provides alternative conditions for testing whether a given π-institution is truth equational with respect to any of the four classes of matrix families considered above.

Proposition 816 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat \subseteq N^\flat$ having a single distinguished argument.*

(a) $\mathcal{I}$ is Leibniz truth equational with witnessing equations $\tau^\flat$ iff, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T);$$

(b) *$\mathcal{I}$ is universally Leibniz truth equational if and only if, for every* **F**-*algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{A}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T);$$

(c) *$\mathcal{I}$ is Suszko truth equational with witnessing equations $\tau^\flat$ iff, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T);$$

(d) *$\mathcal{I}$ is universally Suszko truth equational if and only if, for every* **F**-*algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{A}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Proof:

(a) Suppose, first, that $\mathcal{I}$ is Leibniz truth equational and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}\phi \in T_\Sigma & \text{iff} & \phi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T) \quad \text{(by compatibility)}\\ & \text{iff} & \tau^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by hypothesis)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by definition)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T).\end{array}$$

Assume, conversely, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Let $\langle \mathcal{F}/\Omega(T), T/\Omega(T)\rangle \in \mathrm{LMatFam}^*(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}\phi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T) & \text{iff} & \phi \in T_\Sigma \quad \text{(by compatibility)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(by hypothesis)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by definition)}\\ & \text{iff} & \tau^{\mathcal{F}/\Omega(T)}_\Sigma[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.\end{array}$$

(b) Suppose, first, that $\mathcal{I}$ is universally Leibniz truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an **F**-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then

$$\begin{array}{lll}\phi \in T_\Sigma & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T) \quad \text{(by compatibility)}\\ & \text{iff} & \tau^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}[\phi/\Omega^{\mathcal{A}}_\Sigma(T)] \leq \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)} \quad \text{(by hypothesis)}\\ & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\phi]/\Omega^{\mathcal{A}}(T) \leq \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)} \quad \text{(by definition)}\\ & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).\end{array}$$

Assume, conversely, that, for every **F**-algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T)$. Let $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then

$$\begin{array}{lll}\phi \in T_\Sigma & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T) \quad \text{(by hypothesis)}\\ & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Delta^{\mathcal{A}}. \quad (\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\end{array}$$

Parts (c) and (d) follow along similar lines. ∎

We investigate next the relationships between the various types of truth equationality. Our first result is that Leibniz truth equationality and universal Leibniz truth equationality coincide.

Proposition 817 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is Leibniz truth equational if and only if it is universally Leibniz truth equational.*

Proof: First, note that, since $\mathrm{LMatFam}^*(\mathcal{I}) \subseteq \mathrm{MatFam}^*(\mathcal{I})$, universal Leibniz truth equationality trivially implies Leibniz truth equationality. Suppose, conversely, that $\mathcal{I}$ is Leibniz truth equational, with witnessing equations $\tau^\flat \subseteq N^\flat$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have

$$\begin{array}{lll} \alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \quad \text{(set theory)} \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(\alpha^{-1}(T)) \quad \text{(Proposition 816)} \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\phi]) \leq \Omega^{\mathcal{A}}(T) \quad \text{(set theory)} \\ & \text{iff} & \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 96)} \end{array}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$ and Proposition 816, we conclude that $\mathcal{I}$ is universally Leibniz truth equational. ∎

In the next proposition, we show that (universal) Leibniz truth equationality and universal Suszko truth equationality are also identical properties.

Theorem 818 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is universally Leibniz truth equational if and only if it is universally Suszko truth equational.*

Proof: Since $\mathrm{MatFam}^*(\mathcal{I}) \subseteq \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$, it follows that universal Suszko truth equationality implies universal Leibniz truth equationality. Suppose, conversely, that $\mathcal{I}$ is universally Leibniz truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. By Proposition 816, it suffices to show that

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

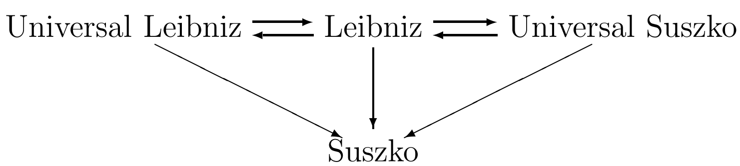
If $\phi \in T_\Sigma$, then $\phi \in T'_\Sigma$, for all $T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, by hypothesis, $\tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T')$. But then we have

$$\tau^{\mathcal{A}}_\Sigma[\phi] \leq \bigcap_{T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})} \Omega^{\mathcal{A}}(T') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Suppose, conversely, that $\tau^{\mathcal{A}}_{\Sigma}[\phi] \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Then, since $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$, we get that $\tau^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T)$, whence, by hypothesis, $\phi \in T_\Sigma$.

Using Proposition 816, we conclude that $\mathcal{I}$ is universally Suszko truth equational. ■

Since, for any π-institution $\mathcal{I}$, $\mathrm{LMatFam}^{\mathsf{Su}}(\mathcal{I}) \subseteq \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$, we have, trivially, that universal Suszko truth equationality implies Suszko truth equationality. Therefore, we get the following picture involving implications between the various truth equationality properties:



Next, we present an example showing that the top-to-bottom implication is not an equivalence in general. I.e., we construct an example of a π-institution, which is Suszko truth equational but not Leibniz truth equational.

Example 819 EXAMPLE NOT FOUND YET!

We call a π-institution that is (universally) Leibniz truth equational, or equivalently, universally Suszko truth equational, a **family truth-equational π-institution**, or more simply, a **truth equational π-institution**.

Combining these results with Corollary 815, we get the following

Corollary 820 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. If $\mathcal{I}$ is truth equational with witnessing equations $\tau^\flat$, then the three classes $\mathrm{LAlgSys}^*(\mathcal{I})$, $\mathrm{AlgSys}^*(\mathcal{I})$ and $\mathrm{AlgSys}^{\mathsf{Su}}(\mathcal{I})$ are $\tau^\flat$-semantics for $\mathcal{I}$.*

Proof: By the definition of truth equationality and Corollary 815. ■

11.6 More on Truth Equationality

We start this section by looking closely at a property similar to the one defining truth equationality.

Lemma 821 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a set of natural transformations in $N^\flat$. The following statements are equivalent:*

(a) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi))$;

(b) *For all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$*.*

Proof: For (a)⇒(b), assume that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi))$, and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in T_\Sigma$,

$$\begin{array}{rcll}\tau^\flat_\Sigma[\phi] & \leq & \widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & \text{(hypothesis)}\\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(T). & \text{(monotonicity of } \widetilde{\Omega}^{\mathcal{I}})\end{array}$$

Therefore, $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$.

For (b)⇒(a), assume that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$, and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, by hypothesis,

$$\tau^\flat_\Sigma[\phi] \leq \tau^\flat[C(\phi)] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

■

A very similar property holds replacing theory families by theory systems and using the arrow operators.

Lemma 822 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *a set of natural transformations in* $N^\flat$*. The following statements are equivalent:*

(a) *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))$*;*

(b) *For all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$*.*

Proof: For (a)⇒(b), assume that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))$, and let $T \in \mathrm{ThSys}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in T_\Sigma$, $C(\overrightarrow{\phi}) \leq T$ and, hence,

$$\begin{array}{rcll}\tau^\flat_\Sigma[\phi] & \leq & \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & \text{(hypothesis)}\\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(T). & \text{(monotonicity of } \widetilde{\Omega}^{\mathcal{I}})\end{array}$$

Therefore, $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$.

For (b)⇒(a), assume that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\tau^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$, and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, by hypothesis,

$$\tau^\flat_\Sigma[\phi] \leq \tau^\flat[C(\overrightarrow{\phi})] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

■

The property studied in Lemma 821 is one that is satisfied by every π-institution possessing a $\tau^\flat$-semantics.

Proposition 823 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *a set of natural transformations in* $N^\flat$*. If* $\mathcal{I}$ *has a* $\tau^\flat$*-semantics, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Suppose that K is a $\tau^\flat$-semantics for $\mathcal{I}$ and let $\delta^\flat \approx \epsilon^\flat$ be an arbitrary equation in $\tau^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Our goal is to show that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\langle \delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}), \epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})\rangle \in \widetilde{\Omega}^{\mathcal{I}}_{\Sigma'}(C(\phi)).$$

By the characterization theorem for membership in the Suszko congruence system, and using symmetry, it suffices to show that, for all $\sigma^\flat \in N^\flat$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$, all $g \in \mathbf{Sign}^\flat(\Sigma',\Sigma'')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma'')$,

$$\begin{array}{ccccc}
\Sigma & \xrightarrow{\quad f \quad} & \Sigma' & \xrightarrow{\quad g \quad} & \Sigma'' \\
\phi & \mapsto & \mathrm{SEN}^\flat(\phi) & \mapsto & \mathrm{SEN}^\flat(gf)(\phi) \\
 & & \vec{\chi} & \mapsto & \mathrm{SEN}^\flat(g)(\vec{\chi}) \\
 & & & & \vec{\xi}
\end{array}$$

$$\begin{array}{l}\sigma^\flat_{\Sigma''}(\mathrm{SEN}^\flat(g)(\epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})),\vec{\xi}) \\ \qquad \in C_{\Sigma''}(\phi,\sigma^\flat_{\Sigma''}(\mathrm{SEN}^\flat(g)(\delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})),\vec{\xi})).\end{array}$$

This is equivalent to showing

$$\begin{array}{l}\sigma^\flat_{\Sigma''}(\epsilon^\flat_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi),\mathrm{SEN}^\flat(g)(\vec{\chi})),\vec{\xi}) \\ \qquad \in C_{\Sigma''}(\phi,\sigma^\flat_{\Sigma''}(\delta^\flat_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi),\mathrm{SEN}^\flat(g)(\vec{\chi})),\vec{\xi})).\end{array}$$

To show this, however, it suffices to show that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi}) \in C_{\Sigma'}(\phi,\sigma^\flat_{\Sigma'}(\delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi})).$$

This, now, follows from the fact that K is a $\tau^\flat$-semantics for $\mathcal{I}$ and that, obviously,

$$\begin{array}{l}\tau^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi})] \\ \qquad \le C^{\mathrm{K}}(\tau^\flat_{\Sigma}[\phi],\tau^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi})]).\end{array}$$

■

Now we obtain the following consequence:

Corollary 824 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *a set of natural transformations in* $N^\flat$*. If* $\mathcal{I}$ *has a* $\tau^\flat$*-semantics, then. for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\tau^\flat[T] \le \widetilde{\Omega}^{\mathcal{I}}(T).$$

Proof: By Proposition 823 and Lemma 821. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. We say that the Suszko operator:

- is **universally family injective** if, for every **F**-algebraic system $\mathcal{A}$, and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,
$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \quad \text{implies} \quad T = T';$$
- has the **universal family minimality** property if, for every **F**-algebraic system $\mathcal{A}$, and every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is the least theory family of $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$.

Universal family injectivity and universal family minimality of the Suszko operator turn out to be equivalent properties.

Theorem 825 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The Suszko operator is universally family injective if and only if it has the universal family minimality property.*

Proof: Suppose, first, that the Suszko operator has the universal family minimality property. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Then both $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ and $T'/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$ are $\mathcal{I}$-filter families on the **F**-algebraic system $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Thus, by the universal family minimality property, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = T'/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Since $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$, we get that $T = T'$. So $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is universally family injective.

Suppose, conversely, that the Suszko operator is universally family injective. Consider an **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let T' be the least $\mathcal{I}$-filter family on $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Since we have $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$, we get, by minimality, that $T' \leq T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. But then, by the monotonicity of the Suszko operator, we get that
$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T') \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}$$
and, therefore,
$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))(= \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}).$$
Hence, by universal family injectivity, $T' = T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$, which proves that the Suszko operator has the universal family minimality property. ■

Finally, recall that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is called **family c-reflective** if, for every $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$
Also recall that, by the Transfer Theorem **??**, $\mathcal{I}$ is family c-reflective if and only if, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,
$$\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

We may call this latter property **universal family complete reflectivity** or **universal family c-reflectivity**.

Our goal, in closing this section is to show that the family injectivity of the Suszko operator (and, hence, by Theorem 825, its universal family minimality) is equivalent to the (universal) family c-reflecitvity of $\mathcal{I}$.

We provide, first, an alternative characterization of universal family c-reflectivity involving both the Suszko and the Leibniz congruence systems.

Lemma 826 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is (universally) family c-reflective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \textit{implies} \quad T \leq T'.$$

Proof: Assume, first, that $\mathcal{I}$ is universally family c-reflective and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Thus, by the definition of the Suszko operator,

$$\bigcap\{\Omega^{\mathcal{A}}(T'') : T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \leq \Omega^{\mathcal{A}}(T').$$

Using universal family c-reflectivity, we get that

$$\bigcap\{T'' : T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \leq T'.$$

Hence, $T \leq T'$, as required.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $T \leq T'$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then we have

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap_{T \in \mathcal{T}} T) & \leq & \bigcap_{T \in \mathcal{T}} \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) & (\text{monotonicity of } \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}) \\ & \leq & \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) & (\text{since } \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)) \\ & \leq & \Omega^{\mathcal{A}}(T'). & (\text{by hypothesis})\end{array}$$

Using the hypothesis, we conclude that $\bigcap \mathcal{T} \leq T'$. Therefore, $\mathcal{I}$ is family c-reflective. ■

Finally, we show that family c-reflectivity is identical with the universal family injectivity of the Suszko operator.

Theorem 827 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is (universally) family c-reflective if and only if the Suszko operator is universally family injective.*

Proof: Suppose, first, that the Suszko operator is universally family injective. To show that $\mathcal{I}$ is family c-reflective, we use Lemma 826. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

This implies that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is compatible with T'. We consider the natural transformation

$$\langle I,\gamma\rangle : \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \to \mathcal{A}/\Omega^{\mathcal{A}}(T').$$

Since $T'/\Omega^{\mathcal{A}}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T'))$, we get

$$\gamma^{-1}(T'/\Omega^{\mathcal{A}}(T')) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)),$$

i.e., $T'/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$. By universal family injectivity of the Suszko operator and Theorem 825, we get that $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \le T'/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Taking into account the compatibility of $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ with T', pointed out above, we get that $T \le T'$.

Assume, conversely, that $\mathcal{I}$ is (universally) family c-reflective. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T,T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Then, we have $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$ and $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \le \Omega^{\mathcal{A}}(T)$, whence, by hypothesis and Lemma 826, $T \le T'$ and $T' \le T$, showing that $T = T'$. Thus, the Suszko operator is universally family injective. ■

In a nutshell we have the following three equivalent properties, given in Theorems 825 and 827.

Suszko is Universally Family Injective

$\downarrow\uparrow$

Suszko has Universal Family Minimality

$\downarrow\uparrow$

$\mathcal{I}$ is (Universally) Family c-Reflective

11.7 Truth Equationality and c-Reflectivity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ was called *family c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \le \Omega(T') \quad \text{implies} \quad \bigcap_{T\in\mathcal{T}} T \le T'.$$

Family c-reflectivity implies family reflectivity, i.e., the property that, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \le \Omega(T')$ implies $T \le T'$. Finally, family c-reflectivity is a property strong enough to imply systemicity. Therefore, a π-institution is family c-reflective if and only if it is system c-reflective and systemic.

Recall, also, that $\mathcal{I}$ was called (*family*) *truth equational* if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \le \Omega(T).$$

In that case, $\tau^\flat$ is termed a **set of witnessing equations** (of/for the truth equationality of $\mathcal{I}$).

Note again that truth equationality implies systemicity. In fact, if $\mathcal{I}$ is truth equational with witnessing equations $\tau^\flat$, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we get

$$\begin{array}{rcl} \tau^\flat_\Sigma[\phi] \le \Omega(\overleftarrow{T}) & \text{iff} & \phi \in \overleftarrow{T}_\Sigma \\ & \text{implies} & \phi \in T_\Sigma \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T) \\ & \text{implies} & \tau^\flat_\Sigma[\phi] \le \Omega(\overleftarrow{T}). \end{array}$$

So all statements above are equivalent showing that $\overleftarrow{T} = T$. Thus, $\mathcal{I}$ is systemic.

It turns out that, if $\mathcal{I}$ is a truth equational π-institution, with witnessing equations $\tau^\flat$, then $\tau^\flat(\Omega(T))$ is exactly equal to T, i.e., that the witnessing equations reflect theory families.

Proposition 828 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, with witnessing equations $\tau^\flat$, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,*

$$\tau^\flat(\Omega(T)) = T.$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rcll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T) & \text{(definition)} \\ & \text{iff} & \phi \in T_\Sigma. & \text{(truth equationality)} \end{array}$$

■

Proposition 828 has as an immediate consequence the important fact that truth equationality implies family c-reflectivity.

Theorem 829 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, then it is family c-reflective.*

Proof: Suppose that $\mathcal{I}$ is truth equational with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \le \Omega(T')$. Then

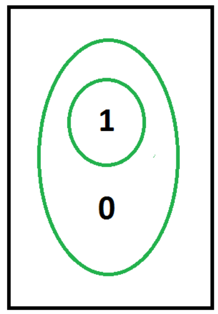
$$\begin{array}{rcll} \bigcap_{T\in\mathcal{T}} T & = & \bigcap_{T\in\mathcal{T}} \tau^\flat(\Omega(T)) & \text{(Proposition 828)} \\ & = & \tau^\flat(\bigcap_{T\in\mathcal{T}} \Omega(T)) & \text{(set theory)} \\ & \le & \tau^\flat(\Omega(T')) & \text{(hypothesis and Lemma 94)} \\ & = & T'. & \text{(Proposition 828)} \end{array}$$

Thus, $\mathcal{I}$ is family c-reflective. ■

The following example shows that the inclusion of Theorem 829 is proper.

Example 830 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

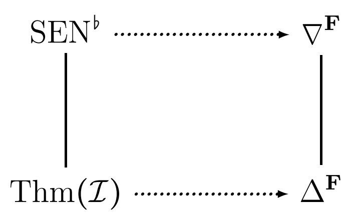
- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial category of natural transformations consisting of the projections only.*



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$*.*

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, which are also theory systems. Clearly,* $\mathrm{Thm}(\mathcal{I}) \leq \mathrm{SEN}^\flat$*. Moreover,* $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ *and* $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$*.* $\mathcal{I}$ *is clearly family c-reflective.*



On the other hand, there does not exist $\tau^\flat \subseteq N^\flat$*, such that* $I^\flat$ *has the required properties to constitute a witnessing set of equations for the truth equationality in* $\mathcal{I}$*. Any set consisting of projections only cannot satisfy the required condition since* $\tau^\flat(\Omega(T))$ *can only be* $\mathrm{SEN}^\flat$ *or* $\overline{\varnothing}$*.*

We now work towards a dual goal. We first provide a characterization of truth equationality in terms of the solubility property of the Suszko core of the π-institution. Then, we provide an exact description of those family c-reflective π-institutions which are truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We define the **Suszko core** $S^{\mathcal{I}}$ of $\mathcal{I}$ to be the collection

$$S^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T))\}.$$

By Lemma 821, this definition is equivalent to setting

$$S^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi)))\}.$$

The Suszko core has a list of interesting properties:

Proposition 831 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) $\iota \approx \iota \in S^{\mathcal{I}}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *denotes the identity;*

(b) If $\delta^\flat \approx \epsilon^\flat \in S^{\mathcal{I}}$*, then* $\epsilon^\flat \approx \delta^\flat \in S^{\mathcal{I}}$*;*

(c) If $\delta^\flat \approx \epsilon^\flat, \epsilon^\flat \approx \zeta^\flat \in S^{\mathcal{I}}$*, then* $\delta^\flat \approx \zeta^\flat \in S^{\mathcal{I}}$*;*

(d) If $\delta^\flat \approx \epsilon^\flat \in S^{\mathcal{I}}$*, then, for all* $\sigma^\flat \in N^\flat$*,*

$$\sigma^\flat \circ \langle \delta^\flat(\vec{p}), \vec{q} \rangle \approx \sigma^\flat \circ \langle \epsilon^\flat(\vec{p}), \vec{q} \rangle \in S^{\mathcal{I}},$$

where $\vec{p}, \vec{q}$ *denote vectors of projections*

$$\vec{p} = \langle p^{k+n-1,0}, \dots, p^{k+n-1,k-1} \rangle, \vec{q} = \langle p^{k+n-1,k}, \dots, p^{k+n-1,k+n-2} \rangle,$$

with k *the maximum arity between* $\delta^\flat$ *and* $\epsilon^\flat$*, and* n *the arity of* $\sigma^\flat$*.*

Proof:

(a) Since, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in T_\Sigma$,

$$(\iota \approx \iota)_\Sigma[\phi] \leq \Delta^{\mathbf{F}} \leq \widetilde{\Omega}^{\mathcal{I}}(T),$$

we get, by definition, $\iota \approx \iota \in S^{\mathcal{I}}$.

(b) Suppose that $\delta^\flat \approx \epsilon^\flat \in S^{\mathcal{I}}$. Then, by definition, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in T_\Sigma$, $(\delta^\flat \approx \epsilon^\flat)_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$. By the symmetry property of the Suszko congruence system $\widetilde{\Omega}^{\mathcal{I}}(T)$, we conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in T_\Sigma$, $(\epsilon^\flat \approx \delta^\flat)_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$. Therefore, $\epsilon^\flat \approx \delta^\flat \in S^{\mathcal{I}}$.

(c) This follows along the lines of Part (b), using the transitivity of the Suszko congruence system $\widetilde{\Omega}^{\mathcal{I}}(T)$ instead of its symmetry.

(d) Suppose that $\delta^\flat \approx \epsilon^\flat \in S^{\mathcal{I}}$ and $\sigma^\flat \in N^\flat$. Then, by definition of $S^{\mathcal{I}}$, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in T_\Sigma$, $(\delta^\flat \approx \epsilon^\flat)_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$. Thus, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\langle \delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \rangle \in \widetilde{\Omega}^{\mathcal{I}}_{\Sigma'}(T).$$

But, then, by the congruence compatibility property of $\widetilde{\Omega}^{\mathcal{I}}(T)$, we get that, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\langle \sigma^\flat_{\Sigma'}(\delta^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi}), \sigma^\flat_{\Sigma'}(\epsilon^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\vec{\xi})\rangle \in \widetilde{\Omega}^{\mathcal{I}}_{\Sigma'}(T).$$

Since $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$ were arbitrary, we get

$$(\sigma^\flat \circ \langle \delta^\flat(\vec{p}),\vec{q}\rangle \approx \sigma^\flat \circ \langle \epsilon^\flat(\vec{p}),\vec{q}\rangle)_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

Finally, since $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in T_\Sigma$ were arbitrary, we conclude that

$$\sigma^\flat \circ \langle \delta^\flat(\vec{p}),\vec{q}\rangle \approx \sigma^\flat \circ \langle \epsilon^\flat(\vec{p}),\vec{q}\rangle \in S^{\mathcal{I}}.$$

■

It is clear, by the definitions involved, that the Suszko core of a π-institution satisfies the following property:

Proposition 832 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T \leq S^{\mathcal{I}}(\Omega(T)).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{implies} & S^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad (\text{definition of } S^{\mathcal{I}}) \\ & \text{implies} & S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{array}$$

Thus, we get that $T \leq S^{\mathcal{I}}(\Omega(T))$. ■

It is possible, but not necessary, that the Suszko core of a π-institution satisfies the reverse inclusion. We call this property solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that the Suszko core of $\mathcal{I}$ is **soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$S^{\mathcal{I}}(\Omega(T)) \leq T.$$

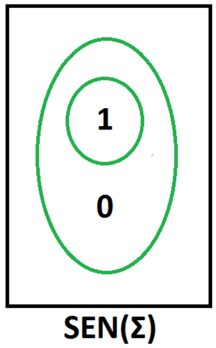
In other words, $S^{\mathcal{I}}$ is soluble if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

We present two examples to showcase the possibilities. In the first example, we look at a π-institution $\mathcal{I}$ whose Suszko core $S^{\mathcal{I}}$ is soluble.

Example 833 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

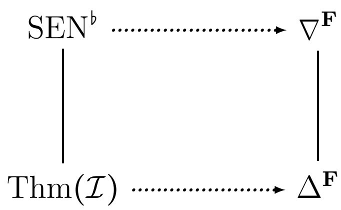
- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*



- *$N^\flat$ is the category of natural transformations generated by the single unary natural transformations $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$, specified by setting $\sigma^\flat_\Sigma(x) = 1$, for all $x \in \mathrm{SEN}^\flat(\Sigma)$.*

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\}$.

$\mathcal{I}$ has two theory families, $\mathrm{Thm}(\mathcal{I})$ and $\mathrm{SEN}^\flat$, which are also theory systems. Moreover, the structure of its posets of theory families and of their associated Leibniz congruence systems is given below.



One can see that the Suszko core of $\mathcal{I}$ is given by

$$S^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^\flat, \sigma^\flat \approx \iota, \sigma^\flat \approx \sigma^\flat\}.$$

Since the implication

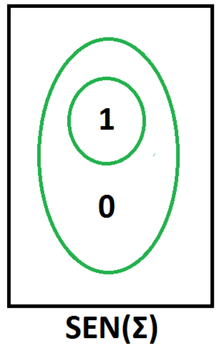
$$S^{\mathcal{I}}_\Sigma[\phi] \le T \quad \textit{implies} \quad \phi \in T_\Sigma$$

holds universally, we conclude that the Suszko core of $\mathcal{I}$ is soluble.

Next, we present an example of a π-institution $\mathcal{I}$ whose Suszko core $S^{\mathcal{I}}$ is not soluble.

Example 834 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

- *$\mathbf{Sign}^\flat$ is the trivial category with single object Σ;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is specified by $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$;*



- *$N^\flat$ is the trivial category of natural transformations consisting of the projections only.*

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be the π-institution determined by $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$.

$\mathcal{I}$ has two theory families, $\mathrm{Thm}(\mathcal{I})$ and $\mathrm{SEN}^\flat$, which are also theory systems. Moreover, the structure of its posets of theory families and of their associated Leibniz congruence systems is given below.

$$\begin{array}{ccc} \mathrm{SEN}^\flat & \cdots\cdots\to & \nabla^{\mathbf{F}} \\ \big| & & \big| \\ \mathrm{Thm}(\mathcal{I}) & \cdots\cdots\to & \Delta^{\mathbf{F}} \end{array}$$

One can see that the Suszko core of $\mathcal{I}$ is given by

$$S^{\mathcal{I}} = \{\iota \approx \iota\}.$$

We, thus, have that

$$S^{\mathcal{I}}_\Sigma[0] \le \Delta^{\mathbf{F}} = \Omega(\mathrm{Thm}(\mathcal{I})) \quad \textit{but} \quad 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I}).$$

Therefore $S^{\mathcal{I}}$ is not soluble.

It turns out that possession of the solubility property by the Suszko core intrinsically characterizes truth equationality. We can show, at the outset, that the Suszko core being soluble is necessary for truth equationality. Thus, there is no point in trying to discover witnessing equations unless the Suszko core of the π-institution $\mathcal{I}$ under scrutiny is soluble.

To show this, observe, first, that, in case a π-institution is truth equational, the witnessing equations form a subset of the Suszko core.

Lemma 835 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, with witnessing equations $\tau^\flat \subseteq N^\flat$, then $\tau^\flat \subseteq S^{\mathcal{I}}$.*

Proof: By truth equationality, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in T_\Sigma & \text{iff} & (\forall T \leq T' \in \mathrm{ThFam}(\mathcal{I}))(\phi \in T'_\Sigma) \\ & \text{iff} & (\forall T \leq T' \in \mathrm{ThFam}(\mathcal{I}))(\tau^\flat_\Sigma[\phi] \leq \Omega(T')) \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThFam}(\mathcal{I})\} \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T).\end{array}$$

We conclude, by the definition of $S^{\mathcal{I}}$, that $\tau^\flat \subseteq S^{\mathcal{I}}$. ∎

Now we prove the necessity of solubility for truth equationality.

Theorem 836 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is truth equational, then* $S^{\mathcal{I}}$ *is soluble.*

Proof: Suppose that $\mathcal{I}$ is truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{llll}S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(Lemma 835)} \\ & \text{iff} & \phi \in T_\Sigma. & \text{(truth equationality)}\end{array}$$

Thus, $S^{\mathcal{I}}$ is soluble. ∎

The reverse implication, which also holds and completes the promised characterization of truth equationality in terms of the Suszko core, is presented in the following result.

Theorem 837 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $S^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is truth equational, with witnessing equations* $S^{\mathcal{I}}$*.*

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 832, whereas the converse is ensured by the postulated solubility of $S^{\mathcal{I}}$. ∎

Theorems 836 and 837 provide the promised characterization of truth equationality in terms of the solubility of the Suszko core.

$$\mathcal{I} \text{ is Truth Equational} \longleftrightarrow S^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 838 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is truth equational if and only if* $S^{\mathcal{I}}$ *is soluble.*

Proof: Theorem 836 gives the "only if" and the "if" is by Theorem 837. ∎

If $\mathcal{I}$ is truth equational, then the Suszko core defines theory families in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 828, since $S^{\mathcal{I}}$ forms a maximal set of witnessing equations for the truth equationality of $\mathcal{I}$.

Proposition 839 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $S^{\mathcal{I}}$ *is soluble, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T = S^{\mathcal{I}}(\Omega(T)).$$

Proof: If $S^{\mathcal{I}}$ is soluble, then, by Theorem 837, $S^{\mathcal{I}}$ forms a set of witnessing equations for the truth equationality of $\mathcal{I}$. Therefore, by Proposition 828, we get that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $T = S^{\mathcal{I}}(\Omega(T))$. ∎

In fact, this property may also be restated as another characterization of truth equationality. Let us say that $S^{\mathcal{I}}$ **defines theory families** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = S^{\mathcal{I}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is Truth Equational} \longleftrightarrow S^{\mathcal{I}} \text{ Defines Theory Families.}$$

Theorem 840 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is truth equational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T = S^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is truth equational, then, by Theorem 838, $S^{\mathcal{I}}$ is soluble. Thus, by Proposition 839, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = S^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = S^{\mathcal{I}}(\Omega(T))$, then $S^{\mathcal{I}}$ is soluble. Thus, again by Theorem 838, $S^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is truth equational. ∎

We finally show that the property that separates family complete reflectivity from truth equationality is exactly the adequacy property of the Suszko core. Roughly speaking, this property ensures that the Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the Suszko core with both Leibniz and Suszko congruence systems.

Proposition 841 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \le \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{implies} & S^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad \text{(definition of the Suszko core)} \\ & \text{implies} & S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{array}$$

Therefore, we have

$$\begin{array}{rcl} \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} & \leq & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\} \\ & \leq & \bigcap\{\Omega(T) : \phi \in T_\Sigma\} \\ & = & \widetilde{\Omega}^{\mathcal{I}}(C(\phi)). \end{array}$$

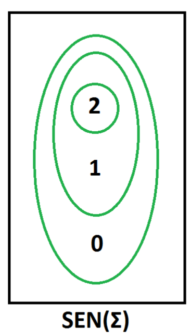
■

We provide an example, next, that shows that the inclusion proven in Proposition 841 is proper, in general. I.e., there exist π-institutions $\mathcal{I}$ in which, for some signature Σ and some Σ-sentence ϕ,

$$\bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \lneqq \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Example 842 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object Σ;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$;*
- $N^\flat$ *is the trivial category of natural transformations, consisting of the projections only.*



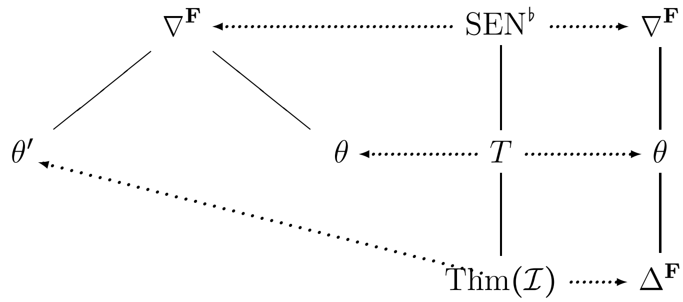
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and $\mathrm{SEN}^\flat$, all of which are theory systems.

Note that $S^{\mathcal{I}} = \{\iota \approx \iota\}$. Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the following diagram, where

$$T = \{\{1, 2\}\}, \quad \theta = \{\{0\}, \{1, 2\}\}, \quad \theta' = \{\{0, 1\}, \{2\}\}.$$



Taking this into account, it is not difficult to see that

$$\bigcap\{\Omega(T) : S^{\mathcal{I}}_{\Sigma}[1] \leq \Omega(T)\} = \Delta^{\mathbf{F}} \lneq \theta = \widetilde{\Omega}^{\mathcal{I}}(C(1)).$$

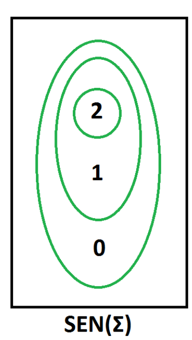
We also give an example of a π-institution $\mathcal{I}$ whose Suszko core $S^{\mathcal{I}}$ is such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap\{\Omega(T) : S^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T)\}.$$

Example 843 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0, 1, 2\} \to \{0, 1, 2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x) = 2.$$



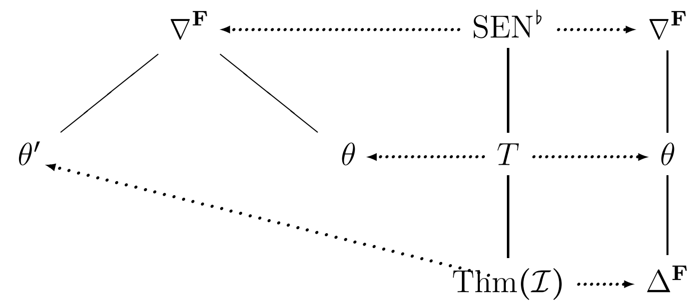
Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *has three theory families* $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{1, 2\}\}$ *and* $\mathrm{SEN}^\flat$*, all of which are theory systems.*

Note that $S^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^\flat, \sigma^\flat \approx \iota, \sigma^\flat \approx \sigma^\flat\}$. *Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the following diagram, where*

$$T = \{\{1,2\}\}, \quad \theta = \{\{0\},\{1,2\}\}, \quad \theta' = \{\{0,1\},\{2\}\}.$$



Now we can check:

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I}}(C(0)) & = & \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat)\\ & = & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[0] \le \Omega(T)\};\\ \widetilde{\Omega}^{\mathcal{I}}(C(1)) & = & \theta = \Omega(\mathrm{SEN}^\flat) \cap \Omega(T)\\ & = & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[1] \le \Omega(T)\};\\ \widetilde{\Omega}^{\mathcal{I}}(C(2)) & = & \Delta^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat) \cap \Omega(T) \cap \Omega(\mathrm{Thm}(\mathcal{I}))\\ & = & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[2] \le \Omega(T)\}.\end{array}$$

We have seen, therefore, through examples, that it is possible, but not necessary, that the Suszko core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 841:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \le \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}.$$

Intuitively speaking, this means that the Suszko core $S^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ-sentence ϕ, the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. We say that the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $S^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 844 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $S^{\mathcal{I}}$ *is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

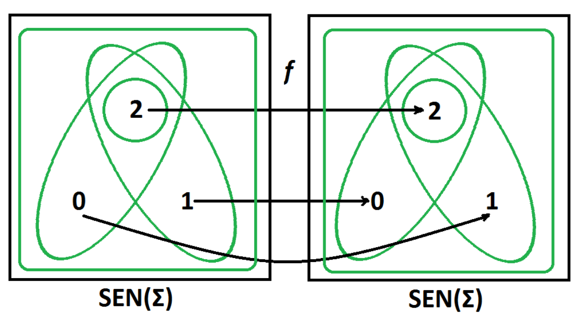
$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & = & \bigcap\{\Omega(T) : \phi \in T_\Sigma\} \quad (\text{definition of } \widetilde{\Omega}^{\mathcal{I}}(C(\phi)))\\ & = & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.\\ & & (\text{solubility of } S^{\mathcal{I}} \text{ and Proposition 839})\end{array}$$

We conclude that $S^{\mathcal{I}}$ is adequate. ■

Here is an example of a π-institution $\mathcal{I}$, with an adequate but not soluble Suszko core.

Example 845 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = i_\Sigma$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the trivial category of natural transformations (consisting of the projections only).*

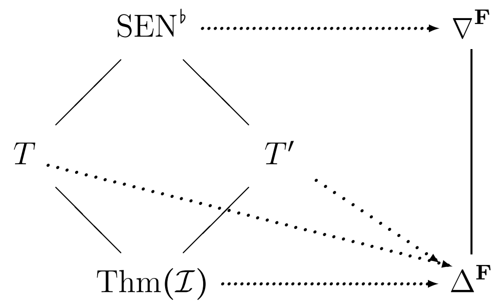


Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families* $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{0,2\}\}$*,* $T' = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$*, but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*. Therefore, being non-systemic, it can be neither family c-reflective nor truth-equational. The fact that it is not truth equational, together with Theorem 838, reveal that the Suszko core* $S^{\mathcal{I}}$ *is not soluble.*

To verify that $S^{\mathcal{I}}$ *is adequate, we look at the posets of theory families (left), Leibniz congruence systems (right) and Suszko congruence systems* *(right, identical with the Leibniz congruence systems, since the π-institution is protoalgebraic).*



Since $S^{\mathcal{I}} = \{\iota \approx \iota\}$, we verify adequacy of $S^{\mathcal{I}}$ by the following calculation, holding for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \Delta^{\mathbf{F}} = \bigcap_{T\in\mathrm{ThFam}(\mathcal{I})} \Omega(T) = \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Thus, $S^{\mathcal{I}}$ is in fact adequate but not soluble.

In the opposite direction, and on the positive side, in a *family c-reflective* π-institution $\mathcal{I}$, if the Suszko core is adequate, then it is also soluble.

Proposition 846 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a family c-reflective π-institution based on $\mathbf{F}$. If $S^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is family c-reflective and that $S^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 832. For the converse, assume that $S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by the adequacy of $S^{\mathcal{I}}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. Thus, by family c-reflectivity and Lemma 826, we conclude that $C(\phi) \leq T$, which gives $\phi \in T_\Sigma$. ∎

We finally show that a π-institution is truth equational if and only if it is family c-reflective and has an adequate Suszko core.

Truth Equationality	=	$S^{\mathcal{I}}$ Soluble
	=	$S^{\mathcal{I}}$ Defines Theory Families
	=	Family c-Reflectivity + $S^{\mathcal{I}}$ Adequate

Theorem 847 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if it is family c-reflective and has an adequate Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is truth equational. Then it is family c-reflective by Theorem 829. Moreover, its Suszko core is soluble by Theorem 838 and, hence, by Corollary 844, its Suszko core is adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with an adequate Suszko core. Then, by Proposition 846, its Suszko core is soluble and, therefore, by Theorem 838, $\mathcal{I}$ is truth equational. ∎

Finally, it is not difficult to see that, in some sense, truth equationality transfers from a π-institution to all $\mathcal{I}$-matrix families.

Theorem 848 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is truth equational, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$*.*

Proof: Suppose $\mathcal{I}$ is truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, whence, by hypothesis, $\alpha^{-1}(T) = \tau^\flat(\Omega(\alpha^{-1}(T)))$. Hence, by Proposition 24, $\alpha^{-1}(T) = \tau^\flat(\alpha^{-1}(\Omega^{\mathcal{A}}(T)))$. Therefore, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we get

$$\begin{array}{lll} \alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \\ & \text{iff} & \alpha(\tau_\Sigma^\flat[\phi]) \leq \Omega^{\mathcal{A}}(T) \\ & \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\langle F, \alpha\rangle \text{ surjective}) \end{array}$$

Taking again into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau_\Sigma^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T)$, i.e., $T = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. ∎

11.8 Left Truth Equationality

In this section, we look at versions of truth equationality and c-reflectivity that can still be applied to general theory families but do not force the π-institutions to be systemic. In the next section we will also look at *system truth equationality*, i.e., truth equationality applied only to theory systems, and at *system c-reflectivity*. In this section we take the "leftist" approach, "left" having the meaning attributed to it in Chapter 3.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **left c-reflective** if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}.$$

Left c-reflectivity is not strong enough to imply systemicity. Moreover, left c-reflectivity is a property intermediate between family c-reflectivity and system c-reflectivity.

We say that the π-institution $\mathcal{I}$ is **left truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \le \Omega(T).$$

In that case, we call $\tau^\flat$ a **set of witnessing equations** (of/for the left truth equationality of $\mathcal{I}$).

If $\mathcal{I}$ is a left truth equational π-institution, with witnessing equations $\tau^\flat$, then $\tau^\flat(\Omega(T))$ is exactly equal to $\overleftarrow{T}$, i.e., the witnessing equations reflect theory families only "up to arrow".

Proposition 849 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat$, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,*

$$\tau^\flat(\Omega(T)) = \overleftarrow{T}.$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T) \quad \text{(definition)} \\ & \text{iff} & \phi \in \overleftarrow{T}_\Sigma. \quad \text{(left truth equationality)} \end{array}$$

■

Proposition 849 has as an immediate consequence the important fact that left truth equationality implies left c-reflectivity.

Theorem 850 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, then it is left c-reflective.*

Proof: Suppose that $\mathcal{I}$ is left truth equational with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T')$. Then

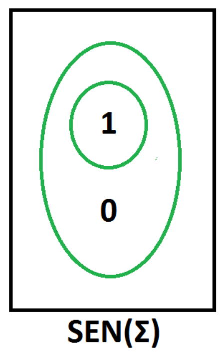
$$\begin{array}{lll} \bigcap_{T \in \mathcal{T}} \overleftarrow{T} & = & \bigcap_{T \in \mathcal{T}} \tau^\flat(\Omega(T)) \quad \text{(Proposition 849)} \\ & = & \tau^\flat(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad \text{(set theory)} \\ & \le & \tau^\flat(\Omega(T')) \quad \text{(hypothesis and Lemma 94)} \\ & = & \overleftarrow{T'}. \quad \text{(Proposition 849)} \end{array}$$

Thus, $\mathcal{I}$ is left c-reflective. ■

The following example shows that the inclusion of Theorem 850 is proper.

Example 851 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial category of natural transformations consisting of the projections only.*



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$*.*

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, which are also theory systems. In other words,* $\overleftarrow{\mathrm{Thm}(\mathcal{I})} = \mathrm{Thm}(\mathcal{I})$ *and* $\overleftarrow{\mathrm{SEN}^\flat} = \mathrm{SEN}^\flat$*. Clearly,* $\mathrm{Thm}(\mathcal{I}) \leq \mathrm{SEN}^\flat$*. Moreover,* $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ *and* $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$*.* $\mathcal{I}$ *is clearly left c-reflective.*

$$\begin{array}{ccc} \mathrm{SEN}^\flat & \cdots\cdots\rightarrow & \nabla^{\mathbf{F}} \\ | & & | \\ \mathrm{Thm}(\mathcal{I}) & \cdots\cdots\rightarrow & \Delta^{\mathbf{F}} \end{array}$$

On the other hand, there does not exist $\tau^\flat \subseteq N^\flat$*, such that* $I^\flat$ *has the required properties to constitute a witnessing set of equations for the left truth equationality in* $\mathcal{I}$*. Any set consisting of projections only cannot satisfy the required condition since* $\tau^\flat(\Omega(T))$ *can only be* $\mathrm{SEN}^\flat$ *or* $\overline{\varnothing}$*.*

We provide, next, a characterization of left truth equationality in terms of the left solubility property of the left Suszko core of the π-institution. Then, we provide an exact description of those left c-reflective π-institutions which are left truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **left Suszko core** of $\mathcal{I}$ is the collection

$$L^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[\overleftarrow{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

There is an alternative way to define the left Suszko core of a π-institution, which may be also viewed as justifying the alternative terminology *system Suszko core* for it, which we state in the form of a property.

Proposition 852 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$L^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

Proof: Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution and set

$$M^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

Our goal is to show that $M^{\mathcal{I}} = L^{\mathcal{I}}$.

Suppose, first, that $\sigma^\flat \in L^{\mathcal{I}}$ and let $T \in \mathrm{ThSys}(\mathcal{I})$. Then, we have

$$\begin{array}{rcll} \sigma^\flat[T] & = & \sigma^\flat[\overleftarrow{T}] & (T \in \mathrm{ThSys}(\mathcal{I})) \\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(T). & (\sigma^\flat \in L^{\mathcal{I}}) \end{array}$$

Therefore $\sigma^\flat \in M^{\mathcal{I}}$.

Suppose, conversely, that $\sigma^\flat \in M^{\mathcal{I}}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have

$$\begin{array}{rcll} \sigma^\flat[\overleftarrow{T}] & \leq & \widetilde{\Omega}^{\mathcal{I}}(\overleftarrow{T}) & (\sigma^\flat \in M^{\mathcal{I}} \text{ and } \overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})) \\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(T). & (\overleftarrow{T} \leq T \text{ and monotonicity of } \widetilde{\Omega}^{\mathcal{I}}) \end{array}$$

We conclude that $\sigma^\flat \in L^{\mathcal{I}}$ and, therefore, $M^{\mathcal{I}} = L^{\mathcal{I}}$. ∎

Note that, since, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} \leq T$, we get that $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$, which implies that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $L^{\mathcal{I}}(\Omega(T)) \leq S^{\mathcal{I}}(\Omega(T))$.

Note, also, that for systemic π-institutions the left Suszko core and the Suszko core are identical.

The left Suszko core of a π-institution satisfies the following property relating to the arrow operator:

Proposition 853 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} \leq L^{\mathcal{I}}(\Omega(T)).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rcll} \phi \in \overleftarrow{T}_\Sigma & \text{implies} & L^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) & (\text{by definition of } L^{\mathcal{I}}) \\ & \text{implies} & L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ & \text{iff} & \phi \in L^{\mathcal{I}}(\Omega(T)). & (\text{by definition}) \end{array}$$

∎

It is possible, but not necessary, that the left Suszko core of a π-institution satisfies the reverse inclusion. We call this property left solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the left Suszko core of $\mathcal{I}$ is **left soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$L^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{T}.$$

In other words, $L^{\mathcal{I}}$ is left soluble if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_\Sigma.$$

We show that this property has an alternative characterization in terms of theory systems.

Proposition 854 *Let $\mathcal{I} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. The left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $L^{\mathcal{I}}(\Omega(T)) = T$.*

Proof: For the "only if", assume that $L^{\mathcal{I}}$ is left soluble and let $T \in \mathrm{ThSys}(\mathcal{I})$. Then

$$\begin{array}{rcll} L^{\mathcal{I}}(\Omega(T)) & = & \overleftarrow{T} & (\text{Left Solubility of } L^{\mathcal{I}}) \\ & = & T. & (T \in \mathrm{ThSys}(\mathcal{I})) \end{array}$$

Conversely, assume that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $L^{\mathcal{I}}(\Omega(T)) = T$ and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have

$$\begin{array}{rcll} L^{\mathcal{I}}(\Omega(T)) & \leq & L^{\mathcal{I}}(\Omega(\overleftarrow{T})) & (\text{Proposition 20 and Lemma 94}) \\ & = & \overleftarrow{T}. & (\text{by hypothesis}) \end{array}$$

Thus, $L^{\mathcal{I}}$ is left soluble. ■

Note that for systemic π-institutions, since the left Suszko core coincides with the Suszko core, left solubility of the left Suszko core coincides with the solubility of the Suszko core. These two properties are, however, different in general and, as the following proposition and example show, solubility of the Suszko core is a stronger property than left solubility of the left Suszko core.

Proposition 855 *Let $\mathcal{I} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$ is soluble, then the left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble.*

Proof: Suppose that $S^{\mathcal{I}}$ is soluble, i.e., for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, since $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$, we get that $S^{\mathcal{I}}[\phi] \leq \Omega(T)$. Moreover, since $\Omega(T) \leq$

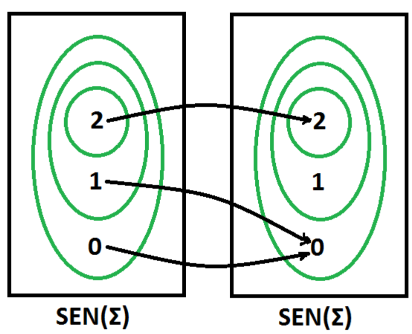
$\Omega(\overleftarrow{T})$, we get that $S^{\mathcal{I}}[\phi] \leq \Omega(\overleftarrow{T})$. Thus, by the solubility of $S^{\mathcal{I}}$, we get that $\phi \in \overleftarrow{T}_{\Sigma}$. We conclude that $L^{\mathcal{I}}$ is left soluble. ∎

The implication of Proposition 855 is proper in general.

Example 856 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by the single unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\} \to \{0,1,2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x) = 2.$$

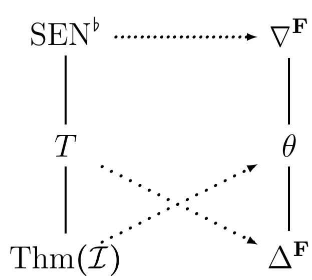


Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has three theory families* $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$*, but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*. So it is not a systemic* π*-institution.*

The posets of theory families and associated Leibniz congruence systems are shown in the following figure (where $T \in \{\{1,2\}\}$ *and* $\theta = \{\{0,1\},\{2\}\}$*):*



Note that

$$S^{\mathcal{I}} = \{\iota \approx \iota, \sigma^\flat \approx \sigma^\flat\},$$

whereas

$$L^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^\flat, \sigma^\flat \approx \iota, \sigma^\flat \approx \sigma^\flat\}.$$

We show that $L^{\mathcal{I}}$ is left soluble, but that $S^{\mathcal{I}}$ is not soluble.

The left solubility of $L^{\mathcal{I}}$ can be seen by looking at the defining implication on a case-by-case basis. The case of the theory family $\mathrm{SEN}^\flat$ *is trivial as is the case for $\phi = 2$. For $\phi = 0$ or 1 and for the theory families T or $\mathrm{ThFam}(\mathcal{I})$, we have:*

- $L^{\mathcal{I}}_\Sigma[0] \le \Omega(T)$ *is false;*
- $L^{\mathcal{I}}_\Sigma[1] \le \Omega(T)$ *is false;*
- $L^{\mathcal{I}}_\Sigma[0] \le \Omega(\mathrm{Thm}(\mathcal{I}))$ *is false;*
- $L^{\mathcal{I}}_\Sigma[1] \le \Omega(\mathrm{Thm}(\mathcal{I}))$ *is false.*

So in every other case the defining condition is vacuously satisfied.

On the other hand, $S^{\mathcal{I}}_\Sigma[0] \le \Omega(T)$, but $0 \notin T_\Sigma$, which shows that $S^{\mathcal{I}}$ is not soluble.

It turns out that possession of left solubility by the left Suszko core intrinsically characterizes left truth equationality. We show, first, that the left Suszko core being left soluble is necessary for left truth equationality. To demonstrate this, observe, first, that, in case a π-institution is left truth equational, the witnessing equations form a subset of the left Suszko core.

Lemma 857 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat \subseteq N^\flat$, then $\tau^\flat \subseteq L^{\mathcal{I}}$.*

Proof: By left truth equationality, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \le \Omega(T).$$

Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}
\phi \in \overleftarrow{T}_\Sigma & \text{iff} & (\forall T \le T' \in \mathrm{ThFam}(\mathcal{I}))(\phi \in \overleftarrow{T'}_\Sigma) \\
& & \text{(by Lemma 1)} \\
& \text{iff} & (\forall T \le T' \in \mathrm{ThFam}(\mathcal{I}))(\tau^\flat_\Sigma[\phi] \le \Omega(T')) \\
& & \text{(left truth equationality; displayed formula above)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \le \bigcap\{\Omega(T') : T \le T' \in \mathrm{ThFam}(\mathcal{I})\} \\
& & \text{(set theoretically)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \le \widetilde{\Omega}^{\mathcal{I}}(T). \\
& & \text{(by definition of } \widetilde{\Omega}^{\mathcal{I}})
\end{array}$$

We conclude, by the definition of $L^{\mathcal{I}}$, that $\tau^\flat \subseteq L^{\mathcal{I}}$. ■

Now we prove the necessity of left solubility of the left Suszko core for left truth equationality.

Theorem 858 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is left truth equational, then* $L^{\mathcal{I}}$ *is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{llll} L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(Lemma 857)} \\ & \text{iff} & \phi \in \overleftarrow{T}_\Sigma. & \text{(left truth equationality)} \end{array}$$

Thus, $L^{\mathcal{I}}$ is left soluble. ■

The reverse implication also holds and completes the promised characterization of left truth equationality in terms of the left Suszko core.

Theorem 859 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $L^{\mathcal{I}}$ *is left soluble, then* $\mathcal{I}$ *is left truth equational, with witnessing equations* $L^{\mathcal{I}}$*.*

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 853, whereas the converse is ensured by the postulated left solubility of $L^{\mathcal{I}}$. ■

Theorems 858 and 859 provide the promised characterization of left truth equationality in terms of the left solubility of the left Suszko core.

$$\mathcal{I} \text{ is Left Truth Equational} \longleftrightarrow L^{\mathcal{I}} \text{ is Left Soluble.}$$

Theorem 860 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is left truth equational if and only if* $L^{\mathcal{I}}$ *is left soluble.*

Proof: Theorem 858 gives the "only if" and the "if" is by Theorem 859. ■

If $\mathcal{I}$ is left truth equational, then the left Suszko core defines theory families in $\mathcal{I}$ "up to arrow" in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 849, since $L^{\mathcal{I}}$ forms a maximal set of witnessing equations of the left truth equationality of $\mathcal{I}$.

Proposition 861 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $L^{\mathcal{I}}$ *is left soluble, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T)).$$

Proof: If $L^{\mathcal{I}}$ is left soluble, then, by Theorem 859, $L^{\mathcal{I}}$ forms a set of witnessing equations for the left truth equationality of $\mathcal{I}$. Therefore, by Proposition 849, we get that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T))$. ■

This property may be restated as another characterization of left truth equationality. We say that $L^{\mathcal{I}}$ **defines theory families up to arrow** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T))$. Then we have:

$\mathcal{I}$ is Left Truth Equational
$\longleftrightarrow L^{\mathcal{I}}$ Defines Theory Families Up to Arrow.

Theorem 862 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is left truth equational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is left truth equational, then, by Theorem 860, $L^{\mathcal{I}}$ is left soluble. Thus, by Proposition 861, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}}(\Omega(T))$, then, $L^{\mathcal{I}}$ is left soluble. Thus, again by Theorem 860, $L^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is left truth equational. ■

We finally show that the property that separates left complete reflectivity from left truth equationality is a property of the left Suszko core, analogous to the adequacy property introduced previously for the Suszko core, that we call *left adequacy*. Similarly to adequacy, informally speaking, this property ensures that the left Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

The following relationship connects the left Suszko core with both Leibniz and Suszko congruence systems.

Recall that given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, and a sentence family $T \in \mathrm{SenFam}(\mathcal{I})$, we denote by $\overrightarrow{T}$ the least sentence system of $\mathcal{I}$ that includes T. Because of the structurality of C, it is not difficult to see that $C(\overrightarrow{T}) = \overrightarrow{C(T)}$, for any sentence family T of $\mathcal{I}$.

Proposition 863 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \le \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{lll}\phi \in \overleftarrow{T}_\Sigma & \text{implies} & L^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad \text{(definition of the left Suszko core)}\\ & \text{implies} & L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T))\end{array}$$

Therefore, we have

$$\begin{array}{lll}\bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} & \leq & \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}\\ & \leq & \bigcap\{\Omega(T) : \phi \in \overleftarrow{T}_\Sigma\}\\ & = & \bigcap\{\Omega(T) : \overrightarrow{\phi} \leq T\}\\ & = & \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).\end{array}$$

■

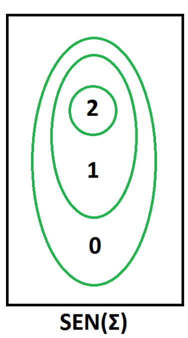
We provide an example, next, that shows that the inclusion proven in Proposition 863 is proper, in general. I.e., there exist π-institutions $\mathcal{I}$ in which, for some signature Σ and some Σ-sentence ϕ,

$$\bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \lneq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Of course, it is convenient that in a systemic π-institution $L^{\mathcal{I}} = S^{\mathcal{I}}$ and, moreover, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\overrightarrow{\phi}) = \overrightarrow{C(\phi)} = C(\phi)$, whence Example 842, used to prove proper inclusion following Proposition 841, may be reused.

Example 864 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the trivial category of natural transformations, consisting of the projections only.*



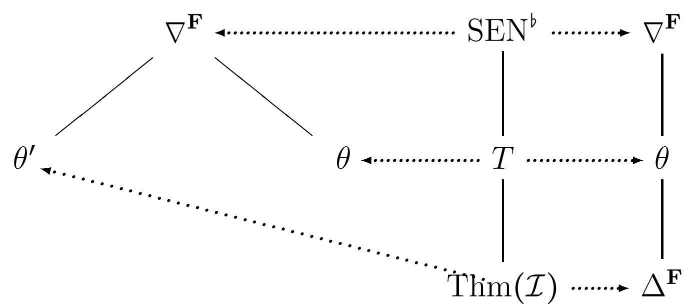
Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *all of which are theory systems. So $\mathcal{I}$ is systemic.*

We have $L^{\mathcal{I}} = S^{\mathcal{I}} = \{\iota \approx \iota\}$. Furthermore, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems are provided in the left and right sides, respectively, of the following diagram, where

$$T = \{\{1,2\}\}, \quad \theta = \{\{0\},\{1,2\}\}, \quad \theta' = \{\{0,1\},\{2\}\}.$$



Taking this into account, it is not difficult to see that

$$\bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[1] \leq \Omega(T)\} = \Delta^{\mathbf{F}} \lneq \theta = \widetilde{\Omega}^{\mathcal{I}}(C(1)) = \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{1})).$$

We also give an example of a π-institution $\mathcal{I}$ whose left Suszko core $L^{\mathcal{I}}$ is such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

This again takes after Example 843, since the π-institution used there was systemic.

Example 865 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

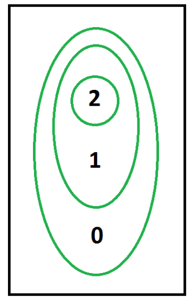
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the single unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\} \to \{0,1,2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x) = 2.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the π-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

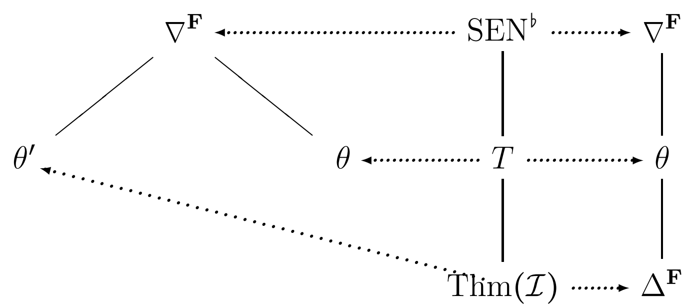
$\mathcal{I}$ has three theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *all of which are theory systems. So $\mathcal{I}$ is systemic.*



SEN(Σ)

Note that $L^{\mathcal{I}} = S^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^\flat, \sigma^\flat \approx \iota, \sigma^\flat \approx \sigma^\flat\}$*. Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the following diagram, where*

$$T = \{\{1,2\}\}, \quad \theta = \{\{0\},\{1,2\}\}, \quad \theta' = \{\{0,1\},\{2\}\}.$$



Now we can check:

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{0})) = \widetilde{\Omega}^{\mathcal{I}}(C(0)) & = & \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat) \\ & = & \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[0] \le \Omega(T)\}; \\ \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{1})) = \widetilde{\Omega}^{\mathcal{I}}(C(1)) & = & \theta = \Omega(\mathrm{SEN}^\flat) \cap \Omega(T) \\ & = & \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[1] \le \Omega(T)\}; \\ \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{2})) =^{\mathcal{I}} \widetilde{\Omega}(C(2)) & = & \Delta^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat) \cap \Omega(T) \cap \Omega(\mathrm{Thm}(\mathcal{I})) \\ & = & \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[2] \le \Omega(T)\}.\end{array}$$

We have seen, therefore, through examples, that it is possible, but not necessary, that the left Suszko core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 863:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \le \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}.$$

Intuitively speaking, this means that the left Suszko core $L^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ-sentence ϕ, the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\overrightarrow{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the left Suszko core $L^\mathcal{I}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^\mathcal{I}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : L^\mathcal{I}_\Sigma[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $L^\mathcal{I}$ is left soluble, then it is left adequate.

Corollary 866 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $L^\mathcal{I}$ *is left soluble, then it is left adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

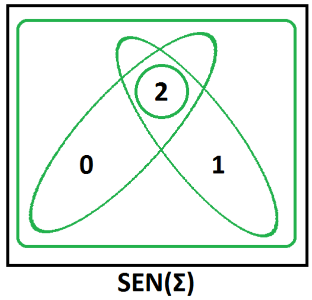
$$\begin{array}{rcll}\widetilde{\Omega}^\mathcal{I}(C(\overrightarrow{\phi})) & = & \bigcap\{\Omega(T) : \overrightarrow{\phi} \leq T\} & (\text{definition of } \widetilde{\Omega}^\mathcal{I}(C(\overrightarrow{\phi}))) \\ & = & \bigcap\{\Omega(T) : \phi \in \overleftarrow{T}_\Sigma\} & (\text{definition of } \overrightarrow{\phi} \text{ and } \overleftarrow{T}) \\ & = & \bigcap\{\Omega(T) : L^\mathcal{I}_\Sigma[\phi] \leq \Omega(T)\}. & \\ & & (\text{left solubility of } L^\mathcal{I} \text{ and Proposition 861}) & \end{array}$$

We conclude that $L^\mathcal{I}$ is left adequate. ■

Here is an example of a π-institution $\mathcal{I}$, with a left adequate but not left soluble left Suszko core.

Example 867 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by two unary natural transformations:*
  - $\rho^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\rho^\flat_\Sigma : \{0, 1, 2\} \to \{0, 1, 2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*
  $$\rho^\flat_\Sigma(x) = \begin{cases} 1, & \text{if } x = 0 \\ 0, & \text{if } x = 1 \\ 2, & \text{if } x = 2 \end{cases}.$$
  - $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0, 1, 2\} \to \{0, 1, 2\}$ *be given, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*, by*
  $$\sigma^\flat_\Sigma(x) = \begin{cases} 2, & \text{if } x = 0 \\ 1, & \text{if } x = 1 \\ 2, & \text{if } x = 2 \end{cases}.$$

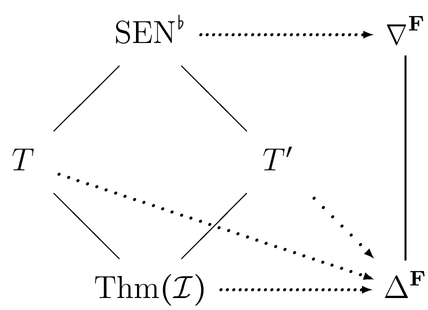


Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has four theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{0,2\}\}$, $T' = \{\{1,2\}\}$ and $\mathrm{SEN}^\flat$, all of which are theory systems. So it is a systemic π-institution.

The posets of theory families (center), associated Leibniz congruence systems (right) and associate Suszko congruence systems (right, identical with Leibniz congruence systems, since $\mathcal{I}$ is protoalgebraic) are shown in the following figure:



Note that $L^{\mathcal{I}} = \{\iota \approx \iota\}$. We show that $L^{\mathcal{I}}$ is left adequate, but not left soluble. We are omitting arrows from the notation is the following verifications since, as $\mathcal{I}$ is based on $\mathbf{F}$ with trivial $\mathbf{Sign}^\flat$, they play no role in this context.

For left adequacy, we have

$$\begin{aligned}
\widetilde{\Omega}^{\mathcal{I}}(C(0)) &= \widetilde{\Omega}^{\mathcal{I}}(T) = \Delta^{\mathbf{F}} = \bigcap\{\Omega(T'') : T'' \in \mathrm{ThFam}(\mathcal{I})\};\\
\widetilde{\Omega}^{\mathcal{I}}(C(1)) &= \widetilde{\Omega}^{\mathcal{I}}(T') = \Delta^{\mathbf{F}} = \bigcap\{\Omega(T'') : T'' \in \mathrm{ThFam}(\mathcal{I})\};\\
\widetilde{\Omega}^{\mathcal{I}}(C(2)) &= \widetilde{\Omega}^{\mathcal{I}}(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}} = \bigcap\{\Omega(T'') : T'' \in \mathrm{ThFam}(\mathcal{I})\}.
\end{aligned}$$

As for left solubility, note that $L^{\mathcal{I}}_\Sigma[0] \leq \Omega(T')$, but that $0 \notin T'_\Sigma$. Thus, $L^{\mathcal{I}}$ is not left soluble.

In the opposite direction, and on the positive side, in a *left c-reflective* π-institution $\mathcal{I}$, if the left Suszko core is left adequate, then it is also left soluble.

First, we note that the following variant of Lemma 826, giving an alternative characterization of left c-reflectivity in terms of both the Suszko and the Leibniz operators, holds.

Lemma 868 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is left c-reflective if and only if, for every* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$

Proof: Assume, first, that $\mathcal{I}$ is left c-reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$. By the definition of the Suszko operator,

$$\bigcap\{\Omega(T'') : T \leq T'' \in \mathrm{ThFam}(\mathcal{I})\} \leq \Omega(T').$$

Using left c-reflectivity, we get that

$$\bigcap\{\overleftarrow{T''} : T \leq T'' \in \mathrm{ThFam}(\mathcal{I})\} \leq \overleftarrow{T'}.$$

Hence, using Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$, as required.

Suppose, conversely, that, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$ implies $\overleftarrow{T} \leq \overleftarrow{T'}$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{rcll}
\widetilde{\Omega}^{\mathcal{I}}(\bigcap_{T \in \mathcal{T}} T) & \leq & \bigcap_{T \in \mathcal{T}} \widetilde{\Omega}^{\mathcal{I}}(T) & (\text{monotonicity of } \widetilde{\Omega}^{\mathcal{I}}) \\
& \leq & \bigcap_{T \in \mathcal{T}} \Omega(T) & (\text{since } \widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\
& \leq & \Omega(T'). & (\text{by hypothesis})
\end{array}$$

Using the hypothesis, we conclude that $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \overleftarrow{T'}$. Thus, by Lemma 3, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is left c-reflective. ■

And now for the promised result showing that in a left c-reflective π-institution $\mathcal{I}$, if the left Suszko core is left adequate, then it is also left soluble.

Proposition 869 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a left c-reflective* π*-institution based on* $\mathbf{F}$*. If* $L^{\mathcal{I}}$ *is left adequate, then it is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left c-reflective and that $L^{\mathcal{I}}$ is left adequate. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 853. For the converse, assume that $L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by the left adequacy of $L^{\mathcal{I}}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \Omega(T)$. Thus, by left c-reflectivity and Lemma 868, we conclude that $\overleftarrow{C(\overrightarrow{\phi})} \leq \overleftarrow{T}$, which gives $\phi \in \overleftarrow{T}_\Sigma$. ■

We finally show that a π-institution is left truth equational if and only if it is left c-reflective and its left Suszko core is left adequate.

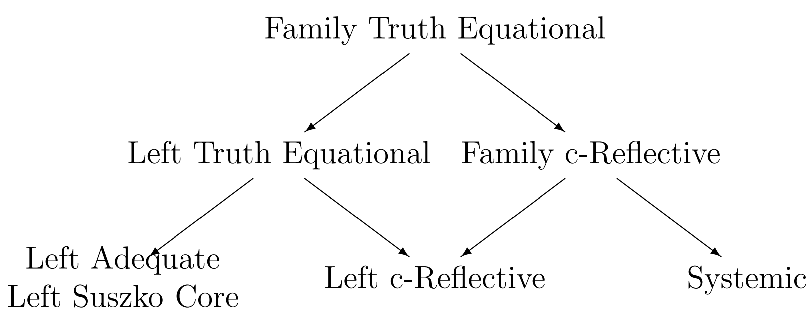
Left Truth Equationality	=	$L^{\mathcal{I}}$ Left Soluble
	=	$L^{\mathcal{I}}$ Defines Theory Families Up to Arrow
	=	Left c-Reflectivity + $L^{\mathcal{I}}$ Left Adequate

Theorem 870 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is left truth equational. Then it is left c-reflective by Theorem 850. Moreover, its left Suszko core is left soluble by Theorem 860 and, hence, by Corollary 866, its left Suszko core is left adequate.

Suppose, conversely, that $\mathcal{I}$ is left c-reflective with a left adequate left Suszko core. Then, by Proposition 869, its left Suszko core is left soluble and, therefore, by Theorem 860, $\mathcal{I}$ is left truth equational. ■

We have now established the following hierarchy of properties:



11.9 System Truth Equationality

In this section, we look at system truth equationality and system c-reflectivity, which can also be applied to a π-institution without forcing it to be systemic. Recall that, by Proposition **??**, system c-reflectivity is a weaker property than left c-reflectivity, i.e., left c-reflectivity, which was used in the characterization of left truth equationality in the preceding section, implies system c-reflectivity.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **system c-reflective** if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T\in\mathcal{T}} T \leq T'.$$

Since left c-reflectivity is not strong enough to imply systemicity, system c-reflectivity has, a fortiori, the same property.

We say that the π-institution $\mathcal{I}$ is **system truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ having a single distinguished argument, such that, for every $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

In that case, we call $\tau^\flat$ a **set of witnessing equations** (of/for the system truth equationality of $\mathcal{I}$).

If $\mathcal{I}$ is a system truth equational π-institution, with witnessing equations $\tau^\flat$, then, for $T \in \mathrm{ThSys}(\mathcal{I})$, $\tau^\flat(\Omega(T))$ is exactly equal to T, i.e., the witnessing equations reflect theory systems.

Proposition 871 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is system truth equational, with witnessing equations* $\tau^\flat$*, then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\tau^\flat(\Omega(T)) = T.$$

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{llll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(definition)} \\ & \text{iff} & \phi \in T_\Sigma. & \text{(system truth equationality)} \end{array}$$

■

Proposition 871 has as an immediate consequence the important fact that system truth equationality implies system c-reflectivity.

Theorem 872 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is system truth equational, then it is system c-reflective.*

Proof: Suppose that $\mathcal{I}$ is system truth equational with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then

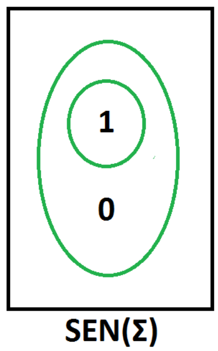
$$\begin{array}{lll} \bigcap_{T\in\mathcal{T}} T & = & \bigcap_{T\in\mathcal{T}} \tau^\flat(\Omega(T)) \quad \text{(Proposition 871)} \\ & = & \tau^\flat(\bigcap_{T\in\mathcal{T}} \Omega(T)) \quad \text{(set theory)} \\ & \leq & \tau^\flat(\Omega(T')) \quad \text{(hypothesis and Lemma 94)} \\ & = & T'. \quad \text{(Proposition 871)} \end{array}$$

Thus, $\mathcal{I}$ is system c-reflective. ■

The following example shows that the inclusion of Theorem 872 is proper.

Example 873 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$*.*

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, which are also theory systems. Clearly,* $\mathrm{Thm}(\mathcal{I}) \leq \mathrm{SEN}^\flat$*. Moreover,* $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ *and* $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$*.* $\mathcal{I}$ *is clearly system c-reflective.*

$$\begin{array}{ccc}
\mathrm{SEN}^\flat & \cdots\cdots\rightarrow & \nabla^{\mathbf{F}} \\
| & & | \\
\mathrm{Thm}(\mathcal{I}) & \cdots\cdots\rightarrow & \Delta^{\mathbf{F}}
\end{array}$$

On the other hand, there does not exist $\tau^\flat \subseteq N^\flat$*, such that* $I^\flat$ *has the required properties to constitute a witnessing set of equations for the system truth equationality in* $\mathcal{I}$*. Any set consisting of projections only cannot satisfy the required condition since* $\tau^\flat(\Omega(T))$ *can only be* $\mathrm{SEN}^\flat$ *or* $\overline{\varnothing}$*.*

We provide, next, a characterization of system truth equationality in terms of the solubility property of the system core of the π-institution. Then, we provide an exact description of those system c-reflective π-institutions which are system truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. First, for $T \in \mathrm{ThSys}(\mathcal{I})$, we introduce the notation

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThSys}(\mathcal{I})\}.$$

We now define the **system core** of $\mathcal{I}$ to be the collection

$$Z^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widehat{\Omega}^{\mathcal{I}}(T)\}.$$

The following proposition clarifies the relation between the Suszko core, the left Suszko core and the system core of a π-institution $\mathcal{I}$.

Proposition 874 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $S^{\mathcal{I}} \subseteq L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$*;*

(b) For every relation family θ *on* $\mathbf{F}$*,* $Z^{\mathcal{I}}(\theta) \leq L^{\mathcal{I}}(\theta) \leq S^{\mathcal{I}}(\theta)$*.*

Proof: For Part (a), $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$ has been shown after Proposition 852. For the second inclusion, assume that $\sigma^\flat \in L^{\mathcal{I}}$ and let $T \in \mathrm{ThSys}(\mathcal{I})$. Then we have

$$\begin{array}{rcll}\sigma^\flat[T] & = & \sigma^\flat[\overleftarrow{T}] & (T \in \mathrm{ThSys}(\mathcal{I}))\\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(T) & (\sigma^\flat \in L^{\mathcal{I}})\\ & \leq & \widehat{\Omega}^{\mathcal{I}}(T). & (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \widehat{\Omega}^{\mathcal{I}}(T))\end{array}$$

Thus $\sigma^\flat \in Z^\flat$ and $L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$. Part (b) follows form Part (a) and the relevant definitions. ■

The system core of a π-institution satisfies the following property related to the Leibniz congruence systems of the theory systems of the π-institution:

Proposition 875 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$T \leq Z^{\mathcal{I}}(\Omega(T)).$$

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rlll}\phi \in T_\Sigma & \text{implies} & Z^{\mathcal{I}}_\Sigma[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) & (\text{by definition of } Z^{\mathcal{I}})\\ & \text{implies} & Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & (\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T))\\ & \text{iff} & \phi \in Z^{\mathcal{I}}(\Omega(T)). & (\text{by definition})\end{array}$$

■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is **soluble** if the converse inclusion to that proven in Proposition 875 holds, i.e., if, for all $T \in \mathrm{ThSys}(\mathcal{I})$

$$Z^{\mathcal{I}}(\Omega(T)) \leq T.$$

Equivalently, $Z^{\mathcal{I}}$ is soluble if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

We show that left solubility of the left Suszko core implies solubility of the system core of a π-institution.

Proposition 876 *Let $\mathcal{I} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If the left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble, then the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is soluble.*

Proof: Suppose that $L^{\mathcal{I}}$ is left soluble and let $T \in \mathrm{ThSys}(\mathcal{I})$. Then we have

$$\begin{array}{lll} Z^{\mathcal{I}}(\Omega(T)) & \leq & L^{\mathcal{I}}(\Omega(T)) \quad \text{(Proposition 874)} \\ & = & T. \quad \text{(hypothesis and Proposition 854)} \end{array}$$

Therefore, $Z^{\mathcal{I}}$ is soluble. ■

It turns out that the property of solubility of the system core intrinsically characterizes system truth equationality. We show, first, that the system core being soluble is necessary for system truth equationality. Observe that, in case a π-institution is system truth equational, the witnessing equations form a subset of the system core.

Lemma 877 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^\flat \subseteq N^\flat$, then $\tau^\flat \subseteq Z^{\mathcal{I}}$.*

Proof: By system truth equationality, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

Thus, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & (\forall T \leq T' \in \mathrm{ThSys}(\mathcal{I}))(\phi \in T'_\Sigma) \\ & \text{iff} & (\forall T \leq T' \in \mathrm{ThSys}(\mathcal{I}))(\tau^\flat_\Sigma[\phi] \leq \Omega(T')) \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThSys}(\mathcal{I})\} \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T). \end{array}$$

We conclude, by the definition of $Z^{\mathcal{I}}$, that $\tau^\flat \subseteq Z^{\mathcal{I}}$. ■

Now we prove the necessity of the solubility of the system core for system truth equationality.

Theorem 878 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, then $Z^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(Lemma 877)} \\ & \text{iff} & \phi \in T_\Sigma. \quad \text{(system truth equationality)} \end{array}$$

Thus, $Z^{\mathcal{I}}$ is soluble. ■

The reverse implication completes the promised characterization of system truth equationality in terms of the system core.

Theorem 879 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is system truth equational, with witnessing equations* $Z^{\mathcal{I}}$*.*

Proof: It suffices to show that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 875, whereas the converse is ensured by the postulated solubility of $Z^{\mathcal{I}}$. ■

Theorems 878 and 879 provide the promised characterization of system truth equationality in terms of the solubility of the system core.

$$\mathcal{I} \text{ is System Truth Equational} \longleftrightarrow Z^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 880 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system truth equational if and only if* $Z^{\mathcal{I}}$ *is soluble.*

Proof: Theorem 878 gives the "only if" and the "if" is by Theorem 879. ■

If $\mathcal{I}$ is system truth equational, then the system core defines theory systems in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 871, since $Z^{\mathcal{I}}$ forms a maximal set of witnessing equations of the system truth equationality of $\mathcal{I}$.

Proposition 881 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}}$ *is soluble, then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$T = Z^{\mathcal{I}}(\Omega(T)).$$

Proof: If $Z^{\mathcal{I}}$ is soluble, then, by Theorem 879, $Z^{\mathcal{I}}$ forms a set of witnessing equations for the system truth equationality of $\mathcal{I}$. Therefore, by Proposition 871, we get that, for every $T \in \mathrm{ThSys}(\mathcal{I})$, $T = Z^{\mathcal{I}}(\Omega(T))$. ■

This property may be restated as another characterization of system truth equationality. We say that $Z^{\mathcal{I}}$ **defines theory systems** if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = Z^{\mathcal{I}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is System Truth Equational} \longleftrightarrow Z^{\mathcal{I}} \text{ Defines Theory Systems.}$$

Theorem 882 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system truth equational if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$T = Z^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is system truth equational, then, by Theorem 990, $Z^{\mathcal{I}}$ is soluble. Thus, by Proposition 881, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = Z^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = Z^{\mathcal{I}}(\Omega(T))$, then, $Z^{\mathcal{I}}$ is soluble. Thus, again by Theorem 990, $Z^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is system truth equational. ∎

We finally show that the property that separates system complete reflectivity from system truth equationality is a property of the system core that we call adequacy. In analogy to the adequacy of the Suszko core and to the left adequacy of the left Suszko core, this property ensures that the system core is rich enough to define the congruence system $\widehat{\Omega}^{\mathcal{I}}(T)$ of a theory system T in terms of the Leibniz congruence systems of collections of theory systems that it selects via inclusion.

Recall, once more, that given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$, and a sentence family $T \in \mathrm{SenFam}(\mathcal{I})$, we denote by $\overrightarrow{T}$ the least sentence system of $\mathcal{I}$ that includes T (see Proposition 2).

Proposition 883 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\begin{array}{llll} \phi \in T_\Sigma & \text{implies} & Z^{\mathcal{I}}_\Sigma[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) & \text{(definition of the system core)} \\ & \text{implies} & Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). & (\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{array}$$

Therefore, we have

$$\begin{aligned} &\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \\ &\quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T)\} \\ &\quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ &\quad = \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\ &\quad = \widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})). \end{aligned}$$

Therefore, the displayed inclusion always holds. ∎

It is possible, but not necessary, that the system core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 883:

$$\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Intuitively speaking, this means that the system core $Z^{\mathcal{I}}$ is rich enough to allow, for every Σ-sentence ϕ, the determination of those theory systems whose Leibniz congruence systems form a covering of the congruence system $\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))$ associated with $C(\overrightarrow{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $Z^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 884 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}}$ *is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcl}
\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\
& & (\text{definition of } \widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))) \\
& = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in T\} \\
& & (T \in \mathrm{ThSys}(\mathcal{I})) \\
& = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}. \\
& & (\text{solubility of } Z^{\mathcal{I}} \text{ and Proposition 881})
\end{array}$$

We conclude that $Z^{\mathcal{I}}$ is adequate. ■

As a partial converse, in a *system c-reflective* π-institution $\mathcal{I}$, if the system core is adequate, then it is also soluble.

First, we prove the following variant of Lemma 826, giving an alternative characterization of system c-reflectivity in terms of both $\widehat{\Omega}^{\mathcal{I}}$ and the Leibniz operator.

Lemma 885 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system c-reflective if and only if, for every* $T, T' \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T') \quad \textit{implies} \quad T \leq T'.$$

Proof: Assume, first, that $\mathcal{I}$ is system c-reflective and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$. By the definition of the hat operator,

$$\bigcap\{\Omega(T'') : T \leq T'' \in \mathrm{ThSys}(\mathcal{I})\} \leq \Omega(T').$$

Using system c-reflectivity, we get that

$$\bigcap\{T'' : T \leq T'' \in \mathrm{ThSys}(\mathcal{I})\} \leq T'.$$

Hence, we conclude $T \leq T'$, as required.

Suppose, conversely, that, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$ implies $T \leq T'$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{lll} \widetilde{\Omega}^{\mathcal{I}}(\bigcap_{T \in \mathcal{T}} T) & \leq & \bigcap_{T \in \mathcal{T}} \widetilde{\Omega}^{\mathcal{I}}(T) \quad \text{(monotonicity of } \widetilde{\Omega}^{\mathcal{I}}) \\ & \leq & \bigcap_{T \in \mathcal{T}} \Omega(T) \quad (\text{since } \widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ & \leq & \Omega(T'). \quad \text{(by hypothesis)} \end{array}$$

Using the hypothesis, we conclude that $\bigcap_{T \in \mathcal{T}} T \leq T'$. Therefore, $\mathcal{I}$ is system c-reflective. ■

And now for the promised result showing that in a system c-reflective π-institution $\mathcal{I}$, if the system core is adequate, then it is also soluble.

Proposition 886 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a system c-reflective* π*-institution based on* $\mathbf{F}$*. If the system core* $Z^{\mathcal{I}}$ *is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is system c-reflective and that $Z^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 875. For the converse, assume that $Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by the adequacy of $Z^{\mathcal{I}}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \Omega(T)$. Thus, by system c-reflectivity and Lemma 885, we conclude that $C(\overrightarrow{\phi}) \leq T$, which gives $\phi \in T_\Sigma$. ■

We finally show that a π-institution is system truth equational if and only if it is system c-reflective and its system core is adequate.

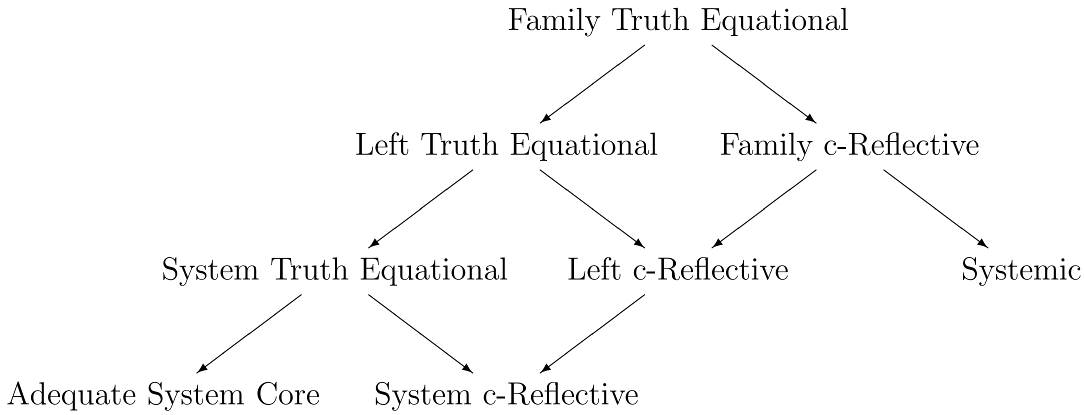
System Truth Equationality	=	$Z^{\mathcal{I}}$ Left Soluble
	=	$Z^{\mathcal{I}}$ Defines Theory Systems
	=	System c-Reflectivity + $Z^{\mathcal{I}}$ Adequate

Theorem 887 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: Suppose, first, that $\mathcal{I}$ is system truth equational. Then it is system c-reflective by Theorem 872. Moreover, its system core is soluble by Theorem 990 and, hence, by Corollary 884, its system core is adequate.

Suppose, conversely, that $\mathcal{I}$ is system c-reflective with an adequate system core. Then, by Proposition 886, its system core is soluble and, therefore, by Theorem 990, $\mathcal{I}$ is system truth equational. ■

We have now established the following hierarchy of properties:



Chapter 12

The Syntactic Leibniz Hierarchy: Edifice

12.1 Translations

In this section we discuss translations, interpretations and equivalence that will be used later in the context of algebraizable π-institutions. In the context of algebraizability, the algebraic counterparts of π-institutions may consist of algebraic closure families that lack the property of structurality, i.e., they are not closure systems, as introduced previously. Since these closure families are not structural in general, the corresponding algebraic structures do not constitute π-institutions. To accommodate these, we deal with more general structures that include all π-institutions, but also pairs of algebraic systems and closure families that are non-structural. We call these π-*structures*.

Definition 888 *A* π-**structure** $\mathcal{K} = \langle \mathbf{K}, D \rangle$ *is a pair consisting of:*

- *an algebraic system* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*;*
- *a* $|\mathbf{Sign}|$*-indexed family* $D = \{D_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ *of closure operators* $D_\Sigma : \mathcal{P}\mathrm{SEN}(\Sigma) \to \mathcal{P}\mathrm{SEN}(\Sigma)$*,* $\Sigma \in |\mathbf{Sign}|$*.*

Such a family D *is called a* **closure family** *on* $\mathbf{K}$*.*

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ and $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be two algebraic systems. A **translation** $\alpha : \mathbf{K} \to \mathbf{K}'$ is a collection

$$\alpha = \{\alpha_\Sigma\}_{\Sigma \in |\mathbf{Sign}|},$$

where, for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SenFam}(\mathbf{K}')$$

assigns to each Σ-sentence ϕ of $\mathbf{K}$ a sentence family

$$\alpha_\Sigma[\phi] = \{\alpha_{\Sigma,\Sigma'}[\phi]\}_{\Sigma' \in |\mathbf{Sign}'|}.$$

For $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \mathrm{SEN}(\Sigma)$, we set

$$\alpha_\Sigma[\Phi] = \bigcup \{\alpha_\Sigma[\phi] : \phi \in \Phi\},$$

where the union is, as usual, taken signature-wise and, hence, $\alpha_\Sigma[\Phi] \in \mathrm{SenFam}(\mathbf{K}')$. More generally, for $T \in \mathrm{SenFam}(\mathbf{K})$, we set

$$\alpha[T] = \bigcup \{\alpha_\Sigma[T_\Sigma] : \Sigma \in |\mathbf{Sign}|\}.$$

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be algebraic systems and $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π-structures based on $\mathbf{K}, \mathbf{K}'$, respectively. An

interpretation $\alpha : \mathcal{K} \to \mathcal{K}'$ is a translation $\alpha : \mathbf{K} \to \mathbf{K}'$, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma[\phi] \leq D'(\alpha_\Sigma[\Phi]).$$

If such an interpretation exists, then $\mathcal{K}$ is said to be **interpretable in** $\mathcal{K}'$.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems and $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ be π-structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively. Let, also,

$$\alpha : \mathcal{K} \to \mathcal{K}' \quad \text{and} \quad \beta : \mathcal{K}' \to \mathcal{K}$$

be interpretations from $\mathcal{K}$ to $\mathcal{K}'$ and from $\mathcal{K}'$ to $\mathcal{K}$, respectively. α and β are said to be **inverses** of each other and the pair $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is referred to as a **conjugate pair** if:

- for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$D(\phi) = D(\beta[\alpha_\Sigma[\phi]]);$$

- for all $\Sigma' \in |\mathbf{Sign}'|$ and all $\psi \in \mathrm{SEN}'(\Sigma')$,

$$D'(\psi) = D'(\alpha[\beta_{\Sigma'}[\psi]]).$$

The π-structures $\mathcal{K}$ and $\mathcal{K}'$ are called **equivalent** if there exists a conjugate pair $\mathcal{K} \overset{(\alpha,\beta)}{\rightleftarrows} \mathcal{K}'$.

Lemma 889 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be π-structures based on* $\mathbf{K}$, $\mathbf{K}'$*, respectively, and* $\alpha : \mathbf{K} \to \mathbf{K}'$, $\beta : \mathbf{K}' \to \mathbf{K}$ *translations. The following are equivalent:*

(i) $\alpha : \mathcal{K} \to \mathcal{K}'$ *is an interpretation and, for all* $\Sigma' \in |\mathbf{Sign}'|$, $\psi \in \mathrm{SEN}'(\Sigma')$, $D'(\psi) = D'(\alpha[\beta_{\Sigma'}[\psi]])$*;*

(ii) $\beta : \mathcal{K}' \to \mathcal{K}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, $D(\phi) = D(\beta[\alpha_\Sigma[\phi]])$*.*

Proof: By symmetry, it suffices to show (i)⇒(ii).

Suppose, first, that $\Sigma' \in |\mathbf{Sign}'|$ and $\Psi \cup \{\psi\} \subseteq \mathrm{SEN}'(\Sigma')$. Then, we have

$$\begin{array}{lll} \psi \in D'_{\Sigma'}(\Psi) & \text{iff} & D'(\psi) \leq D'(\Psi) \\ & \text{iff} & D'(\alpha[\beta_{\Sigma'}[\psi]]) \leq D'(\alpha[\beta_{\Sigma'}[\Psi]]) \\ & \text{iff} & \alpha[\beta_{\Sigma'}[\psi]] \leq D'(\alpha[\beta_{\Sigma'}[\Psi]]) \\ & \text{iff} & \beta_{\Sigma'}[\psi] \leq D(\beta_{\Sigma'}[\Psi]). \end{array}$$

So $\beta : \mathcal{K}' \to \mathcal{K}$ is an interpretation.

Assume, next, that $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then, by the hypothesis applied to $\alpha_\Sigma[\phi] \in \mathrm{SenFam}(\mathbf{K}')$, we have

$$D'(\alpha[\beta[\alpha_\Sigma[\phi]]]) = D'(\alpha_\Sigma[\phi]).$$

Hence, we get that

$$\alpha_\Sigma[\phi] \le D'(\alpha[\beta[\alpha_\Sigma[\phi]]]) \quad \text{and} \quad \alpha[\beta[\alpha_\Sigma[\phi]]] \le D'(\alpha_\Sigma[\phi]).$$

Therefore, by the fact that α is an interpretation,

$$\phi \in D_\Sigma(\beta[\alpha_\Sigma[\phi]]) \quad \text{and} \quad \beta[\alpha_\Sigma[\phi]] \le D(\phi).$$

So we conclude that $D(\phi) = D(\beta[\alpha_\Sigma[\phi]])$. ∎

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems and $\alpha : \mathbf{K} \to \mathbf{K}'$ a translation. Define the **residual α^* of the translation α**,

$$\alpha^* : \mathrm{SenFam}(\mathbf{K}') \to \mathrm{SenFam}(\mathbf{K})$$

by letting, for all $T' \in \mathrm{SenFam}(\mathbf{K}')$,

$$\alpha^*(T') = \{\alpha^*_\Sigma(T')\}_{\Sigma \in |\mathbf{Sign}|}$$

be given, for all $\Sigma \in |\mathbf{Sign}|$, by

$$\alpha^*_\Sigma(T') = \{\phi \in \mathrm{SEN}(\Sigma) : \alpha_\Sigma[\phi] \le T'\}.$$

The following proposition shows that, when applied to interpretations between π-structures the star operator restricts to mappings from theory families to theory families.

Proposition 890 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ be π-structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $\alpha : \mathcal{K} \to \mathcal{K}'$ an interpretation. Then, for all $T' \in \mathrm{ThFam}(\mathcal{K}')$, $\alpha^*(T') \in \mathrm{ThFam}(\mathcal{K})$.*

Proof: Suppose $T' \in \mathrm{ThFam}(\mathcal{K}')$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\alpha^*_\Sigma(T'))$. Then, since $\alpha : \mathcal{K} \to \mathcal{K}'$ is an interpretation, we have

$$\alpha_\Sigma[\phi] \le D'(\alpha[\alpha^*_\Sigma(T')]) \le D'(T') = T'.$$

Hence $\phi \in \alpha^*_\Sigma(T')$. Since $\Sigma \in |\mathbf{Sign}|$ was arbitrary, we conclude that $\alpha^*_\Sigma(T') \in \mathrm{ThFam}(\mathcal{K})$. ∎

In addition, we show that, when $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ form a conjugate pair, then $\beta^* : \mathrm{ThFam}(\mathcal{K}) \to \mathrm{ThFam}(\mathcal{K}')$ and $\alpha^* : \mathrm{ThFam}(\mathcal{K}') \to \mathrm{ThFam}(\mathcal{K})$ are inverse mappings.

Lemma 891 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be* π*-structures based on* $\mathbf{K}$, $\mathbf{K}'$, *respectively, and* $(\alpha,\beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *a conjugate pair. Then, for all* $T \in \mathrm{ThFam}(\mathcal{K})$,

$$\alpha^*(\beta^*(T)) = T.$$

Proof: Suppose $(\alpha,\beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair, $T \in \mathrm{ThFam}(\mathcal{K})$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{lll}\phi \in \alpha^*_\Sigma(\beta^*(T)) & \text{iff} & \alpha_\Sigma[\phi] \leq \beta^*(T)\\ & \text{iff} & \beta[\alpha_\Sigma[\phi]] \leq T\\ & \text{iff} & D(\beta[\alpha_\Sigma[\phi]]) \leq T\\ & \text{iff} & D_\Sigma(\phi) \leq T_\Sigma\\ & \text{iff} & \phi \in T_\Sigma.\end{array}$$

Thus, we conclude that $\alpha^*(\beta^*(T)) = T$. ■

Based on Lemma 891, we can show that $\beta^* : \mathrm{ThFam}(\mathcal{K}) \to \mathrm{ThFam}(\mathcal{K}')$ and $\alpha^* : \mathrm{ThFam}(\mathcal{K}') \to \mathrm{ThFam}(\mathcal{K})$ are bijections.

Lemma 892 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be* π*-structures based on* $\mathbf{K}$, $\mathbf{K}'$, *respectively, and* $(\alpha,\beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *a conjugate pair. Then* $\alpha^* : \mathrm{ThFam}(\mathcal{K}') \to \mathrm{ThFam}(\mathcal{K})$ *is a bijection.*

Proof: Let $(\alpha,\beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ be a conjugate pair. First, by Proposition 890, $\alpha^* : \mathrm{ThFam}(\mathcal{K}') \to \mathrm{ThFam}(\mathcal{K})$ is well-defined. To see that it is surjective, let $T \in \mathrm{ThFam}(\mathcal{K})$. Then, by Proposition 890, $\beta^*(T) \in \mathrm{ThFam}(\mathcal{K}')$ and, by Lemma 891, $\alpha^*(\beta^*(T)) = T$. Thus, α^* is indeed surjective. For injectivity, assume $S', T' \in \mathrm{ThFam}(\mathcal{K}')$, such that $\alpha^*(S') = \alpha^*(T')$. Then, by surjectivity, there exist $S, T \in \mathrm{ThFam}(\mathcal{K})$, such that $\beta^*(S) = S'$ and $\beta^*(T) = T'$. Therefore, we get

$$S = \alpha^*(\beta^*(S)) = \alpha^*(S') = \alpha^*(T') = \alpha^*(\beta^*(T)) = T.$$

But then we get $S' = \beta^*(S) = \beta^*(T) = T'$. we conclude that α^* is also injective and, hence, it is a bijection. ■

In the main theorem of this section, it is shown that if $\mathcal{K}$ and $\mathcal{K}'$ are equivalent π-structures via a conjugate pair $(\alpha,\beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$, then $\beta^* : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}')$ and $\alpha^* : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ form a pair of mutually inverse order isomorphisms between the complete lattices of the corresponding theory families.

Recall that, given a π-institution $\mathcal{I}$, we denote by

$$\mathbf{ThFam}(\mathcal{I}) = \langle \mathrm{ThFam}(\mathcal{I}), \leq\rangle$$

the complete lattice of theory families of $\mathcal{I}$ ordered by signature-wise inclusion. We extend the notation to the collections of theory families of π-structures. Thus, given a π-structure $\mathcal{K} = \langle \mathbf{K}, D\rangle$, we define

$$\mathbf{ThFam}(\mathcal{K}) = \langle \mathrm{ThFam}(\mathcal{K}), \leq\rangle.$$

Theorem 893 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be π-structures based on* $\mathbf{K}$, $\mathbf{K}'$, *respectively, and* $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *a conjugate pair. Then*

$$\beta^* : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}') \quad \textit{and} \quad \alpha^* : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$$

are mutually inverse order isomorphisms.

Proof: We know, by Lemma 892, that β^* and α^* are mutually inverse bijections. Moreover, by definition, they are both order preserving. Thus, each is also order-reflecting, since, e.g., for all $S', T' \in \mathrm{ThFam}(\mathcal{K}')$,

$$\begin{array}{lll}\alpha^*(S') \leq \alpha^*(T') & \text{implies} & \beta^*(\alpha^*(S')) \leq \beta^*(\alpha^*(T')) \\ & \text{implies} & S' \leq T',\end{array}$$

the latter implication following by Lemma 891. ∎

Conversely, it is true that given mutually inverse order isomorphisms between the complete lattices of two π-structures, one may define a conjugate pair between the two that establishes this order-isomorphism via the process that was described above. We provide, next, more details on this inverse process.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ be π-structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and

$$h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$$

an order isomorphism between the corresponding complete lattices of theory families.

Define $\overrightarrow{h} = \{\overrightarrow{h}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ by letting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\overrightarrow{h}_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SenFam}(\mathbf{K}')$$

be given, for all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\overrightarrow{h}_\Sigma[\phi] = h^{-1}(D(\phi)).$$

Further, define $\overleftarrow{h} = \{\overleftarrow{h}_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}'|}$ by letting, for all $\Sigma' \in |\mathbf{Sign}'|$,

$$\overleftarrow{h}_{\Sigma'} : \mathrm{SEN}'(\Sigma') \to \mathrm{SenFam}(\mathbf{K})$$

be given, for all $\psi \in \mathrm{SEN}'(\Sigma')$, by

$$\overleftarrow{h}_{\Sigma'}[\psi] = h(D'(\psi)).$$

We show that, the two translations $\overrightarrow{h} : \mathbf{K} \to \mathbf{K}'$ and $\overleftarrow{h} : \mathbf{K}' \to \mathbf{K}$, defined above, constitute interpretations between the corresponding π-structures.

Lemma 894 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be* π*-structures based on* $\mathbf{K}$, $\mathbf{K}'$*, respectively, and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *an order isomorphism. Then* $\overleftarrow{h} : \mathcal{K}' \to \mathcal{K}$ *is an interpretation.*

Proof: Suppose $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ is an order isomorphism and let $\Sigma' \in |\mathbf{Sign}'|$ and $\Psi \cup \{\psi\} \subseteq \mathrm{SEN}'(\Sigma')$. Then we have

$$\begin{array}{rll} \psi \in D'_{\Sigma'}(\Psi) & \text{iff} & D'(\psi) \leq D'(\Psi) \\ & \text{iff} & h(D'(\psi)) \leq h(D'(\Psi)) \\ & \text{iff} & h(D'(\psi)) \leq h(\bigvee\{D'(\chi) : \chi \in \Psi\}) \\ & \text{iff} & h(D'(\psi)) \leq \bigvee\{h(D'(\chi)) : \chi \in \Psi\} \\ & \text{iff} & \overleftarrow{h}_{\Sigma'}[\psi] \leq \bigvee\{\overleftarrow{h}_{\Sigma'}[\chi] : \chi \in \Psi\} \\ & \text{iff} & \overleftarrow{h}_{\Sigma'}[\psi] \leq D(\overleftarrow{h}_{\Sigma'}[\Psi]). \end{array}$$

Thus, $\overleftarrow{h} : \mathcal{K}' \to \mathcal{K}$ is indeed an interpretation. ■

We now know (by symmetry, based on Lemma 894) that $\overrightarrow{h} : \mathcal{K} \to \mathcal{K}'$ and $\overleftarrow{h} : \mathcal{K}' \to \mathcal{K}$ are interpretations. It is, in fact, the case that $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ form a conjugate pair, as is shown next.

Lemma 895 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be* π*-structures based on* $\mathbf{K}$, $\mathbf{K}'$*, respectively, and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *an order isomorphism. Then* $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *is a conjugate pair.*

Proof: By Lemma 889, it suffices to show that $\overleftarrow{h} : \mathcal{K}' \to \mathcal{K}$ is an interpretation and that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $D(\phi) = D(\overleftarrow{h}[\overrightarrow{h}_\Sigma[\phi]])$. The former has been shown in Lemma 894. So it suffices to show the latter. To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{rcl} D(\overleftarrow{h}[\overrightarrow{h}_\Sigma[\phi]]) & = & D(\overleftarrow{h}[h^{-1}(D(\phi))]) \\ & = & D(\bigcup\{\overleftarrow{h}[\chi] : \chi \in h^{-1}(D(\phi))\}) \\ & = & \bigvee\{h(D'(\chi)) : \chi \in h^{-1}(D(\phi))\} \\ & = & h(\bigvee\{D'(\chi) : \chi \in h^{-1}(D(\phi))\}) \\ & = & h(h^{-1}(D(\phi))) \\ & = & D(\phi). \end{array}$$

We conclude that $(\overrightarrow{h},\overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair. ■

Based on Lemma 895, we can now formulate one of the main theorems of this section to the effect that every order isomorphism between the complete lattices of theory families of two π-structures gives rise to a conjugate pair of interpretations that induce the isomorphism via the star construction.

Theorem 896 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be algebraic systems,* $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ *be π-structures based on* $\mathbf{K}$, $\mathbf{K}'$, *respectively, and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *an order isomorphism. Then* $(\overrightarrow{h},\overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *is a conjugate pair, such that* $\overrightarrow{h}^* = h$ *and* $\overleftarrow{h}^* = h^{-1}$.

Proof: By Lemma 895, we know that $(\overrightarrow{h},\overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ form a conjugate pair. We show that $\overrightarrow{h}^* = h$. The equality $\overleftarrow{h}^* = h^{-1}$ may be proved similarly. To this end, let $T' \in \mathrm{ThFam}(\mathcal{K}')$. Then we have

$$\begin{array}{rcl}\overrightarrow{h}^*_\Sigma(T') & = & \{\phi \in \mathrm{SEN}(\Sigma) : \overrightarrow{h}_\Sigma[\phi] \leq T'\}\\ & = & \{\phi \in \mathrm{SEN}(\Sigma) : h^{-1}(D(\phi)) \leq T'\}\\ & = & D_\Sigma(\{\phi \in \mathrm{SEN}(\Sigma) : h^{-1}(D(\phi)) \leq T'\})\\ & = & D_\Sigma(\{\phi \in \mathrm{SEN}(\Sigma) : D(\phi) \leq h(T')\})\\ & = & D_\Sigma(\{\phi \in \mathrm{SEN}(\Sigma) : \phi \in h_\Sigma(T')\})\\ & = & D_\Sigma(h_\Sigma(T'))\\ & = & h_\Sigma(T').\end{array}$$

Similarly, $\overleftarrow{h}^* = h^{-1}$. ■

12.2 Transformations

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $k \geq 1$ be an integer. Then a **power algebraic system**

$$\mathbf{K}^k = \langle \mathbf{Sign}, \mathrm{SEN}^k, N^k\rangle$$

is the algebraic system whose sentence functor $\mathrm{SEN}^k : \mathbf{Sign} \to \mathbf{Set}$ is the k-th direct power of SEN and whose category N^k of natural transformations consists of k-tuples of natural transformations having the same arity in N.

Let $k, \ell \geq 1$ be integers. A translation $\alpha : \mathbf{K}^k \to \mathbf{K}^\ell$ is called a **transformation** if there exists a set

$$\tau : \mathrm{SEN}^\omega \to \mathrm{SEN}^\ell,$$

in N, with k distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$,

$$\alpha_\Sigma[\vec{\phi}] = \tau_\Sigma[\vec{\phi}].$$

Moreover a translation $\alpha : \mathbf{K}^k \to \mathbf{K}^\ell$ is called a **natural transformation** if it is a parameter-free transformation, i.e., if there exists $\tau : \mathrm{SEN}^k \to \mathrm{SEN}^\ell$ in N, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$,

$$\alpha_\Sigma[\vec{\phi}] = \tau_\Sigma[\vec{\phi}].$$

Based on the results obtained in Section 12.1, we may formulate some propositions concerning interpretability and equivalence based on transformations.

Proposition 897 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathcal{K} = \langle \mathbf{F}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ *be two* π*-structures.* $\mathcal{K}$ *is interpretable in* $\mathcal{K}'$ *via a transformation if and only if there exists a set* $\tau : \mathrm{SEN}^\omega \to \mathrm{SEN}^\ell$, *with* k *distinguished arguments, such that, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\Phi \cup \{\vec{\phi}\} \subseteq \mathrm{SEN}(\Sigma)^k$,

$$\vec{\phi} \in D_\Sigma(\Phi) \quad \textit{iff} \quad \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]).$$

If $\mathcal{K}$ *is interpretable in* $\mathcal{K}'$ *as above, then it is equivalent to* $\mathcal{K}'$ *via a conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of transformations if and only if, for all* $\Sigma \in |\mathbf{Sign}|$, *all* $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$ *and all* $\Psi \cup \{\vec{\psi}\} \subseteq \mathrm{SEN}(\Sigma)^\ell$,

- $\vec{\psi} \in D'_\Sigma(\Psi)$ *iff* $I_\Sigma[\vec{\psi}] \leq D(I_\Sigma[\Psi])$;
- $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;
- $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: This is a restatement of the definition of interpretability under the additional hypothesis that the corresponding interpretations are transformations. ■

Proposition 898 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ *be two* π*-structures.* $\mathcal{K}$ *is equivalent to* $\mathcal{K}'$ *via a conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of transformations if and only if one of the following equivalent conditions hold:*

(a) $\tau : \mathcal{K} \to \mathcal{K}'$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\vec{\psi} \in \mathrm{SEN}(\Sigma)^\ell$, $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;

(b) $I : \mathcal{K}' \to \mathcal{K}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$, $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: Directly by Lemma 889. ■

Taking the point of view of order isomorphisms between lattices of theory families, we would like to have a concept ensuring that such an isomorphism is induced not merely by a conjugate pair of translations, as is asserted by

Theorem 896, but, more emphatically, by a conjugate pair of transformations. We focus on this task next.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures based on $\mathbf{K}^k$, $\mathbf{K}^\ell$, respectively. An order isomorphism $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ is called **transformational** if there exist sets

- $\tau : \mathrm{SEN}^\omega \to \mathrm{SEN}^\ell$ in N, with k distinguished arguments;
- $I : \mathrm{SEN}^\omega \to \mathrm{SEN}^k$ in N, with ℓ distinguished arguments,

such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$ and all $\vec{\psi} \in \mathrm{SEN}(\Sigma)^\ell$,

$$\overrightarrow{h}_\Sigma[\vec{\phi}] = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad \overleftarrow{h}_\Sigma[\vec{\psi}] = D(I_\Sigma[\vec{\psi}]).$$

These conditions are, by definition, equivalent, respectively, to the conditions

$$h^{-1}(D(\vec{\phi})) = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad h(D'(\vec{\psi})) = D(I_\Sigma[\vec{\psi}]).$$

In this case, we say that h is **induced by** $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$. (Note that, since we will be able to show that (τ, I) is a conjugate pair of transformations, this notation makes sense.)

In fact, the defining conditions yield some crucial relations between theory families, as in shown in the following lemma.

Lemma 899 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures and $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ a transformational order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$. Then, for all $\Sigma \in |\mathbf{Sign}|$, all $\Phi \subseteq \mathrm{SEN}(\Sigma)^k$ and all $\Psi \subseteq \mathrm{SEN}(\Sigma)^\ell$,*

$$h^{-1}(D(\Phi)) = D'(\tau_\Sigma[\Phi]) \quad \textit{and} \quad h(D'(\Psi)) = D(I_\Sigma[\Psi]).$$

Proof: By symmetry, it suffices to show the first equation. We have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)^k$,

$$\begin{array}{rcll} h^{-1}(D(\Phi)) & = & h^{-1}(\bigvee_{\phi\in\Phi} D(\phi)) & (\text{join in } \mathbf{ThFam}(\mathcal{K})) \\ & = & \bigvee_{\phi\in\Phi} h^{-1}(D(\phi)) & (h^{-1} \text{ order isomorphism}) \\ & = & \bigvee_{\phi\in\Phi} D'(\tau_\Sigma[\phi]) & (h^{-1}(D(\phi)) = \overrightarrow{h}_\Sigma[\phi]) \\ & = & D'(\bigcup_{\phi\in\Phi} \tau_\Sigma[\phi]) & (\text{join in } \mathbf{ThFam}(\mathcal{K}')) \\ & = & D'(\tau_\Sigma[\Phi]). & (\text{by definition}) \end{array}$$

The second equation now follows by symmetry. ■

Now we are in a position to show that a transformational order isomorphism between the lattices of theory families of two π-structures is induced by a conjugate pair of transformations between the two π-structures and, as a consequence, gives rise to an equivalence $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ via a conjugate pair of transformations.

Theorem 900 *Let* $\mathbf{K} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathcal{K} = \langle\mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle\mathbf{K}^\ell, D'\rangle$ *be two* π*-structures and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *a transformational order isomorphism induced by* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$*. Then* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *is a conjugate pair of transformations.*

Proof: We use Proposition 898. Let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\vec{\phi}\} \subseteq \mathrm{SEN}(\Sigma)^k$ and $\vec{\psi} \in \mathrm{SEN}(\Sigma)^\ell$. We then have:

$$\begin{array}{lll}\vec{\phi} \in D_\Sigma(\Phi) & \text{iff} & D_\Sigma(\vec{\phi}) \leq D_\Sigma(\Phi)\\ & \text{iff} & h^{-1}(D(\vec{\phi})) \leq h^{-1}(D(\Phi)) \quad (h \text{ order isomorphism})\\ & \text{iff} & D'(\tau_\Sigma[\vec{\phi}]) \leq D'(\tau_\Sigma[\Phi]) \quad (\text{Lemma 899})\\ & \text{iff} & \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]).\end{array}$$

Thus, $\tau : \mathcal{K} \to \mathcal{K}'$ is an interpretation. Moreover, we have:

$$\begin{array}{lll}D'(\vec{\psi}) & = & h^{-1}(h(D'(\vec{\psi}))) \quad (h \text{ order isomorphism})\\ & = & h^{-1}(D(I_\Sigma[\vec{\psi}])) \quad (h \text{ transformational})\\ & = & D'(\tau[I_\Sigma[\vec{\psi}]]). \quad (\text{Lemma 899})\end{array}$$

We conclude by Proposition 898, that $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair of transformations. ∎

As a consequence, we have the following

Theorem 901 *Let* $\mathbf{K} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathcal{K} = \langle\mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle\mathbf{K}^\ell, D'\rangle$ *be two* π*-structures and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *a transformational order isomorphism induced by* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$*. Then the* π*-structures* $\mathcal{K}$ *and* $\mathcal{K}'$ *are equivalent via the conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of transformations.*

Proof: This follows directly by Theorem 900. ∎

Similarly, for interpretability and equivalence based on natural transformations, we have the following corresponding propositions.

Proposition 902 *Let* $\mathbf{K} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathcal{K} = \langle\mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle\mathbf{K}^\ell, D'\rangle$ *be two* π*-structures.* $\mathcal{K}$ *is interpretable in* $\mathcal{K}'$ *via a natural transformation if and only if there exists a set* $\tau : \mathrm{SEN}^k \to \mathrm{SEN}^\ell$ *in* N*, such that, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\Phi \cup \{\vec{\phi}\} \subseteq \mathrm{SEN}(\Sigma)^k$,

$$\vec{\phi} \in D_\Sigma(\Phi) \quad \textit{iff} \quad \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]).$$

If $\mathcal{K}$ *is interpretable in* $\mathcal{K}'$ *as above, then it is equivalent to* $\mathcal{K}'$ *via a conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of natural transformations if and only if, for all* $\Sigma \in |\mathbf{Sign}|$*, all* $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$ *and all* $\Psi \cup \{\vec{\psi}\} \subseteq \mathrm{SEN}(\Sigma)^\ell$,

- $\vec{\psi} \in D'_\Sigma(\Psi)$ *iff* $I_\Sigma[\vec{\psi}] \leq D(I_\Sigma[\Psi])$;

- $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;
- $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: This is a restatement of the definition of interpretability under the additional hypothesis that the corresponding interpretations are natural transformations. ∎

Proposition 903 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ *be two* π*-structures.* $\mathcal{K}$ *is equivalent to* $\mathcal{K}'$ *via a conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of natural transformations if and only if one of the following equivalent conditions hold:*

(a) $\tau : \mathcal{K} \to \mathcal{K}'$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\vec{\psi} \in \mathrm{SEN}(\Sigma)^\ell$, $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;

(b) $I : \mathcal{K}' \to \mathcal{K}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$, $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: Directly by Lemma 889. ∎

In terms of order isomorphisms between lattices of theory families, we have analogs of preceding results that allow us to work with isomorphisms that are induced by conjugate pairs of natural transformations.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures based on $\mathbf{K}^k$, $\mathbf{K}^\ell$, respectively. An order isomorphism $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ is called **natural** if there exist sets

- $\tau : \mathrm{SEN}^k \to \mathrm{SEN}^\ell$ in N;
- $I : \mathrm{SEN}^\ell \to \mathrm{SEN}^k$ in N,

such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$ and $\vec{\psi} \in \mathrm{SEN}(\Sigma)^\ell$,

$$\overrightarrow{h}_\Sigma[\vec{\phi}] = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad \overleftarrow{h}_\Sigma[\vec{\psi}] = D(I_\Sigma[\vec{\psi}]).$$

In this case, we say that h is **induced by** the pair of natural transformations $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$.

Similarly, with the case of a transformational isomorphism, we can show that a natural order isomorphism between the lattices of theory families of two π-structures is induced by a conjugate pair of natural transformations between the two π-structures.

Theorem 904 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ *be two* π*-structures and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *a natural order isomorphism induced by* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$*. Then* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *is a conjugate pair of natural transformations.*

Proof: This follows from Theorem 900. ∎

As a consequence, we have the following analog of Theorem 901.

Theorem 905 *Let* $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ *be two* π*-structures and* $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ *a natural order isomorphism induced by* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$. *Then the* π*-structures* $\mathcal{K}$ *and* $\mathcal{K}'$ *are equivalent via the conjugate pair* $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ *of natural transformations.*

Proof: This follows directly by Theorem 904. ∎

We now revert to the case of a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ based on $\mathbf{F}$. Our focus, in this standard context, will be on $\mathbf{F}$ itself, on the one hand, and on $\mathbf{F}^2$, on the other. In the context of $\mathbf{F}^2$, given $\Sigma \in |\mathbf{Sign}^\flat|$, we sometimes denote a pair $\langle \phi, \psi\rangle \in \mathrm{SEN}^\flat(\Sigma)^2$ in the equational form

$$\phi \approx \psi.$$

Given a π-structure $\mathcal{Q} = \langle \mathbf{F}^2, D\rangle$, we say that $\mathcal{Q}$ is **equational** if the following five axioms hold:

(R) $\phi \approx \phi \in D_\Sigma(\varnothing)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$;

(S) $\psi \approx \phi \in D_\Sigma(\phi \approx \psi)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$;

(T) $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$;

(C) $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in D_\Sigma(\{\phi_i \approx \psi_i : i < k\})$, for all $\sigma^\flat \in N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$;

(I) $\mathrm{SEN}^\flat(f)(\phi) \approx \mathrm{SEN}^\flat(f)(\psi) \in D_{\Sigma'}(\phi \approx \psi)$, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

Note that according to the relevant definitions introduced in Chapter 2, the meaning of (I) is that the Σ'-component of the least theory family including $\phi \approx \psi$ in its Σ-component includes $\mathrm{SEN}^\flat(f)(\phi) \approx \mathrm{SEN}^\flat(f)(\psi)$.

These properties are termed **reflexivity**, **symmetry**, **transitivity**, **compatibility** and **invariance**, respectively. The first three ensure that, for all $E \in \mathrm{SenFam}(\mathbf{F}^2)$, $D(E)$ is an equivalence family. The fourth one ensures that $D(E)$ is a congruence family and the last that it is a congruence system, i.e., invariant under the action of signature morphisms. In fact, the following characterization theorem holds, showing that a π-structure is equational if and only if it is structural and all its closure families are congruence systems on $\mathbf{F}$ if and only if it is the equational π-structure relative to a class K of $\mathbf{F}$-algebraic systems according to the definition given in Section 2.17.

Theorem 906 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{Q} = \langle \mathbf{F}^2, D\rangle$ *a* π*-structure. The following statements are equivalent:*

(i) $\mathcal{Q}$ *is equational;*

(ii) *For all* $\theta \in \mathrm{SenFam}(\mathcal{Q})$, $D(\theta) \in \mathrm{ConSys}(\mathbf{F})$*;*

(iii) *For some class* K *of* $\mathbf{F}$*-algebraic systems,* $D = D^{\mathsf{K}}$.

Proof:

(i)⇒(ii) Suppose $\mathcal{Q}$ is equational and let $\theta \in \mathrm{SenFam}(\mathcal{Q})$. We must show that $D(\theta) = \{D_\Sigma(\theta)\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ is a congruence system on $\mathbf{F}$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q}$ is equational, we have $\phi \approx \phi \in D_\Sigma(\varnothing) \subseteq D_\Sigma(\theta)$. So $D_\Sigma(\theta)$ is reflexive. Suppose, next, that $\phi \approx \psi \in D_\Sigma(\theta)$. Since $\mathcal{Q}$ is equational, we get $\psi \approx \phi \in D_\Sigma(\phi \approx \psi) \subseteq D_\Sigma(\theta)$. Hence, $D_\Sigma(\theta)$ is also symmetric. Further, if $\phi \approx \psi, \psi \approx \chi \in D_\Sigma(\theta)$, then, since $\mathcal{Q}$ is equational, we get $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi) \subseteq D_\Sigma(\theta)$. Thus, $D_\Sigma(\theta)$ is also transitive and, hence, an equivalence relation on $\mathrm{SEN}^\flat(\Sigma)$.

Suppose, now, that $\sigma^\flat \in N^\flat$, $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, for $i < k$, such that $\phi_i \approx \psi_i \in D_\Sigma(\theta)$, for all $i < k$. Since $\mathcal{Q}$ is equational, we get $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in D_\Sigma(\{\phi_i \approx \psi_i : i < k\}) \subseteq D_\Sigma(\theta)$. Hence, $D_\Sigma(\theta)$ is a congruence family on $\mathbf{F}$. Finally, if $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi \in D_\Sigma(\theta)$, then, again based on the fact that $\mathcal{Q}$ is equational, we obtain $\mathrm{SEN}^\flat(f)(\phi) \approx \mathrm{SEN}^\flat(f)(\psi) \in D_{\Sigma'}(\phi \approx \psi) \subseteq D_{\Sigma'}(\theta)$, whence $D(\theta)$ is a congruence system on $\mathbf{F}$, as was to be shown.

(ii)⇒(iii) Suppose D satisfies (ii). We construct a class K of $\mathbf{F}$-algebraic systems as follows. For $\theta \in \mathrm{SenFam}(\mathcal{Q})$, define

$$\mathcal{F}^\theta = \langle \mathbf{F}^\theta, \langle I, \pi^\theta \rangle\rangle := \langle \mathbf{F}/D(\theta), \langle I, \pi^{D(\theta)}\rangle\rangle$$

and set

$$\mathsf{K} = \{\mathcal{F}^\theta : \theta \in \mathrm{SenFam}(\mathcal{Q})\}.$$

Note that the definition of $\mathcal{F}^\theta$ makes sense, since, by hypothesis, $D(\theta) \in \mathrm{ConSys}(\mathbf{F})$, for all $\theta \in \mathrm{SenFam}(\mathcal{Q})$. Our task now is to show that $D = D^{\mathsf{K}}$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\theta \cup \{\phi \approx \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)^2$.

Suppose, first, that $\phi \approx \psi \in D_\Sigma(\theta)$ and let $\theta' \in \mathrm{SenFam}(\mathcal{Q})$, such that $\pi^{\theta'}_\Sigma(\theta) \subseteq \Delta^{\mathbf{F}/D(\theta')}_\Sigma$. This is equivalent to $\theta_\Sigma \subseteq D_\Sigma(\theta'_\Sigma)$. Hence, we obtain $\phi \approx \psi \in D_\Sigma(\theta) \subseteq D_\Sigma(\theta')$. Thus, $\pi^{\theta'}_\Sigma(\phi) = \pi^{\theta'}_\Sigma(\psi)$. We conclude that $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(\theta)$. Hence, $D \leq D^{\mathsf{K}}$.

Assume, conversely, that $\phi \approx \psi \notin D_\Sigma(\theta)$. Then, clearly, for $\mathcal{F}^\theta \in \mathsf{K}$, we get $\pi^\theta_\Sigma(D_\Sigma(\theta)) \subseteq \Delta^{\mathbf{F}/D(\theta)}_\Sigma$, but $\pi^\theta_\Sigma(\phi) \neq \pi^\theta_\Sigma(\psi)$. Hence, $\phi \approx \psi \notin D^{\mathsf{K}}_\Sigma(\theta)$. Therefore, $D^{\mathsf{K}} \leq D$ and, hence, $D = D^{\mathsf{K}}$.

(iii)⇒(i) This implication was shown in Proposition 115, which was proven by appealing to the implication (iii)⇒(ii), which was, in turn, the content of Proposition 30.

∎

We have the following useful technical lemma, where, for $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, we use the abbreviation

$$\vec{\phi} \approx \vec{\psi} = \{\phi_i \approx \psi_i : i < k\}.$$

Lemma 907 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ *an equational* π*-structure. Then, for all* $\delta^\flat, \epsilon^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\delta^\flat_\Sigma(\vec{\psi}) \approx \epsilon^\flat_\Sigma(\vec{\psi}) \in D_\Sigma(\vec{\phi} \approx \vec{\psi}, \delta^\flat_\Sigma(\vec{\phi}) \approx \epsilon^\flat_\Sigma(\vec{\phi})).$$

Proof: We have, for all $\delta^\flat, \epsilon^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\delta^\flat_\Sigma(\vec{\psi}) \approx \epsilon^\flat_\Sigma(\vec{\psi}) & \in & D_\Sigma(\delta^\flat_\Sigma(\vec{\psi}) \approx \delta^\flat_\Sigma(\vec{\phi}), \delta^\flat_\Sigma(\vec{\phi}) \approx \epsilon^\flat_\Sigma(\vec{\phi}), \epsilon^\flat_\Sigma(\vec{\phi}) \approx \epsilon^\flat_\Sigma(\vec{\psi})) \\ & & \text{(by transitivity)} \\ & \subseteq & D_\Sigma(\vec{\phi} \approx \vec{\psi}, \delta^\flat_\Sigma(\vec{\phi}) \approx \epsilon^\flat_\Sigma(\vec{\phi})). \\ & & \text{(by symmetry and compatibility)}\end{array}$$

This proves the lemma. ∎

Lemma 907 has the following corollary:

Corollary 908 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ *an equational* π*-structure. Then, for all* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, with* k *distinguished arguments, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\tau^\flat_\Sigma[\vec{\psi}] \le D(\vec{\phi} \approx \vec{\psi}, \tau^\flat_\Sigma[\vec{\phi}]).$$

Proof: This follows from Lemma 907, using the reflexivity and the invariance of the closure family D. ∎

We next show that, if a π-institution $\mathcal{I}$, based on an algebraic system $\mathbf{F}$, happens to be equivalent to an equational π-structure $\mathcal{Q}$, based on $\mathbf{F}^2$, via a conjugate pair $(\tau, I) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically protoalgebraic with set of witnessing transformations I.

Theorem 909 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ *an equational* π*-structure. If* $\mathcal{I}$ *is equivalent to* $\mathcal{Q}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}$ *of transformations, then* $\mathcal{I}$ *is syntactically protoalgebraic with witnessing transformations* $I^\flat$*.*

Proof: By definition, it suffices to show that $I^\flat : \mathrm{SEN}^\omega \to \mathrm{SEN}$, with two distinguished arguments, is reflexive, globally family transitive and has the global family compatibility and the global family modus ponens in $\mathcal{I}$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have, in turn:

- By reflexivity of $\mathcal{Q}$, $\phi \approx \phi \in D_\Sigma(\varnothing)$. Hence, by interpretability, we get $I^\flat_\Sigma[\phi, \phi] \leq C(\varnothing)$. Therefore, $I^\flat$ is reflexive in $\mathcal{I}$;
- By transitivity of $\mathcal{Q}$, $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$. Hence, by interpretability, we get $I^\flat_\Sigma[\phi, \chi] \leq C(I^\flat_\Sigma[\phi, \psi], I^\flat_\Sigma[\psi, \chi])$. Therefore, $I^\flat$ is globally family transitive in $\mathcal{I}$;
- By the reflexivity and compatibility of $\mathcal{Q}$, we have, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in N and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, that $\sigma^\flat_\Sigma(\phi, \vec{\chi}) \approx \sigma^\flat_\Sigma(\psi, \vec{\chi}) \in D_\Sigma(\phi \approx \psi)$. Hence, by interpretability,
$$I^\flat_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \leq C(I^\flat_\Sigma[\phi, \psi]).$$
Therefore, $I^\flat$ has the global family compatibility in $\mathcal{I}$;
- Finally, for global family MP, we have
$$\begin{array}{rcl} C(\psi) & = & C(I^\flat[\tau^\flat_\Sigma[\psi]]) \quad \text{(by equivalence)} \\ & \leq & C(I^\flat_\Sigma[\phi, \psi], I^\flat[\tau^\flat_\Sigma[\phi]]) \\ & & \text{(by Lemma 907 and interpretability)} \\ & = & C(I^\flat_\Sigma[\phi, \psi], \phi). \quad \text{(by equivalence)} \end{array}$$
Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, if $\phi \in T_\Sigma$ and $I^\flat_\Sigma[\phi, \psi] \leq T$, then $\psi \in T_\Sigma$, i.e., $I^\flat$ has the global family modus ponens in $\mathcal{I}$.

We conclude that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. ∎

As a consequence of Theorem 909, we obtain

Corollary 910 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π-structure. If $\mathcal{I}$ is equivalent to $\mathcal{Q}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of natural transformations, then $\mathcal{I}$ is syntactically equivalential with witnessing transformations $I^\flat$.*

Proof: By Theorem 909, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. Since $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ is parameter free, we conclude that $\mathcal{I}$ is syntactically equivalential with witnessing transformations $I^\flat$. ∎

Using Theorem 909, we can also show that, if a π-institution $\mathcal{I}$, based on an algebraic system $\mathbf{F}$, happens to be equivalent to an equational π-structure $\mathcal{Q}$, based on $\mathbf{F}^2$, via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is family truth equational, with witnessing equations $\tau^\flat$.

Theorem 911 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ *an equational* π*-structure. If* $\mathcal{I}$ *is equivalent to* $\mathcal{Q}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}$ *of transformations, then* $\mathcal{I}$ *is family truth equational, with witnessing equations* $\tau^\flat$*.*

Proof: By definition, it suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

We, indeed, have, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & I^\flat[\tau_\Sigma[\phi]] \leq T \quad ((\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q} \text{ an equivalence}) \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T). \quad (\text{by Theorem 909 and Corollary 791}) \end{array}$$

Therefore, $\mathcal{I}$ is family truth equational, with witnessing equations $\tau^\flat$. ■

We close the section by showing that equivalence between a given π-institution and an equational π-structure established via conjugate pairs of transformations is essentially unique in the sense that both the closure family on $\mathbf{F}^2$ must be unique and the closures of the translations used must be identical. More precisely, we have the following

Theorem 912 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Suppose that* $\mathcal{Q}^1 = \langle \mathbf{F}^2, D^1 \rangle$ *and* $\mathcal{Q}^2 = \langle \mathbf{F}^2, D^2 \rangle$ *are equational* π*-structures that are equivalent to* $\mathcal{I}$ *via the conjugate pairs* $\langle \tau^1, I^1 \rangle : \mathcal{I} \rightleftarrows \mathcal{Q}^1$ *and* $\langle \tau^2, I^2 \rangle : \mathcal{I} \rightleftarrows \mathcal{Q}^2$*, respectively, of transformations. Then, we have:*

(a) $D^1 = D^2$ $(=: D)$ *and, hence,* $\mathcal{Q}^1 = \mathcal{Q}^2$ $(=: \mathcal{Q})$*;*

(b) For all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,* $C(I^1_\Sigma[\phi, \psi]) = C(I^2_\Sigma[\phi, \psi])$*;*

(c) For all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $D(\tau^1_\Sigma[\phi]) = D(\tau^2_\Sigma[\phi])$*.*

Proof: By Theorem 909, we know that both I^1 and I^2 are witnessing the syntactic protoalgebraicity of $\mathcal{I}$. Thus, by Corollary 791, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^1_\Sigma[\phi, \psi] \leq T \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad I^2_\Sigma[\phi, \psi] \leq T.$$

We conclude that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(I^1_\Sigma[\phi, \psi]) = C(I^2_\Sigma[\phi, \psi])$, which proves Part (b).

For Part (a), suppose that $\Sigma \in |\mathbf{Sign}^\flat|$ and $E \cup \{\phi \approx \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)^2$. Then, we have

$$\begin{array}{lll} \phi \approx \psi \in D^1_\Sigma(E) & \text{iff} & I^1_\Sigma[\phi, \psi] \leq C(I^1_\Sigma[E]) \quad (\text{interpretability}) \\ & \text{iff} & C(I^1_\Sigma[\phi, \psi]) \leq C(I^1_\Sigma[E]) \\ & \text{iff} & C(I^2_\Sigma[\phi, \psi]) \leq C(I^2_\Sigma[E]) \quad (\text{Part (b)}) \\ & \text{iff} & I^2_\Sigma[\phi, \psi] \leq C(I^2_\Sigma[E]) \\ & \text{iff} & \phi \approx \psi \in D^2_\Sigma(E). \quad (\text{interpretability}) \end{array}$$

Therefore, we get that $D^1 = D^2$. This justifies using $D := D^1 = D^2$ and since the π-structures $\mathcal{Q}^1$ and $\mathcal{Q}^2$, which are both based on $\mathbf{F}^2$, have the same closure families, we obtain $\mathcal{Q} := \mathcal{Q}^1 = \mathcal{Q}^2$.

Finally, for Part (c), suppose that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have

$$\begin{array}{lll} D(\tau^1_\Sigma[\phi]) \leq D(\tau^2_\Sigma[\phi]) & \text{iff} & \tau^1_\Sigma[\phi] \leq D(\tau^2_\Sigma[\phi]) \\ & \text{iff} & I^2[\tau^1_\Sigma[\phi]] \leq C(I^2[\tau^2_\Sigma[\phi]]) \quad \text{(interpretability)} \\ & \text{iff} & I^2[\tau^1_\Sigma[\phi]] \leq C(\phi) \quad \text{(equivalence)} \\ & \text{iff} & I^1[\tau^1_\Sigma[\phi]] \leq C(\phi) \quad \text{(Part (b))} \\ & \text{iff} & \phi \in C_\Sigma(\phi). \quad \text{(equivalence)} \end{array}$$

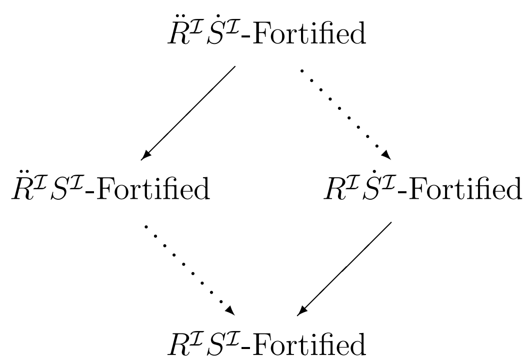
By symmetry, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $D(\tau^1_\Sigma[\phi]) = D(\tau^2_\Sigma[\phi])$. This proves Part (c) and concludes the proof of the theorem. ■

12.3 Syntactic Weak Family Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We say that:

- $\mathcal{I}$ is $R^{\mathcal{I}}S^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $S^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $\dot{S}^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $S^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $\dot{S}^{\mathcal{I}}$ is adequate.

Recall that, by Proposition 997, if $\dot{S}^{\mathcal{I}}$ is adequate, then $S^{\mathcal{I}}$ is adequate. Moreover, since, by Proposition 952, $\ddot{R}^{\mathcal{I}} \subseteq R^{\mathcal{I}}$, it follows that, under the assumption of prealgebraicity, if $\ddot{R}^{\mathcal{I}}$ is Leibniz, then $R^{\mathcal{I}}$ is Leibniz. Thus, we have the following **syntactic fortification hierarchy** (in which the dotted arrows hold under prealgebraicity):



$\mathcal{I}$ is **syntactically weakly family algebraizable** (abbreviated to **syntactically WF algebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified;
- $\mathcal{I}$ is protoalgebraic;
- $\mathcal{I}$ is family injective.

By Theorem 288, under protoalgebraicity, the properties of family injectivity, family reflectivity and family c-reflectivity coincide. This enables us to formulate the following alternative characterization of syntactic WF algebraizability.

Theorem 913 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if it is syntactically protoalgebraic and family truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically WF algebraizable. Then, on the one hand, it is protoalgebraic and has a Leibniz reflexive core. Thus, by Theorem 805, it is syntactically protoalgebraic. On the other, it is, by Theorem 288, family c-reflective and has an adequate Suszko core. Therefore, by Theorem 847, it is family truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically protoalgebraic and family truth equational. Then, by Theorem 805, it is protoalgebraic and has a Leibniz reflexive core, and, by Theorem 847, it is family c-reflective and has an adequate Suszko core. Therefore, $\mathcal{I}$ is syntactically WF algebraizable. ∎

Directly from the definitions, we may derive the following relationship between the semantic and syntactic WF algebraizability classes of π-institutions.

Theorem 914 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if* $\mathcal{I}$ *is WF algebraizable and* $R^{\mathcal{I}}S^{\mathcal{I}}$*-fortified.*

Proof: $\mathcal{I}$ is syntactically WF algebraizable if and only if, by definition, it is $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified, protoalgebraic and family injective, i.e., iff it is, by definition, $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified and WF algebraizable. ∎

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak family algebraizability in terms of isomorphisms between complete lattices of theory families.

Theorem 915 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if it is* $R^{\mathcal{I}}S^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: We have that $\mathcal{I}$ is syntacticaly WF algebraizable if and only if, by Theorem 914, it is $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified and WF algebraizable, if and only if, by Theorem 296, it it $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. ■

Next, we show that syntactic WF algebraizability may also be characterized by the existence of an equivalence between the π-institution and its algebraic π-structure counterpart via a pair of conjugate transformations.

We embark on the path by defining first the algebraic π-structure $\mathcal{Q}^{\mathcal{I}*}$ associated with a given π-institution $\mathcal{I}$. We recall some concepts that we have already introduced previously which culminate in the definition of $\mathcal{Q}^{\mathcal{I}*}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall the definition of the class $\mathrm{AlgSys}^*(\mathcal{I})$ of all reduced $\mathbf{F}$-algebraic systems:

$$\mathrm{AlgSys}^*(\mathcal{I}) = \{\mathcal{A} : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}.$$

Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, we define the class of $\mathcal{I}^*$**-congruence systems on** $\mathcal{A}$ by

$$\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathbf{A}) : \mathcal{A}/\theta \in \mathrm{AlgSys}^*(\mathcal{I})\}.$$

It turns out that congruence systems in $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ have a straightforward characterization.

Proposition 916 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$. *Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$,

$$\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathbf{A}) : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \theta)\}.$$

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system.

Suppose, first, that $\theta \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. By definition, $\mathcal{A}/\theta \in \mathrm{AlgSys}^*(\mathcal{I})$. Thus, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$, such that

$$\Omega^{\mathcal{A}/\theta}(T') = \Delta^{\mathcal{A}/\theta}.$$

By applying the inverse of the quotient morphism $\langle I, \pi^\theta\rangle : \mathcal{A} \to \mathcal{A}/\theta$, we get

$$(\pi^\theta)^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = (\pi^\theta)^{-1}(\Delta^{\mathcal{A}/\theta}).$$

Since $\langle I, \pi^\theta\rangle$ is surjective, we get by Proposition 24 and by Corollary 55, that $(\pi^\theta)^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and

$$\Omega^{\mathcal{A}}((\pi^\theta)^{-1}(T')) = \theta.$$

Therefore, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \theta$.

Suppose, conversely, that $\theta \in \mathrm{ConSys}(\mathbf{A})$, with $\Omega^{\mathcal{A}}(T) = \theta$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, we have $\Omega^{\mathcal{A}/\theta}(T/\theta) = \Delta^{\mathcal{A}/\theta}$ and, therefore, by definition, $\mathcal{A}/\theta \in \mathrm{AlgSys}^*(\mathcal{I})$, implying that $\theta \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ■

In general, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and an $\mathbf{F}$-algebraic system $\mathcal{A}$, the family $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ of $\mathcal{I}^*$-congruence systems on $\mathcal{A}$ need not be closed under signature-wise intersections, i.e., may not form a closure family on $\mathbf{A}^2$. However, we can show that, if $\mathcal{I}$ is protoalgebraic, this is always the case.

Proposition 917 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic π-institution based on* $\mathbf{F}$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is closed under arbitrary intersections and, therefore, forms a closure family on* $\mathbf{A}^2$.

Proof: First, note that $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ has a top element $\nabla^{\mathcal{A}}$. To see this, observe that $\mathcal{A}/\nabla^{\mathcal{A}}$ is a trivial algebraic system, which is always a member of $\mathrm{AlgSys}^*(\mathcal{I})$.

It suffices now to show that $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is closed under arbitrary intersections. To this end, suppose $\theta^i \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$, for $i \in I$. By Proposition 916, for all $i \in I$, there exists $T^i \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T^i) = \theta^i$. But, by Lemma 23 and protoalgebraicity, we get that

$$\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i) = \bigcap_{i\in I} \Omega^{\mathcal{A}}(T^i) = \bigcap_{i\in I} \theta^i.$$

Now, again by Proposition 916, we conclude that $\bigcap_{i\in I} \theta^i \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ■

Applying Proposition 917 to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$, where $\langle I, \iota\rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism, we get the following

Corollary 918 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic π-institution based on* $\mathbf{F}$*. Then,* $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F})$ *is closed under arbitrary intersections and, therefore, forms a closure family on* $\mathbf{F}^2$.

Proof: This is a special case of Proposition 917. ■

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a protoalgebraic π-institution. We define, in accordance with Corollary 918, the **algebraic π-structure $\mathcal{Q}^{\mathcal{I}*}$ associated with $\mathcal{I}$** to be the π-structure

$$\mathcal{Q}^{\mathcal{I}*} = \langle \mathbf{F}^2, D^{\mathcal{I}*}\rangle,$$

where $D^{\mathcal{I}*}$ is the closure (operator) family corresponding to the closure family $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F})$.

Our first result in connecting syntactic WF algebraizability with the associated algebraic π-structure shows that, if a π-institution is syntactically WF algebraizable, then it is equivalent to its associated algebraic π-structure via a conjugate pair of transformations.

Theorem 919 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically WF algebraizable* π*-institution based on* $\mathbf{F}$*. Then* $\mathcal{I}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, \overleftrightarrow{I}^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations. More precisely:*

- $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, is a set of witnessing transformations of the syntactic protoalgebraicity of* $\mathcal{I}$*;*
- $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$*, with a single distinguished argument, is a set of witnessing equations for the family truth equationality of* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically WF algebraizable. Then, by definition, $\mathcal{I}$ is syntactically protoalgebraic and family truth equational. Therefore, there exist a set $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$, with two distinguished arguments, witnessing the syntactic protoalgebraicity of $\mathcal{I}$, and a set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, with a single distinguished argument, witnessing family truth equationality. To verify the conclusion, observe, first, that $\tau^\flat_\Sigma : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\tau^\flat_\Sigma[\phi]$ and $\overleftrightarrow{I}^\flat{}_\Sigma : \mathrm{SEN}^\flat(\Sigma)^2 \to \mathrm{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\overleftrightarrow{I}^\flat{}_\Sigma[\phi, \psi]$ are as required. Therefore, by Proposition 898, it suffices to show that:

(a) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq D^{\mathcal{I}*}(\tau^\flat_\Sigma[\Phi]);$$

(b) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^\flat[\overleftrightarrow{I}^\flat{}_\Sigma[\phi, \psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Note that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we have, by family truth equationality,

$$\begin{array}{lll} \Phi \subseteq T_\Sigma & \text{iff} & \tau^\flat_\Sigma[\Phi] \leq \Omega(T); \\ \phi \in T_\Sigma & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T). \end{array}$$

Therefore, $\phi \in C_\Sigma(\Phi)$ if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\tau^\flat_\Sigma[\Phi] \leq \Omega(T)$ implies $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, if and only if, by Proposition 916, $\tau^\flat_\Sigma[\phi] \leq D^{\mathcal{I}*}(\tau^\flat_\Sigma[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{llll} \phi \approx \psi \in \Omega_\Sigma(T) & \text{iff} & \overleftrightarrow{I}^\flat{}_\Sigma[\phi, \psi] \leq T & \text{(Corollary 791)} \\ & \text{iff} & \tau^\flat[\overleftrightarrow{I}^\flat{}_\Sigma[\phi, \psi]] \leq \Omega(T). & \text{(truth equationality)} \end{array}$$

Using again Proposition 916, we conclude that

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^\flat[\overleftrightarrow{I^\flat}_\Sigma[\phi,\psi]]).$$

Therefore $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via $(\tau^\flat, \overleftrightarrow{I^\flat}) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$. ∎

Putting together Theorems 909, 911 and 919, we get the following fundamental result to the effect that syntactic WF algebraizability boils down to the equivalence of a π-institution with its associated algebraic π-structure via a conjugate pair of transformations.

Theorem 920 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if it is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations.*

Proof: If $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of transformations, then, by Theorem 909, it is syntactically protoalgebraic and, by Theorem 911, it is family truth equational. Therefore, by definition, it is syntactically WF algebraizable.

If, conversely, $\mathcal{I}$ is syntactically WF algebraizable, then, by Theorem 919, it is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of transformations. ∎

We close the section by slightly generalizing the preceding characterization. Namely, we show that existence of an equivalence with an algebraic π-structure induced by conjugate transformations is sufficient to yield syntactic WF algebraizability.

Theorem 921 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if it is equivalent to an algebraic* π*-structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically WF algebraizable, then the conclusion follows from Theorem 920. Conversely, if $\mathcal{I}$ is equivalent to an algebraic π-structure via a conjugate pair of transformations, then it is syntactically protoalgebraic by Theorem 909 and family truth equational by Theorem 911, whence it is syntactically WF algebraizable. ∎

Taking into account Theorem 901, we have the following alternative characterization of syntactically WF algebraizable π-institutions:

Theorem 922 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WF algebraizable if and only if there is a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ThFam}(\mathcal{Q})$*, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 921 and Theorem 893. The "if" is given by Theorem 901 and Theorem 921. ∎

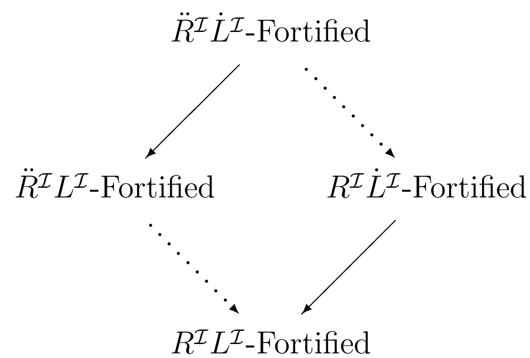
12.4 Syntactic Weak Algebraizability

Syntactic WF algebraizability determines one of the highest levels of the main algebraic hierarchy of π-institutions. Since every syntactically WF algebraizable π-institution is, in particular, family reflective, it follows that every syntactically WF algebraizable π-institution is systemic. To avoid systemicity, one has to weaken the hypothesis of family reflectivity. In this section we follow this line of thought by keeping the assumption of syntactic protoalgebraicity, but insisting only that the π-institution is system truth equational, rather than family truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that:

- $\mathcal{I}$ is $R^{\mathcal{I}}L^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $L^{\mathcal{I}}$ is left adequate;
- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $\dot{L}^{\mathcal{I}}$ is left adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $L^{\mathcal{I}}$ is left adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $\dot{L}^{\mathcal{I}}$ is left adequate.

Similarly with the Suszko core, it can be seen that, if $\dot{L}^{\mathcal{I}}$ is left adequate, then $L^{\mathcal{I}}$ is left adequate. Moreover, since, by Proposition 952, $\ddot{R}^{\mathcal{I}} \subseteq R^{\mathcal{I}}$, it follows that, under the assumption of prealgebraicity, if $\ddot{R}^{\mathcal{I}}$ is Leibniz, then $R^{\mathcal{I}}$ is Leibniz. Thus, we have the following **syntactic left fortification hierarchy** (in which the dotted arrows hold under prealgebraicity):



$\mathcal{I}$ is **syntactically weakly algebraizable** (abbreviated to **syntactically W algebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}L^{\mathcal{I}}$-fortified;
- $\mathcal{I}$ is protoalgebraic;

- $\mathcal{I}$ is system injective.

By Corollary 300, under protoalgebraicity, the six properties of system injectivity, left injectivity, system reflectivity, left reflectivity, system complete reflectivity and left complete reflectivity coincide. This enables us to formulate the following alternative characterization of syntactic weak algebraizability.

Theorem 923 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if it is syntactically protoalgebraic and system (or, equivalently, left) truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically weakly algebraizable. Then, on the one hand, it is protoalgebraic and has a Leibniz reflexive core. Thus, by Theorem 805, it is syntactically protoalgebraic. On the other, it is, by Theorem 300, left c-reflective and has a left adequate left Suszko core. Therefore, by Theorem **??**, it is left truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically protoalgebraic and left truth equational. Then, by Theorem 805, it is protoalgebraic and has a Leibniz reflexive core, and, by Theorem 870, it is left c-reflective and has a left adequate left Suszko core. Therefore, by definition, $\mathcal{I}$ is syntactically weakly algebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic weak algebraizability classes of π-institutions.

Theorem 924 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if* $\mathcal{I}$ *is weakly algebraizable and* $R^{\mathcal{I}} L^{\mathcal{I}}$*-fortified.*

Proof: $\mathcal{I}$ is syntactically weakly algebraizable if and only if, by definition, it is $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified, protoalgebraic and system injective, i.e., iff it is, by definition, $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified and weakly algebraizable. ■

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak algebraizability in terms of isomorphisms between complete lattices of theory systems.

Theorem 925 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if it is* $R^{\mathcal{I}} L^{\mathcal{I}}$*-fortified, stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: We have that $\mathcal{I}$ is syntactically weakly algebraizable if and only if, by Theorem 924, it is $R^{\mathcal{I}}L^{\mathcal{I}}$-fortified and weakly algebraizable, if and only if, by Theorem 298, it it $R^{\mathcal{I}}L^{\mathcal{I}}$-fortified, stable and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. ■

Next, we show that syntactic weak algebraizability may also be characterized by stability in conjunction with the existence of an equivalence between the systemic skeleton of a π-institution and its algebraic π-structure counterpart via a pair of conjugate transformations. To start, we define the *systemic skeleton* of a given π-institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathrm{ThSys}(\mathcal{I})$ forms a complete lattice $\mathbf{ThSys}(\mathcal{I}) = \langle \mathrm{ThSys}(\mathcal{I}), \leq\rangle$ under signature wise inclusion. Therefore, we are justified in defining the π-structure

$$\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}}\rangle$$

of $\mathcal{I}$ by stipulating that $K^{\mathcal{I}} : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ is the closure family on $\mathbf{F}$ corresponding to the closed set family $\mathrm{ThSys}(\mathcal{I})$. We call $\mathcal{K}^{\mathcal{I}}$ the **systemic skeleton** of $\mathcal{I}$.

We give an example to show that, in general, $K^{\mathcal{I}}$ is not a π-institution, since $K^{\mathcal{I}} : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ may not satisfy structurality.

Example 926 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be defined as follows:*

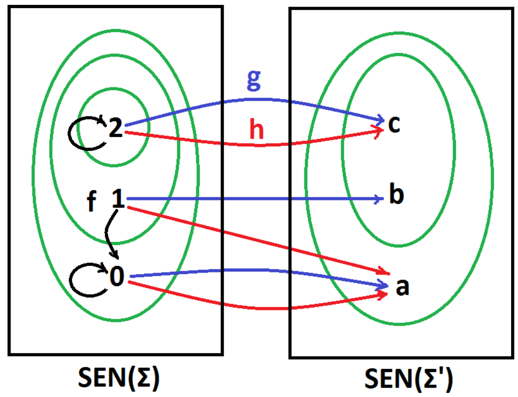
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ, Σ' *and, except the identities, a morphism* $f : \Sigma \to \Sigma$ *and two morphisms* $g, h : \Sigma \to \Sigma'$*, satisfying the following composition rules:*

$$f \circ f = f, \quad gf = h, \quad hf = h.$$

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$ *and*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\mathrm{SEN}^\flat(f)(x)$	$\mathrm{SEN}^\flat(g)(x)$	$\mathrm{SEN}^\flat(h)(x)$
0	0	a	a
1	0	b	a
2	2	c	c

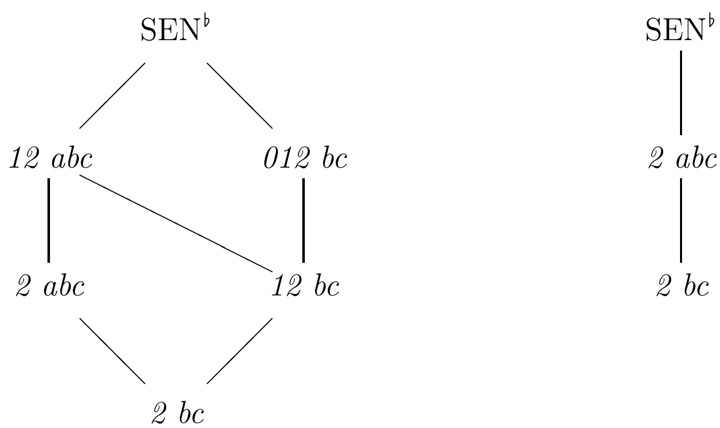
- *Finally,* $N^\flat$ *is the trivial category of natural transformations (consisting of the projections only).*



Next define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b,c\}, \{a,b,c\}\}.$$

This π-institution has six theory families, having the lattice structure shown on the left below. It has, however, only three theory systems, whose lattice structure is given on the right.



The theory systems of $\mathcal{I}$ are the theory families of the systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$. We can see that $\mathcal{K}^{\mathcal{I}}$ is not a π-institution by considering $\Phi = \{1\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{rcl}\mathrm{SEN}^\flat(g)(K^{\mathcal{I}}_\Sigma(\{1\})) & = & \mathrm{SEN}^\flat(g)(\bigcap\{T_\Sigma : \{\{1\}, \varnothing\} \leq T \in \mathrm{ThSys}(\mathcal{I})\}) \\ & = & \mathrm{SEN}^\flat(g)(\{0,1,2\}) \\ & = & \{a,b,c\}.\end{array}$$

On the other hand,

$$\begin{array}{rcl}K^{\mathcal{I}}_{\Sigma'}(\mathrm{SEN}^\flat(g)(\{1\})) & = & K^{\mathcal{I}}_{\Sigma'}(\{b\}) \\ & = & \bigcap\{T_{\Sigma'} : \{\varnothing, \{b\}\} \leq T \in \mathrm{ThSys}(\mathcal{I})\} \\ & = & \{b,c\}.\end{array}$$

Therefore

$$\mathrm{SEN}^\flat(g)(K^{\mathcal{I}}_\Sigma(\{1\})) \notin K^{\mathcal{I}}_{\Sigma'}(\mathrm{SEN}^\flat(g)(\{1\}))$$

showing that $K^{\mathcal{I}}$ *is not structural and, hence,* $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}}\rangle$ *is a* π*-structure, but not a* π*-institution.*

We now resume our work on the characterization of syntactic weak algebraizability. We will again make use of the algebraic π-structure $\mathcal{Q}^{\mathcal{I}*} = \langle \mathbf{F}^2, D^{\mathcal{I}*}\rangle$ associated with a protoalgebraic π-institution $\mathcal{I}$. Recall that this is the π-structure whose closure family is the one corresponding to the closure set family $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F})$.

Our first result connecting syntactic weak algebraizability of a π-institution with the associated algebraic π-structure shows that, if a π-institution is syntactically weakly algebraizable, then its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to its associated algebraic π-structure $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of transformations.

Theorem 927 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a syntactically weakly algebraizable* π*-institution based on* $\mathbf{F}$*. Then* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, \overleftrightarrow{I}^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations. More precisely:*

- $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, is a set of witnessing transformations of the syntactic protoalgebraicity of* $\mathcal{I}$*;*
- $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$*, with a single distinguished argument, is a set of witnessing equations for the left truth equationality of* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically weakly algebraizable. Then, by definition, $\mathcal{I}$ is syntactically protoalgebraic and left truth equational. Therefore, there exist a set $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$, with two distinguished arguments, witnessing the syntactic protoalgebraicity of $\mathcal{I}$, and a set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, with a single distinguished argument, witnessing left truth equationality. To verify the conclusion, observe, first, that $\tau^\flat_\Sigma : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\tau^\flat_\Sigma[\phi]$ and $\overleftrightarrow{I}^\flat_\Sigma : \mathrm{SEN}^\flat(\Sigma)^2 \to \mathrm{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\overleftrightarrow{I}^\flat_\Sigma[\phi, \psi]$ are as required. Therefore, by Proposition 898, it suffices to show that:

(a) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in K^{\mathcal{I}}_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq D^{\mathcal{I}*}(\tau^\flat_\Sigma[\Phi]);$$

(b) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^\flat[\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Note that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, we have

$$\begin{array}{lll} \Phi \subseteq T_\Sigma & \text{iff} & \Phi \subseteq \overleftarrow{T}_\Sigma \quad (T \in \mathrm{ThSys}(\mathcal{I})) \\ & \text{iff} & \tau^\flat_\Sigma[\Phi] \leq \Omega(T) \quad \text{(left truth equationality)} \end{array}$$

and, similarly,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

Therefore, $\phi \in K^{\mathcal{I}}_\Sigma(\Phi)$ if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\tau^\flat_\Sigma[\Phi] \leq \Omega(T)$ implies $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, if and only if, by stability, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\tau^\flat_\Sigma[\Phi] \leq \Omega(T)$ implies $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, if and only if, by Proposition 916, $\tau^\flat_\Sigma[\phi] \leq D^{\mathcal{I}*}(\tau^\flat_\Sigma[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\begin{array}{lll} \phi \approx \psi \in \Omega_\Sigma(T) & \text{iff} & \overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \leq T \quad \text{(Corollary 791)} \\ & \text{iff} & \overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \leq \overleftarrow{T} \quad (T \in \mathrm{ThSys}(\mathcal{I})) \\ & \text{iff} & \tau^\flat[\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi]] \leq \Omega(T). \quad \text{(left truth equationality)} \end{array}$$

Using again Proposition 916 and stability, we conclude that

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^\flat[\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi]]).$$

Therefore $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via $(\tau^\flat, \overleftrightarrow{I^\flat}) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$. ■

Towards the converse, we show, first, that, if a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is such that there exists an equivalence $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$, via a conjugate pair of transformations, between its systemic skeleton and an algebraic π-structure $\mathcal{Q}$, then $I^\flat$ defines Leibniz congruence systems of theory systems of $\mathcal{I}$.

Recall that for a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, and a set $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$, with two distinguished arguments, we define, for all $T \in \mathrm{SenFam}(\mathcal{I})$, $I^\flat(T) = \{I^\flat_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$I^\flat_\Sigma(T) = \{\langle \phi, \psi \rangle \in \mathrm{SEN}^\flat(\Sigma)^2 : I^\flat_\Sigma[\phi, \psi] \leq T\}.$$

Proposition 928 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an algebraic π-structure $\mathcal{Q}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = I^\flat(T)$.*

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$. It suffices to show, by Corollary 98, that $I^\flat(T)$ is a congruence system on $\mathbf{F}$ compatible with T. We know by Lemma 93 that it is a relation system on $\mathbf{F}$.

Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q} = \langle \mathbf{F}^2, D\rangle$ is algebraic, we have $\phi \approx \phi \in D_\Sigma(\varnothing)$. Therefore, by interpretability, $I^\flat_\Sigma[\phi,\phi] \le K^{\mathcal{I}}(\varnothing) = C(\varnothing) \le T$. Hence, $\langle \phi,\phi\rangle \in I^\flat_\Sigma(T)$ and $I^\flat(T)$ is reflexive.

Suppose, now, that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q}$ is algebraic, we have that $\psi \approx \phi \in D_\Sigma(\phi \approx \psi)$. Therefore, by interpretability, $I^\flat_\Sigma[\psi,\phi] \le K^{\mathcal{I}}(I^\flat_\Sigma[\phi,\psi])$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, this implies that, if $I^\flat_\Sigma[\phi,\psi] \le T$, then $I^\flat_\Sigma[\psi,\phi] \le T$. In other words $\langle\phi,\psi\rangle \in I^\flat_\Sigma(T)$ implies $\langle\psi,\phi\rangle \in I^\flat_\Sigma(T)$. Therefore, $I^\flat(T)$ is also symmetric.

Suppose, next, that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi,\chi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q}$ is algebraic, we have that $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$. Therefore, by interpretability, $I^\flat_\Sigma[\phi,\chi] \le K^{\mathcal{I}}(I^\flat_\Sigma[\phi,\psi], I^\flat_\Sigma[\psi,\chi])$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, this implies that, if $I^\flat_\Sigma[\phi,\psi], I^\flat_\Sigma[\psi,\chi] \le T$, then $I^\flat_\Sigma[\phi,\chi] \le T$. In other words, $\langle\phi,\psi\rangle, \langle\psi,\chi\rangle \in I^\flat_\Sigma(T)$ imply $\langle\phi,\chi\rangle \in I^\flat_\Sigma(T)$. Therefore, $I^\flat(T)$ is transitive.

We have now shown that $I^\flat(T)$ is an equivalence system on $\mathbf{F}$. It remains to show that it satisfies the congruence property and that it is compatible with T.

Suppose that $\sigma^\flat \in N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi},\vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q}$ is algebraic, we have that $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in D_\Sigma(\vec{\phi} \approx \vec{\psi})$ (recall that $\vec{\phi} \approx \vec{\psi}$ means $\{\phi_i \approx \psi_i : i < k\}$). Therefore, by interpretability,

$$I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \le K^{\mathcal{I}}(\bigcup\{I^\flat_\Sigma[\phi_i,\psi_i] : i < k\}).$$

Since $T \in \mathrm{ThSys}(\mathcal{I})$, this implies that, if, for all $i < k$, $I^\flat_\Sigma[\phi_i,\psi_i] \le T$, then $I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \le T$. In other words $\langle\phi_i,\psi_i\rangle \in I^\flat_\Sigma(T)$, for all $i < k$, imply $\langle\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})\rangle \in I^\flat_\Sigma(T)$. Therefore, $I^\flat(T)$ satisfies the congruence property.

Finally, to see that $I^\flat(T)$ is compatible with T, suppose that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{Q}$ is algebraic and $\tau^\flat \in N^\flat$, we have, by Lemma 907,

$$\tau^\flat_\Sigma[\psi] \le D(\tau^\flat_\Sigma[\phi], \phi \approx \psi).$$

By interpretability, this yields

$$I^\flat[\tau^\flat_\Sigma[\psi]] \le K^{\mathcal{I}}(I^\flat[\tau^\flat_\Sigma[\phi]], I^\flat_\Sigma[\phi,\psi]).$$

Since $(\tau^\flat, I^\flat)$ is a conjugate pair, the latter is equivalent to

$$\psi \in K^{\mathcal{I}}_\Sigma(\phi, I^\flat_\Sigma[\phi,\psi]).$$

In other words, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\phi \in T_\Sigma \quad \text{and} \quad \langle\phi,\psi\rangle \in I^\flat_\Sigma(T) \quad \text{imply} \quad \psi \in T_\Sigma.$$

Hence $I^\flat(T)$ is compatible with T. ■

Using Proposition 928, we can show that stability and the existence of an equivalence between the systemic skeleton and an algebraic π-structure ensure syntactic protoalgebraicity.

Theorem 929 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is stable and its systemic skeleton* $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ *is equivalent to an algebraic* π*-structure* $\mathcal{Q}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ *of transformations, then* $\mathcal{I}$ *is syntactically protoalgebraic, with witnessing transformations* $I^\flat$.

Proof: Suppose that $\mathcal{I}$ is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an algebraic π-structure $\mathcal{Q}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations. Then, we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{rcll} \Omega(T) & = & \Omega(\overleftarrow{T}) & \text{(by stability)} \\ & = & I^\flat(\overleftarrow{T}) & \text{(by Proposition 928)} \\ & = & I^\flat(T). & \text{(by Proposition 99)} \end{array}$$

Therefore, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. ■

Finally, before the main theorem, we show that stability and the existence of a transformational equivalence between the systemic skeleton and an algebraic π-structure ensure left truth equationality.

Theorem 930 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is stable and its systemic skeleton* $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ *is equivalent to an algebraic* π*-structure* $\mathcal{Q}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ *of transformations, then* $\mathcal{I}$ *is left truth equational, with witnessing equations* $\tau^\flat$.

Proof: We have, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rlll} \phi \in \overleftarrow{T}_\Sigma & \text{iff} & I^\flat[\tau^\flat_\Sigma[\phi]] \le \overleftarrow{T} & ((\tau^\flat, I^\flat) \text{ an equivalence}) \\ & \text{iff} & I^\flat[\tau^\flat_\Sigma[\phi]] \le T & \text{(by Proposition 99)} \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T). & \text{(by Theorem 929)} \end{array}$$

Therefore, $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat$. ■

Putting together Theorems 929, 930 and 927, we get the following fundamental result to the effect that syntactic weak algebraizability boils down to stability, together with the equivalence of the systemic skeleton of a π-institution with its associated algebraic π-structure via a conjugate pair of transformations.

Theorem 931 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if it is stable and its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of transformations. Then, by Theorem 929, it is syntactically protoalgebraic and, by Theorem 930, it is left truth equational. Therefore, by definition, it is syntactically weakly algebraizable.

If, conversely, $\mathcal{I}$ is syntactically weakly algebraizable, then, on the one hand, it is protoalgebraic and, therefore, stable, and, on the other, by Theorem 927, it is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of transformations. ∎

Generalizing again, we show that stability together with the existence of an equivalence of the systemic skeleton with an algebraic π-structure, induced by conjugate transformations, is sufficient to yield syntactic weak algebraizability.

Theorem 932 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if it is stable and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of transformations.*

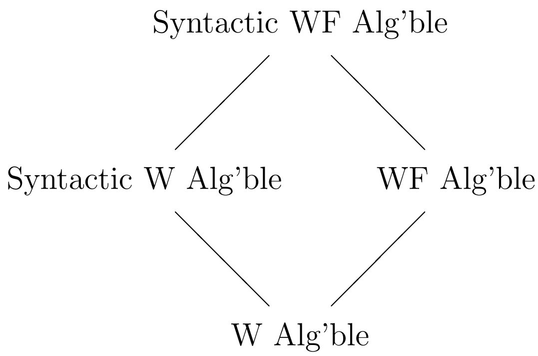
Proof: If $\mathcal{I}$ is syntactically weakly algebraizable, then the conclusion follows from Theorem 931. Conversely, if $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically protoalgebraic by Theorem 929 and left truth equational by Theorem 930, whence it is syntactically weakly algebraizable. ∎

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically weakly algebraizable π-institutions:

Theorem 933 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly algebraizable if and only if it is stable and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$*, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 932 and Theorem 893. The "if" is given by Theorem 901 and Theorem 932. ∎

Let us give, in closing the section, the picture of the **weak algebraizability hierarchy** that we have established, consisting of both semantic and syntactic classes of π-institutions.



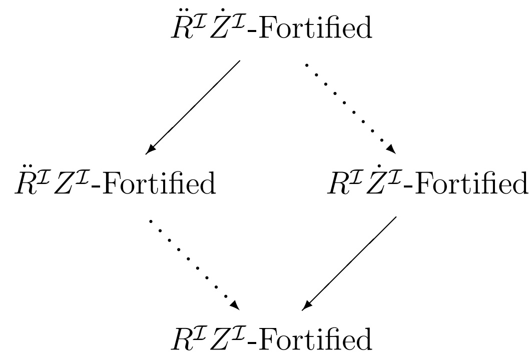
12.5 Syntactic WS PreAlgebraizability

Syntactic WS prealgebraizability, requires, like syntactic WF algebraizability, the monotonicity of the Leibniz operator on theory systems and the injectivity of the Leibniz operator on theory systems but, unlike WF algebraizability, it requires these two properties only on theory systems and not on the entire complete lattice of theory families. As a consequence of this weakened requirement, syntactic WS prealgebraizability implies neither systemicity (as does syntactic WF algebraizability) nor the even weaker condition of stability (as do both kinds of syntactic algebraizability). Thus, as other conditions that were under our scrutiny previously, it allows us to consider for membership π-institutions that are not necessarily stable.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that:

- $\mathcal{I}$ is $R^{\mathcal{I}}Z^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $Z^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-(**syntactically**) **fortified** if $R^{\mathcal{I}}$ is Leibniz and $\dot{Z}^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $Z^{\mathcal{I}}$ is adequate;
- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-(**syntactically**) **fortified** if $\ddot{R}^{\mathcal{I}}$ is Leibniz and $\dot{Z}^{\mathcal{I}}$ is adequate.

Similarly with the Suszko core, it can be seen that, if $\dot{Z}^{\mathcal{I}}$ is adequate, then $Z^{\mathcal{I}}$ is adequate. Moreover, since, by Proposition 952, $\ddot{R}^{\mathcal{I}} \subseteq R^{\mathcal{I}}$, it follows that, under the assumption of prealgebraicity, if $\ddot{R}^{\mathcal{I}}$ is Leibniz, then $R^{\mathcal{I}}$ is Leibniz. Thus, we have the following **syntactic system fortification hierarchy** (in which the dotted arrows hold under prealgebraicity):



$\mathcal{I}$ is **syntactically weakly system prealgebraizable** (abbreviated to **syntactically WS prealgebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}Z^{\mathcal{I}}$-fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is system injective.

By Theorem 248, under prealgebraicity, the properties of system injectivity, system reflectivity and system complete reflectivity coincide. As a result, we have the following alternative characterization of syntactic weak system prealgebraizability.

Theorem 934 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if it is syntactically prealgebraic and system truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically weakly system prealgebraizable. Then, on the one hand, it is prealgebraic and has a Leibniz reflexive core. Thus, by Theorem 788, it is syntactically prealgebraic. On the other, it is, by Theorem 248, system c-reflective and has an adequate system core. Therefore, by Theorem 887, it is system truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically prealgebraic and system truth equational. Then, by Theorem 788, it is prealgebraic and has a Leibniz reflexive core, and, by Theorem 887, it is system c-reflective and has an adequate system core. Therefore, by definition, $\mathcal{I}$ is syntactically weakly system prealgebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic weak system prealgebraizability classes of π-institutions.

Theorem 935 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if* $\mathcal{I}$ *is weakly system prealgebraizable and* $R^{\mathcal{I}} Z^{\mathcal{I}}$*-fortified.*

Proof: $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if, by definition, it is $R^{\mathcal{I}} Z^{\mathcal{I}}$-fortified, prealgebraic and system injective, i.e., iff it is, by definition, $R^{\mathcal{I}} Z^{\mathcal{I}}$-fortified and weakly system prealgebraizable. ∎

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak system prealgebraizability in terms of morphisms between complete lattices of theory systems.

Theorem 936 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if it is* $R^{\mathcal{I}} Z^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding.

Proof: We have that $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if, by Theorem 935, it is $R^{\mathcal{I}} Z^{\mathcal{I}}$-fortified and weakly system prealgebraizable, if and only if, by Theorem 256, it it $R^{\mathcal{I}} Z^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding ∎

Next, we show that syntactic weak system prealgebraizability may also be characterized by the existence of an equivalence between the systemic skeleton of a π-institution and an algebraic π-structure associated with the π-institution (different, in general, than $\mathcal{Q}^{\mathcal{I}*}$) via a pair of conjugate transformations.

We embark on the path by defining first the algebraic π-structure $\mathcal{Q}^{\mathcal{I}\bullet}$ associated with a given π-institution $\mathcal{I}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall the definition of the class $\mathrm{AlgSys}^\bullet(\mathcal{I})$ of all $\mathbf{F}$-algebraic systems reduced with respect to $\mathcal{I}$-filter systems:

$$\mathrm{AlgSys}^\bullet(\mathcal{I}) = \{\mathcal{A} : (\exists T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}.$$

Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, we define the class of $\mathcal{I}^\bullet$-**congruence systems on** $\mathcal{A}$ by

$$\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathbf{A}) : \mathcal{A}/\theta \in \mathrm{AlgSys}^\bullet(\mathcal{I})\}.$$

It turns out that congruence systems in $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ have a straightforward characterization.

Proposition 937 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathbf{A}) : (\exists T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \theta)\}.$$

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system.

Suppose, first, that $\theta \in \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. By definition, $\mathcal{A}/\theta \in \mathrm{AlgSys}^\bullet(\mathcal{I})$. Thus, there exists $T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}/\theta)$, such that

$$\Omega^{\mathcal{A}/\theta}(T') = \Delta^{\mathcal{A}/\theta}.$$

By applying the inverse of the quotient morphism $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}/\theta$, we get

$$(\pi^\theta)^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = (\pi^\theta)^{-1}(\Delta^{\mathcal{A}/\theta}).$$

Since $\langle I, \pi^\theta \rangle$ is surjective, we get by Proposition 24 and Corollary 55, that $(\pi^\theta)^{-1}(T') \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ and

$$\Omega^{\mathcal{A}}((\pi^\theta)^{-1}(T')) = \theta.$$

Therefore, there exists $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \theta$.

Suppose, conversely, that $\theta \in \mathrm{ConSys}(\mathbf{A})$, with $\Omega^{\mathcal{A}}(T) = \theta$, for some $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$. Then, we have $\Omega^{\mathcal{A}/\theta}(T/\theta) = \Delta^{\mathcal{A}/\theta}$ and, therefore, by definition, $\mathcal{A}/\theta \in \mathrm{AlgSys}^\bullet(\mathcal{I})$, implying that $\theta \in \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. ■

In general, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and an $\mathbf{F}$-algebraic system $\mathcal{A}$, the family $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ of systemic $\mathcal{I}$-congruence systems on $\mathcal{A}$ need not be closed under signature-wise intersections, i.e., may not form a closure family on $\mathbf{A}^2$. However, we can show that, if $\mathcal{I}$ is prealgebraic, this is always the case.

Proposition 938 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a prealgebraic* π*-institution based on* $\mathbf{F}$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ *is closed under arbitrary intersections and, therefore, forms a closure family on* $\mathbf{A}^2$*.*

Proof: First, note that $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ has a top element $\nabla^{\mathcal{A}}$. To see this, observe that $\mathcal{A}/\nabla^{\mathcal{A}}$ is a trivial algebraic system, which is always a member of $\mathrm{AlgSys}^\bullet(\mathcal{I})$.

It suffices now to show that $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ is closed under arbitrary intersections. To this end, suppose $\theta^i \in \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$, for $i \in I$. By Proposition 937, for all $i \in I$, there exists $T^i \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}/\theta^i)$, such that $\Omega^{\mathcal{A}}(T^i) = \theta^i$. But, by Lemma 23 and prealgebraicity, we get that

$$\Omega^{\mathcal{A}}(\bigcap_{i \in I} T^i) = \bigcap_{i \in I} \Omega^{\mathcal{A}}(T^i) = \bigcap_{i \in I} \theta^i.$$

Now, again by Proposition 937, we conclude that $\bigcap_{i\in I}\theta^i \in \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. ■

Applying Proposition 938 to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$, where $\langle I, \iota\rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism, we get the following

Corollary 939 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a protoalgebraic π-institution based on $\mathbf{F}$. Then, $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{F})$ is closed under arbitrary intersections and, therefore, forms a closure family on $\mathbf{F}^2$.*

Proof: This is a special case of Proposition 938. ■

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a prealgebraic π-institution. We define, in accordance with Corollary 939, the **systemic algebraic π-structure $\mathcal{Q}^{\mathcal{I}\bullet}$ associated with $\mathcal{I}$** to be the π-structure $\mathcal{Q}^{\mathcal{I}\bullet} = \langle \mathbf{F}^2, D^{\mathcal{I}\bullet}\rangle$, where $D^{\mathcal{I}\bullet}$ is the closure (operator) family corresponding to the closure family $\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{F})$.

We recall, also, the defining of the systemic skeleton of $\mathcal{I}$, i.e., of the π-structure

$$\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}}\rangle$$

of $\mathcal{I}$, where $K^{\mathcal{I}} : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ is the closure family on $\mathbf{F}$ corresponding to the closet set family $\mathrm{ThSys}(\mathcal{I})$.

Now we have the components needed to resume work on the characterization of syntactic weak system prealgebraizability. Our first result connecting syntactic weak system prealgebraizability of a π-institution with the associated systemic algebraic π-structure shows that, if a π-institution is syntactically weakly system prealgebraizable, then its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to its associated systemic algebraic π-structure $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations.

Theorem 940 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a syntactically weakly system prealgebraizable π-institution based on $\mathbf{F}$. Then $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, \overleftrightarrow{I}^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations. More precisely:*

- *$I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, is a set of witnessing transformations of the syntactic prealgebraicity of $\mathcal{I}$;*
- *$\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, with a single distinguished argument, is a set of witnessing equations for the system truth equationality of $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is syntactically weakly system prealgebraizable. Then, by definition, $\mathcal{I}$ is syntactically prealgebraic and system truth equational. Therefore, there exist a set $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$, with two distinguished arguments, witnessing the syntactic prealgebraicity of $\mathcal{I}$, and a set $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, with a single distinguished argument, witnessing system truth equationality. To verify the conclusion, observe, first, that

$\tau^\flat_\Sigma : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\tau^\flat_\Sigma[\phi]$, and $\overleftrightarrow{I}^\flat{}_\Sigma : \mathrm{SEN}^\flat(\Sigma)^2 \to \mathrm{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, as the sentence family $\overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi]$, are as required. Therefore, by Proposition 898, it suffices to show that:

(a) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in K^{\mathcal{I}}_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \le D^{\mathcal{I}\bullet}(\tau^\flat_\Sigma[\Phi]);$$

(b) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathcal{I}\bullet}(\phi \approx \psi) = D^{\mathcal{I}\bullet}(\tau^\flat[\overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Note that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, we have, by system truth equationality,

$$\begin{array}{lll} \Phi \subseteq T_\Sigma & \text{iff} & \tau^\flat_\Sigma[\Phi] \le \Omega(T) \\ \phi \in T_\Sigma & \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T). \end{array}$$

Therefore, $\phi \in K^{\mathcal{I}}_\Sigma(\Phi)$ if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\tau^\flat_\Sigma[\Phi] \le \Omega(T)$ implies $\tau^\flat_\Sigma[\phi] \le \Omega(T)$, if and only if, by Proposition 937, $\tau^\flat_\Sigma[\phi] \le D^{\mathcal{I}\bullet}(\tau^\flat_\Sigma[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\begin{array}{llll} \phi \approx \psi \in \Omega_\Sigma(T) & \text{iff} & \overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi] \le T & \text{(Corollary 770)} \\ & \text{iff} & \tau^\flat[\overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi]] \le \Omega(T). & \\ & & \text{(system truth equationality)} & \end{array}$$

Using again Proposition 937, we conclude that

$$D^{\mathcal{I}\bullet}(\phi \approx \psi) = D^{\mathcal{I}\bullet}(\tau^\flat[\overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi]]).$$

Therefore $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via $(\tau^\flat, \overleftrightarrow{I}^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$. ■

We show, next that the existence of an equivalence between the systemic skeleton of a given π-institution and an algebraic π-structure ensures syntactic prealgebraicity.

Theorem 941 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If the systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}}\rangle$ of $\mathcal{I}$ is equivalent to an algebraic π-structure $\mathcal{Q}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations $I^\flat$.*

Proof: Suppose that $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an algebraic π-structure $\mathcal{Q}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations. Then, we have, by Proposition 928, that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = I^\flat(T)$. Therefore, $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $I^\flat$. ∎

Finally, as a last step before the main theorem, we show that the existence of a transformational equivalence between the systemic skeleton of a given π-institution and an algebraic π-structure ensures system truth equationality.

Theorem 942 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If the systemic skeleton* $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ *of* $\mathcal{I}$ *is equivalent to an algebraic* π*-structure* $\mathcal{Q}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ *of transformations, then* $\mathcal{I}$ *is system truth equational, with witnessing equations* $\tau^\flat$.

Proof: We have, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & I^\flat[\tau^\flat_\Sigma[\phi]] \leq T \quad ((\tau^\flat, I^\flat) \text{ an equivalence}) \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T). \quad (\text{by Theorem 941}) \end{array}$$

Therefore, $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^\flat$. ∎

Putting together Theorems 941, 942 and 940, we get the following fundamental result to the effect that syntactic weak system prealgebraizability boils down to the existence of an equivalence of the systemic skeleton of a π-institution with its associated systemic algebraic π-structure via a conjugate pair of transformations.

Theorem 943 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of transformations.*

Proof: Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations. Then, by Theorem 941, it is syntactically prealgebraic and, by Theorem 942, it is system truth equational. Therefore, by definition, it is syntactically weakly system prealgebraizable. If, conversely, $\mathcal{I}$ is syntactically weakly system prealgebraizable, then, by Theorem 940, it is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations. ∎

It turns out that the existence of an equivalence of the systemic skeleton with an algebraic π-structure, induced by conjugate transformations, is sufficient to yield syntactic weak system prealgebraizability.

Theorem 944 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically weakly system prealgebraizable, then the conclusion follows from Theorem 943. Conversely, if $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically prealgebraic by Theorem 941 and system truth equational by Theorem 942, whence it is syntactically weakly system prealgebraizable. ∎

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically weakly system prealgebraizable π-institutions:

Theorem 945 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically weakly system prealgebraizable if and only if there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$*, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 944 and Theorem 893. The "if" is given by Theorem 901 and Theorem 944. ∎

12.6 Syntactic WLC PreAlgebraizability

Between syntactic WS prealgebraizability and syntactic weak algebraizability we find the class of syntactic weakly left c-reflective prealgebraizability. This strengthens WS prealgebraizability by replacing system c-reflectivity by the stronger condition of left c-reflectivity. Alternatively, it weakens syntactic weak algebraizability by replacing ptotoalgebraicity by prealgebraicity.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **syntactically weakly left c-reflectively prealgebraizable** (abbreviated to **syntactically WLC prealgebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}L^{\mathcal{I}}$-fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is left c-reflective.

We have the following alternative characterization of syntactic WLC prealgebraizability.

Theorem 946 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if it is syntactically prealgebraic and left truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically WLC prealgebraizable. Then, on the one hand, it is prealgebraic and has a Leibniz reflexive core. Thus, by

Theorem 788, it is syntactically prealgebraic. On the other, it is left c-reflective and has a left adequate left Suszko core. Therefore, by Theorem 870, it is left truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically prealgebraic and left truth equational. Then, by Theorem 788, it is prealgebraic and has a Leibniz reflexive core, and, by Theorem 870, it is left c-reflective and has a left adequate left Suszko core. Therefore, by definition, $\mathcal{I}$ is syntactically WLC prealgebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic WLC prealgebraizability classes of π-institutions.

Theorem 947 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if* $\mathcal{I}$ *is WLC prealgebraizable and* $R^{\mathcal{I}} L^{\mathcal{I}}$*-fortified.*

Proof: $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if, by definition, it is $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified, prealgebraic and left c-reflective, i.e., iff it is, by definition, $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified and WLC prealgebraizable. ■

For an alternative characterization of syntactic WLC prealgebraizability, we take advantage of the corresponding characterization of WLC prealgebraizability in terms of morphisms between complete lattices of theory systems.

Theorem 948 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if it is* $R^{\mathcal{I}} L^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: We have that $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if, by Theorem 947, it is $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified and WLC prealgebraizable, if and only if, by Theorem 276, it it $R^{\mathcal{I}} L^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ■

Recall that syntactic weak system prealgebraizability was characterized by the existence of an equivalence between the systemic skeleton $K^{\mathcal{I}}$ of a

π-institution $\mathcal{I}$ and the systemic algebraic π-structure $\mathcal{Q}^{\mathcal{I}\bullet}$ associated with the π-institution, via a pair of conjugate transformations. To adapt this characterization to capture syntactic WLC prealgebraizability, we need to postulate alongside this equivalence the property of left truth equationality of the π-institution.

Theorem 949 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if it is left truth equational and its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is left truth equational and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations. Then, $\mathcal{I}$ is left truth equational and, by Theorem 941, it is syntactically prealgebraic. Therefore, by definition, it is syntactically WLC prealgebraizable. If, conversely, $\mathcal{I}$ is syntactically WLC prealgebraizable, then, by Theorem 946, it is left truth equational and it is weakly system prealgebraizable. Thus, by Theorem 940, it is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations. ∎

Because of Theorem 944, left truth equationality and the existence of an equivalence of the systemic skeleton with an algebraic π-structure, induced by conjugate transformations, is sufficient to yield syntactic WLC prealgebraizability.

Theorem 950 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if it is left truth equational and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of transformations.*

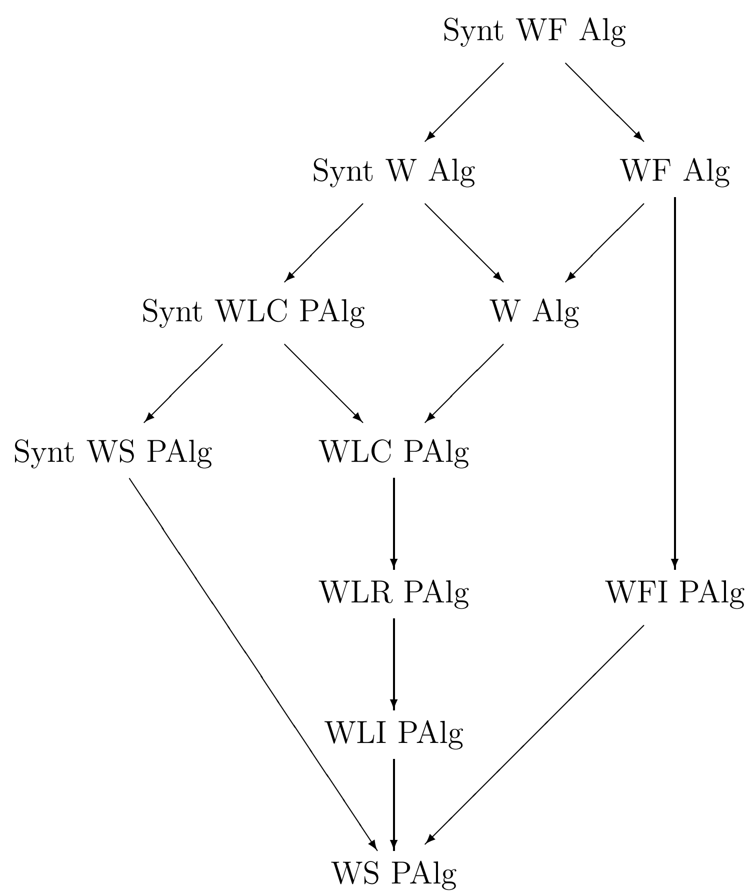
Proof: If $\mathcal{I}$ is syntactically WLC prealgebraizable, then the conclusion follows from Theorem 949. Conversely, if $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically prealgebraic by Theorem 941. Since, by hypothesis, it is also left truth equational, it is syntactically WLC prealgebraizable. ∎

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically WLC prealgebraizable π-institutions:

Theorem 951 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically WLC prealgebraizable if and only if it is left truth equational and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$*, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 950 and Theorem 893. The "if" is given by Theorem 901 and Theorem 950. ■

Let us give, in closing the section, the picture of the **weak prealgebraizability hierarchy** that we have established, consisting of both semantic and syntactic classes of π-institutions.



Chapter 13

The Syntactic Leibniz Hierarchy: Parameterlessness

13.1 The Binary Reflexive Core

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that the **reflexive core** of $\mathcal{I}$ is the collection

$$\begin{aligned} R^{\mathcal{I}} &= \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I}))\} \\ &= \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)) \\ &\qquad\qquad (\rho^\flat_\Sigma(\phi,\phi,\vec{\chi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I}))\}. \end{aligned}$$

We define the **binary reflexive core** of $\mathcal{I}$ as the collection

$$B^{\mathcal{I}} : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$$

of binary natural transformations in $N^\flat$ given by:

$$\begin{aligned} B^{\mathcal{I}} &= \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I}))\} \\ &= \{\rho^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma(\phi,\phi) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I}))\}. \end{aligned}$$

It turns out that the binary reflexive core of $\mathcal{I}$ coincides with the collection $\ddot{R}^{\mathcal{I}}$.

Proposition 952 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Then $B^{\mathcal{I}} = \ddot{R}^{\mathcal{I}}$.*

Proof: By Theorem 107. ■

In view of Proposition 952, we drop the notation $B^{\mathcal{I}}$ and denote the binary reflexive core of $\mathcal{I}$ by the symbol $\ddot{R}^{\mathcal{I}}$, without fear of ambiguity.

13.2 Syntactic PreEquivalentiality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is **preequivalential** if it is prealgebraic and system extensional, i.e., if:

- For all $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T');$$

- For all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma(T \cap \langle \phi, \psi \rangle).$$

We say that $\mathcal{I}$ is **syntactically preequivalential** if there exists $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, without parameters, such that $I^\flat$ has:

- reflexivity;

- global system transitivity;
- global system compatibility; and
- global system modus ponens.

Note that because all these conditions are imposed on theory systems and because $I^\flat$ is parameter-free, they are all equivalent to the corresponding local properties. Therefore, an equivalent definition would require reflexivity, local system transitivity, local system compatibility and local system modus ponens. Because of this, we sometimes omit the global/local specification and simply say "system" in qualifying the corresponding property.

In case $\mathcal{I}$ is syntactically preequivalential, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of/for the syntactic preequivalentiality of $\mathcal{I}$).

An interesting first observation, that will prove handy later, is that syntactic preequivalentiality is inherited by all π-subinstitutions of a syntactically preequivalential π-institution.

Theorem 953 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ *a* π*-subinstitution of* $\mathcal{I}$ *induced by the algebraic subsystem* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle \le \mathbf{F}$*. If* $\mathcal{I}$ *is syntactically preequivalential with witnessing transformations* $I^\flat \subseteq N^\flat$*, then* $\mathcal{I}'$ *is also syntactically preequivalential, with witnessing transformations* $I'^\flat \in N'^\flat$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$. To prove the conclusion, it suffices to show that $I'^\flat$ is reflexive, system transitive and has both the system compatibility and the system modus ponens in $\mathcal{I}'$.

Let, first, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}'^\flat(\Sigma)$. Then, clearly, $I'^\flat_\Sigma[\phi, \phi] \le \mathrm{SEN}'^\flat$ and $I'^\flat_\Sigma[\phi, \phi] = I^\flat_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I})$. So we get that

$$I'^\flat_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I}) \cap \mathrm{SEN}'^\flat = \mathrm{Thm}(\mathcal{I}').$$

It follows that $I'^\flat$ is reflexive in $\mathcal{I}'$.

Suppose, next, that $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}'^\flat(\Sigma)$, such that

$$I'^\flat_\Sigma[\phi, \psi] \le T \cap \mathrm{SEN}'^\flat \quad \text{and} \quad I'^\flat_\Sigma[\psi, \chi] \le T \cap \mathrm{SEN}'^\flat.$$

Then $I^\flat_\Sigma[\phi, \psi] \le T$ and $I^\flat_\Sigma[\psi, \chi] \le T$, whence, by the global system transitivity of $I^\flat$ in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \chi] \le T$. Since, by hypothesis, $\phi, \chi \in \mathrm{SEN}'^\flat(\Sigma)$, we get that $I'^\flat_\Sigma[\phi, \chi] \le T \cap \mathrm{SEN}'^\flat$. This shows that $I'^\flat$ is globally system transitive in $\mathcal{I}'$.

For system compatibility, let $T \in \mathrm{ThSys}(\mathcal{I})$, $\sigma^\flat \in N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \vec{\chi} \in \mathrm{SEN}'^\flat(\Sigma)$, such that $\overleftrightarrow{I'^\flat}_\Sigma[\phi, \psi] \le T \cap \mathrm{SEN}'^\flat$. Then we get that

$\overset{\leftrightarrow}{I}^\flat{}_\Sigma[\phi,\psi] \le T$, whence, we obtain $I^\flat_\Sigma[\sigma^\flat_\Sigma(\phi,\vec{\chi}),\sigma^\flat_\Sigma(\psi,\vec{\chi})] \le T$. Since $\sigma^\flat \in N^\flat$ and $\phi,\psi,\vec{\chi} \in \mathrm{SEN}'^\flat(\Sigma)$, this yields that

$$I'^\flat_\Sigma[\sigma'^\flat_\Sigma(\phi,\vec{\chi}),\sigma'^\flat_\Sigma(\psi,\vec{\chi})] \le T \cap \mathrm{SEN}'^\flat.$$

Therefore, $I'^\flat$ has the system compatibility in $\mathcal{I}'$.

For the system MP, assume that $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}'^\flat(\Sigma)$, such that $\phi \in T_\Sigma \cap \mathrm{SEN}'^\flat(\Sigma)$ and $I'^\flat_\Sigma[\phi,\psi] \le T \cap \mathrm{SEN}'^\flat$. Then $\phi \in T_\Sigma$ and $I^\flat_\Sigma[\phi,\psi] \le T$, whence we get that $\psi \in T_\Sigma$. Since, by hypothesis, $\psi \in \mathrm{SEN}'^\flat(\Sigma)$, we get that $\psi \in T_\Sigma \cap \mathrm{SEN}'^\flat(\Sigma)$. Therefore, $I'^\flat$ has the system MP in $\mathcal{I}'$.

We conclude that $\mathcal{I}'$ is also syntactically preequivalential with witnessing transformations $I'^\flat$. ∎

Since $I^\flat$ is, a fortiori, a set of witnessing transformations for the syntactic prealgebraicity of $\mathcal{I}$, we get the following result, based on Corollary 770.

Corollary 954 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically preequivalential, with witnessing transformations* $I^\flat$*, if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\overset{\leftrightarrow}{I}^\flat(T) = \Omega(T).$$

Proof: The "only if" is by Corollary 770. The "if" is clear, since the given condition implies that $\overset{\leftrightarrow}{I}^\flat$ satisfies reflexivity, global system transitivity, global system compatibility and global system modus ponens. ∎

Based on Corollary 954, it is easy to see that syntactic preequivalentiality transfers from a π-institution to all its gmatrix families.

Theorem 955 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically preequivalential, with witnessing transformations* $I^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$*, the* $\mathcal{I}$*-gmatrix family* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ *is syntactically preequivalential.*

Proof: The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$. For the "only if", assume that $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $I^\flat$, and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have

$$\begin{array}{rll}\langle \alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle \in \overset{\leftrightarrow}{I}{}^{\mathcal{A}}_{F(\Sigma)}(T) & \text{iff} & \overset{\leftrightarrow}{I}{}^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)] \le T\\ & \text{iff} & \overset{\leftrightarrow}{I}{}^\flat_\Sigma[\phi,\psi] \le \alpha^{-1}(T)\\ & \text{iff} & \langle \phi,\psi\rangle \in \Omega_\Sigma(\alpha^{-1}(T))\\ & \text{iff} & \langle \phi,\psi\rangle \in \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T))\\ & \text{iff} & \langle \alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T).\end{array}$$

Taking into account the surjectivity of $\langle F,\alpha\rangle$, it follows, by Corollary 954, that $\langle\mathcal{A},C^{\mathcal{I},\mathcal{A}}\rangle$ is also syntactically preequivalential, with witnessing transformations $I^{\mathcal{A}}$. ■

It turns out that syntactic preequivalentiality implies preequivalentiality.

Theorem 956 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically preequivalential, then it is preequivalential.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $I^\flat:(\mathrm{SEN}^\flat)^2\to\mathrm{SEN}^\flat$. Then, it is a fortiori syntactically prealgebraic and, hence, by Theorem 771, prealgebraic. Thus, the Leibniz operator is monotone on theory systems. It suffices, therefore, to show that $\mathcal{I}$ is system extensional. To this end, let $T\in\mathrm{ThSys}(\mathcal{I})$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\phi,\psi\in\mathrm{SEN}^\flat(\Sigma)$, such that

$$\langle\phi,\psi\rangle\in\Omega_\Sigma^{\langle\phi,\psi\rangle}(T\cap\langle\phi,\psi\rangle).$$

Thus, by Theorem 953 and Corollary 954,

$$\overleftrightarrow{I'^\flat}_\Sigma[\phi,\psi]\leq T\cap\langle\phi,\psi\rangle.$$

Therefore, $\overleftrightarrow{I^\flat}_\Sigma[\phi,\psi]\leq T$, which, again by Corollary 954, implies that $\langle\phi,\psi\rangle\in\Omega_\Sigma(T)$. Since, by Proposition 89, the reverse inclusion always holds, $\mathcal{I}$ is also system extensional and, hence, preequivalential. ■

Apart from the definability of Leibniz congruence systems of theory systems, syntactic preequivalentiality has some additional important consequences. Namely, it implies that the binary reflexive core has the system modus ponens and that it also has the extensionality property. Before we look at those results more closely, we give a key lemma to the effect that in a syntactically preequivalential π-institution, any set of witnessing transformations is included in the binary reflexive core of the π-institution.

Lemma 957 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a syntactically preequivalential* π*-institution, with witnessing transformations* $I^\flat:(\mathrm{SEN}^\flat)^2\to\mathrm{SEN}^\flat$*. Then* $I^\flat\subseteq\ddot{R}^{\mathcal{I}}$*.*

Proof: Since $I^\flat$ is parameter free and reflexive in $\mathcal{I}$, we get, by definition of $B^{\mathcal{I}}$ and Proposition 952, that $I^\flat\subseteq B^{\mathcal{I}}=\ddot{R}^{\mathcal{I}}$. ■

Now we formalize the fact that syntactic preequivalentiality implies the system modus ponens property for the binary reflexive core.

Proposition 958 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically preequivalential, then* $\ddot{R}^{\mathcal{I}}$ *has the system modus ponens in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \le T$. Then $\phi \in T_\Sigma$ and, by Lemma 957, $I^\flat_\Sigma[\phi, \psi] \le T$. Since $I^\flat$ has the system MP in $\mathcal{I}$, we conclude that $\psi \in T_\Sigma$. Therefore, $\ddot{R}^{\mathcal{I}}$ has the system MP in $\mathcal{I}$. ■

The next property that is implied by syntactic preequivalentiality is the extensionality of the binary reflexive core. Before introducing the concept, we take a look at a technical lemma that will serve to justify its formulation.

Lemma 959 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $X, Y \in \mathrm{SenSys}(\mathcal{I})$. *Then the following conditions are equivalent:*

(a) For all $T \in \mathrm{ThFam}(\mathcal{I})$, $X \le T$ *if and only if* $Y \le T$*;*

(b) For all $T \in \mathrm{ThSys}(\mathcal{I})$, $X \le T$ *if and only if* $Y \le T$.

Proof: That (a)⇒(b) is obvious, since every theory system of $\mathcal{I}$ is also a theory family. For (b)⇒(a), assume that (b) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$, such that $X \le T$. Then, by Lemma 1, $\overleftarrow{X} \le \overleftarrow{T}$. Since $X \in \mathrm{SenSys}(\mathcal{I})$, by Proposition 2, we get that $X \le \overleftarrow{T}$. Therefore, by hypothesis, since $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we obtain $Y \le \overleftarrow{T} \le T$. By symmetry, we conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $X \le T$ if and only if $Y \le T$. ■

Due to Lemma 959 and the fact that both the reflexive core and the binary reflexive core yield sentence systems of $\mathcal{I}$ under substitution, we make the following definition (without the need for distinguishing between a family versus system version):

Definition 960 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. *The binary reflexive core* $\ddot{R}^{\mathcal{I}}$ *is* **extensional in** $\mathcal{I}$ *if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$ *(or equivalently, by Lemma 959, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*), all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \le T \quad \textit{if and only if} \quad R^{\mathcal{I}}_\Sigma[\phi, \psi] \le T.$$

Note that, since, by Lemma 104, $\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \le R^{\mathcal{I}}_\Sigma[\phi, \psi]$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, the right-to-left implication in Definition 960 always holds. Therefore one has, equivalently, that $\ddot{R}^{\mathcal{I}}$ is extensional if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \le T \quad \text{implies} \quad R^{\mathcal{I}}_\Sigma[\phi, \psi] \le T.$$

This can be taken to justify the name chosen for this property.

As mentioned previously, and shown in the next proposition, syntactic preequivalentiality implies the extensionality of the binary reflexive core:

Proposition 961 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically preequivalential, then* $\ddot{R}^{\mathcal{I}}$ *is extensional.*

Proof: Suppose $\mathcal{I}$ is a syntactically preequivalential π-institution, with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Then, by Lemma 957, we get that $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \leq T$. Thus, by Corollary 954, we get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Since $\mathcal{I}$ is syntactically preequivalential, it is a fortiori syntactically prealgebraic, whence, by Theorems 781 and 782, we get that $R^{\mathcal{I}}$ is a set of witnessing transformations for the prealgebraicity of $\mathcal{I}$ and, hence, by Theorems 782 and 783, $R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Since the reverse inclusion always holds, we conclude that $\ddot{R}^{\mathcal{I}}$ is indeed extensional in $\mathcal{I}$. ■

As a result of preceding work we obtain the following

Theorem 962 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically preequivalential, then* $\ddot{R}^{\mathcal{I}}$ *has the system modus ponens and is extensional in* $\mathcal{I}$*.*

Proof: By Propositions 958 and 961. ■

We provide, next, a characterization of syntactic preequivalentiality in terms of the preceding two properties of the binary reflexive core of the π-institution, namely system modus ponens and extensionality. Later, we use this characterization to provide an exact description of those preequivalential π-institutions which are syntactically preequivalential.

In proving the reverse implication of that included in Theorem 962, we now show that, if $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically preequivalential.

Theorem 963 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\ddot{R}^{\mathcal{I}}$ *has the system modus ponens and is extensional in* $\mathcal{I}$*, then* $\mathcal{I}$ *is syntactically preequivalential, with witnessing transformations* $\ddot{R}^{\mathcal{I}}$*.*

Proof: If $\ddot{R}^{\mathcal{I}}$ has the system MP, then, by Lemma 104, $R^{\mathcal{I}}$ has a fortiori the global system MP. Thus, by Theorem 781, $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $R^{\mathcal{I}}$. Thus, $R^{\mathcal{I}}$ is globally system reflexive, globally system transitive, has the global system compatibility property and the global system MP. Moreover, by the extensionality of $\ddot{R}^{\mathcal{I}}$, all these properties transfer from $R^{\mathcal{I}}$ to $\ddot{R}^{\mathcal{I}}$. We conclude that $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ■

Theorems 962 and 963 provide the promised characterization of syntactic preequivalentiality in terms of the system modus ponens and the extensionality of the binary reflexive core.

$$\mathcal{I} \text{ is Syntactically Preequivalential} \longleftrightarrow \begin{array}{ll} & \ddot{R}^{\mathcal{I}} \text{ has System MP} \\ + & \ddot{R}^{\mathcal{I}} \text{ is Extensional.} \end{array}$$

Theorem 964 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically preequivalential if and only if* $\ddot{R}^{\mathcal{I}}$ *has the system modus ponens and is extensional in* $\mathcal{I}$*.*

Proof: Theorem 962 gives the "only if" and the "if" is by Theorem 963. ■

If $\mathcal{I}$ is syntactically preequivalential, then $\ddot{R}^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 954, since $\ddot{R}^{\mathcal{I}}$ forms a set of witnessing transformations.

Proposition 965 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\ddot{R}^{\mathcal{I}}$ *has system modus ponens and is extensional in* $\mathcal{I}$*, then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) = \ddot{R}^{\mathcal{I}}(T).$$

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional, then, by Theorem 963, $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Therefore, by Corollary 954, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = \ddot{R}^{\mathcal{I}}(T)$. ■

We also get another related characterization of syntactic preequivalentiality.

$$\begin{array}{l} \mathcal{I} \text{ is Syntactically Preequivalential} \\ \qquad \longleftrightarrow \ddot{R}^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ \qquad\qquad \text{of Theory Systems in } \mathcal{I}. \end{array}$$

Theorem 966 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically preequivalential if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) = \ddot{R}^{\mathcal{I}}(T).$$

Proof: If $\mathcal{I}$ is syntactically preequivalential, then, by Theorem 962, $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$. Thus, by Proposition 965, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = \ddot{R}^{\mathcal{I}}(T)$.

Conversely, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\ddot{R}^{\mathcal{I}}(T) = \Omega(T)$, then, $\ddot{R}^{\mathcal{I}}$ is reflexive, system transitive, has the system compatibility and the system modus ponens. Thus, $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ∎

We finally show that the property that separates preequivalentiality from syntactic preequivalentiality is exactly a sort of a local Leibniz compatibility property with respect to the theory system generated by the binary reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $R^{\mathcal{I}}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

Similarly, we say that $\ddot{R}^{\mathcal{I}}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma(C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

We show next that, if $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is Leibniz.

Proposition 967 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is Leibniz.*

Proof: Suppose that $\ddot{R}^{\mathcal{I}}$ has the system MP and is extensional and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. By Theorem 963, $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Hence, it is a fortiori syntactically prealgebraic, with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Thus, by Theorem 788, we get

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

Then, by Theorem 89, we get

$$\langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

By hypothesis (more precisely the extensionality of $\ddot{R}^{\mathcal{I}}$), we get $C(R^{\mathcal{I}}_\Sigma[\phi, \psi]) = C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi])$. Therefore, we conclude that $\langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma(C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi]) \cap \langle \phi, \psi \rangle)$. So $\ddot{R}^{\mathcal{I}}$ is Leibniz. ∎

In the opposite direction, in a *preequivalential* π-institution $\mathcal{I}$, if the binary reflexive core is Leibniz, then it has the system modus ponens and is extensional in $\mathcal{I}$.

Proposition 968 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a preequivalential π-institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ is Leibniz, then $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is preequivalential and that $\ddot{R}^{\mathcal{I}}$ is Leibniz.

For the system MP, suppose that $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$, $\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$. Then, since $\ddot{R}^{\mathcal{I}}$ is Leibniz,

$$\langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma (C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi]) \cap \langle \phi, \psi \rangle).$$

Thus, since $\mathcal{I}$ is system extensional,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma (C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi])).$$

By hypothesis, $C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi]) \leq T$, whence, by preequivalentiality,

$$\Omega(C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi])) \leq \Omega(T).$$

We, thus, get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, by compatibility of $\Omega(T)$ with T, we obtain $\psi \in T_\Sigma$, showing that $\ddot{R}^{\mathcal{I}}$ has the system MP in $\mathcal{I}$.

For extensionality, assume that $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\ddot{R}^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$. Following the initial argument of the preceding paragraph mutatis mutandis we obtain that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. But since $\ddot{R}^{\mathcal{I}}$ has the system MP, a fortiori $R^{\mathcal{I}}$ has the global system MP, whence, by Proposition 783, $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$. Since the reverse inclusion always holds, we conclude that $\ddot{R}^{\mathcal{I}}$ is extensional. ∎

We now show that a π-institution is syntactically preequivalential if and only if it is preequivalential and it has a Leibniz binary reflexive core.

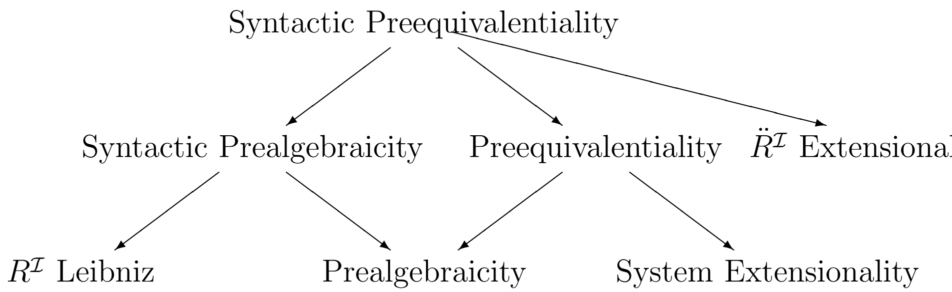
Syntactic Preequivalentiality
= $\ddot{R}^{\mathcal{I}}$ has System MP + $\ddot{R}^{\mathcal{I}}$ is Extensional
= $\ddot{R}^{\mathcal{I}}$ Defines Leibniz Congruence Systems
of Theory Systems in $\mathcal{I}$
= Preequivalentiality + $\ddot{R}^{\mathcal{I}}$ is Leibniz

Theorem 969 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically preequivalential if and only if it is preequivalential and has a Leibniz binary reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically preequivalential. Then it is preequivalential by Theorem 956. Moreover, its binary reflexive core has the system modus ponens and is extensional, by Theorem 964, and, hence, by Proposition 967, its binary reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is preequivalential with a Leibniz binary reflexive core. Then, by Proposition 968, its binary reflexive core has the system MP and is extensional. Therefore, by Theorem 964, $\mathcal{I}$ is syntactically preequivalential. ∎

We have the following part of a hierarchy:



13.3 Syntactic Equivalentiality

We now define the class of syntactically equivalential π-institutions. The difference between equivalentiality and preequivalentiality is that the system versions of the properties defining the latter are replaced by their corresponding family versions. Otherwise, the developments are exactly parallel.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **equivalential** if it is protoalgebraic and family extensional, i.e., if:

- For all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T');$$

- For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle).$$

Recall, also, that protoalgebraicity implies stability. If a π-institution is stable, then it is family extensional if and only if it is system extensional. Thus, under protoalgebraicity, system and family extensionality coincide, and, therefore, $\mathcal{I}$ being equivalential is equivalent to $\mathcal{I}$ being protoalgebraic and system extensional.

We say that $\mathcal{I}$ is **syntactically equivalential** if there exists $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, without parameters, such that $I^\flat$ has:

- reflexivity;
- global family transitivity;
- global family compatibility; and
- global family modus ponens.

We emphasize that, in opposition to the case of the corresponding system properties, in this case, the latter three conditions are not equivalent to the corresponding local properties. So one cannot dispense with the qualification "global" in the defining conditions.

In case $\mathcal{I}$ is syntactically equivalential, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic equivalentiality of $\mathcal{I}$).

As was the case with syntactic preequivalentiality, syntactic equivalentiality is inherited by all π-subinstitutions of a syntactically equivalential π-institution.

Theorem 970 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ *a* π*-subinstitution of* $\mathcal{I}$ *induced by the algebraic subsystem* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle \le \mathbf{F}$*. If* $\mathcal{I}$ *is syntactically equivalential with witnessing transformations* $I^\flat \subseteq N^\flat$*, then* $\mathcal{I}'$ *is also syntactically equivalential, with witnessing transformations* $I'^\flat \in N'^\flat$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$. To prove the conclusion, it suffices to show that $I'^\flat$ is reflexive, globally family transitive and has both the global family compatibility and the global family modus ponens in $\mathcal{I}'$.

Let, first, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}'^\flat(\Sigma)$. Then, clearly, $I'^\flat_\Sigma[\phi, \phi] \le \mathrm{SEN}'^\flat$ and $I'^\flat_\Sigma[\phi, \phi] = I^\flat_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I})$. So we get that

$$I'^\flat_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I}) \cap \mathrm{SEN}'^\flat = \mathrm{Thm}(\mathcal{I}').$$

It follows that $I'^\flat$ is reflexive in $\mathcal{I}'$.

Suppose, next, that $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}'^\flat(\Sigma)$, such that

$$I'^\flat_\Sigma[\phi, \psi] \le T \cap \mathrm{SEN}'^\flat \quad \text{and} \quad I'^\flat_\Sigma[\psi, \chi] \le T \cap \mathrm{SEN}'^\flat.$$

Then $I^\flat_\Sigma[\phi, \psi] \le T$ and $I^\flat_\Sigma[\psi, \chi] \le T$, whence by the global family transitivity of $I^\flat$ in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \chi] \le T$. Since, by hypothesis, $\phi, \chi \in \mathrm{SEN}'^\flat(\Sigma)$, we get that $I'^\flat_\Sigma[\phi, \chi] \le T \cap \mathrm{SEN}'^\flat$. This shows that $I'^\flat$ is globally family transitive in $\mathcal{I}'$.

For global family compatibility, let $T \in \mathrm{ThFam}(\mathcal{I})$, $\sigma^\flat \in N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \vec{\chi} \in \mathrm{SEN}'^\flat(\Sigma)$, such that $\overleftrightarrow{I'^\flat}_\Sigma[\phi, \psi] \le T \cap \mathrm{SEN}'^\flat$. Then we get that $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \le T$, whence, we obtain $I^\flat_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \le T$. Since $\sigma^\flat \in N^\flat$ and $\phi, \psi, \vec{\chi} \in \mathrm{SEN}'^\flat(\Sigma)$, this yields that

$$I'^\flat_\Sigma[\sigma'^\flat_\Sigma(\phi, \vec{\chi}), \sigma'^\flat_\Sigma(\psi, \vec{\chi})] \le T \cap \mathrm{SEN}'^\flat.$$

Therefore, $I'^\flat$ has the global family compatibility in $\mathcal{I}'$.

For the global family MP, assume that $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}'^\flat(\Sigma)$, such that $\phi \in T_\Sigma \cap \mathrm{SEN}'^\flat(\Sigma)$ and $I'^\flat_\Sigma[\phi, \psi] \le T \cap \mathrm{SEN}'^\flat$. Then $\phi \in T_\Sigma$ and $I^\flat_\Sigma[\phi, \psi] \le T$, whence we get that $\psi \in T_\Sigma$. Since, by hypothesis, $\psi \in \mathrm{SEN}'^\flat(\Sigma)$, we get that $\psi \in T_\Sigma \cap \mathrm{SEN}'^\flat(\Sigma)$. Therefore, $I'^\flat$ has the global family MP in $\mathcal{I}'$.

We conclude that $\mathcal{I}'$ is also syntactically equivalential with witnessing transformations $I'^\flat$. ∎

Since $I^\flat$ is, a fortiori, a set of witnessing transformations for the syntactic protoalgebraicity of $\mathcal{I}$, we get the following result, based on Corollary 791.

Corollary 971 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $I^\flat$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,*

$$\overleftrightarrow{I^\flat}(T) = \Omega(T).$$

Proof: The "only if" is by Corollary 791. The "if" is clear, since the given condition implies that $\overleftrightarrow{I^\flat}$ satisfies reflexivity, global family transitivity, global family compatibility and global family modus ponens. ∎

Based on Corollary 971, it is easy to see that syntactic equivalentiality also transfers from a π-institution to all its gmatrix families.

Theorem 972 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $I^\flat$, if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$-gmatrix family $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is syntactically equivalential.*

Proof: Analogous to the proof of Theorem 955. ∎

Syntactic equivalentiality implies equivalentiality.

Theorem 973 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential, then it is equivalential.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$. Then, it is a fortiori syntactically protoalgebraic and, hence, by Theorem 792, protoalgebraic. Thus, the Leibniz operator is monotone on theory families. Since syntactical equivalentiality implies syntactical preequivalentiality, by Theorem 956, we get that $\mathcal{I}$ is also system extensional. ∎

In analogy with syntactic preequivalentiality, syntactic equivalentiality implies that the binary reflexive core has the global family modus ponens and that it also has the extensionality property.

We first formalize the fact that syntactic equivalentiality implies the global family modus ponens property of the binary reflexive core.

Proposition 974 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically equivalential, then* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $I^\flat$, and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Then $\phi \in T_\Sigma$ and, by Lemma 957, $I^\flat_\Sigma[\phi, \psi] \leq T$. Since $I^\flat$ has the global family MP in $\mathcal{I}$, we conclude that $\psi \in T_\Sigma$. Therefore, $\ddot{R}^{\mathcal{I}}$ also has the global family MP in $\mathcal{I}$. ■

We now show that syntactic equivalentiality implies the extensionality of the binary reflexive core.

Corollary 975 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically equivalential, then* $\ddot{R}^{\mathcal{I}}$ *is extensional.*

Proof: Since syntactic equivalentiality implies syntactic preequivalentiality, we get the conclusion by applying Proposition 961. ■

We summarize these two important consequences of syntactic equivalentiality in the following

Theorem 976 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically equivalential, then* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$*.*

Proof: By Propositions 974 and 975. ■

We provide, next, a characterization of syntactic equivalentiality in terms of the preceding two properties of the binary reflexive core of the π-institution, namely global family modus ponens and extensionality. As with preequivalentiality, we use this characterization to provide an exact description of those equivalential π-institutions which are syntactically equivalential.

In proving the reverse implication of that included in Theorem 976, we show that, if $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically equivalential.

Theorem 977 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$*, then* $\mathcal{I}$ *is syntactically equivalential, with witnessing transformations* $\ddot{R}^{\mathcal{I}}$*.*

Proof: If $\ddot{R}^{\mathcal{I}}$ has the global family MP, then, by Lemma 104, $R^{\mathcal{I}}$ has a fortiori the global family MP. Thus, by Theorem 798, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $R^{\mathcal{I}}$. Thus, $R^{\mathcal{I}}$ is reflexive, globally family transitive, has the global family compatibility property and the global family

MP. Moreover, by the extensionality of $\ddot{R}^{\mathcal{I}}$, all these properties transfer from $R^{\mathcal{I}}$ to $\ddot{R}^{\mathcal{I}}$. We conclude that $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ∎

Theorems 976 and 977 provide the promised characterization of syntactic equivalentiality in terms of the global family modus ponens and the extensionality of the binary reflexive core.

$$\mathcal{I} \text{ is Syntactically Equivalential } \longleftrightarrow \begin{array}{ll} & \ddot{R}^{\mathcal{I}} \text{ has Global Family MP} \\ + & \ddot{R}^{\mathcal{I}} \text{ is Extensional.} \end{array}$$

Theorem 978 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically equivalential if and only if* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$.

Proof: Theorem 976 gives the "only if" and the "if" is by Theorem 977. ∎

If $\mathcal{I}$ is syntactically equivalential, then $\ddot{R}^{\mathcal{I}}$ defines Leibniz congruence systems of theory families in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 971, since $\ddot{R}^{\mathcal{I}}$ forms a set of witnessing transformations.

Proposition 979 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$*, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(T) = \ddot{R}^{\mathcal{I}}(T).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. If $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional, then, by Theorem 977, $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Therefore, by Corollary 971, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \ddot{R}^{\mathcal{I}}(T)$. ∎

We also get another related characterization of syntactic equivalentiality.

$$\begin{array}{l} \mathcal{I} \text{ is Syntactically Equivalential} \\ \qquad \longleftrightarrow \ddot{R}^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ \qquad\qquad \text{of Theory Families in } \mathcal{I}. \end{array}$$

Theorem 980 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically equivalential if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(T) = \ddot{R}^{\mathcal{I}}(T).$$

Proof: If $\mathcal{I}$ is syntactically equivalential, then, by Theorem 976, $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$. Thus, by Proposition 979, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \ddot{R}^{\mathcal{I}}(T)$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\ddot{R}^{\mathcal{I}}(T) = \Omega(T)$, then, $\ddot{R}^{\mathcal{I}}$ is reflexive, globally family transitive and has the global family compatibility and the global family modus ponens. Thus, $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ■

We finally show that the property that separates equivalentiality from syntactic equivalentiality is the Leibniz property of the binary reflexive core.

We show first that, if $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is Leibniz.

Corollary 981 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$*, then* $\ddot{R}^{\mathcal{I}}$ *is Leibniz.*

Proof: Since $\ddot{R}^{\mathcal{I}}$ having the global family MP is stronger than having the system MP, the conclusion follows from Proposition 967. ■

In the opposite direction, in an *equivalential* π-institution $\mathcal{I}$, if the binary reflexive core is Leibniz, then it has the global family modus ponens and is extensional in $\mathcal{I}$.

Proposition 982 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *an equivalential* π*-institution based on* $\mathbf{F}$*. If* $\ddot{R}^{\mathcal{I}}$ *is Leibniz, then* $\ddot{R}^{\mathcal{I}}$ *has the global family modus ponens and is extensional in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is equivalential and that $\ddot{R}^{\mathcal{I}}$ is Leibniz.

For the global family MP, suppose that $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$, $\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Then, since $\ddot{R}^{\mathcal{I}}$ is Leibniz,

$$\langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_\Sigma (C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

Thus, since $\mathcal{I}$ is system extensional,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma (C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

By hypothesis, $C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi]) \leq T$, whence, by equivalentiality,

$$\Omega(C(\ddot{R}^{\mathcal{I}}_\Sigma[\phi, \psi])) \leq \Omega(T).$$

We, thus, get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, by compatibility of $\Omega(T)$ with T, we obtain $\psi \in T_\Sigma$, showing that $\ddot{R}^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$.

Since equivalentiality implies preequivalentiality, the extensionality of $\ddot{R}^{\mathcal{I}}$ follows from Proposition 968. ■

We now show that a π-institution is syntactically equivalential if and only if it is equivalential and has a Leibniz binary reflexive core.

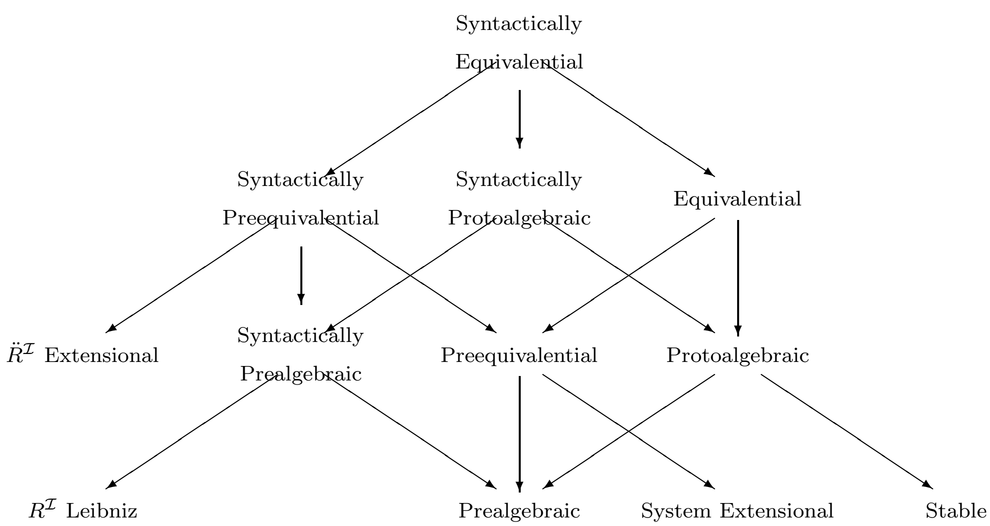
Syntactic Equivalentiality
$= \ddot{R}^{\mathcal{I}}$ has Global Family MP + $\ddot{R}^{\mathcal{I}}$ is Extensional
$= \ddot{R}^{\mathcal{I}}$ Defines Leibniz Congruence Systems of Theory Families in $\mathcal{I}$
= Equivalentiality + $\ddot{R}^{\mathcal{I}}$ is Leibniz

Theorem 983 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential if and only if it is equivalential and has a Leibniz binary reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically equivalential. Then it is equivalential by Theorem 973. Moreover, its binary reflexive core has the global family modus ponens and is extensional, by Theorem 978, and, hence, by Corollary 981, its binary reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is equivalential with a Leibniz binary reflexive core. Then, by Proposition 982, its binary reflexive core has the global family MP and is extensional. Therefore, by Theorem 978, $\mathcal{I}$ is syntactically equivalential. ■

We have now established the following hierarchy of properties:



13.4 Strong Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly (family) truth equational** if there exists a set $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ (with a single distinguished argument), such that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

In that case, we call $\tau^\flat$ a **set of witnessing equations** (of/for the strong truth equationality of $\mathcal{I}$).

Note that, since $\tau^\flat$ is parameter-free and $\Omega(T)$ is invariant under signature morphisms, strong truth equationality may be defined equivalently by the condition, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma(\phi) \subseteq \Omega_\Sigma(T).$$

Since truth equationality implies systemicity, we get, a fortiori, that strong truth equationality implies systemicity.

We introduce next the unary Suszko core of a π-institution. Analogously with the Suszko core, the unary Suszko core enables one to obtain:

- A characterization of strong truth equationality in terms of the solubility property of the unary Suszko core of the π-institution.
- An exact description of those family c-reflective π-institutions which are strongly truth equational.
- A characterization of those truth equational π-institutions which are strongly truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. The **unary Suszko core** of $\mathcal{I}$ is the collection

$$\dot{S}^{\mathcal{I}} = \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

By Lemma 821, this definition is equivalent to setting

$$\begin{aligned}\dot{S}^{\mathcal{I}} \quad = \quad & \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ & \qquad (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\sigma^\flat_\Sigma(\phi) \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi))\}.\end{aligned}$$

Note that the unary Suszko core of a π-institution is included in the Suszko core, i.e., we have

Lemma 984 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then* $\dot{S}^{\mathcal{I}} \subseteq S^{\mathcal{I}}$.

Proof: Every pair of unary natural transformations in $N^\flat$ that satisfies the membership criterion for $\dot{S}^{\mathcal{I}}$ also satisfies the condition for membership in $S^{\mathcal{I}}$. ■

Lemma 984 yields immediately the following consequence.

Corollary 985 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThFam}(\mathcal{I})$*, we have*

$$S^{\mathcal{I}}(\Omega(T)) \leq \dot{S}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rcll} \phi \in S^{\mathcal{I}}_\Sigma(\Omega(T)) & \text{iff} & S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{(definition)} \\ & \text{implies} & \dot{S}^{\mathcal{I}}[\phi] \leq \Omega(T) & \text{(Lemma 984)} \\ & \text{iff} & \phi \in \dot{S}^{\mathcal{I}}_\Sigma(\Omega(T)). & \text{(definition)} \end{array}$$

Therefore, $S^{\mathcal{I}}(\Omega(T)) \leq \dot{S}^{\mathcal{I}}(\Omega(T))$. ∎

Either directly by the definition or using Proposition 832 together with Corollary 985, we get the following

Proposition 986 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T \leq \dot{S}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have $T \leq S^{\mathcal{I}}(\Omega(T)) \leq \dot{S}^{\mathcal{I}}(\Omega(T))$, where the first inclusion is by Lemma 832 and the second by Corollary 985. ∎

Similarly with the Suszko core, the unary Suszko core of a π-institution may or may not satisfy the reverse inclusion of Proposition 986, a property that was called *solubility*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary Suszko core of $\mathcal{I}$ is **soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\dot{S}^{\mathcal{I}}(\Omega(T)) \leq T.$$

Note that $\dot{S}^{\mathcal{I}}$ is soluble if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\dot{S}^{\mathcal{I}}_\Sigma(\phi) \subseteq \Omega_\Sigma(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

It turns out that possession of the solubility property by the unary Suszko core intrinsically characterizes strong truth equationality. To show the necessity of solubility observe, first, that, in case a π-institution is strongly truth equational, the witnessing equations form a subset of the unary Suszko core.

Lemma 987 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is strongly truth equational, with witnessing equations* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \subseteq N^\flat$*, then* $\tau^\flat \subseteq \dot{S}^{\mathcal{I}}$*.*

Proof: Suppose that $\mathcal{I}$ is strongly truth equational with witnessing equations $\tau^\flat$. Then, $\mathcal{I}$ is, a fortiori, truth equational, with the same witnessing equations. It follows, by Lemma 835, that $\tau^\flat \subseteq S^{\mathcal{I}}$. Since $\tau^\flat$ consists of unary equations and they satisfy the membership criterion for $S^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{S}^{\mathcal{I}}$. Therefore, we get that $\tau^\flat \subseteq \dot{S}^{\mathcal{I}}$. ∎

Now we prove the necessity of the solubility of the unary Suszko core for strong truth equationality.

Theorem 988 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is strongly truth equational, then* $\dot{S}^{\mathcal{I}}$ *is soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly truth equational, with witnessing equations $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{llll} \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(Lemma 987)} \\ & \text{iff} & \phi \in T_\Sigma. & \text{(strong truth equationality)} \end{array}$$

Thus, $\dot{S}^{\mathcal{I}}$ is soluble. ■

The reverse implication also holds and completes the promised characterization of strong truth equationality in terms of the solubility of the unary Suszko core.

Theorem 989 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\dot{S}^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is strongly truth equational, with witnessing equations* $\dot{S}^{\mathcal{I}}$.

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 986, whereas the converse is ensured by the postulated solubility of $\dot{S}^{\mathcal{I}}$. ■

Theorems 988 and 989 provide the promised characterization of strong truth equationality in terms of the solubility of the unary Suszko core.

$$\mathcal{I} \text{ is Strongly Truth Equational} \longleftrightarrow \dot{S}^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 990 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is strongly truth equational if and only if* $\dot{S}^{\mathcal{I}}$ *is soluble.*

Proof: Theorem 988 gives the "only if" and the "if" is by Theorem 989. ■

If $\mathcal{I}$ is strongly truth equational, then the unary Suszko core defines theory families in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 828, since $\dot{S}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong truth equationality of $\mathcal{I}$.

Proposition 991 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\dot{S}^{\mathcal{I}}$ *is soluble, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$,

$$T = \dot{S}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\dot{S}^{\mathcal{I}}$ is soluble, then, by Theorem 989, $\dot{S}^{\mathcal{I}}$ forms a set of witnessing equations for the strong truth equationality of $\mathcal{I}$. Therefore, by Proposition 828, we get that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \dot{S}^{\mathcal{I}}(\Omega(T))$. ∎

This property provides another characterization of strong truth equationality. We say that $\dot{S}^{\mathcal{I}}$ **defines theory families** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \dot{S}^{\mathcal{I}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is Strongly Truth Equational} \longleftrightarrow \dot{S}^{\mathcal{I}} \text{ Defines Theory Families.}$$

Theorem 992 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly truth equational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T = \dot{S}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is truth equational, then, by Theorem 990, $\dot{S}^{\mathcal{I}}$ is soluble. Thus, by Proposition 991, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \dot{S}^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \dot{S}^{\mathcal{I}}(\Omega(T))$, then, $\dot{S}^{\mathcal{I}}$ is soluble. Thus, again by Theorem 990, $\dot{S}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly truth equational. ∎

It turns out that the property that separates family complete reflectivity from strong truth equationality is exactly the adequacy property of the unary Suszko core. Roughly speaking, this property ensures that the unary Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the unary Suszko core with both Leibniz and Suszko congruence systems.

Proposition 993 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \le \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we have, using Lemma 984,

$$S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T) \quad \text{implies} \quad \dot{S}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T).$$

Therefore, $\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \subseteq \{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}$. We conclude that

$$\bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \le \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\} \le \widetilde{\Omega}^{\mathcal{I}}(C(\phi)),$$

where the last inclusion is based on Proposition 841. ∎

Again it is possible, but not necessary, that the unary Suszko core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 993:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Intuitively speaking, this means that the unary Suszko core $\dot{S}^{\mathcal{I}}$ is rich enough to allow, for every Σ-sentence ϕ, the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary Suszko core $\dot{S}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{S}^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 994 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcll} \widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & = & \bigcap\{\Omega(T) : \phi \in T_\Sigma\} & (\text{definition of } \widetilde{\Omega}^{\mathcal{I}}(C(\phi))) \\ & = & \bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}. & \\ & & (\text{solubility of } \dot{S}^{\mathcal{I}} \text{ and Proposition 991}) & \end{array}$$

We conclude that $\dot{S}^{\mathcal{I}}$ is adequate. ■

In the opposite direction, in a *family c-reflective* π-institution $\mathcal{I}$, if the unary Suszko core is adequate, then it is also soluble.

Proposition 995 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a family c-reflective π-institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is family c-reflective and that $\dot{S}^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$

$$\phi \in T_\Sigma \quad \text{iff} \quad \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 986. For the converse, assume that $\dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by the adequacy of $\dot{S}^{\mathcal{I}}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. Thus, by family c-reflectivity and Lemma 826, we conclude that $C(\phi) \leq T$, which gives $\phi \in T_\Sigma$. ■

We finally show that a π-institution is strongly truth equational if and only if it is family c-reflective and has an adequate unary Suszko core.

$$\begin{array}{lll} \text{Strong Truth Equationality} & = & \dot{S}^{\mathcal{I}} \text{ Soluble} \\ & = & \dot{S}^{\mathcal{I}} \text{ Defines Theory Families} \\ & = & \text{Family c-Reflectivity} + \dot{S}^{\mathcal{I}} \text{ Adequate} \end{array}$$

Theorem 996 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is strongly truth equational if and only if it is family c-reflective and has an adequate unary Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly truth equational. Then it is family c-reflective by Theorem 829. Moreover, its unary Suszko core is soluble by Theorem 990 and, hence, by Corollary 994, its unary Suszko core is adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with an adequate unary Suszko core. Then, by Proposition 995, its unary Suszko core is soluble and, therefore, by Theorem 990, $\mathcal{I}$ is strongly truth equational. ■

We close the section with a result relating the unary Suszko core with the Suszko core. More precisely, we show that adequacy of the unary Suszko core implies adequacy of the Suszko core.

Proposition 997 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\dot{S}^{\mathcal{I}}$ *is adequate, then* $S^{\mathcal{I}}$ *is adequate.*

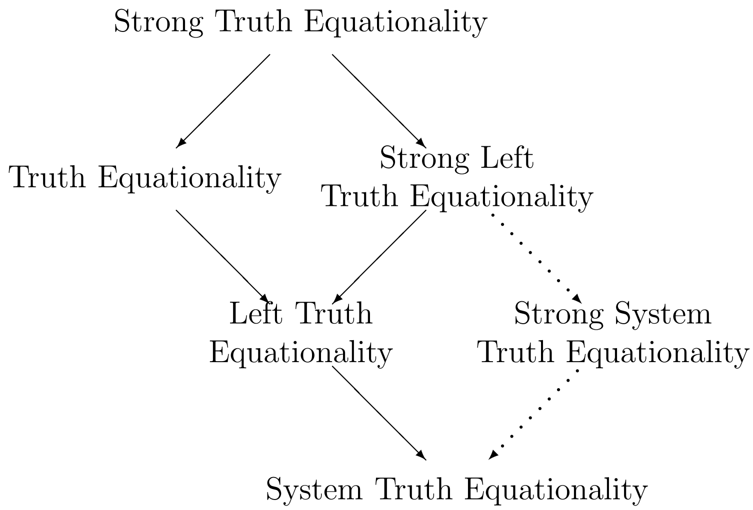
Proof: Suppose that $\dot{S}^{\mathcal{I}}$ is adequate. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rll} \widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & \leq & \bigcap\{\Omega(T) : \dot{S}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \quad (\dot{S}^{\mathcal{I}} \text{ adequate}) \\ & \leq & \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \quad (\dot{S}^{\mathcal{I}} \subseteq S^{\mathcal{I}}) \\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(C(\phi)). \quad \text{(Proposition 841)} \end{array}$$

Hence, $\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap\{\Omega(T) : S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}$, and $S^{\mathcal{I}}$ is adequate. ■

13.5 Strong Left Truth Equationality

We now undertake the study of strong left truth equationality. This combines, in a certain sense, the study of left truth equationality with that of strong truth equationality. Strong left truth equationality has the same relation to left truth equationality as strong truth equationality has to (family) truth equationality. After this study, we will have the following hierarchy of truth equationality properties, which will be further augmented in the following section by adjoining strong system truth equationality:



Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly left truth equational** if there exists a set $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ (with a single distinguished argument), such that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

In that case, we call $\tau^\flat$ a **set of witnessing equations** (of the strong left truth equationality of $\mathcal{I}$).

Note that, similarly to strong truth equationality, since $\tau^\flat$ is parameter-free and $\Omega(T)$ is invariant under signature morphisms, strong left truth equationality may be defined equivalently by the condition, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma(\phi) \subseteq \Omega_\Sigma(T).$$

Recall that strong truth equationality implies systemicity. Therefore, if a π-institution $\mathcal{I}$ is strongly truth equational, we get, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T),$$

whence $\mathcal{I}$ is also strongly left truth equational.

We introduce next the unary left Suszko core of a π-institution. Analogously with the left Suszko core and the unary Suszko core, the unary left Suszko core enables one to obtain:

- A characterization of strong left truth equationality in terms of the solubility property of the unary left Suszko core of the π-institution.

- An exact description of those left c-reflective π-institutions which are strongly left truth equational.
- A characterization of those left truth equational π-institutions which are strongly left truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **unary left Suszko core** of $\mathcal{I}$ is the collection

$$\dot{L}^{\mathcal{I}} = \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[\overleftarrow{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

There are a couple of different possible characterizations of the unary left Suszko core that can be given. One is in terms of theory systems in place of theory families and another uses theory systems generated by single sentences.

Proposition 998 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. Then*

$$\dot{L}^{\mathcal{I}} = \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

Proof: By Proposition 852, we have that

$$L^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\}.$$

Thus, the conclusion follows by applying the $\dot{}$ operator on both sides, i.e., by intersecting both sides with the set of all pairs of unary natural transformations in $N^\flat$. ∎

With Proposition 998 at hand, the second characterization follows from Lemma 822.

Corollary 999 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. Then*

$$\begin{array}{rcl}\dot{L}^{\mathcal{I}} & = & \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ & & \qquad (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\sigma^\flat_\Sigma(\phi) \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\overrightarrow{\phi}))\}.\end{array}$$

Proof: By combining Proposition 998 with Lemma 822. ∎

Note that the unary left Suszko core of a π-institution is included in the left Suszko core, i.e., we have

Lemma 1000 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. Then* $\dot{L}^{\mathcal{I}} \subseteq L^{\mathcal{I}}$*.*

Proof: Every pair of unary natural transformations in $N^\flat$ that satisfies the membership criterion for $\dot{L}^{\mathcal{I}}$ also satisfies the condition for membership in $L^{\mathcal{I}}$. ∎

Lemma 1000 yields immediately the following consequence.

Corollary 1001 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For all $T \in \mathrm{ThFam}(\mathcal{I})$, we have*

$$L^{\mathcal{I}}(\Omega(T)) \leq \dot{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: By Theorem 107 and Corollary 105. ∎

Either directly by the definition or using Proposition 853 together with Corollary 1001, we get the following

Proposition 1002 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For every $T \in \mathrm{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} \leq \dot{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have $\overleftarrow{T} \leq L^{\mathcal{I}}(\Omega(T)) \leq \dot{L}^{\mathcal{I}}(\Omega(T))$, where the first inclusion is by Lemma 853 and the second by Corollary 1001. ∎

Similarly with the left Suszko core, the unary left Suszko core of a π-institution may or may not satisfy the reverse inclusion of Proposition 1002, a property that was called left solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary left Suszko core of $\mathcal{I}$ is **left soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\dot{L}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{T}.$$

Note that $\dot{L}^{\mathcal{I}}$ is left soluble if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\dot{L}^{\mathcal{I}}_\Sigma(\phi) \subseteq \Omega_\Sigma(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_\Sigma.$$

It turns out that possession of left solubility by the unary left Suszko core intrinsically characterizes strong left truth equationality. To show the necessity of left solubility observe, first, that, in case a π-institution is strongly left truth equational, the witnessing equations form a subset of the unary left Suszko core.

Lemma 1003 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly truth equational, with witnessing equations $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \subseteq N^\flat$, then $\tau^\flat \subseteq \dot{L}^{\mathcal{I}}$.*

Proof: Suppose that $\mathcal{I}$ is strongly left truth equational with witnessing equations $\tau^\flat$. Then, $\mathcal{I}$ is, a fortiori, left truth equational, with the same witnessing equations. It follows, by Lemma 857, that $\tau^\flat \subseteq L^{\mathcal{I}}$. Since $\tau^\flat$ consists of unary equations and they satisfy the membership criterion for $L^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{L}^{\mathcal{I}}$. Therefore, we get that $\tau^\flat \subseteq \dot{L}^{\mathcal{I}}$. ■

Now we prove the necessity of the left solubility of the unary left Suszko core for strong left truth equationality.

Theorem 1004 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is strongly left truth equational, then* $\dot{L}^{\mathcal{I}}$ *is left soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly left truth equational, with witnessing equations $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(Lemma 1003)} \\ & \text{iff} & \phi \in \overleftarrow{T}_\Sigma. \quad \text{(strong left truth equationality)} \end{array}$$

Thus, $\dot{L}^{\mathcal{I}}$ is left soluble. ■

The reverse implication also holds and provides the characterization of strong left truth equationality in terms of the left solubility of the unary left Suszko core.

Theorem 1005 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{L}^{\mathcal{I}}$ *is left soluble, then* $\mathcal{I}$ *is strongly left truth equational, with witnessing equations* $\dot{L}^{\mathcal{I}}$*.*

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 1002, whereas the converse is ensured by the postulated left solubility of $\dot{L}^{\mathcal{I}}$. ■

Theorems 1004 and 1005 provide the promised characterization of strong left truth equationality in terms of the left solubility of the unary left Suszko core.

$$\mathcal{I} \text{ is Strongly Left Truth Equational} \longleftrightarrow \dot{L}^{\mathcal{I}} \text{ is Left Soluble.}$$

Theorem 1006 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly left truth equational if and only if* $\dot{L}^{\mathcal{I}}$ *is left soluble.*

Proof: Theorem 1004 gives the "only if" and the "if" is by Theorem 1005. ∎

If $\mathcal{I}$ is strongly left truth equational, then the unary left Suszko core defines theory families in $\mathcal{I}$, up to arrow, in terms of their Leibniz congruence systems. So, analogously to preceding situations, $\dot{L}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong left truth equationality of $\mathcal{I}$.

Proposition 1007 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{L}^{\mathcal{I}}$ *is left soluble, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\dot{L}^{\mathcal{I}}$ is left soluble, then, by Theorem 1005, $\dot{L}^{\mathcal{I}}$ forms a set of witnessing equations for the strong left truth equationality of $\mathcal{I}$. Therefore, by Proposition 849, we get that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T))$. ∎

This property provides another characterization of strong left truth equationality. We say that $\dot{L}^{\mathcal{I}}$ **defines theory families up to arrow** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T))$. Then we have:

$\mathcal{I}$ is Strongly Left Truth Equational
$\longleftrightarrow$ $\dot{L}^{\mathcal{I}}$ Defines Theory Families Up to Arrow.

Theorem 1008 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly left truth equational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is strongly left truth equational, then, by Theorem 1006, $\dot{L}^{\mathcal{I}}$ is left soluble. Thus, by Proposition 1007, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \dot{L}^{\mathcal{I}}(\Omega(T))$, then, $\dot{L}^{\mathcal{I}}$ is left soluble. Thus, again by Theorem 1006, $\dot{L}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly left truth equational. ∎

In analogy with strong truth equationality and family c-reflectivity, the property that separates left complete reflectivity from strong left truth equationality is exactly the left adequacy of the unary left Suszko core. Roughly speaking, this property ensures that the unary left Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the unary left Suszko core with both Leibniz and Suszko congruence systems.

Proposition 1009 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we have, using Lemma 1000,

$$L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

Therefore, $\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \subseteq \{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}$. We conclude that

$$\bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})),$$

where the last inclusion is based on Proposition 863. ∎

Again it is possible, but not necessary, that the unary left Suszko core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 1009:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Intuitively speaking, this means that the unary left Suszko core $\dot{L}^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and for every Σ-sentence ϕ, the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\overrightarrow{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary left Suszko core $\dot{L}^{\mathcal{I}}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{L}^{\mathcal{I}}$ is left soluble, then it is left adequate.

Corollary 1010 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\dot{L}^{\mathcal{I}}$ *is left soluble, then it is left adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & = & \bigcap\{\Omega(T) : \overrightarrow{\phi} \leq T\} & (\text{definition of } \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))) \\ & = & \bigcap\{\Omega(T) : \phi \in \overleftarrow{T}_\Sigma\} & (\text{definition of } \overleftarrow{T}) \\ & = & \bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}. & \\ & & (\text{left solubility of } \dot{L}^{\mathcal{I}} \text{ and Proposition 1007}) & \end{array}$$

We conclude that $\dot{L}^{\mathcal{I}}$ is left adequate. ∎

In the opposite direction, in a *left c-reflective* π-institution $\mathcal{I}$, if the unary left Suszko core is left adequate, then it is also left soluble.

Proposition 1011 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a left c-reflective* π*-institution based on* $\mathbf{F}$*. If* $\dot{L}^{\mathcal{I}}$ *is left adequate, then it is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left c-reflective and that $\dot{L}^{\mathcal{I}}$ is left adequate. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \dot{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 1002. For the converse, assume that $\dot{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)$. Then, by the left adequacy of $\dot{L}^{\mathcal{I}}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \le \Omega(T)$. Thus, by left c-reflectivity and Lemma 868, we conclude that $\overleftarrow{C(\overrightarrow{\phi})} \le \overleftarrow{T}$. This implies $\phi \in \overleftarrow{T}_\Sigma$. ■

We finally show that a π-institution is strongly left truth equational if and only if it is left c-reflective and has a left adequate unary left Suszko core.

Strong Left Truth Equationality
= $\dot{L}^{\mathcal{I}}$ Left Soluble
= $\dot{L}^{\mathcal{I}}$ Defines Theory Families Up to Arrow
= Left c-Reflectivity + $\dot{L}^{\mathcal{I}}$ Left Adequate

Theorem 1012 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly left truth equational if and only if it is left c-reflective and has a left adequate unary left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly left truth equational. Then it is left c-reflective by Theorem 850. Moreover, its unary left Suszko core is left soluble by Theorem 1006 and, hence, by Corollary 1010, its unary left Suszko core is left adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with a left adequate unary left Suszko core. Then, by Proposition 1011, its unary left Suszko core is left soluble. Hence, by Theorem 1006, $\mathcal{I}$ is strongly left truth equational. ■

We close the section with a result relating the unary left Suszko core with the left Suszko core. More precisely, we show that left adequacy of the unary left Suszko core implies left adequacy of the left Suszko core.

Proposition 1013 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{L}^{\mathcal{I}}$ *is left adequate, then* $L^{\mathcal{I}}$ *is left adequate.*

Proof: Suppose that $\dot{L}^{\mathcal{I}}$ is left adequate. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & \leq & \bigcap\{\Omega(T) : \dot{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} & (\dot{L}^{\mathcal{I}} \text{ left adequate})\\ & \leq & \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} & (\dot{L}^{\mathcal{I}} \subseteq L^{\mathcal{I}})\\ & \leq & \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})). & \text{(Proposition 863)}\end{array}$$

Hence, $\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : L^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}$, and $L^{\mathcal{I}}$ is left adequate. ∎

13.6 Strong System Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly system truth equational** if there exists a set $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ (with a single distinguished argument), such that, for every $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

In that case, we call $\tau^\flat$ a **set of witnessing equations** (of/for the strong system truth equationality of $\mathcal{I}$).

Again, since $\tau^\flat$ is parameter-free and $\Omega(T)$ is invariant under signature morphisms, strong system truth equationality may be defined equivalently by the condition, for every $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma(\phi) \subseteq \Omega_\Sigma(T).$$

We introduce next the unary system core of a π-institution. Analogously with the system core, the unary system core enables one to obtain:

- A characterization of strong system truth equationality in terms of the solubility property of the unary system core of the π-institution.
- An exact description of those system c-reflective π-institutions which are strongly system truth equational.
- A characterization of those system truth equational π-institutions which are strongly system truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall that, for $T \in \mathrm{ThSys}(\mathcal{I})$, we have introduced the notation

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThSys}(\mathcal{I})\}.$$

This is a variant of the Suszko operator, allowing one to zoom in on the theory system structure of the π-institution under consideration, which forms naturally the focus in the present section.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **unary system core** of $\mathcal{I}$ is the collection

$$\dot{Z}^{\mathcal{I}} = \{\sigma^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\sigma^\flat[T] \leq \widehat{\Omega}^{\mathcal{I}}(T))\}.$$

Note that the unary system core of a π-institution is included in the system core, i.e., we have

Lemma 1014 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Then $\dot{Z}^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$.*

Proof: Every pair of unary natural transformations in $N^\flat$ that satisfies the membership criterion for $\dot{Z}^{\mathcal{I}}$ also satisfies the condition for membership in $Z^{\mathcal{I}}$. ■

Moreover, we have the following relationship between the sentence families defined via the Leibniz congruence systems by the system and the unary system core.

Corollary 1015 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For all $T \in \mathrm{ThFam}(\mathcal{I})$, we have*

$$Z^{\mathcal{I}}(\Omega(T)) \leq \dot{Z}^{\mathcal{I}}(\Omega(T)).$$

Proof: By Theorem 107 and Corollary 105. ■

The relation between the unary Suszko core, the unary left Suszko core and the unary system core of a π-institution $\mathcal{I}$ is given in the following proposition, forming an analog of Proposition 874, concerning the general (non-unary) analogs of these sets.

Proposition 1016 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\dot{S}^{\mathcal{I}} \subseteq \dot{L}^{\mathcal{I}} \subseteq \dot{Z}^{\mathcal{I}}$;

(b) For every relation family θ on $\mathbf{F}$, $\dot{Z}^{\mathcal{I}}(\theta) \leq \dot{L}^{\mathcal{I}}(\theta) \leq \dot{S}^{\mathcal{I}}(\theta)$.

Proof: From Proposition 874, we have that $S^{\mathcal{I}} \subseteq L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$. Thus, Part (a) follows by applying the $\dot{}$ operator (which is monotone) to this chain of inclusions. Part (b) follows form Part (a) and the relevant definitions. ■

Either directly by the definition or using Proposition 875 together with Corollary 1015, we get the following

Proposition 1017 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For every $T \in \mathrm{ThSys}(\mathcal{I})$,*

$$T \leq \dot{Z}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have $T \leq Z^{\mathcal{I}}(\Omega(T)) \leq \dot{Z}^{\mathcal{I}}(\Omega(T))$, where the first inclusion is by Lemma 875 and the second by Corollary 1015. ■

The unary system core of a π-institution may or may not satisfy the reverse inclusion of Proposition 1017, a property that was called previously, in similar contexts, *solubility*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary system core of $\mathcal{I}$ is **soluble** if, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\dot{Z}^{\mathcal{I}}(\Omega(T)) \leq T.$$

Note that $\dot{Z}^{\mathcal{I}}$ is soluble if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\dot{Z}^{\mathcal{I}}_\Sigma(\phi) \subseteq \Omega_\Sigma(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

It turns out that possession of the solubility property by the unary system core intrinsically characterizes strong system truth equationality. To show the necessity of solubility, we observe, once again, that, in case a π-institution is strongly system truth equational, the witnessing equations form a subset of the unary system core.

Lemma 1018 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly system truth equational, with witnessing equations $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2 \subseteq N^\flat$, then $\tau^\flat \subseteq \dot{Z}^{\mathcal{I}}$.*

Proof: Suppose that $\mathcal{I}$ is strongly system truth equational with witnessing equations $\tau^\flat$. Then, $\mathcal{I}$ is, a fortiori, system truth equational, with the same witnessing equations. It follows, by Lemma 877, that $\tau^\flat \subseteq Z^{\mathcal{I}}$. Since $\tau^\flat$ consists of unary equations and they satisfy the membership criterion for $Z^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{Z}^{\mathcal{I}}$. Therefore, we get that $\tau^\flat \subseteq \dot{Z}^{\mathcal{I}}$. ■

Now we prove the necessity of the solubility of the unary system core for strong system truth equationality.

Theorem 1019 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly system truth equational, then $\dot{Z}^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly system truth equational, with witnessing equations $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rcll} \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(Lemma 1018)} \\ & \text{iff} & \phi \in T_\Sigma, & \end{array}$$

where the last equivalence is based on the postulated strong system truth equationality of $\mathcal{I}$. Thus, $\dot{Z}^{\mathcal{I}}$ is soluble. ■

The reverse implication completes the promised characterization of strong system truth equationality in terms of the solubility of the unary system core.

Theorem 1020 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{Z}^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is strongly system truth equational, with witnessing equations* $\dot{Z}^{\mathcal{I}}$*.*

Proof: It suffices to show that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 1017, whereas the converse is ensured by the postulated solubility of $\dot{Z}^{\mathcal{I}}$. ■

Theorems 1019 and 1020 provide the promised characterization of strong system truth equationality in terms of the solubility of the unary system core.

$$\mathcal{I} \text{ is Strongly System Truth Equational} \longleftrightarrow \dot{Z}^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 1021 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly system truth equational if and only if* $\dot{Z}^{\mathcal{I}}$ *is soluble.*

Proof: Theorem 1019 gives the "only if" and the "if" is by Theorem 1020. ■

If $\mathcal{I}$ is strongly system truth equational, then the unary system core defines theory systems in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 871, since $\dot{Z}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong system truth equationality of $\mathcal{I}$.

Proposition 1022 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{Z}^{\mathcal{I}}$ *is soluble, then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$T = \dot{Z}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\dot{Z}^{\mathcal{I}}$ is soluble, then, by Theorem 1020, $\dot{Z}^{\mathcal{I}}$ forms a set of witnessing equations for the strong system truth equationality of $\mathcal{I}$. Therefore, by Proposition 871, we get that, for every $T \in \mathrm{ThSys}(\mathcal{I})$, $T = \dot{Z}^{\mathcal{I}}(\Omega(T))$. ■

This property provides another characterization of strong system truth equationality. We say that $\dot{Z}^{\mathcal{I}}$ **defines theory systems** if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = \dot{Z}^{\mathcal{I}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is Strongly System Truth Equational} \\ \longleftrightarrow \dot{Z}^{\mathcal{I}} \text{ Defines Theory Systems.}$$

Theorem 1023 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is strongly system truth equational if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$,

$$T = \dot{Z}^{\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is strongly system truth equational, then, by Theorem 1021, $\dot{Z}^{\mathcal{I}}$ is soluble. Thus, by Proposition 1022, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = \dot{Z}^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = \dot{Z}^{\mathcal{I}}(\Omega(T))$, then, $\dot{Z}^{\mathcal{I}}$ is soluble. Thus, again by Theorem 1021, $\dot{Z}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly system truth equational. ∎

It turns out that the property that separates system complete reflectivity from strong system truth equationality is exactly the adequacy property of the unary system core. Roughly speaking, this property ensures that the unary system core is rich enough to define the congruence system $\widetilde{\Omega}^{\mathcal{I}}(T)$ of a theory system T in terms of the Leibniz congruence systems of theory systems that it selects via inclusion.

Proposition 1024 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \textit{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, we have, using Lemma 1014,

$$Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

Therefore,

$$\begin{aligned}\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}\\ \subseteq \{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.\end{aligned}$$

We conclude that

$$\begin{aligned}&\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}\\ &\quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})),\end{aligned}$$

where the last inclusion is based on Proposition 883. ∎

It is possible, but not necessary, that the unary system core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 1024:

$$\widetilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Intuitively speaking, this means that the unary system core $\dot{Z}^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ-sentence ϕ, the determination of those theory systems whose Leibniz congruence systems form a covering of $\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the unary system core $\dot{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap \{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{Z}^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 1025 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcl}\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & = & \bigcap \{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ & & (\text{definition of } \widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi}))) \\ & = & \bigcap \{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}. \\ & & (\text{solubility of } \dot{Z}^{\mathcal{I}} \text{ and Proposition 1022})\end{array}$$

We conclude that $\dot{Z}^{\mathcal{I}}$ is adequate. ∎

In the opposite direction, in a *system c-reflective* π-institution $\mathcal{I}$, if the unary system core is adequate, then it is also soluble.

Proposition 1026 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a system c-reflective π-institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is system c-reflective and that $\dot{Z}^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 1017. For the converse, assume that $\dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by the adequacy of $\dot{Z}^{\mathcal{I}}$, we get that $\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \Omega(T)$. Thus, by system c-reflectivity and Lemma 885, we conclude that $C(\overrightarrow{\phi}) \leq T$, which gives $\phi \in T_\Sigma$. ∎

We finally show that a π-institution is strongly system truth equational if and only if it is system c-reflective and has an adequate unary system core.

Strong System Truth Equationality
= $\dot{Z}^{\mathcal{I}}$ Soluble
= $\dot{Z}^{\mathcal{I}}$ Defines Theory Systems
= System c-Reflectivity + $\dot{Z}^{\mathcal{I}}$ Adequate

Theorem 1027 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is strongly system truth equational if and only if it is system c-reflective and has an adequate unary system core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly system truth equational. Then it is system c-reflective by Theorem 872. Moreover, its unary system core is soluble by Theorem 1021 and, hence, by Corollary 1025, its unary system core is adequate.

Suppose, conversely, that $\mathcal{I}$ is system c-reflective with an adequate unary system core. Then, by Proposition 1026, its unary system core is soluble and, therefore, by Theorem 1021, $\mathcal{I}$ is strongly system truth equational. ∎

We close the section with a result relating the unary system core with the system core. More precisely, we show that adequacy of the unary system core implies adequacy of the system core.

Proposition 1028 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\dot{Z}^{\mathcal{I}}$ *is adequate, then* $Z^{\mathcal{I}}$ *is adequate.*

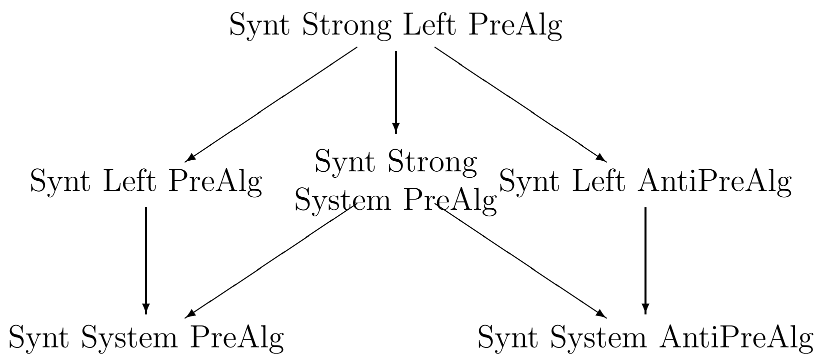
Proof: Suppose that $\dot{Z}^{\mathcal{I}}$ is adequate. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcl}\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) & \leq & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \\ & & (\dot{Z}^{\mathcal{I}} \text{ adequate}) \\ & \leq & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \\ & & (\dot{Z}^{\mathcal{I}} \subseteq Z^{\mathcal{I}}) \\ & \leq & \widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})). \quad \text{(Proposition 883)}\end{array}$$

Hence, $\widehat{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) = \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } Z^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}$, and $Z^{\mathcal{I}}$ is adequate. ∎

13.7 Syntactic Left PreAlgebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution. Recall that $\mathcal{I}$ belongs to one of the classes of the *prealgebraizability hierarchy* when its Leibniz operator is monotone on theory systems and it has a certain kind of extensionality and a certain kind of injectivity or reflectivity or complete reflectivity property. We now turn to corresponding properties defined via "syntactic" means. Keeping a level of consistency, we will call *syntactically prealgebraizable* any π-institution whose Leibniz operator on theory systems is definable via a set of binary natural transformations in $N^\flat$, i.e., a parameter free set of natural transformations in $N^\flat$, and, additionally, has a certain kind of definability property of truth, via a, possibly, parameter free set of equations in $N^\flat$. If the situation is reversed and definability of truth is required to be via a parameter free set of equations, but that is not demanded of the definability of Leibniz congruence systems, then we obtain the classes of *anti-prealgebraizable π-institutions*, a term concocted here to convey a kind of chiral symmetry in applying "parameterlessness". The hierarchy we aim for consists of the six classes depicted in the following diagram.



Membership in the classes of the central column imposes parameter free definability of both the Leibniz operator on theory systems and a kind of parameter free definability of truth. Membership in the classes in the left column insists only on parameter free definability of the Leibniz operator, whereas, symmetrically, membership in the classes of the right column postulates only a kind of parameter free definability of truth.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. In agreement with preestablished nomenclature, we say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-**fortified** if it has

- a Leibniz binary reflexive core and
- a left adequate unary left Suszko core.

We say that $\mathcal{I}$ is **syntactically strongly left prealgebraizable** if it is

- $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified;
- preequivalential (i.e., prealgebraic and system extensional);
- left c-reflective.

Our preceding work in this chapter has paved the way for the following important characterization of syntactic strong left prealgebraizability.

Theorem 1029 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is syntactically preequivalential and strongly left truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by definition, it is

- preequivalential and has a Leibniz binary reflexive core;
- left c-reflective and has a left adequate unary left Suszko core;

if and only if, by Theorems 969 and 1012, is it syntactically preequivalential and strongly left truth equational. ∎

An alternative characterization along similar lines relates the syntactic with the corresponding semantic notions introduced in the context of prealgebraizability.

Theorem 1030 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is LC prealgebraizable and* $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$*-fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by definition,

- it is preequivalential and left c-reflective;
- it has a Leibniz binary reflexive core and a left adequate unary left Suszko core;

if and only if, by definition, it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified. ∎

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield yet another characterization of syntactic strong left prealgebraizability, which may also be viewed as a kind of transfer property for this class in its own right.

Theorem 1031 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter systems, system extensional and left c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by Theorem 1030, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and LC prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems, system extensional and left c-reflective. ∎

Turning now to characterizations involving property preserving mappings between posets of filter families and congruence systems, we have the following result:

Theorem 1032 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by Theorem 1030, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and LC prealgebraizable if and only if, by Theorem 355 it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ that commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 949.

Theorem 1033 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly left truth equational and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of natural transformations. Then it is strongly left truth equational and, by Theorem 941, it is syntactically preequivalential. Thus, by Theorem 1029, it is syntactically strongly left prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly left prealgebraizable. Then, by Theorem 1029, it is strongly left truth equational and syntactically preequivalential. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic preequivalentiality and $\tau^\flat$ the syntactic strong left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

Again, the equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of natural transformations, coupled with strong left truth equationality, is sufficient to ensure syntactic strong left prealgebraizability.

Theorem 1034 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly left prealgebraizable, then, by Theorem 1033, it is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Then, it is strongly left truth equational and, by Proposition 928, it is syntactically preequivalential. Therefore, by Theorem 1029, it is syntactically strongly left prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically strongly left prealgebraizable π-institutions:

Theorem 1035 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of natural transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 1034 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1034. ■

Flanking the class of syntactically strongly left prealgebraizable π-institutions are the classes of *syntactically left prealgebraizable* and *syntactically left antiprealgebraizable* π-institutions. These two classes are defined formally now.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

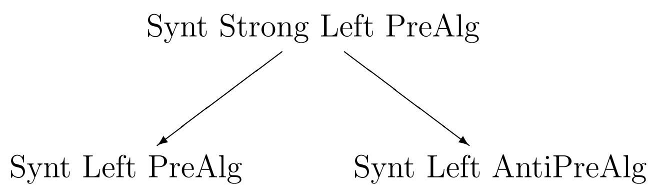
- $\mathcal{I}$ is **syntactically left prealgebraizable** if it is:
  - $\ddot{R}^{\mathcal{I}} L^{\mathcal{I}}$-fortified;
  - preequivalential;
  - left c-reflective;
- $\mathcal{I}$ is **syntactically left antiprealgebraizable** if it is:
  - $R^{\mathcal{I}} \dot{L}^{\mathcal{I}}$-fortified;
  - prealgebraic;

  – left c-reflective.

For both of these classes we have analogs of many of the results proven above for syntactic strong left prealgebraizability. Before formulating them, let us observe that, since:

- preequivalentiality is stronger than prealgebraicity;
- under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ Leibniz implies $R^{\mathcal{I}}$ Leibniz; and
- $\dot{L}^{\mathcal{I}}$ left adequate implies $L^{\mathcal{I}}$ left adequate,

we get, immediately from the definitions, the following hierarchical relations between the upper three classes in the echelon formation of the preceding diagram.



We now provide examples to show that the two inclusions are proper. The first is an example of a π-institution which is syntactically left prealgebraizable but not syntactically strongly left prealgebraizable.

Example 1036 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically left antiprealgebraizable π-institution which fails to be syntactically strongly left prealgebraizable.

Example 1037 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1029 relates these two chiral types of syntactic left prealgebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1038 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically left prealgebraizable if and only if it is syntactically preequivalential and left truth equational.*

(b) $\mathcal{I}$ *is syntactically left antiprealgebraizable if and only if it is syntactically prealgebraic and strongly left truth equational.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by definition, it is preequivalential, with a Leibniz binary reflexive core, and left c-reflective, with a left adequate left Suszko core, if and only if, by Theorems 969 and 870, is it syntactically preequivalential and left truth equational.

(b) Similarly, $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if, by definition, it is prealgebraic, with a Leibniz reflexive core, and left c-reflective, with a left adequate unary left Suszko core, if and only if, by Theorems 788 and 1012, is it syntactically prealgebraic and strongly left truth equational.

■

An alternative characterization, analogous to that of Theorem 1030, relates the syntactic with the corresponding semantic notions.

Theorem 1039 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically left prealgebraizable if and only if it is LC prealgebraizable and* $\ddot{R}^{\mathcal{I}} L^{\mathcal{I}}$*-fortified.*

(b) $\mathcal{I}$ *is syntactically left antiprealgebraizable if and only if it is weakly LC prealgebraizable and* $R^{\mathcal{I}} \dot{L}^{\mathcal{I}}$*-fortified.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by definition, it is preequivalential and left c-reflective and, moreover, it has a Leibniz binary reflexive core and a left adequate left Suszko core. This happens if and only if, by definition, it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}} L^{\mathcal{I}}$-fortified.

(b) Similarly, $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if, by definition, it is prealgebraic and left c-reflective and, moreover, it has a Leibniz reflexive core and a left adequate unary left Suszko core. This happens if and only if, by definition, it is weakly LC prealgebraizable and $R^{\mathcal{I}} \dot{L}^{\mathcal{I}}$-fortified.

■

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield a kind of transfer property for syntactic left (anti)prealgebraizability.

Theorem 1040 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems, system extensional and left c-reflective.*

(b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems and left c-reflective.*

Proof: We prove only Part (a), since Part (b) is similar. We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by Theorem 1039, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and LC prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems, system extensional and left c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result:

Theorem 1041 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ that commutes with inverse logical extensions.

(b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$.

Proof: Again we show only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by Theorem 1039, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and LC prealgebraizable if and only if, by Theorem 355 it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ that commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1033.

Theorem 1042 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically left prealgebraizable if and only if it is left truth equational and its systemic skeleton* $\mathcal{K}^\mathcal{I}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^\mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of transformations, with* $I^\flat$ *natural.*

(b) $\mathcal{I}$ *is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and its systemic skeleton* $\mathcal{K}^\mathcal{I}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^\mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of transformations, with* $\tau^\flat$ *natural.*

Proof:

(a) Suppose, first, that $\mathcal{I}$ is left truth equational and $\mathcal{K}^\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then it is left truth equational and, by Theorem 941, it is syntactically preequivalential. Thus, by Theorem 1038, it is syntactically left prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically left prealgebraizable. Then, by Theorem 1038, it is left truth equational and syntactically preequivalential. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I^\flat})$, where $I^\flat$ witnesses the syntactic preequivalentiality and $\tau^\flat$ the left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $I^\flat$ natural.

(b) Suppose, first, that $\mathcal{I}$ is strongly left truth equational and $\mathcal{K}^\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then it is strongly left truth equational and, by Theorem 941, it is syntactically prealgebraic. Thus, by Theorem 1038, it is syntactically left antiprealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically left antiprealgebraizable. Then, by Theorem 1038, it is strongly left truth equational and syntactically prealgebraic. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I^\flat})$, where $I^\flat$ witnesses the syntactic prealgebraicity and $\tau^\flat$ the strong left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $\tau^\flat$ natural.

■

The equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, coupled with either left truth equationality or strong left truth equationality, depending on the case considered, is sufficient to ensure syntactic left (anti)prealgebraizability.

Theorem 1043 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically left prealgebraizable if and only if it is left truth equational and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $I^\flat$ *natural.*

(b) $\mathcal{I}$ *is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $\tau^\flat$ *natural.*

Proof:

(a) If $\mathcal{I}$ is syntactically left prealgebraizable, then, by Theorem 1042, it is left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations with $I^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, it is left truth equational and, by Proposition 928, it is syntactically preequivalential. Therefore, by Theorem 1038, it is syntactically left prealgebraizable.

(b) If $\mathcal{I}$ is syntactically left antiprealgebraizable, then, by Theorem 1042, it is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, it is strongly left truth equational and, by Proposition 928, it is syntactically prealgebraic. Therefore, by Theorem 1038, it is syntactically left antiprealgebraizable.

■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically left (anti)prealgebraizable π-institutions:

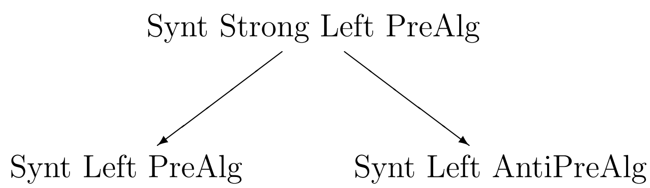
Theorem 1044 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically left prealgebraizable if and only if it is left truth equational and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$, *induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure and* $I^\flat$ *is natural.*

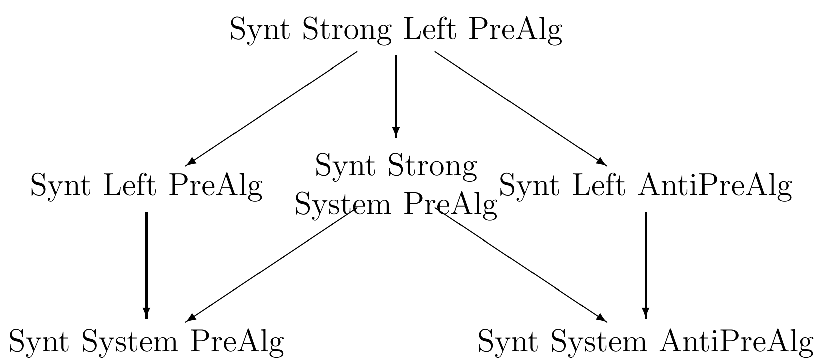
(b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, where $\mathcal{Q}$ is an algebraic π-structure and $\tau^\flat$ is natural.*

Proof: The "only if" follows by Theorem 1043 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1043. ■

In this section we have introduced the three syntactic left prealgebraizability classes



In the next section, we shall introduce, following a similar path, the remaining three syntactic prealgebraizability classes, namely those of the system prealgebraizable π-institutions, in order to complete the syntactic prealgebraizability hierarchy that was described at the beginning of the section:



13.8 Syntactic System PreAlgebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$**-fortified** if it has

- a Leibniz binary reflexive core; and
- an adequate unary system core.

We say that $\mathcal{I}$ is **syntactically strongly system prealgebraizable** if it is

- $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified;
- preequivalential (i.e., prealgebraic and system extensional);

- system c-reflective.

An analog of Theorem 1029 provides an important characterization of syntactic strong system prealgebraizability in terms of lower classes in the syntactic hierarchy.

Theorem 1045 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if it is syntactically preequivalential and strongly system truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by definition, it is

- preequivalential and has a Leibniz binary reflexive core;
- system c-reflective and has an adequate unary system core;

if and only if, by Theorems 969 and 1027, is it syntactically preequivalential and strongly system truth equational. ■

An analog of Theorem 1030 gives an alternative characterization of the syntactic notion in terms of the corresponding semantic notions.

Theorem 1046 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if it is system prealgebraizable and* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by definition,

- it is preequivalential and system c-reflective;
- it has a Leibniz binary reflexive core and an adequate unary system core;

if and only if, by definition, it is system prealgebraizable and, also, $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified. ■

This characterization in terms of semantic properties and preceding work on transference of properties from theory systems to filter systems on arbitrary algebraic systems yield yet another characterization of syntactic strong system prealgebraizability analogous to that of Theorem 1031, which may also be viewed as a kind of transfer property for this class.

Theorem 1047 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}}$ *is monotone on theory systems, system extensional and system c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by Theorem 1046, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and system prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems, system extensional and system c-reflective. ∎

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result:

Theorem 1048 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order embedding which commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by Theorem 1046, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and system prealgebraizable if and only if, by Theorem 353, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding which commutes with inverse logical extensions. ∎

Finally, in an analog of Theorem 1033, using conjugate pairs of transformations, we get

Theorem 1049 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}\bullet}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ *of natural transformations.*

Proof: Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of natural transformations. Then, by Theorem 942, it is strongly system truth equational and, by Theorem 941, it is syntactically preequivalential. Thus, by Theorem 1045, it is syntactically strongly system prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly system prealgebraizable. Then, by Theorem 1045, it is strongly system truth equational and syntactically preequivalential. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic preequivalentiality and $\tau^\flat$ the syntactic strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ∎

Analogously with Theorem 1034, the equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of natural transformations suffices to ensure syntactic strong system prealgebraizability.

Theorem 1050 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly system prealgebraizable, then, by Theorem 1049, its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Suppose, conversely, that the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Then, by Proposition 928, it is syntactically preequivalential and, by Theorem 942, it is strongly system truth equational. Therefore, by Theorem 1045, it is syntactically strongly system prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1035, providing an alternative characterization of syntactically strongly system prealgebraizable π-institutions.

Theorem 1051 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly system prealgebraizable if and only if there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of natural transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 1050 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1050. ■

In the case of syntactic strong left prealgebraizability, studied in the preceding section, below that class sat two wider classes obtained by weakening the naturality requirement either on the side of the witnesses of prealgebraicity or on the side of the witnesses of truth equationality. Similarly here, we get below the class of syntactically strongly system prealgebraizable π-institutions the classes of *syntactically system prealgbebraizable* and *syntactically system antiprealgebraizable* π-institutions. These two classes are defined formally now.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

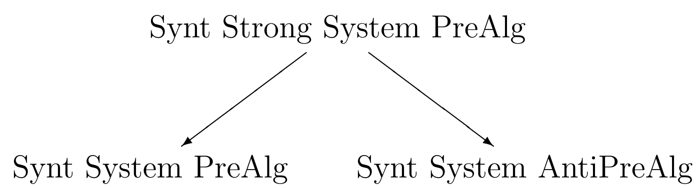
- $\mathcal{I}$ is **syntactically system prealgebraizable** if it is:
  - $\ddot{R}^{\mathcal{I}} Z^{\mathcal{I}}$-fortified;
  - preequivalential;
  - system c-reflective;
- $\mathcal{I}$ is **syntactically system antiprealgebraizable** if it is:

  - $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified;
  - prealgebraic;
  - system c-reflective.

For both of these classes we have analogs of many of the results proven above for syntactic strong system prealgebraizability. Again, since:

- preequivalentiality is stronger than prealgebraicity;
- under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ Leibniz implies $R^{\mathcal{I}}$ Leibniz; and
- $\dot{Z}^{\mathcal{I}}$ adequate implies $Z^{\mathcal{I}}$ adequate,

we get, immediately from the definitions the following hierarchical relations between the upper three classes in the echelon formation of the preceding diagram.



We now provide examples to show that the two inclusions are proper. The first is an example of a π-institution which is syntactically system prealgebraizable but not syntactically strongly system prealgebraizable.

Example 1052 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically system antiprealgebraizable π-institution which fails to be syntactically strongly system prealgebraizable.

Example 1053 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1038 relates these two chiral types of syntactic system prealgebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1054 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically system prealgebraizable if and only if it is syntactically preequivalential and system truth equational.*

(b) $\mathcal{I}$ *is syntactically system antiprealgebraizable if and only if it is syntactically prealgebraic and strongly system truth equational.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by definition, it is preequivalential, with a Leibniz binary reflexive core, and system c-reflective, with an adequate system core, if and only if, by Theorems 969 and 887, is it syntactically preequivalential and system truth equational.

(b) We have that $\mathcal{I}$ is syntactically system antiprealgebraizable if and only if, by definition, it is prealgebraic, with a Leibniz reflexive core, and system c-reflective, with an adequate unary system core, if and only if, by Theorems 788 and 1027, is it syntactically prealgebraic and strongly system truth equational.

■

An alternative characterization, analogous to that of Theorem 1039, relates the syntactic with the corresponding semantic notions.

Theorem 1055 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically system prealgebraizable if and only if it is system prealgebraizable and* $\ddot{R}^{\mathcal{I}} Z^{\mathcal{I}}$*-fortified.*

(b) $\mathcal{I}$ *is syntactically system antiprealgebraizable if and only if it is weakly system prealgebraizable and* $R^{\mathcal{I}} \dot{Z}^{\mathcal{I}}$*-fortified.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by definition, it is preequivalential and system c-reflective and, moreover, it has a Leibniz binary reflexive core and an adequate system core. This happens if and only if, by definition, it is system prealgebraizable and $\ddot{R}^{\mathcal{I}} Z^{\mathcal{I}}$-fortified.

(b) Similarly, $\mathcal{I}$ is syntactically system antiprealgebraizable if and only if, by definition, it is prealgebraic and system c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary system core. This happens if and only if, by definition, it is weakly system prealgebraizable and $R^{\mathcal{I}} \dot{Z}^{\mathcal{I}}$-fortified.

■

As far as transferring the properties defining syntactic system (anti)prealgebraizability from theory systems to filter systems on arbitrary algebraic systems, we get the following transfer theorem.

Theorem 1056 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically system prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter systems, system extensional and system c-reflective.*

(b) $\mathcal{I}$ *is syntactically system antiprealgebraizable if and only if it is* $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter systems and system c-reflective.*

Proof: We prove only Part (a). The proof of Part (b) follows along similar lines. We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by Theorem 1055, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and system prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems, system extensional and system c-reflective. ■

As far as characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1041.

Theorem 1057 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically system prealgebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order embedding which commutes with inverse logical extensions.

(b) $\mathcal{I}$ *is syntactically system antiprealgebraizable if and only if it is* $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order embedding.

Proof: Again we show only Part (a), since Part (b) follows similar reasoning. We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by Theorem 1055, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and system prealgebraizable if and only if, by Theorem 353 it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding which commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1042.

Theorem 1058 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with $I^\flat$ natural.*

(b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with $\tau^\flat$ natural.*

Proof:

(a) Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Theorem 941, it is syntactically preequivalential and, by Theorem 942, it is system truth equational. Thus, by Theorem 1054, it is syntactically system prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically system prealgebraizable. Then, by Theorem 1054, it is syntactically preequivalential and system truth equational. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic preequivalentiality and $\tau^\flat$ the system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $I^\flat$ natural.

(b) Suppose, first, $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, by Theorem 941, it is syntactically prealgebraic and, by Theorem 942, it is strongly system truth equational. Thus, by Theorem 1054, it is syntactically system antiprealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically system antiprealgebraizable. Then, by Theorem 1054, it is syntactically prealgebraic and strongly system truth equational. Hence, by Theorem 934, it is syntactically WS prealgebraizable. Now it follows by Theorem 940 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic prealgebraicity and $\tau^\flat$ the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $\tau^\flat$ natural.

■

The equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, is sufficient to ensure syntactic system (anti)prealgebraizability. This constitutes an analog of Theorem 1043.

Theorem 1059 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural.*

(b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural.*

Proof:

(a) If $\mathcal{I}$ is syntactically system prealgebraizable, then, by Theorem 1058, its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations with $I^\flat$ natural. Suppose, conversely, that the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Proposition 928, it is syntactically preequivalential and, by Theorem 942, it is system truth equational. Therefore, by Theorem 1054, it is syntactically system prealgebraizable.

(b) If $\mathcal{I}$ is syntactically system antiprealgebraizable, then, by Theorem 1058, its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Suppose, conversely, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, by Proposition 928, it is syntactically prealgebraic and, by Theorem 942, it is strongly system truth equational. Therefore, by Theorem 1054, it is syntactically system antiprealgebraizable.

■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1044, giving an alternative characterization of syntactically system (anti)prealgebraizable π-institutions:

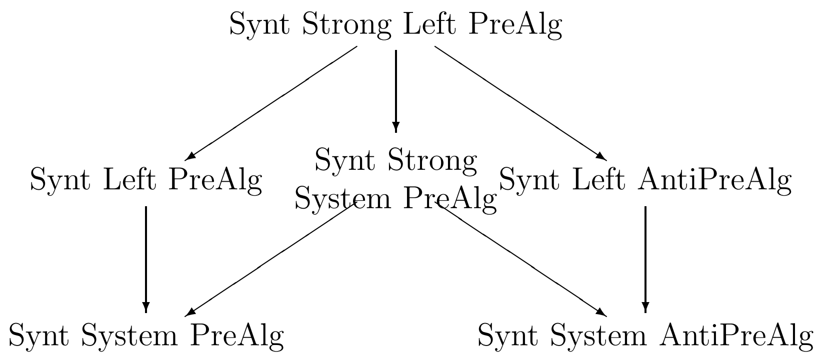
Theorem 1060 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, where $\mathcal{Q}$ is an algebraic π-structure and $I^\flat$ is natural.*

(b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, where $\mathcal{Q}$ is an algebraic π-structure and $\tau^\flat$ is natural.*

Proof: The "only if" follows by Theorem 1059 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1059. ■

Finally, since we have now described in detail the six classes of the syntactic prealgebraizability hierarchy, it is only appropriate to pause and look for examples that separate the left prealgebraizability from the system prealgebraizability classes, i.e., examples showing that the vertical arrows in the following 6-class diagram

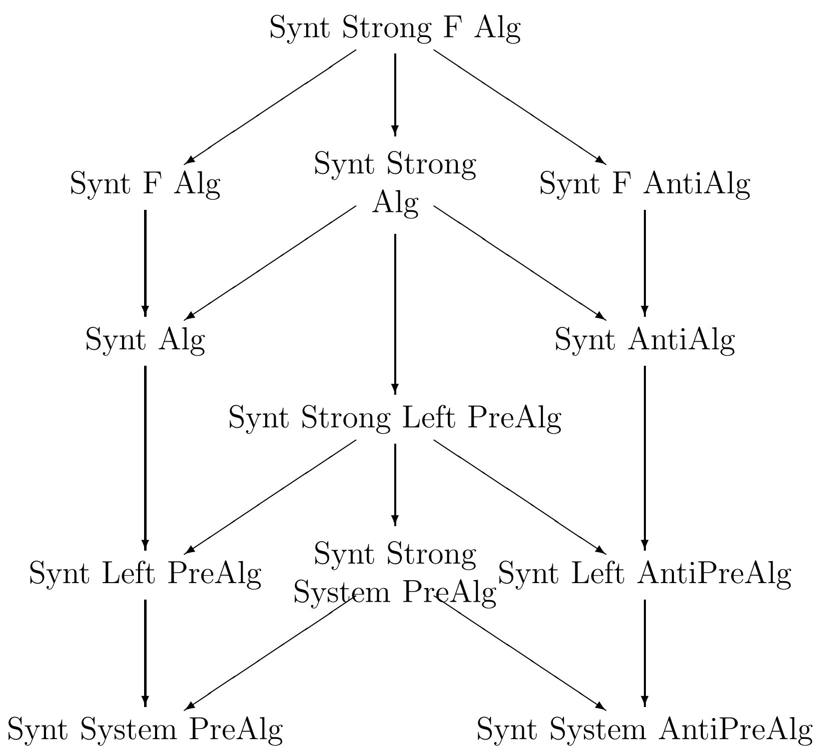


represent, in fact, proper inclusions. We can do this in one swoop by exhibiting an example of a syntactically strong system prealgebraizable π-institution which is neither syntactically left prealgebraizable nor syntactically left antiprealgebraizable.

Example 1061 EXAMPLE NOT FOUND YET!

13.9 Syntactic Family Algebraizability

We now preview the full hierarchy of syntactically prealgebraizable π-institutions that will be established in this section. The bottom six classes are the ones established in the preceding two sections, where prealgebraizability refers to the fact that monotonicity is only applied to theory systems. The top six classes concern syntactic algebraizability, where monotonicity is applied to all theory families. The bottom row of this upper tier consists of those π-institutions, where c-reflectivity is postulated only for theory systems. The very top row above it refers to applying left c-reflectivity to theory families. In the second from top class, system (or, equivalently, left c-reflectivity) is postulated in conjunction with family monotonicity and at the very top row family c-reflectivity is combined with family monotonicity. Finally, as far as columns go, they incorporate meanings similar to the ones described for the cohorts of classes introduced in the preceding sections. The left column applies parameter freeness only to the equivalence natural transformations witnessing syntactic protoalgebraicity. The right column insists on parameter freeness for the defining equations that witness the truth equationality of the π-institution, whereas the middle column is combing those properties and consists of those classes of π-institutions that are syntactically protoalgebraic and syntactic truth equational, with both properties having parameter free witnessing transformations and witnessing equations, respectively. The complete picture that emerges at the end of this and the next section adds to the six-class diagram concluding the previous section six more classes, those positioned at the top two rows.



We start by defining the class at the apex of the diagram. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$**-fortified** if it has

- a Leibniz binary reflexive core; and
- an adequate unary Suszko core.

We say that $\mathcal{I}$ is **syntactically strongly family algebraizable** if it is

- $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified;
- equivalential (i.e., protoalgebraic and family extensional);
- family c-reflective.

Based on previous work, we can formulate the following important characterization of syntactic strong family algebraizability.

Theorem 1062 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is syntactically equivalential and strongly truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by definition, it is

- equivalential and has a Leibniz binary reflexive core;
- family c-reflective and has an adequate unary Suszko core;

if and only if, by Theorems 983 and 996, is it syntactically preequivalential and strongly left truth equational. ∎

An alternative characterization along similar lines relates the syntactic with the corresponding semantic notions introduced in the context of algebraizability.

Theorem 1063 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is family algebraizable and* $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$*-fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by definition,

- it is equivalential and family c-reflective;
- it has a Leibniz binary reflexive core and an adequate unary Suszko core;

if and only if, by definition, it is family algebraizable (recall that family injectivity and family c-reflectivity coincide under protoalgebraicity) and $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified. ∎

This characterization in terms of semantic properties and preceding work on transference of properties from theory families to filter families on arbitrary algebraic systems yields another characterization of syntactic strong family algebraizability, which may also be viewed as a kind of transfer property in its own right.

Theorem 1064 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families, family extensional and family c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by Theorem 1063, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified and family algebraizable if and only if, by Theorem 364, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone and injective (equivalently c-reflective) on $\mathcal{I}$-filter families and family extensional. ∎

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result:

Theorem 1065 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by Theorem 1063, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified and family algebraizable if and only if, by Theorem 366 it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ∎

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 949.

Theorem 1066 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is equivalent to its associated algebraic* π*-structure* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of natural transformations. Then it is syntactically equivalential by Corollary 910 and it is family truth equational by Theorem 911. Thus, by Theorem 1062, it is syntactically strongly family algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly family algebraizable. Then, by Theorem 1062, it is strongly family truth equational and syntactically equivalential. Hence, by Theorem 913, it is syntactically WF algebraizable. Now it follows by Theorem 919 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic equivalentiality and $\tau^\flat$ the syntactic strong truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ∎

It turns out, in this case also, that the equivalence of the π-institution with some algebraic π-structure via a conjugate pair of natural transformations is sufficient to ensure syntactic strong family algebraizability.

Theorem 1067 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if it is equivalent to an algebraic* π*-structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly family algebraizable, then, by Theorem 1066, it is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Then, it is syntactically equivalential by Corollary 910 and it is strongly family truth equational by Theorem 911. Therefore, by Theorem 1062, it is syntactically strongly family algebraizable. ∎

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically strongly family algebraizable π-institutions:

Theorem 1068 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly family algebraizable if and only if there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of natural transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 1067 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1067. ∎

Lying just underneath the class of syntactically strongly family algebraizable π-institutions are the classes of *syntactically family algebraizable* and *syntactically family antialgebraizable* π-institutions. These two classes are defined formally now.

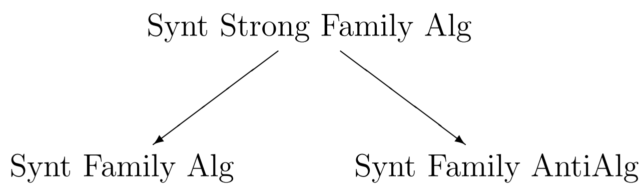
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically family algebraizable** if it is:
  - $\ddot{R}^{\mathcal{I}} S^{\mathcal{I}}$-fortified;
  - equivalential;
  - family c-reflective;
- $\mathcal{I}$ is **syntactically family antialgebraizable** if it is:
  - $R^{\mathcal{I}} \dot{S}^{\mathcal{I}}$-fortified;
  - protoalgebraic;
  - family c-reflective.

We formulate analogs of many of the results proven previously for the various kinds of syntactic prealgebraizability properties. Observe, first, that, since:

- equivalentiality is stronger than protoalgebraicity;
- under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ Leibniz implies $R^{\mathcal{I}}$ Leibniz; and
- $\dot{S}^{\mathcal{I}}$ adequate implies $S^{\mathcal{I}}$ adequate,

we get, immediately from the definitions the following hierarchical relations between the three topmost classes in the syntactic algebraizability hierarchy.



We now provide examples to show that the two inclusions are proper. The first is an example of a π-institution which is syntactically family algebraizable but not syntactically strongly family algebraizable.

Example 1069 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically family antialgebraizable π-institution which fails to be syntactically strongly family algebraizable.

Example 1070 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1062 relates these two chiral sorts of syntactic family (anti)algebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1071 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if it is syntactically equivalential and family truth equational.*

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is syntactically protoalgebraic and strongly family truth equational.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by definition, it is equivalential, with a Leibniz binary reflexive core, and family c-reflective, with an adequate Suszko core, if and only if, by Theorems 983 and 847, is it syntactically equivalential and family truth equational.

(b) We have that $\mathcal{I}$ is syntactically family antialgebraizable if and only if, by definition, it is protoalgebraic, with a Leibniz reflexive core, and family c-reflective, with an adequate unary Suszko core, if and only if, by Theorems 805 and 996, is it syntactically protoalgebraic and strongly family truth equational.

■

An alternative characterization, analogous to that of Theorem 1063, relates the syntactic with the corresponding semantic notions.

Theorem 1072 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if it is family algebraizable and* $\ddot{R}^{\mathcal{I}} S^{\mathcal{I}}$*-fortified.*

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is family algebraizable and* $R^{\mathcal{I}} \dot{S}^{\mathcal{I}}$*-fortified.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by definition, it is equivalential and family c-reflective and, moreover, it has a Leibniz binary reflexive core and an adequate Suszko core. This happens if and only if, by definition, it is family algebraizable and $\ddot{R}^{\mathcal{I}} S^{\mathcal{I}}$-fortified.

(b) Similarly, $\mathcal{I}$ is syntactically family antialgebraizable if and only if, by definition, it is equivalential and family c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary Suszko core. This happens if and only if, by definition, it is family algebraizable and $R^{\mathcal{I}} \dot{S}^{\mathcal{I}}$-fortified.

■

The characterization in terms of semantic properties and preceding work on transference of properties from theory families to filter families on arbitrary algebraic systems yield a transfer property for syntactic family (anti)-prealgebraizability.

Theorem 1073 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}} S^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families, family extensional and family c-reflective.*

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is* $R^{\mathcal{I}} \dot{S}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families and family c-reflective.*

Proof: We prove only Part (a), since Part (b) is similar. We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by Theorem 1072, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$-fortified and family algebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle\rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter families, family extensional and family c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result:

Theorem 1074 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle\rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is* $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle\rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism.

Proof: Again we show only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by Theorem 1072, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$-fortified and family algebraizable if and only if, by Theorem 366 it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle\rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ■

In terms of conjugate pairs of transformations, we get the following analog of Theorem 1066.

Theorem 1075 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if it is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations, with* $I^\flat$ *natural.*

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of transformations, with* $\tau^\flat$ *natural.*

Proof:

(a) Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Corollary 910, it is syntactically equivalential and, by Theorem 911, it is family truth equational. Thus, by Theorem 1071, it is syntactically family algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically family algebraizable. Then, by Theorem 1071, it is left truth equational and syntactically equivalential. Hence, by Theorem 913, it is syntactically WF prealgebraizable. Now it follows by Theorem 919 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a pair $(\tau^\flat, \overset{\leftrightarrow}{I^\flat})$, where $I^\flat$ witnesses the syntactic equivalentiality and $\tau^\flat$ the syntactic family truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $I^\flat$ natural.

(b) Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, by Theorem 909, it is syntactically protoalgebraic and, by Theorem 911, it is strongly family truth equational. Thus, by Theorem 1071, it is syntactically family antialgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically family antialgebraizable. Then, by Theorem 1071, it is strongly left truth equational and syntactically protoalgebraic. Hence, by Theorem 913, it is syntactically WF prealgebraizable. Now it follows by Theorem 919 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a pair $(\tau^\flat, \overset{\leftrightarrow}{I^\flat})$, where $I^\flat$ witnesses the syntactic protoalgebraicity and $\tau^\flat$ the strong family truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $\tau^\flat$ natural.

■

The equivalence of the π-institution with some algebraic π-structure via a conjugate pair of transformations exhibiting the required one-sided naturality condition suffices to ensure syntactic family (anti)algebraizability.

Theorem 1076 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $I^\flat$ *natural.*

(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if it is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $\tau^\flat$ *natural.*

Proof:

(a) If $\mathcal{I}$ is syntactically family algebraizable, then, by Theorem 1075, it is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations with $I^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Theorem 909, it is syntactically equivalential and, by Theorem 911, it is family truth equational. Therefore, by Theorem 1071, it is syntactically family algebraizable.

(b) If $\mathcal{I}$ is syntactically family antialgebraizable, then, by Theorem 1075, it is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, by Theorem 909, it is syntactically protoalgebraic and by Theorem 911, it is strongly family truth equational. Therefore, by Theorem 1071, it is syntactically family antialgebraizable.

■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactic family (anti)algebraizability:

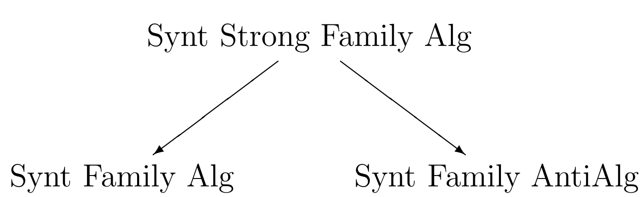
Theorem 1077 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically family algebraizable if and only if there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure and* $I^\flat$ *is natural.*

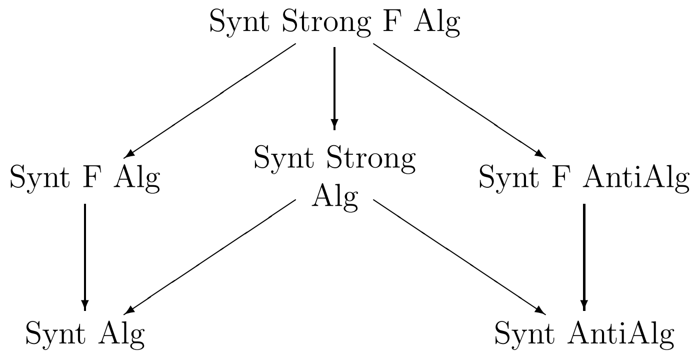
(b) $\mathcal{I}$ *is syntactically family antialgebraizable if and only if there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure and* $\tau^\flat$ *is natural.*

Proof: The "only if" follows by Theorem 1076 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1076. ■

In this section we have introduced the three syntactic family algebraizability classes



In the next section, we shall introduce the remaining three syntactic algebraizability classes, namely those of the syntactically algebraizable π-institutions, in order to complete the syntactic algebraizability hierarchy that was described at the beginning of the section:



13.10 Syntactic Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$**-fortified** if it has a Leibniz binary reflexive core and an adequate unary system core. We say that $\mathcal{I}$ is **syntactically strongly algebraizable** if it is

- $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified;
- equivalential (i.e., protoalgebraic and family extensional);
- system c-reflective.

An analog of Theorem 1062 provides an important characterization of syntactic strong algebraizability in terms of lower classes in the syntactic hierarchy.

Theorem 1078 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is syntactically equivalential and strongly system truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by definition, it is

- equivalential and has a Leibniz binary reflexive core;
- system c-reflective and has an adequate unary system core;

if and only if, by Theorems 983 and 1027, is it syntactically preequivalential and strongly system truth equational. ■

An analog of Theorem 1063 gives an alternative characterization of the syntactic notion in terms of the corresponding semantic notions.

Theorem 1079 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is (system) algebraizable and* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by definition,

- it is equivalential and system c-reflective;
- it has a Leibniz binary reflexive core and an adequate unary system core;

if and only if, by definition, it is algebraizable and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified. ∎

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield another characterization of syntactic strong algebraizability analogous to that of Theorem 1064, which may also be viewed as a kind of transfer property for syntactically strongly algebraizable π-institutions.

Theorem 1080 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families, family extensional and system c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by Theorem 1079, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and algebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter families, family extensional and system c-reflective. ∎

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1065.

Theorem 1081 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified, stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly (system) algebraizable if and only if, by Theorem 1079, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and algebraizable if and only if, by Theorem 365, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified, stable and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ■

Finally, in an analog of Theorem 1066, using conjugate pairs of transformations, we get

Theorem 1082 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is stable and its systemic skeleton* $\mathcal{K}^{\mathcal{I}}$ *is equivalent to* $\mathcal{Q}^{\mathcal{I}*}$ *via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ *of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is stable and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of natural transformations. Then, by Theorem 929, it is syntactically equivalential and, by Theorem 941, it is strongly system truth equational. Thus, by Theorem 1078, it is syntactically strongly algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly algebraizable. Then, by Theorem 1078, it is syntactically equivalential and strongly system truth equational. Hence, by Theorem 923, it is syntactically weakly algebraizable. Now it follows by Theorem 927 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic equivalentiality and $\tau^\flat$ the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

Analogously with Theorem 1067, the equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of natural transformations, coupled with stability, suffices to ensure syntactic strong algebraizability.

Theorem 1083 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is stable and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly algebraizable, then, by Theorem 1082, it is stable and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is stable and that its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair of natural transformations. Then, by Theorem 929, it is syntactically equivalential and, by Theorem 930, it is strongly system truth equational. Therefore, by Theorem 1078, it is syntactically strongly algebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1065, providing an alternative characterization of syntactic strong algebraizability.

Theorem 1084 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically strongly algebraizable if and only if it is stable and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^\mathcal{I}) \to \mathbf{ThFam}(\mathcal{Q})$*, induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of natural transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure.*

Proof: The "only if" follows by Theorem 1083 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1083. ∎

As with all other strong (pre)algebraizability classes, studied before, below the class of syntactically strongly algebraizable π-institutions sit two wider classes obtained by weakening the naturality requirement either on the side of the witnesses of prealgebraicity or on the side of the witnesses of truth equationality, namely the classes of *syntactically algebraizable* and *syntactically antialgebraizable* π-institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

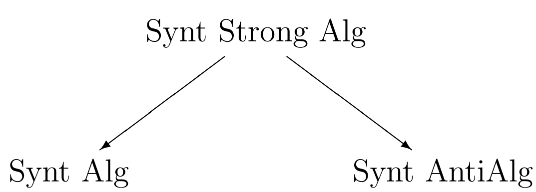
- $\mathcal{I}$ is **syntactically algebraizable** if it is:
  - $\ddot{R}^\mathcal{I} Z^\mathcal{I}$-fortified;
  - equivalential;
  - system c-reflective;
- $\mathcal{I}$ is **syntactically antialgebraizable** if it is:
  - $R^\mathcal{I} \dot{Z}^\mathcal{I}$-fortified;
  - protoalgebraic;
  - system c-reflective.

We now conclude the chapter by formulating analogs of many of the results proven above for syntactic strong algebraizability for these two new classes of π-institutions.

Firs, observe, once more, that, since:

- equivalentiality implies protoalgebraicity;
- under protoalgebraicity, $\ddot{R}^\mathcal{I}$ Leibniz implies $R^\mathcal{I}$ Leibniz; and
- $\dot{Z}^\mathcal{I}$ adequate implies $Z^\mathcal{I}$ adequate,

we get the following hierarchical relations between the three classes in the second-from-top tier of the syntactic algebraizability hierarchy.



Examples are in order to show that the two inclusions are proper. The first is an example of a π-institution which is syntactically algebraizable but not syntactically strongly algebraizable.

Example 1085 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically antialgebraizable π-institution which fails to be syntactically strongly algebraizable.

Example 1086 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1078 relates the two chiral types of syntactic algebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1087 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically algebraizable if and only if it is syntactically equivalential and system truth equational.*

(b) $\mathcal{I}$ *is syntactically antialgebraizable if and only if it is syntactically protoalgebraic and strongly system truth equational.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by definition, it is equivalential, with a Leibniz binary reflexive core, and system c-reflective, with an adequate system core, if and only if, by Theorems 983 and 887, is it syntactically equivalential and system truth equational.

(b) We have that $\mathcal{I}$ is syntactically antialgebraizable if and only if, by definition, it is protoalgebraic, with a Leibniz reflexive core, and system c-reflective, with an adequate unary system core, if and only if, by Theorems 805 and 1027, is it syntactically protoalgebraic and strongly system truth equational.

■

An alternative characterization, analogous to that of Theorem 1079, relates the syntactic with the corresponding semantic notions.

Theorem 1088 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically algebraizable if and only if it is algebraizable and* $\ddot{R}^{\mathcal{I}} Z^{\mathcal{I}}$*-fortified.*

(b) $\mathcal{I}$ *is syntactically antialgebraizable if and only if it is weakly algebraizable and* $R^{\mathcal{I}} \dot{Z}^{\mathcal{I}}$*-fortified.*

Proof:

(a) We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by definition, it is equivalential and system c-reflective and, moreover, it has a Leibniz binary reflexive core and an adequate system core. This happens if and only if, by definition, it is algebraizable and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified.

(b) Similarly, $\mathcal{I}$ is syntactically antialgebraizable if and only if, by definition, it is protoalgebraic and system c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary system core. This happens if and only if, by definition, it is weakly algebraizable and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified.

■

The properties defining syntactic (anti)algebraizability transfer from theory families/systems to filter families/systems on arbitrary algebraic systems. More precisely, we obtain the following analog of Theorem 1080.

Theorem 1089 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families, family extensional and system c-reflective.*

(b) $\mathcal{I}$ *is syntactically antialgebraizable if and only if it is* $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$*-fortified and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone on* $\mathcal{I}$*-filter families and system c-reflective.*

Proof: We prove only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by Theorem 1088, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and algebraizable if and only if, by Theorem 363, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter families, family extensional and system c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1081.

Theorem 1090 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is syntactically algebraizable if and only if it is* $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$*-fortified, stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

(b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified, stable and, for every* **F***-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism.

Proof:

(a) $\mathcal{I}$ is syntactically algebraizable if and only if, by Theorem 1088, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified and algebraizable if and only if, by Theorem 365 it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$-fortified, stable and, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions.

(b) $\mathcal{I}$ is syntactically antialgebraizable if and only if, by Theorem 1088, it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified and weakly algebraizable if and only if, by Theorem 298 it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$-fortified, stable and, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1082.

Theorem 1091 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on* **F***.*

(a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}}$ of transformations, with $I^\flat$ natural.*

(b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}}$ of transformations, with $\tau^\flat$ natural.*

Proof:

(a) Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Theorem 929, it is syntactically equivalential and, by Theorem 930, it is system truth equational. Thus, by Theorem 1087, it is syntactically algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically algebraizable. Then, by Theorem 1087, it is syntactically equivalential and system truth equational. Hence, by Theorem 923, it is syntactically weakly algebraizable. Now it follows by Theorem 927 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic equivalentiality and $\tau^\flat$ the system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $I^\flat$ natural.

(b) Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Then, by Theorem 929, it is syntactically protoalgebraic and, by Theorem 930, it is strongly system truth equational. Thus, by Theorem 1087, it is syntactically antialgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically antialgebraizable. Then, by Theorem 1087, it is syntactically protoalgebraic and strongly system truth equational. Hence, by Theorem 923, it is syntactically weakly algebraizable. Now it follows by Theorem 927 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a pair $(\tau^\flat, \overleftrightarrow{I}^\flat)$, where $I^\flat$ witnesses the syntactic protoalgebraicity and $\tau^\flat$ the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with $\tau^\flat$ natural.

■

The equivalence of the systemic skeleton with some algebraic π-structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, is sufficient to ensure syntactic system (anti)algebraizability. This constitutes an analog of Theorem 1083.

Theorem 1092 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically algebraizable if and only if it is stable and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $I^\flat$ *natural.*

(b) $\mathcal{I}$ *is syntactically antialgebraizable if and only if it is stable and its systemic skeleton is equivalent to an algebraic* π*-structure via a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, with* $\tau^\flat$ *natural.*

Proof:

(a) If $\mathcal{I}$ is syntactically algebraizable, then, by Theorem 1091, it is stable and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations with $I^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is stable and that its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $I^\flat$ natural. Then, by Proposition 929, it is syntactically equivalential and, by Theorem 930, it is system truth equational. Therefore, by Theorem 1087, it is syntactically algebraizable.

(b) If $\mathcal{I}$ is syntactically antialgebraizable, then, by Theorem 1091, it is stable and its systemic skeleton is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with $\tau^\flat$ natural. Suppose, conversely, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π-structure via a conjugate pair $(\tau^\flat, I^\flat)$ of transformations, with

$\tau^\flat$ natural. Then, by Proposition 929, it is syntactically protoalgebraic and, by Theorem 930, it is strongly system truth equational. Therefore, by Theorem 1087, it is syntactically antialgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1084, giving an alternative characterization of syntactically (anti)algebraizable π-institutions:

Theorem 1093 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is stable and there exists a transformational order isomorphism* $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q})$, *induced by a conjugate pair* $(\tau^\flat, I^\flat)$ *of transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure and* $I^\flat$ *is natural.*

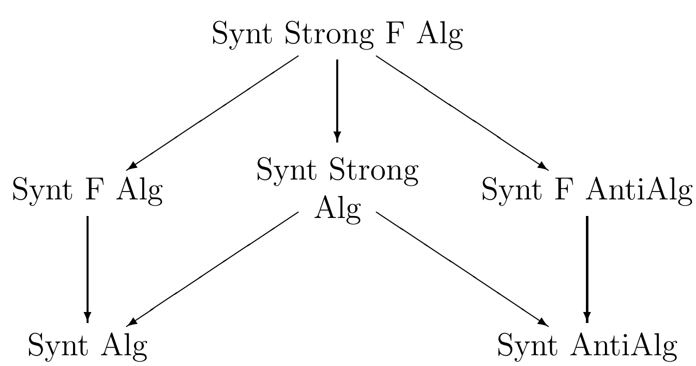
(b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is stable and there exists a transformational order isomorphism*

$$h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \to \mathbf{ThFam}(\mathcal{Q}),$$

induced by a conjugate pair $(\tau^\flat, I^\flat)$ *of transformations, where* $\mathcal{Q}$ *is an algebraic* π*-structure and* $\tau^\flat$ *is natural.*

Proof: The "only if" follows by Theorem 1092 and Theorem 893. The "if" is given by Theorem 901 and Theorem 1092. ■

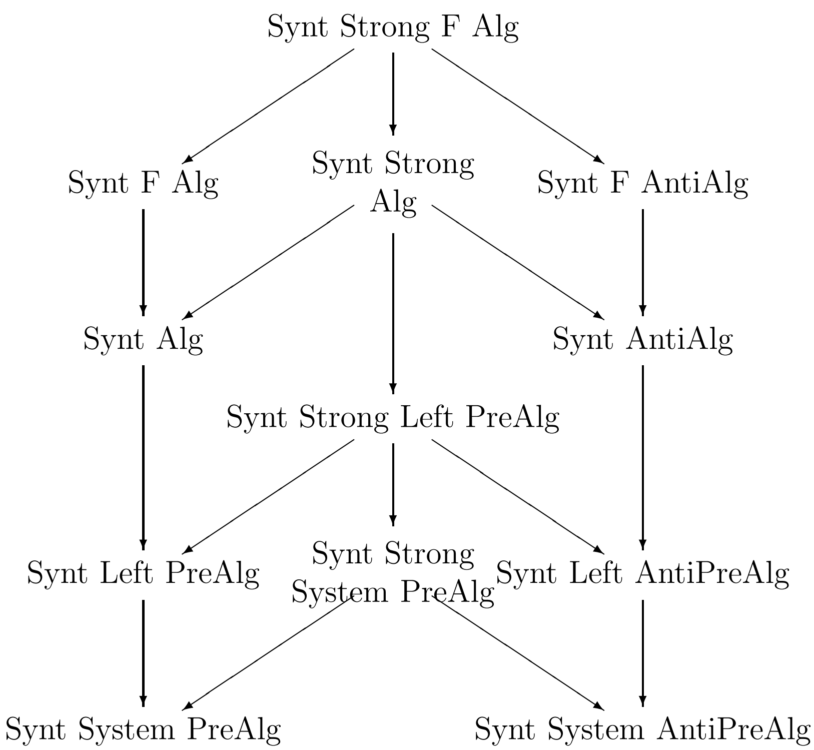
To close the chapter, we have some class separating work to do. First of all, since we have now described in detail the six classes of the syntactic algebraizability hierarchy, it is only appropriate to pause and look for examples that separate the family algebraizability classes, i.e., those in the top-most tier, from the algebraizability classes, that is those immediately below them. In other words, we are looking for examples that show that the vertical arrows in the accompanying diagram



represent, in fact, proper inclusions. We can do this all at once by exhibiting an example of a syntactically strongly algebraizable π-institution which is neither syntactically family algebraizable nor syntactically family antialgebraizable.

Example 1094 EXAMPLE NOT FOUND YET!

Last, since the syntactic algebraizability classes, shown in the bottom row of the preceding diagram, dominate the syntactic left prealgebraizability classes in the 12-class hierarchy, we also need examples to separate syntactically algebraizable from syntactically left prealgebraizable π-institutions, i.e., examples showing that the longish vertical arrows in the diagram



represent proper inclusions. Again, in a single strike, this can be accomplished by providing an example of a syntactically strongly left prealgebraizable π-institution which is neither syntactically algebraizable nor syntactically antialgebraizable.

Example 1095 EXAMPLE NOT FOUND YET!

Chapter 14

The Syntactic Leibniz Hierarchy: Basement I

14.1 Rough/Narrow Truth Equationality

In this section, we study *rough/narrow truth equationality*, the syntactic analog of rough c-reflectivity, which, recalling Corollary 482, coincides with narrow c-reflectivty. It has the same relation to truth equationality as rough c-reflectivity has to c-reflectivity. In other words, it mimics truth equationality, but it is applied only to theory families of a π-institution all of whose components are nonempty.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly** or **narrowly (family) truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.$$

Recall that, by Proposition 369, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\widetilde{T}) = \Omega(T)$. Thus, $\Omega(T)$ is compatible with $\widetilde{T}$ and, hence, the preceding definition makes sense. The collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ is referred to as a set of **witnessing equations** (of/for the rough/narrow truth equationality of $\mathcal{I}$).

Paralleling Proposition 816, we get the following alternative characterization.

Proposition 1096 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a collection of natural transformations in $N^\flat$, with a single distinguished argument. $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in \widetilde{T}_\Sigma \quad \textit{iff} \quad \tau_\Sigma^\flat[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is roughly truth equational and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}
\phi \in \widetilde{T}_\Sigma & \text{iff} & \phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{(Proposition 369 and compatibility)} \\
& \text{iff} & \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(rough truth equationality)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by definition)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(T).
\end{array}$$

Suppose, conversely, that the given condition holds. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}
\phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) & \text{iff} & \phi \in \widetilde{T}_\Sigma \quad \text{(Proposition 369 and compatibility)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(T) \quad \text{(by hypothesis)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \\
& \text{iff} & \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}. \quad \text{(definition)}
\end{array}$$

Therefore, $\mathcal{I}$ is roughly truth equational. ■

It is not difficult to see that an alternative way to express rough truth equationality is to assert the same condition that defines truth equationality, excluding, however, those theory families with at least one empty component.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall from Chapter 6 that we denote by $\mathrm{ThFam}^{\not\varnothing}(\mathcal{I})$ the collection of all theory families T of $\mathcal{I}$, such that $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}^\flat|$:

$$\mathrm{ThFam}^{\not\varnothing}(\mathcal{I}) = \{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma \neq \varnothing)\}.$$

Recall, also, that, if $\mathcal{I}$ has theorems, then $\mathrm{ThFam}^{\not\varnothing}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$. In particular, this is the case if $\mathcal{I}$ happens to be truth equational.

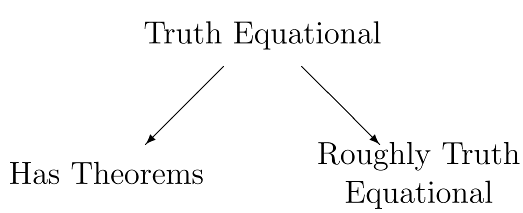
Proposition 1097 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a collection of natural transformations in $N^\flat$, with a single distinguished argument. $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThFam}^{\not\varnothing}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}^{\not\varnothing}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then $\widetilde{T} = T$, whence, by Proposition 1096, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$.

Suppose, conversely, that the displayed condition holds. Consider $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, since, by definition of $\widetilde{T}$, we have $\widetilde{T} \in \mathrm{ThFam}^{\not\varnothing}(\mathcal{I})$, we get, by hypothesis, $\phi \in \widetilde{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(\widetilde{T})$, whence, using Proposition 369, we conclude that $\phi \in \widetilde{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Therefore, $\mathcal{I}$ is roughly truth equational. ■

As a corollary, we obtain the following key relationship between rough truth equationality and truth equationality.



Corollary 1098 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if it is roughly truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$, and that it has theorems. Availability of theorems implies that $\mathrm{ThFam}^{\nrightarrow}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$. Thus, by Proposition 1097, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is truth equational, with the same witnessing equations $\tau^\flat$.

Assume, conversely, that $\mathcal{I}$ is truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, and, hence, a fortiori, for all $T \in \mathrm{ThFam}^{\nrightarrow}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Hence, again by Proposition 1097, $\mathcal{I}$ is roughly truth equational. Finally, by Theorem 829, $\mathcal{I}$ is family c-reflective and, by Proposition 243, it is family reflective and, hence, family injective. Thus, it must have theorems. ∎

Our next goal is to prove an analog of the characterization theorem, Theorem 838, of truth equationality in terms of the solubility of the Suszko core for rough truth equationality.

Rough truth equationality allows the following expression for all theory families with nonempty components, forming an analog of Proposition 828.

Proposition 1099 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is roughly truth equational, with witnessing equations* $\tau^\flat$*;*

(ii) For all $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\tau^\flat(\Omega(T)) = \widetilde{T}$*;*

(iii) For all $T \in \mathrm{ThFam}^{\nrightarrow}(\mathcal{I})$*,* $\tau^\flat(\Omega(T)) = T$*.*

Proof:

(i)⇒(ii) Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$, and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{llll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) & \text{(definition)} \\ & \text{iff} & \phi \in \widetilde{T}_\Sigma. & \text{(rough truth equationality)} \end{array}$$

(ii)⇒(iii) Suppose Condition (ii) holds. Let $T \in \mathrm{ThFam}^{\nrightarrow}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since $T \in \mathrm{ThFam}^{\nrightarrow}(\mathcal{I})$, $T = \widetilde{T}$, whence, by hypothesis, $T = \tau^\flat(\Omega(T))$.

(iii)⇒(i) If, conversely, for all $T \in \mathrm{ThFam}^{\nrightarrow}(\mathcal{I})$, $T = \tau^\flat(\Omega(T))$, then, by Proposition 1097, $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$.

∎

Recall from Chapter 6 that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly family c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}.$$

We are now able to show that rough truth equationality implies rough family c-reflectivity. This is an analog of Theorem 829.

Theorem 1100 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly truth equational, then it is roughly family c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{rcll} \bigcap_{T\in\mathcal{T}} \widetilde{T} & = & \bigcap_{T\in\mathcal{T}} \tau^\flat(\Omega(T)) & \text{(Proposition 1099)} \\ & = & \tau^\flat(\bigcap_{T\in\mathcal{T}} \Omega(T)) & \text{(set theory)} \\ & \leq & \tau^\flat(\Omega(T')) & \text{(hypothesis)} \\ & = & \widetilde{T}'. & \text{(Proposition 1099)} \end{array}$$

Thus, $\mathcal{I}$ is roughly family c-reflective. ∎

In the context of rough truth equationality, the notion paralleling the Suszko core is the *rough Suszko core*, a modification of the original which is defined, naturally enough and as, perhaps, was to be expected, by circumventing theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **rough Suszko core** $S^{\mathcal{I}\not\,}$ of $\mathcal{I}$ is the collection

$$S^{\mathcal{I}\not\,} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[\widetilde{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(\widetilde{T}))\}.$$

As before, an alternative characterization avoids $\widetilde{\ }$ at the expense of restricting quantification over $\mathrm{ThFam}^{\not\,}(\mathcal{I})$.

Proposition 1101 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$S^{\mathcal{I}\not\,} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}^{\not\,}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T))\}.$$

Proof: Inside this proof we set

$$M^{\mathcal{I}} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}^{\not\,}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T))\}.$$

Our goal is to show that $S^{\mathcal{I}\not\,} = M^{\mathcal{I}}$. Suppose, first, that $\sigma^\flat \in S^{\mathcal{I}\not\,}$ and let $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Since $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, we get $\widetilde{T} = T$. Hence, by hypothesis, $\phi \in \widetilde{T}_\Sigma$. Thus, since $\sigma^\flat \in S^{\mathcal{I}\not\,}$, we get

$$\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(\widetilde{T}) = \widetilde{\Omega}^{\mathcal{I}}(T).$$

This proves that $\sigma^\flat \in M^{\mathcal{I}}$. Assume, conversely, that $\sigma^\flat \in M^{\mathcal{I}}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$. Since $\widetilde{T} \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$ and $\sigma^\flat \in M^{\mathcal{I}}$, we get $\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(\widetilde{T})$, whence, $\sigma^\flat \in S^{\mathcal{I}\not\,}$. This proves that $S^{\mathcal{I}\not\,} = M^{\mathcal{I}}$. ∎

From the definition, it is not difficult to see that any theory family T with all its components nonempty is always included in $S^{\mathcal{I}\not\,}(\Omega(T))$. This forms an analog in the rough context of Proposition 832.

Proposition 1102 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$*,*

$$T \leq S^{\mathcal{I}\lightning}(\Omega(T)).$$

Proof: Suppose $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$, and $\sigma^\flat \in S^{\mathcal{I}\lightning}$. Then, by Proposition 1101, $\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)$. Hence, $S^{\mathcal{I}\lightning}_\Sigma[\phi] \leq \Omega(T)$. By definition, then, $\phi \in S^{\mathcal{I}\lightning}_\Sigma(\Omega(T))$. Since Σ and $\phi \in T_\Sigma$ were arbitrary, we conclude that $T \leq S^{\mathcal{I}\lightning}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we say that the rough Suszko core of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The rough Suszko core $S^{\mathcal{I}\lightning}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$S^{\mathcal{I}\lightning}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

An alternative way to express solubility is to again expand the view to all theory families at the balancing expense of adding rough equivalence representatives.

Lemma 1103 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $S^{\mathcal{I}\lightning}$ *is soluble if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\widetilde{T} = S^{\mathcal{I}\lightning}(\Omega(T)).$$

Proof: $S^{\mathcal{I}\lightning}$ is soluble if and only if, by definition and Proposition 1102, for all $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $T = S^{\mathcal{I}\lightning}(\Omega(T))$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T} = S^{\mathcal{I}\lightning}(\Omega(\widetilde{T}))$, if and only if, by Proposition 369, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T} = S^{\mathcal{I}\lightning}(\Omega(T))$. ■

As was the case with truth equationality (see Lemma 835), it turns out that, if a given π-institution is roughly truth equational, then any collection of witnessing equations must be included in the rough Suszko core of $\mathcal{I}$. Differently put, in case of rough truth equationality, the rough Suszko core is a candidate for the largest set of witnessing equations.

Lemma 1104 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly truth equational, with witnessing equations* $\tau^\flat$*, then* $\tau^\flat \subseteq S^{\mathcal{I}\lightning}$*.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Then, for all $T \leq T' \in \mathrm{ThFam}(\mathcal{I})$, we have $T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$ and $\phi \in T'_\Sigma$. Thus, by rough truth equationality, and Proposition 1097, $\tau^\flat_\Sigma[\phi] \leq \Omega(T')$. Since T', with the postulated properties was arbitrary,

$$\tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T') : T \leq T'\} = \widetilde{\Omega}^{\mathcal{I}}(T).$$

We conclude, using Proposition 1101, that $\tau^\flat \subseteq S^{\mathcal{I}\nleq}$. ∎

We are now ready to prove the equivalence between rough truth equationality and the solubility of the rough Suszko core. In the next theorem, we show that truth equationality implies the solubility of the rough Suszko core. This forms a rough analog of Theorem 836.

Theorem 1105 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly truth equational, then* $S^{\mathcal{I}\nleq}$ *is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $S^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)$. Then, by rough truth equationality and Lemma 1104, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Again, using rough truth equationality and Proposition 1097, we conclude that $\phi \in T_\Sigma$. This shows that $S^{\mathcal{I}\nleq}$ is soluble. ∎

Conversely, in a rough analog of Theorem 837, we show that the solubility of the rough Suszko core of a π-institution implies rough truth equationality.

Theorem 1106 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $S^{\mathcal{I}\nleq}$ *is soluble, then* $\mathcal{I}$ *is roughly truth equational, with witnessing equations* $S^{\mathcal{I}\nleq}$*.*

Proof: Assume $S^{\mathcal{I}\nleq}$ is soluble and let $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. By Proposition 1097, it suffices to show that

$$\phi \in T_\Sigma \quad \text{iff} \quad S^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T).$$

If $\phi \in T_\Sigma$, then, by Proposition 1102, $\phi \in S^{\mathcal{I}\nleq}_\Sigma(\Omega(T))$, i.e., $S^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the solubility of $S^{\mathcal{I}\nleq}$. Thus, $\mathcal{I}$ is roughly truth equational, with witnessing equations $S^{\mathcal{I}\nleq}$. ∎

Theorems 1105 and 1106 provide the first characterization of rough truth equationality in terms of the solubility of the rough Suszko core. This parallels Theorem 838, which asserted a similar characterization for truth equationality in terms of the solubility of the Suszko core of a π-institution.

$$\mathcal{I} \text{ Roughly Truth Equational} \longleftrightarrow S^{\mathcal{I}\nleq} \text{ Soluble}$$

Theorem 1107 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly truth equational if and only if* $S^{\mathcal{I}\nleq}$ *is soluble.*

Proof: The "if" is by Theorem 1106. The "only if" by Theorem 1105. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the rough Suszko core $S^{\mathcal{I}\nmid}$ of $\mathcal{I}$ **roughly defines theory families** if, for al $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$T = S^{\mathcal{I}\nmid}(\Omega(T)).$$

Another characterization of rough truth equationality, along the lines of Theorem 840, asserts that it is equivalent to the rough definability of the theory families by the rough Suszko core.

$$\begin{array}{l}\mathcal{I} \text{ Roughly Truth Equational} \\ \qquad\qquad \longleftrightarrow\ S^{\mathcal{I}\nmid} \text{ Roughly Defines Theory Families}\end{array}$$

Theorem 1108 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational if and only if $S^{\mathcal{I}\nmid}$ roughly defines theory families in $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational. By Theorem 1107, $S^{\mathcal{I}\nmid}$ is soluble. Hence, by definition, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $S^{\mathcal{I}\nmid}(\Omega(T)) \le T$. Since, by Proposition 1102, the reverse always holds, we get, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $T = S^{\mathcal{I}\nmid}(\Omega(T))$. Thus, $S^{\mathcal{I}\nmid}$ roughly defines theory families in $\mathcal{I}$. Conversely, if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $T = S^{\mathcal{I}\nmid}(\Omega(T))$, then $S^{\mathcal{I}\nmid}$ is soluble and, therefore, by Theorem 1107, $\mathcal{I}$ is roughly truth equational. ■

We embark, next, in the process of establishing a connection between rough truth equationality and rough family c-reflectivity by means of the Suszko operator. We start by showing that, in every π-institution $\mathcal{I}$, $T \le S^{\mathcal{I}\nmid}(\Omega(T))$ actually holds for every theory family of $\mathcal{I}$ and not only for those theory families in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$.

Lemma 1109 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{implies} \quad S^{\mathcal{I}\nmid}_\Sigma[\phi] \le \Omega(T).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{llll}\phi \in T_\Sigma & \text{implies} & \phi \in \widetilde{T}_\Sigma & (T \le \widetilde{T}) \\ & \text{implies} & S^{\mathcal{I}\nmid}_\Sigma[\phi] \le \widetilde{\Omega}^{\mathcal{I}}(\widetilde{T}) & (\text{definition of } S^{\mathcal{I}\nmid}) \\ & \text{implies} & S^{\mathcal{I}\nmid}_\Sigma[\phi] \le \Omega(\widetilde{T}) & (\widetilde{\Omega}^{\mathcal{I}} \le \Omega) \\ & \text{iff} & S^{\mathcal{I}\nmid}_\Sigma[\phi] \le \Omega(T). & (\text{Proposition 369})\end{array}$$

This establishes the displayed implication. ■

In the sequel, in dealing with intersections of Leibniz congruence systems, as, e.g., when computing a Suszko congruence system, we shall have the need to switch between arbitrary collections of theory families and collections of theory families having all components nonempty. In all those situations, the following straightforward technical lemma is quite useful.

Lemma 1110 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $X \in \mathrm{SenFam}(\mathbf{F})$ *and* $\theta \in \mathrm{SenFam}(\mathbf{F}^2)$*.*

(a) $\{\Omega(T) : X \leq T \in \mathrm{ThFam}(\mathcal{I})\} = \{\Omega(T) : X \leq T \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})\}$*;*

(b) $\{\Omega(T) : X \leq T \in \mathrm{ThFam}(\mathcal{I})$ *and* $\theta \leq \Omega(T)\} = \{\Omega(T) : X \leq T \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})$ *and* $\theta \leq \Omega(T)\}$*.*

Proof:

(a) Since $\mathrm{ThFam}^{\nparallel}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, it is clear that

$$\{\Omega(T) : X \leq T \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})\} \subseteq \{\Omega(T) : X \leq T \in \mathrm{ThFam}(\mathcal{I})\}.$$

To prove the reverse inclusion, let $T \in \mathrm{ThFam}(\mathcal{I})$, such that $X \leq T$. Consider $\widetilde{T} \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})$. We get $X \leq T \leq \widetilde{T}$ and, moreover, by Proposition 369, $\Omega(\widetilde{T}) = \Omega(T)$. This proves that $\{\Omega(T) : X \leq T \in \mathrm{ThFam}(\mathcal{I})\} \subseteq \{\Omega(T) : X \leq T \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})\}$.

(b) As in Part (a), the right-to-left inclusion is obvious. For the reverse, consider $T \in \mathrm{ThFam}(\mathcal{I})$, such that $X \leq T$ and $\theta \leq \Omega(T)$. Then, again, $\widetilde{T} \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})$, such that both $X \leq T \leq \widetilde{T}$ and $\theta \leq \Omega(T) = \Omega(\widetilde{T})$. This shows that the left-to-right inclusion also holds.

■

As a corollary, we obtain, for instance, an alternative expression for the Suszko congruence system associated with a given theory family of a π-institution $\mathcal{I}$.

Corollary 1111 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\widetilde{\Omega}^{\mathcal{I}}(T) = \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})\}.$$

Proof: Immediate by the definition of $\widetilde{\Omega}^{\mathcal{I}}$ and Lemma 1110. ■

Based on Lemma 1109, we may show that, for every theory family T, $T \leq S^{\mathcal{I}\nparallel}(\widetilde{\Omega}^{\mathcal{I}}(T))$.

Proposition 1112 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi \in T_\Sigma \quad \text{implies} \quad S^{\mathcal{I}\nparallel}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rll}\phi \in T_\Sigma & \text{implies} & \phi \in T'_\Sigma, \text{ for all } T \le T' \in \mathrm{ThFam}(\mathcal{I})\\ & \text{implies} & S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T'), \text{ for all } T \le T' \in \mathrm{ThFam}(\mathcal{I})\\ & & \quad\text{(by Lemma 1109)}\\ & \text{iff} & S^{\mathcal{I}\natural}_\Sigma[\phi] \le \widetilde{\Omega}^{\mathcal{I}}(T). \quad \text{(definition of } \widetilde{\Omega}^{\mathcal{I}})\end{array}$$

■

In analogy with the case of rough truth equationality, we may introduce the notion of *adequacy* of the rough Suszko core, which will help in characterizing the relationship between rough truth equationality and rough c-reflectivity. The following proposition, a rough analog of Proposition 841, partially justifies the notion of adequacy that will follow.

Proposition 1113 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcap\{\Omega(T) : S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)\} \le \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{rll}\phi \in T_\Sigma & \text{implies} & S^{\mathcal{I}\natural}_\Sigma[\phi] \le \widetilde{\Omega}^{\mathcal{I}}(T) \quad \text{(Proposition 1112)}\\ & \text{implies} & S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T). \quad (\widetilde{\Omega}^{\mathcal{I}} \le \Omega)\end{array}$$

Hence,

$$\begin{array}{rcl}\bigcap\{\Omega(T) : S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)\} & \le & \bigcap\{\Omega(T) : S^{\mathcal{I}\natural}_\Sigma[\phi] \le \widetilde{\Omega}^{\mathcal{I}}(T)\}\\ & \le & \bigcap\{\Omega(T) : \phi \in T_\Sigma\}\\ & = & \widetilde{\Omega}^{\mathcal{I}}(C(\phi)).\end{array}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1113 holds, then we say that the rough Suszko core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that the rough Suszko core $S^{\mathcal{I}\natural}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \le \bigcap\{\Omega(T) : S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)\}.$$

We can show right away that solubility of the rough Suszko core implies adequacy.

Corollary 1114 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $S^{\mathcal{I}\natural}$ *is soluble, then it is adequate.*

Proof: Suppose $S^{\mathcal{I}\natural}$ is soluble and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ & & \text{(definition of } \widetilde{\Omega}^{\mathcal{I}}) \\ & = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\natural}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ & & \text{(Lemma 1110)} \\ & = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\natural}(\mathcal{I}) \text{ and } S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)\} \\ & & \text{(solubility of } S^{\mathcal{I}\natural}) \\ & = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)\}. \\ & & \text{(Lemma 1110)}\end{array}$$

Thus, $S^{\mathcal{I}\natural}$ is adequate. ■

We prove, next, the converse of Corollary 1114, under the additional assumption that the π-institution $\mathcal{I}$ under consideration is roughly family c-reflective. This constitutes an analog of Proposition 846.

Proposition 1115 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a roughly family c-reflective π-institution based on $\mathbf{F}$. If $S^{\mathcal{I}\natural}$ is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly family c-reflective and $S^{\mathcal{I}\natural}$ is adequate. Let $T \in \mathrm{ThFam}^{\natural}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $S^{\mathcal{I}\natural}_\Sigma[\phi] \le \Omega(T)$. By the adequacy of $S^{\mathcal{I}\natural}$, we get that $\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \le \Omega(T)$. By Lemma 1110,

$$\bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\natural}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \le \Omega(T).$$

By rough family c-reflectivity, $\bigcap\{T \in \mathrm{ThFam}^{\natural}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \le T$. Hence, $\phi \in T_\Sigma$. We conclude that $S^{\mathcal{I}\natural}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating rough truth equationality with rough family c-reflectivity, an analog of Theorem 847, which characterized truth equationality in terms of family c-reflectivity and the adequacy of the Suszko core.

Rough Truth Equationality	=	$S^{\mathcal{I}\natural}$ Soluble
	=	$S^{\mathcal{I}\natural}$ Roughly Defines Theory Families
	=	Rough Family c-Reflectivity
		+ $S^{\mathcal{I}\natural}$ Adequate

Theorem 1116 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational if and only if it is roughly family c-reflective and has an adequate rough Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly truth equational. By Theorem 1100, it is roughly family c-reflective. By Theorem 1105, its rough Suszko core is soluble. Thus, by Corollary 1114, its rough Suszko core is also adequate.

Assume, conversely, that $\mathcal{I}$ is roughly family c-reflective and has an adequate rough Suszko core. Then, by Proposition 1115, its rough Suszko core is also soluble. Hence, by Theorem 1107, $\mathcal{I}$ is roughly truth equational. ■

Even though Theorem 847 formed the inspiration for the formulation of Theorem 1116, we show that it can be obtained as a corollary of the latter. This also exhibits the close connection between the two results which should have been anticipated, given the fact that the work done here is intended to mimic the former, while circumventing potential obstacles due to the absence of theorems.

Corollary 1117 (Theorem 847) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is truth equational if and only if it is family c-reflective and has an adequate Suszko core.*

Proof: $\mathcal{I}$ is truth equational if and only if, by Corollary 1098, it is roughly truth equational and has theorems if and only if, by Theorem 1116, it is roughly family c-reflective, has theorems and has an adequate rough Suszko core if and only if, by Theorem 468 and the definitions of the Suszko core, the rough Suszko core and their adequacy properties, $\mathcal{I}$ is family c-reflective and its Suszko core is adequate. ■

We close the section by looking at a couple of results that may be perceived either as alternative characterizations of rough truth equationality, involving arbitrary $\mathbf{F}$-algebraic systems, or as transfer theorems.

Theorem 1118 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in \widetilde{T}_\Sigma \quad \textit{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$. This yields immediately that $\mathcal{I}$ is roughly truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rll}
\alpha_\Sigma(\phi) \in \widetilde{T}_{F(\Sigma)} & \text{iff} & \phi \in \alpha^{-1}_\Sigma(\widetilde{T}_{F(\Sigma)}) \\
& \text{iff} & \phi \in \widetilde{\alpha^{-1}_\Sigma(T_{F(\Sigma)})} \quad \text{(Theorem 377)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(\alpha^{-1}(T)) \quad \text{(hypothesis)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\
& \text{iff} & \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 95)}
\end{array}$$

Hence, taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that the displayed condition holds. ∎

In analogy with the notation $\mathrm{ThFam}^{\nmid}(\mathcal{I})$, we introduce the following for filter families over arbitrary $\mathbf{F}$-algebraic systems all of whose components are nonempty.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, an $\mathbf{F}$-algebraic system. Define $\mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$ to be the collection of all $\mathcal{I}$-filter families T on $\mathcal{A}$, such that $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}|$:

$$\mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A}) = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : (\forall \Sigma \in |\mathbf{Sign}|)(T_\Sigma \neq \varnothing)\}.$$

We now get immediately the following corollary.

Corollary 1119 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational, with witnessing equations $\tau^\flat$, if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, all $T \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: Suppose that $\mathcal{I}$ is roughly truth equational. Then, if $\mathcal{A}$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, we get

$$\begin{array}{rcll} T & = & \widetilde{T} & (T \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})) \\ & = & \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T)). & \text{(Theorem 1118)} \end{array}$$

Suppose, conversely, that the displayed condition holds. Then, if $\mathcal{A}$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get, taking into account that $\widetilde{T} \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$,

$$\begin{array}{rcll} \widetilde{T} & = & \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(\widetilde{T})) & \text{(hypothesis)} \\ & = & \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T)). & \text{(Proposition 369)} \end{array}$$

This establishes the claimed equivalence. ∎

14.2 Rough Left Truth Equationality

We now turn to *rough left truth equationality*. As the terminology suggests:

- It is in the same relation to rough left c-reflectivity as rough truth equationality is to rough c-reflectivity;
- It is in the same relation to rough truth equationality as left truth equationality is to truth equationality.

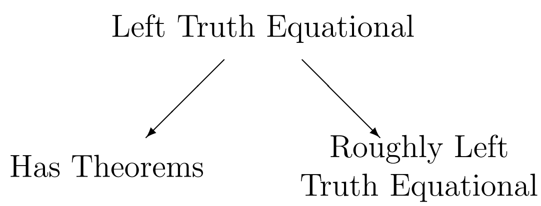
Roughly speaking (in both senses), rough left truth equationality is defined analogously to left truth equationality, but it is applied to rough representatives of theory families so as to avoid theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly left truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \widetilde{\overleftarrow{T}}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

The collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ is referred to as a set of **witnessing equations** (of/for the rough left truth equationality of $\mathcal{I}$).

The following relationship between rough left truth equationality and left truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1098, holds.



Proposition 1120 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is roughly left truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\tau^\flat$, and that it has theorems. Availability of theorems implies that $\mathrm{ThFam}^\lightning(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$. Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is left truth equational, with the same witnessing equations $\tau^\flat$.

Assume, conversely, that $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ iff $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems, since, otherwise, given that $\Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat)$, we would get $\mathrm{SEN}^\flat = \overleftarrow{\mathrm{SEN}^\flat} = \overleftarrow{\overline{\varnothing}} = \overline{\varnothing}$, a contradiction. Moreover, due to the availability of theorems, we get, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ if and only if $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is roughly left truth equational. ∎

Our next goal is to prove an analog of the characterization theorem, Theorem 860, of left truth equationality in terms of the left solubility of the left Suszko core for rough left truth equationality.

Rough left truth equationality allows an expression for $\widetilde{\overleftarrow{T}}$, for all theory families T, in terms of the Leibniz congruence system of T. The following proposition forms an analog of Proposition 1099.

Proposition 1121 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly left truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\widetilde{\overleftarrow{T}} = \tau^\flat(\Omega(T))$.

Proof: $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ iff $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, if and only if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\overleftarrow{T}} = \tau^\flat(\Omega(T))$. ■

Recall from Chapter 6 that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly left c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}.$$

We are now able to show that rough left truth equationality implies rough left c-reflectivity. This is an analog of Theorem 1100.

Theorem 1122 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly left truth equational, then it is roughly left c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{rcll}
\bigcap_{T \in \mathcal{T}} \widetilde{\overleftarrow{T}} & = & \bigcap_{T \in \mathcal{T}} \tau^\flat(\Omega(T)) & \text{(Proposition 1121)} \\
 & = & \tau^\flat(\bigcap_{T \in \mathcal{T}} \Omega(T)) & \text{(set theory)} \\
 & \leq & \tau^\flat(\Omega(T')) & \text{(hypothesis)} \\
 & = & \widetilde{\overleftarrow{T'}}. & \text{(Proposition 1121)}
\end{array}$$

Thus, $\mathcal{I}$ is roughly left c-reflective. ■

In the context of rough left truth equationality, the notion paralleling the left Suszko core is the *rough left Suszko core*, a modification of the original, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **rough left Suszko core** $\widetilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is the collection

$$\begin{array}{rcl}
\widetilde{L}^{\mathcal{I}} & = & \{\sigma^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma)) \\
 & & \quad (\sigma^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T) : \phi \in \widetilde{\overleftarrow{T}}_\Sigma\})\}.
\end{array}$$

From the definition, it is not difficult to see that, for any theory family T, $\widetilde{\overleftarrow{T}}$ is always included in $\widetilde{L}^{\mathcal{I}}(\Omega(T))$. This forms an analog in the rough left context of Proposition 1102.

Proposition 1123 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\overleftarrow{T}} \leq \widetilde{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: Suppose $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$, and $\sigma^\flat \in \widetilde{L}^{\mathcal{I}}$. Then, by the definition of $\widetilde{L}^{\mathcal{I}}$, $\sigma^\flat_\Sigma[\phi] \leq \Omega(T)$. Hence, $\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Thus, by definition of $\widetilde{L}^{\mathcal{I}}(\Omega(T))$, $\phi \in \widetilde{L}^{\mathcal{I}}_\Sigma(\Omega(T))$. Since Σ and $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ were arbitrary, we conclude that $\widetilde{\overleftarrow{T}} \leq \widetilde{L}^{\mathcal{I}}(\Omega(T))$. ∎

The reverse inclusion may or may not hold. If it does, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we say that the rough left Suszko core of $\mathcal{I}$ is *left soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The rough left Suszko core $\widetilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is said to be **left soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \widetilde{\overleftarrow{T}}_\Sigma.$$

As was the case with rough truth equationality (see Lemma 1104), it turns out that, if a given π-institution is roughly left truth equational, then any collection of witnessing equations must be included in the rough left Suszko core of $\mathcal{I}$. In other words, in case of rough left truth equationality, the rough left Suszko core forms a candidate for the largest collection of witnessing equations.

Lemma 1124 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is roughly left truth equational, with witnessing equations* $\tau^\flat$, *then* $\tau^\flat \subseteq \widetilde{L}^{\mathcal{I}}$.

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$. Then, by rough left truth equationality, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Since T was arbitrary,

$$\tau^\flat_\Sigma[\phi] \leq \bigcap \{\Omega(T) : \phi \in \widetilde{\overleftarrow{T}}_\Sigma\}.$$

Hence, since $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$ were arbitrary, we conclude that $\tau^\flat \subseteq \widetilde{L}^{\mathcal{I}}$. ∎

We are now ready to prove the equivalence between rough left truth equationality and the left solubility of the rough left Suszko core. In the next theorem, we show that rough left truth equationality implies the left solubility of the rough left Suszko core. This forms an analog of Theorem 1105.

Theorem 1125 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly left truth equational, then* $\widetilde{L}^{\mathcal{I}}$ *is left soluble.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by rough left truth equationality and Lemma 1124, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Again, using rough left truth equationality, we conclude that $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$. This shows that $\widetilde{L}^{\mathcal{I}}$ is left soluble. ■

Conversely, in an analog of Theorem 1106, we show that the left solubility of the rough left Suszko core of a π-institution implies rough left truth equationality.

Theorem 1126 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\widetilde{L}^{\mathcal{I}}$ *is left soluble, then* $\mathcal{I}$ *is roughly left truth equational, with witnessing equations* $\widetilde{L}^{\mathcal{I}}$*.*

Proof: Assume $\widetilde{L}^{\mathcal{I}}$ is left soluble and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We must show that

$$\phi \in \overleftarrow{\widetilde{T}}_\Sigma \quad \text{iff} \quad \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

If $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$, then, by Proposition **??**, $\phi \in \widetilde{L}^{\mathcal{I}}_\Sigma(\Omega(T))$, i.e., $\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated left solubility of $\widetilde{L}^{\mathcal{I}}$. Thus, $\mathcal{I}$ is indeed roughly left truth equational, with witnessing equations $\widetilde{L}^{\mathcal{I}}$. ■

Theorems 1125 and 1126 provide the first characterization of rough left truth equationality in terms of the left solubility of the rough left Suszko core. This parallels Theorem 1107, which asserted a similar characterization for rough truth equationality in terms of the solubility of the rough Suszko core of a π-institution.

$$\mathcal{I} \text{ Roughly Left Truth Equational } \longleftrightarrow \widetilde{L}^{\mathcal{I}} \text{ Left Soluble}$$

Theorem 1127 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly left truth equational if and only if* $\widetilde{L}^{\mathcal{I}}$ *is left soluble.*

Proof: The "if" is by Theorem 1126. The "only if" by Theorem 1125. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the rough left Suszko core $\widetilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ **roughly defines theory families up to arrow** if, for al $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\overleftarrow{\widetilde{T}} = \widetilde{L}^{\mathcal{I}}(\Omega(T)).$$

Another characterization of rough left truth equationality, along the lines of Theorem 1108, asserts that it is equivalent to the rough definability up to arrow of the theory families by the rough left Suszko core.

$$\mathcal{I} \text{ Roughly Left Truth Equational} \\ \longleftrightarrow \widetilde{L}^{\mathcal{I}} \text{ Roughly Defines Theory Families Up to Arrow}$$

Theorem 1128 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly left truth equational if and only if* $\widetilde{L}^{\mathcal{I}}$ *roughly defines theory families in* $\mathcal{I}$ *up to arrow.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational. By Theorem 1125, $\widetilde{L}^{\mathcal{I}}$ is left soluble. Hence, by definition, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{L}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\overleftarrow{T}}$. Since, by Proposition 1123, the reverse always holds, we get, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{\overleftarrow{T}} = \widetilde{L}^{\mathcal{I}}(\Omega(T))$. Thus, $\widetilde{L}^{\mathcal{I}}$ roughly defines theory families in $\mathcal{I}$ up to arrow. Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{\overleftarrow{T}} = \widetilde{L}^{\mathcal{I}}(\Omega(T))$, then $\widetilde{L}^{\mathcal{I}}$ is left soluble and, therefore, by Theorem 1126, $\mathcal{I}$ is roughly left truth equational. ■

We establish, next, a connection between rough left truth equationality and rough left c-reflectivity by means of the rough left Suszko core. To help us is this task, in analogy with the case of rough truth equationality, we introduce the notion of *left adequacy* of the rough left Suszko core. The following proposition, a "left" analog of Proposition 1113, motivates and, in a sense, justifies, the notion of left adequacy that will follow. Its role parallels that of Proposition 1113 in motivating the definition of adequacy of the rough Suszko core.

Proposition 1129 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcap\{\Omega(T) : \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \leq \bigcap\{\Omega(T) : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\}.$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\phi \in \overleftarrow{\overleftarrow{T}}_\Sigma \quad \text{implies} \quad \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). \quad (\text{Definition of } \widetilde{L}^{\mathcal{I}})$$

Hence,

$$\bigcap\{\Omega(T) : \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\} \quad \leq \quad \bigcap\{\Omega(T) : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\}.$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1129 holds, then we say that the rough left Suszko core of $\mathcal{I}$ is *left adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the rough left Suszko core $\widetilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcap\{\Omega(T) : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\} \le \bigcap\{\Omega(T) : \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}.$$

We can show, in analogy with Corollary 1114, that the left solubility of the rough left Suszko core implies left adequacy.

Corollary 1130 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\widetilde{L}^{\mathcal{I}}$ is left soluble, then it is left adequate.*

Proof: Suppose $\widetilde{L}^{\mathcal{I}}$ is left soluble and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, by left solubility and Proposition 1123, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\phi \in \overleftarrow{\overleftarrow{T}}_\Sigma$ if and only if $\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)$. Therefore,

$$\bigcap\{\Omega(T) : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\} \quad = \quad \bigcap\{\Omega(T) : \widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)\}.$$

Thus, $\widetilde{L}^{\mathcal{I}}$ is left adequate. ■

We prove, next, the converse of Corollary 1130, under the additional assumption that the π-institution $\mathcal{I}$ under consideration is roughly left c-reflective. This constitutes an analog of Proposition 1115.

Proposition 1131 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a roughly left c-reflective π-institution based on $\mathbf{F}$. If $\widetilde{L}^{\mathcal{I}}$ is left adequate, then it is left soluble.*

Proof: Suppose $\mathcal{I}$ is roughly left c-reflective and $\widetilde{L}^{\mathcal{I}}$ is left adequate. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\widetilde{L}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)$. By the postulated left adequacy of $\widetilde{L}^{\mathcal{I}}$, we get that $\bigcap\{\Omega(T) : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\} \le \Omega(T)$. By rough left truth equationality, $\bigcap\{\overleftarrow{\overleftarrow{T}} : \phi \in \overleftarrow{\overleftarrow{T}}_\Sigma\} \le \overleftarrow{\overleftarrow{T}}$. Therefore, $\phi \in \overleftarrow{\overleftarrow{T}}_\Sigma$. We conclude that $\widetilde{L}^{\mathcal{I}}$ is left soluble. ■

We are now in a position to prove the main characterization theorem relating rough left truth equationality with rough left c-reflectivity, an analog of Theorem 1116, which characterized rough truth equationality in terms of rough family c-reflectivity and the adequacy of the rough Suszko core.

Rough Left Truth Equationality	=	$\widetilde{L}^{\mathcal{I}}$ Left Soluble
	=	$\widetilde{L}^{\mathcal{I}}$ Roughly Defines Theory Families Up to Arrow
	=	Rough Left c-Reflectivity + $\widetilde{L}^{\mathcal{I}}$ Left Adequate

Theorem 1132 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly left truth equational if and only if it is roughly left c-reflective and has a left adequate rough left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left truth equational. By Theorem 1122, it is roughly left c-reflective. By Theorem 1125, its rough left Suszko core is left soluble. Thus, by Corollary 1130, its rough left Suszko core is also left adequate.

Assume, conversely, that $\mathcal{I}$ is roughly left c-reflective and has a left adequate rough left Suszko core. Then, by Proposition 1131, its rough left Suszko core is also left soluble. Hence, by Theorem 1126, $\mathcal{I}$ is roughly left truth equational. ∎

Based on Proposition 1120 and Theorem 468, it is not difficult to show, in an analog of Corollary 1117, that the characterization theorem, Theorem 870, of left truth equationality in terms of left c-reflectivity and the left adequacy of the left Suszko core, can be inferred from Theorem 1132.

Corollary 1133 (Theorem 870) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: $\mathcal{I}$ is left truth equational if and only if, by Proposition 1120, it is roughly left truth equational and has theorems, if and only if, by Theorem 1132, it is roughly left c-reflective, with a left adequate rough left Suszko core and has theorems, if and only if, by Theorem 468 and the definitions of left Suszko core and rough left Suszko core, it is left c-reflective and has a left adequate left Suszko core. ∎

We close the section by looking at a result, an analog of Theorem 1118, which may be perceived either as an alternative characterization of rough left truth equationality, involving arbitrary $\mathbf{F}$-algebraic systems, or as a transfer theorem.

Theorem 1134 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly left truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in \overset{\approx}{\overleftarrow{T}}_\Sigma \quad \text{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is roughly left truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly left truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rll}
\alpha_\Sigma(\phi) \in \widetilde{\widetilde{\overleftarrow{T}}}_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(\underset{\sim}{\widetilde{\overleftarrow{T}}_{F(\Sigma)}}) \\
& \text{iff} & \phi \in \alpha_\Sigma^{-1}(\underset{\sim}{\overleftarrow{T}_{F(\Sigma)}}) \quad \text{(Theorem 377)} \\
& \text{iff} & \phi \in \overleftarrow{\alpha_\Sigma^{-1}(T_{F(\Sigma)})} \quad \text{(Lemma 6)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(\alpha^{-1}(T)) \quad \text{(hypothesis)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\
& \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 95)}
\end{array}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.3 Narrow Left Truth Equationality

We now turn to *narrow left truth equationality*. As the terminology suggests:

- It is in the same relation to narrow left c-reflectivity as rough left truth equationality is to rough left c-reflectivity;
- It is in the same relation to rough/narrow truth equationality as left truth equationality is to truth equationality.

In a nutshell, narrow left truth equationality is defined analogously to left truth equationality, but care is taken to bypass theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **narrowly left truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThFam}^{\nsubseteq}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^\flat[\phi] \leq \Omega(T).$$

The collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ is referred to as a set of **witnessing equations** (of/for the narrow left truth equationality of $\mathcal{I}$).

An alternative characterization quantifies the relevant condition over all theory families, but it does so at the expense of using the rough operator on one side (and implicitly also on the other).

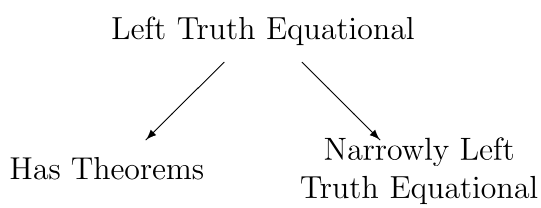
Lemma 1135 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly left truth equational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi \in \overleftarrow{\widetilde{T}}_\Sigma \quad \textit{iff} \quad \tau_\Sigma^\flat[\phi] \leq \Omega(T).$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$, and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, since $\widetilde{T} \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, we get, by hypothesis, $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \le \Omega(\widetilde{T})$. Therefore, by Proposition 369, $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \le \Omega(T)$.

Suppose, conversely, that the displayed equivalence holds and let $T \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$. Then $\widetilde{T} = T$. Thus, by hypothesis, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \le \Omega(T)$. Therefore, $\mathcal{I}$ is narrowly left truth equational. ■

The following relationship between rough left truth equationality and left truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1098, holds. Note that narrow left truth equationality is in the same relationship to left truth equationality as rough left truth equationality is to left truth equationality, as detailed in Proposition 1120.



Proposition 1136 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is left truth equational if and only if it is narrowly left truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$, and that it has theorems. Availability of theorems implies that $\mathrm{ThFam}^{\not\emptyset}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$. Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \le \Omega(T)$. Thus, $\mathcal{I}$ is left truth equational, with the same witnessing equations $\tau^\flat$.

Assume, conversely, that $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ iff $\tau^\flat_\Sigma[\phi] \le \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems, since, otherwise, given that $\Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat)$, we would get $\mathrm{SEN}^\flat = \overleftarrow{\mathrm{SEN}^\flat} = \overleftarrow{\overline{\varnothing}} = \overline{\varnothing}$, a contradiction. Moreover, since $\mathrm{ThFam}^{\not\emptyset}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, left truth equationality implies trivially narrow left truth equationality. ■

Our next goal is to prove an analog of the characterizations, Theorem 860 and Proposition 1121, of left truth equationality and rough left truth equationality, respectively, for narrow left truth equationality.

Narrow left truth equationality allows an expression for $\overleftarrow{T}$, for all theory families T without empty components, or alternatively, for $\overleftarrow{\widetilde{T}}$, for all theory families T, in terms of the Leibniz congruence system of T. The following proposition forms an analog of Proposition 1121.

Proposition 1137 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then the following statements are equivalent:*

(i) $\mathcal{I}$ *is narrowly left truth equational, with witnessing equations* $\tau^\flat$*;*

(ii) For all $T \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, $\overleftarrow{T} = \tau^\flat(\Omega(T))$*;*

(iii) For all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{\widetilde{T}} = \tau^\flat(\Omega(T))$*.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$, and let $T \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(definition)} \\ & \text{iff} & \phi \in \overleftarrow{T}_\Sigma. \quad \text{(hypothesis)} \end{array}$$

Suppose, next, that Condition (ii) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then $\widetilde{T} \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, whence, by hypothesis, $\overleftarrow{\widetilde{T}} = \tau^\flat(\Omega(\widetilde{T})) = \tau^\flat(\Omega(T))$, where the last equality holds by Proposition 369. Finally, suppose that Condition (iii) holds and let $T \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$. Then $\widetilde{T} = T$, whence, we get, by hypothesis, $\overleftarrow{T} = \tau^\flat(\Omega(T))$, showing that $\mathcal{I}$ is narrowly left truth equational. ■

Recall from Chapter 6 that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *narrowly left c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}.$$

We are now able to show that narrow left truth equationality implies narrow left c-reflectivity. This is an analog of Theorem 1122.

Theorem 1138 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly left truth equational, then it is narrowly left c-reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{lll} \bigcap_{T \in \mathcal{T}} \overleftarrow{T} & = & \bigcap_{T \in \mathcal{T}} \tau^\flat(\Omega(T)) \quad \text{(Proposition 1137)} \\ & = & \tau^\flat(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad \text{(set theory)} \\ & \leq & \tau^\flat(\Omega(T')) \quad \text{(hypothesis)} \\ & = & \overleftarrow{T'}. \quad \text{(Proposition 1137)} \end{array}$$

Thus, $\mathcal{I}$ is narrowly left c-reflective. ■

In the context of narrow left truth equationality, the notion paralleling the left Suszko core is the *narrow left Suszko core*, a modification of the original, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **narrow left Suszko core** $L^{\mathcal{I}\nmid}$ of $\mathcal{I}$ is the collection

$$L^{\mathcal{I}\nmid} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}^{\nmid}(\mathcal{I}))(\sigma^\flat[\overleftarrow{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(T))\}.$$

From the definition, it is not difficult to see that, for any theory family T, with all components nonempty, $\overleftarrow{T}$ is always included in $L^{\mathcal{I}\nmid}(\Omega(T))$. This forms an analog in the narrow left context of Propositions 1102 and 1123.

Proposition 1139 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$*,*

$$\overleftarrow{T} \leq L^{\mathcal{I}\nmid}(\Omega(T)).$$

Proof: Suppose $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \overleftarrow{T}_\Sigma$, and $\sigma^\flat \in L^{\mathcal{I}\nmid}$. Then, by the definition of $L^{\mathcal{I}\nmid}$, $\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)$. Hence, $L^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T)$. Thus, by definition of $L^{\mathcal{I}\nmid}(\Omega(T))$, $\phi \in L^{\mathcal{I}\nmid}_\Sigma(\Omega(T))$. Since Σ and $\phi \in \overleftarrow{T}_\Sigma$ were arbitrary, we conclude that $\overleftarrow{T} \leq L^{\mathcal{I}\nmid}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we say that the narrow left Suszko core of $\mathcal{I}$ is *left soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The narrow left Suszko core $L^{\mathcal{I}\nmid}$ of $\mathcal{I}$ is said to be **left soluble** if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$L^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_\Sigma.$$

As was the case with rough left truth equationality (see Lemma 1124), it turns out that, if a given π-institution is narrowly left truth equational, then any collection of witnessing equations must be included in the narrow left Suszko core of $\mathcal{I}$; differently put, in case of narrow left truth equationality, the narrow left Suszko core forms a candidate for the largest collection of witnessing equations.

Lemma 1140 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly left truth equational, with witnessing equations* $\tau^\flat$*, then* $\tau^\flat \subseteq L^{\mathcal{I}\nmid}$*.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \overleftarrow{T}_\Sigma$. Then, for all $T \leq T' \in \mathrm{ThFam}(\mathcal{I})$, $\phi \in \overleftarrow{T'}_\Sigma$, whence, by narrow left truth equationality, $\tau^\flat_\Sigma[\phi] \leq \Omega(T')$. Since T', with the postulated properties was arbitrary,

$$\tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThFam}(\mathcal{I})\} = \widetilde{\Omega}^{\mathcal{I}}(T).$$

Hence, $\tau^\flat[\overleftarrow{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(T)$. Since $T \in \mathrm{ThFam}^\natural(\mathcal{I})$ was arbitrary, we conclude that $\tau^\flat \subseteq L^{\mathcal{I}\natural}$. ∎

We are now ready to prove the equivalence between narrow left truth equationality and the left solubility of the narrow left Suszko core. In the next theorem, we show that narrow left truth equationality implies the left solubility of the narrow left Suszko core. This forms an analog of Theorem 1125.

Theorem 1141 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is narrowly left truth equational, then* $L^{\mathcal{I}\natural}$ *is left soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $L^{\mathcal{I}\natural}_\Sigma[\phi] \leq \Omega(T)$. Then, by narrow left truth equationality and Lemma 1140, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Again, using narow left truth equationality, we conclude that $\phi \in \overleftarrow{T}_\Sigma$. This shows that $L^{\mathcal{I}\natural}$ is left soluble. ∎

Conversely, in an analog of Theorem 1126, we show that the left solubility of the narrow left Suszko core of a π-institution implies narrow left truth equationality.

Theorem 1142 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $L^{\mathcal{I}\natural}$ *is left soluble, then* $\mathcal{I}$ *is narrowly left truth equational, with witnessing equations* $L^{\mathcal{I}\natural}$.

Proof: Assume $L^{\mathcal{I}\natural}$ is left soluble and let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We must show that

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad L^{\mathcal{I}\natural}_\Sigma[\phi] \leq \Omega(T).$$

If $\phi \in \overleftarrow{T}_\Sigma$, then, by Proposition 1139, $\phi \in L^{\mathcal{I}\natural}_\Sigma(\Omega(T))$, i.e., $L^{\mathcal{I}\natural}_\Sigma[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated left solubility of $L^{\mathcal{I}\natural}$. Thus, $\mathcal{I}$ is indeed narrowly left truth equational, with witnessing equations $L^{\mathcal{I}\natural}$. ∎

Theorems 1141 and 1142 provide the first characterization of narrow left truth equationality in terms of the left solubility of the narrow left Suszko core. This parallels Theorem 1127, which asserted a similar characterization for rough left truth equationality in terms of the left solubility of the rough left Suszko core of a π-institution.

$$\mathcal{I} \text{ Narrowly Left Truth Equational } \longleftrightarrow L^{\mathcal{I}\nmid} \text{ Left Soluble}$$

Theorem 1143 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly left truth equational if and only if* $L^{\mathcal{I}\nmid}$ *is left soluble.*

Proof: The "if" is by Theorem 1142. The "only if" by Theorem 1141. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow left Suszko core $L^{\mathcal{I}\nmid}$ of $\mathcal{I}$ **narrowly defines theory families up to arrow** if, for al $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$\overleftarrow{T} = L^{\mathcal{I}\nmid}(\Omega(T)).$$

Another characterization of narrow left truth equationality, along the lines of Theorem 1128, asserts that it is equivalent to the narrow definability up to arrow of the theory families by the narrow left Suszko core.

$$\begin{array}{l} \mathcal{I} \text{ Narrowly Left Truth Equational} \\ \qquad \longleftrightarrow L^{\mathcal{I}\nmid} \text{ Narrowly Defines Theory} \\ \qquad\qquad \text{Families Up to Arrow} \end{array}$$

Theorem 1144 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly left truth equational if and only if* $L^{\mathcal{I}\nmid}$ *narrowly defines theory families in* $\mathcal{I}$ *up to arrow.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational. By Theorem 1141, $L^{\mathcal{I}\nmid}$ is left soluble. Hence, by definition, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $L^{\mathcal{I}\nmid}(\Omega(T)) \leq \overleftarrow{T}$. Since, by Proposition 1139, the reverse always holds, we get, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}\nmid}(\Omega(T))$. Thus, $L^{\mathcal{I}\nmid}$ narrowly defines theory families in $\mathcal{I}$ up to arrow. Conversely, if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\overleftarrow{T} = L^{\mathcal{I}\nmid}(\Omega(T))$, then $L^{\mathcal{I}\nmid}$ is left soluble and, therefore, by Theorem 1142, $\mathcal{I}$ is narrowly left truth equational. ∎

We would like, next to establish a connection between narrow left truth equationality and narrow left c-reflectivity by means of the narrow left Suszko core. To accomplish this, we introduce an apparently modified version of the Suszko operator, which, however, is identical to the Suszko operator itself. This modified version is convenient for the purpose of handling proofs in a more straightforward and efficient way.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define the **narrow Suszko operator** $\widetilde{\Omega}^{\mathcal{I}\nleq}$ by setting, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\Omega}^{\mathcal{I}\nleq}(T) = \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})\}.$$

By Corollary 1111, we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}\nleq}(T) = \widetilde{\Omega}^{\mathcal{I}}(T)$. So this is indeed an apparent and not a substantial change and one can think, without any loss, of $\widetilde{\Omega}^{\mathcal{I}\nleq}$ as the Suszko operator.

In analogy with the case of rough truth equationality and rough left truth equationality, we may introduce the notion of *left adequacy* of the narrow left Suszko core, which will help in characterizing the relationship between narrow left truth equationality and narrow left c-reflectivity. The following proposition, a "left" analog of Proposition 1113 and an analog of Proposition 1129, justifies the notion of left adequacy that will follow.

Proposition 1145 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\bigcap\{\Omega(T) : L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^{\mathcal{I}\nleq}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$,

$$\begin{array}{llll}\phi \in \overleftarrow{T}_\Sigma & \text{implies} & L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) & (\text{Definition of } L^{\mathcal{I}\nleq}) \\ & \text{implies} & L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T). & (\widetilde{\Omega}^{\mathcal{I}} \leq \Omega)\end{array}$$

Hence,

$$\begin{array}{l}\bigcap\{\Omega(T) : L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)\} \\ \quad = \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nleq}(\mathcal{I}) \text{ and } L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)\} \\ \quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nleq}(\mathcal{I}) \text{ and } L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T)\} \\ \quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nleq}(\mathcal{I}) \text{ and } \phi \in \overleftarrow{T}_\Sigma\} \\ \quad = \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nleq}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\ \quad = \widetilde{\Omega}^{\mathcal{I}\nleq}(C(\overrightarrow{\phi})).\end{array}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1145 holds, then we say that the narrow left Suszko core of $\mathcal{I}$ is *left adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow left Suszko core $L^{\mathcal{I}\nleq}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}\nleq}(C(\overrightarrow{\phi})) \leq \bigcap\{\Omega(T) : L^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)\}.$$

We can show, in analogy with Corollary 1130, that the left solubility of the narrow left Suszko core implies left adequacy.

Corollary 1146 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $L^{\mathcal{I}\nmid}$ *is left soluble, then it is left adequate.*

Proof: Suppose $L^{\mathcal{I}\nmid}$ is left soluble and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{aligned}
\widetilde{\Omega}^{\mathcal{I}\nmid}(C(\overrightarrow{\phi})) &= \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nmid}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\
&\quad \text{(definition of } \widetilde{\Omega}^{\mathcal{I}\nmid}) \\
&= \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nmid}(\mathcal{I}) \text{ and } \phi \in \overleftarrow{T}_\Sigma\} \\
&\quad \text{(Definition of } \overrightarrow{\phi} \text{ and } \overleftarrow{T}) \\
&= \bigcap\{\Omega(T) : T \in \mathrm{ThFam}^{\nmid}(\mathcal{I}) \text{ and } L^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T)\} \\
&\quad \text{(Left solubility of } L^{\mathcal{I}\nmid}) \\
&= \bigcap\{\Omega(T) : L^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T)\}. \quad \text{(Lemma 1110)}
\end{aligned}$$

Thus, $L^{\mathcal{I}\nmid}$ is left adequate. ∎

In order to prove a partial converse of Corollary 1146, we will employ the following characterization of narrow left c-reflectivity.

Lemma 1147 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly left c-reflective if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $T' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$*,*

$$\widetilde{\Omega}^{\mathcal{I}\nmid}(T) \leq \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left c-reflective and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $T' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\widetilde{\Omega}^{\mathcal{I}\nmid}(T) \leq \Omega(T')$. Then, by definition,

$$\bigcap\{\Omega(T'') : T \leq T'' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})\} \leq \Omega(T').$$

Hence, by narrow left c-reflectivity, $\bigcap\{\overleftarrow{T''} : T \leq T'' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})\} \leq \overleftarrow{T'}$. However, $T \leq T''$ implies that $\overleftarrow{T} \leq \overleftarrow{T''}$. Hence, we obtain $\overleftarrow{T} \leq \overleftarrow{T'}$.

Suppose, conversely, that the displayed condition in the statement holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, since $\mathcal{T} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we get that

$$\bigcap\{\Omega(T'') : \bigcap\mathcal{T} \leq T'' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})\} \leq \Omega(T').$$

By definition, then, $\widetilde{\Omega}^{\mathcal{I}\nmid}(\bigcap\mathcal{T}) \leq \Omega(T')$, whence, by hypothesis, $\overleftarrow{\bigcap\mathcal{T}} \leq \overleftarrow{T'}$. Therefore, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. This shows that $\mathcal{I}$ is narrowly left c-reflective. ∎

We prove, next, the converse of Corollary 1146, under the additional assumption that the π-institution $\mathcal{I}$ under consideration is narrowly left c-reflective. This constitutes an analog of Proposition 1131.

Proposition 1148 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a narrowly left c-reflective* π*-institution based on* $\mathbf{F}$. *If* $L^{\mathcal{I}\natural}$ *is left adequate, then it is left soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly left c-reflective and $L^{\mathcal{I}\natural}$ is left adequate. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $L^{\mathcal{I}\natural}_\Sigma[\phi] \leq \Omega(T)$. By the postulated left adequacy of $L^{\mathcal{I}\natural}$, we get that $\widetilde{\Omega}^{\mathcal{I}\natural}(C(\overrightarrow{\phi})) \leq \Omega(T)$. By narrow left truth equationality and Lemma 1147, $\overleftarrow{C(\overrightarrow{\phi})} \leq \overleftarrow{T}$. Therefore, $\phi \in \overleftarrow{T}_\Sigma$. We conclude that $L^{\mathcal{I}\natural}$ is left soluble. ■

We are now in a position to prove the main characterization theorem relating narrow left truth equationality with narrow left c-reflectivity, an analog of Theorem 1132, which characterized rough left truth equationality in terms of rough left c-reflectivity and the adequacy of the rough left Suszko core.

$$\begin{array}{rcl}\text{Narrow Left Truth Equationality} & = & L^{\mathcal{I}\natural} \text{ Left Soluble}\\ & = & L^{\mathcal{I}\natural} \text{ Narrowly Defines Theory}\\ & & \quad\text{Families Up to Arrow}\\ & = & \text{Narrow Left c-Reflectivity}\\ & & + \; L^{\mathcal{I}\natural} \text{ Left Adequate}\end{array}$$

Theorem 1149 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is narrowly left truth equational if and only if it is narrowly left c-reflective and has a left adequate narrow left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational. By Theorem 1138, it is narrowly left c-reflective. By Theorem 1141, its narrow left Suszko core is left soluble. Thus, by Corollary 1146, its narrow left Suszko core is also left adequate.

Assume, conversely, that $\mathcal{I}$ is narrowly left c-reflective and has a left adequate narrow left Suszko core. Then, by Proposition 1148, its narrow left Suszko core is also left soluble. Hence, by Theorem 1142, $\mathcal{I}$ is narrowly left truth equational. ■

Based on Proposition 1136 and Theorem 468, it is not difficult to show, in an analog of Corollary 1133, that the characterization theorem, Theorem 870, of left truth equationality in terms of left c-reflectivity and the left adequacy of the left Suszko core, can be inferred from Theorem 1149.

Corollary 1150 (Theorem 870) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: $\mathcal{I}$ is left truth equational if and only if, by Proposition 1136, it is narrowly left truth equational and has theorems, if and only if, by Theorem 1149, it is narrowly left c-reflective, with a left adequate narrow left Suszko core and has theorems, if and only if, by Theorem 468 and the definitions of left Suszko core and narrow left Suszko core, it is left c-reflective and has a left adequate left Suszko core. ■

We close the section by looking at a result, an analog of Theorem 1134, which may be perceived either as an alternative characterization of narrow left truth equationality, involving arbitrary **F**-algebraic systems, or as a transfer theorem.

Theorem 1151 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly left truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}\natural}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the **F**-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is narrowly left truth equational.

Suppose, conversely, that $\mathcal{I}$ is narrowly left truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}\natural}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll}
\alpha_\Sigma(\phi) \in \overleftarrow{T}_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(\overleftarrow{T}_{F(\Sigma)}) \\
& \text{iff} & \phi \in \overleftarrow{\alpha_\Sigma^{-1}(T_{F(\Sigma)})} \quad \text{(Lemma 6)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(\alpha^{-1}(T)) \quad \text{(hypothesis)} \\
& \text{iff} & \tau_\Sigma^\flat[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\
& \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 95)}
\end{array}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.4 Rough System Truth Equationality

We now turn to *rough system truth equationality*. As the terminology suggests:

- It is in the same relation to rough system c-reflectivity as rough left truth equationality is to rough left c-reflectivity;
- It is in the same relation to rough left truth equationality as system truth equationality is to left truth equationality.

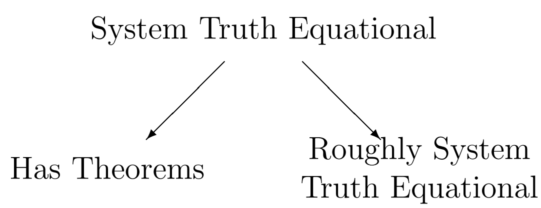
Roughly speaking, rough system truth equationality is defined analogously to system truth equationality, but it is applied to rough representatives of theory systems so as to avoid theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly system truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \widetilde{T}_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

The collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ is referred to as a set of **witnessing equations** (of/for the rough system truth equationality of $\mathcal{I}$).

The following relationship between rough system truth equationality and system truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1098, holds.



Proposition 1152 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is roughly system truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$, and that it has theorems. Availability of theorems implies that $\mathrm{ThSys}^{\lightning}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$. Thus, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\phi \in \widetilde{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is system truth equational, with the same witnessing equations $\tau^\flat$.

Assume, conversely, that $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ iff $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems. Moreover, due to the availability of theorems, we get, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \widetilde{T}_\Sigma$ if and only if $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is roughly system truth equational. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 1127, of rough left truth equationality in terms of the left solubility of the rough left Suszko core for rough system truth equationality.

Rough system truth equationality allows an expression for $\widetilde{T}$, for all theory systems T, in terms of the Leibniz congruence system of T. The following proposition forms an analog of Proposition 1121.

Proposition 1153 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly system truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $\widetilde{T} = \tau^\flat(\Omega(T))$*.*

Proof: $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in \widetilde{T}_\Sigma$ iff $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{T} = \tau^\flat(\Omega(T))$. ■

Recall from Chapter 6 that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly system c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}.$$

We are now able to show that rough system truth equationality implies rough system c-reflectivity. This is an analog of Theorem 1122.

Theorem 1154 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly system truth equational, then it is roughly system c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{rcll} \bigcap_{T \in \mathcal{T}} \widetilde{T} & = & \bigcap_{T \in \mathcal{T}} \tau^\flat(\Omega(T)) & \text{(Proposition 1153)} \\ & = & \tau^\flat(\bigcap_{T \in \mathcal{T}} \Omega(T)) & \text{(set theory)} \\ & \leq & \tau^\flat(\Omega(T')) & \text{(hypothesis)} \\ & = & \widetilde{T'}. & \text{(Proposition 1153)} \end{array}$$

Thus, $\mathcal{I}$ is roughly system c-reflective. ■

In the context of rough system truth equationality, the notion paralleling the rough left Suszko core is the *rough system core*, a modification of the system core, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **rough system core** $\widetilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is the collection

$$\begin{array}{rcl} \widetilde{Z}^{\mathcal{I}} & = & \{\sigma^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma)) \\ & & \quad (\sigma^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\})\}. \end{array}$$

From the definition, it is not difficult to see that, for any theory system T, $\widetilde{T}$ is always included in $\widetilde{Z}^{\mathcal{I}}(\Omega(T))$. This forms an analog in the rough left context of Proposition 1123.

Proposition 1155 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\widetilde{T} \leq \widetilde{Z}^{\mathcal{I}}(\Omega(T)).$$

Proof: Suppose $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$, and $\sigma^\flat \in \widetilde{Z}^{\mathcal{I}}$. Then, by the definition of $\widetilde{Z}^{\mathcal{I}}$, $\sigma^\flat_\Sigma[\phi] \leq \Omega(T)$. Hence, $\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Thus, by definition of $\widetilde{Z}^{\mathcal{I}}(\Omega(T))$, $\phi \in \widetilde{Z}^{\mathcal{I}}_\Sigma(\Omega(T))$. Since Σ and $\phi \in \widetilde{T}_\Sigma$ were arbitrary, we conclude that $\widetilde{T} \leq \widetilde{Z}^{\mathcal{I}}(\Omega(T))$. ∎

The reverse inclusion may or may not hold. If it does, for all $T \in \mathrm{ThSys}(\mathcal{I})$, we say that the rough system core of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The rough system core $\widetilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \widetilde{T}_\Sigma.$$

As was the case with rough left truth equationality (see Lemma 1124), if a given π-institution is roughly system truth equational, then any collection of witnessing equations must be included in the rough system core of $\mathcal{I}$. In other words, in case of rough system truth equationality, the rough system core forms a candidate for the largest collection of witnessing equations.

Lemma 1156 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$, then $\tau^\flat \subseteq \widetilde{Z}^{\mathcal{I}}$.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$. Then, by rough system truth equationality, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Since T was arbitrary,

$$\tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\}.$$

Hence, since $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$ were arbitrary, we conclude that $\tau^\flat \subseteq \widetilde{Z}^{\mathcal{I}}$. ∎

We are now ready to prove the equivalence between rough system truth equationality and the solubility of the rough system core. In the next theorem, we show that rough system truth equationality implies the solubility of the rough system core. This forms an analog of Theorem 1125.

Theorem 1157 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system truth equational, then $\widetilde{Z}^{\mathcal{I}}$ is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Then, by rough system truth equationality and Lemma 1156, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Again, using rough system truth equationality, we conclude that $\phi \in \widetilde{T}_\Sigma$. This shows that $\widetilde{Z}^{\mathcal{I}}$ is soluble. ∎

Conversely, in an analog of Theorem 1126, we show that the solubility of the rough system core of a π-institution implies rough system truth equationality.

Theorem 1158 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\widetilde{Z}^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is roughly system truth equational, with witnessing equations* $\widetilde{Z}^{\mathcal{I}}$*.*

Proof: Assume $\widetilde{Z}^{\mathcal{I}}$ is soluble and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We must show that

$$\phi \in \widetilde{T}_\Sigma \quad \text{iff} \quad \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T).$$

If $\phi \in \widetilde{T}_\Sigma$, then, by Proposition 1155, $\phi \in \widetilde{Z}^{\mathcal{I}}_\Sigma(\Omega(T))$, i.e., $\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \le \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated solubility of $\widetilde{Z}^{\mathcal{I}}$. Thus, $\mathcal{I}$ is indeed roughly system truth equational, with witnessing equations $\widetilde{Z}^{\mathcal{I}}$. ∎

Theorems 1157 and 1158 provide the first characterization of rough system truth equationality in terms of the solubility of the rough system core. This parallels Theorem 1127, which asserted a similar characterization for rough left truth equationality in terms of the left solubility of the rough left Suszko core of a π-institution.

$$\mathcal{I} \text{ Roughly System Truth Equational } \longleftrightarrow \widetilde{Z}^{\mathcal{I}} \text{ Soluble}$$

Theorem 1159 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly system truth equational if and only if* $\widetilde{Z}^{\mathcal{I}}$ *is left soluble.*

Proof: The "if" is by Theorem 1158. The "only if" by Theorem 1157. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the rough system core $\widetilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ **roughly defines theory systems** if, for al $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\widetilde{T} = \widetilde{Z}^{\mathcal{I}}(\Omega(T)).$$

Another characterization of rough system truth equationality, along the lines of Theorem 1128, asserts that it is equivalent to the rough definability of the theory systems by the rough system core.

$$\begin{array}{l}\mathcal{I} \text{ Roughly System Truth Equational} \\ \qquad \longleftrightarrow \widetilde{Z}^{\mathcal{I}} \text{ Roughly Defines Theory Systems}\end{array}$$

Theorem 1160 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly system truth equational if and only if* $\widetilde{Z}^{\mathcal{I}}$ *roughly defines theory systems in* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational. By Theorem 1157, $\widetilde{Z}^{\mathcal{I}}$ is soluble. Hence, by definition, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{Z}^{\mathcal{I}}(\Omega(T)) \leq \widetilde{T}$. Since, by Proposition 1155, the reverse inclusion always holds, we get, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{T} = \widetilde{Z}^{\mathcal{I}}(\Omega(T))$. Thus, $\widetilde{Z}^{\mathcal{I}}$ roughly defines theory systems in $\mathcal{I}$. Conversely, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{T} = \widetilde{Z}^{\mathcal{I}}(\Omega(T))$, then $\widetilde{Z}^{\mathcal{I}}$ is soluble and, therefore, by Theorem 1158, $\mathcal{I}$ is roughly system truth equational. ∎

We establish, next, a connection between rough system truth equationality and rough system c-reflectivity by means of the rough system core. In analogy with the case of rough left truth equationality, we introduce, first, the notion of *adequacy* of the rough system core. The following proposition, a system analog of Proposition 1129, motivates the notion of adequacy that will follow.

Proposition 1161 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}\\ \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\}.\end{aligned}$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\phi \in \widetilde{T}_\Sigma \quad \text{implies} \quad \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T). \quad (\text{Definition of } \widetilde{Z}^{\mathcal{I}})$$

Hence,

$$\begin{aligned}\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}\\ \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\}.\end{aligned}$$

This is the displayed formula in the statement. ∎

If the reverse inclusion of that proven in Proposition 1161 holds, then we say that the rough system core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the rough system core $\widetilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\}\\ \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.\end{aligned}$$

We can show, in analogy with Corollary 1130, that the solubility of the rough system core implies its adequacy.

Corollary 1162 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\widetilde{Z}^{\mathcal{I}}$ *is soluble, then it is adequate.*

Proof: Suppose $\widetilde{Z}^{\mathcal{I}}$ is soluble and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, by solubility and Proposition 1155, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $\phi \in \widetilde{T}_\Sigma$ if and only if $\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. Therefore,

$$\begin{aligned}&\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\}\\ &\qquad = \bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.\end{aligned}$$

Thus, $\widetilde{Z}^{\mathcal{I}}$ is adequate. ■

We prove, next, the converse of Corollary 1162, under the additional assumption that the π-institution $\mathcal{I}$ under consideration is roughly system c-reflective. This constitutes an analog of Proposition 1131.

Proposition 1163 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a roughly system c-reflective* π*-institution based on* $\mathbf{F}$*. If* $\widetilde{Z}^{\mathcal{I}}$ *is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly system c-reflective and $\widetilde{Z}^{\mathcal{I}}$ is adequate. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\widetilde{Z}^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. By the postulated adequacy of $\widetilde{Z}^{\mathcal{I}}$, we get that $\bigcap\{\Omega(T) : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\} \leq \Omega(T)$. By rough system truth equationality, $\bigcap\{\widetilde{T} : T \in \mathrm{ThSys}(\mathcal{I}) \text{ and } \phi \in \widetilde{T}_\Sigma\} \leq \widetilde{T}$. Therefore, $\phi \in \widetilde{T}_\Sigma$. We conclude that $\widetilde{Z}^{\mathcal{I}}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating rough system truth equationality with rough system c-reflectivity, an analog of Theorem 1132, which characterized rough left truth equationality in terms of rough left c-reflectivity and the left adequacy of the rough left Suszko core.

Rough System Truth Equationality
= $\widetilde{Z}^{\mathcal{I}}$ Soluble
= $\widetilde{Z}^{\mathcal{I}}$ Roughly Defines Theory Systems
= Rough System c-Reflectivity + $\widetilde{Z}^{\mathcal{I}}$ Adequate

Theorem 1164 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly system truth equational if and only if it is roughly system c-reflective and has an adequate rough system core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly system truth equational. By Theorem 1154, it is roughly system c-reflective. By Theorem 1157, its rough system core is soluble. Thus, by Corollary 1162, its rough system core is also adequate.

Assume, conversely, that $\mathcal{I}$ is roughly system c-reflective and has an adequate rough system core. Then, by Proposition 1163, its rough system core is also soluble. Hence, by Theorem 1158, $\mathcal{I}$ is roughly system truth equational. ■

Based on Proposition 1152 and Theorem 468, it is not difficult to show, in an analog of Corollary 1133, that the characterization theorem, Theorem 887, of system truth equationality in terms of system c-reflectivity and the adequacy of the system core, can be inferred from Theorem 1164.

Corollary 1165 (Theorem 887) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: $\mathcal{I}$ is system truth equational if and only if, by Proposition 1152, it is roughly system truth equational and has theorems, if and only if, by Theorem 1164, it is roughly system c-reflective, with an adequate rough system core and has theorems, if and only if, by Theorem 468 and the definitions of system core and rough system core, it is system c-reflective and has an adequate system core. ■

We close the section by looking at a result, an analog of Theorem 1134, which may be perceived either as an alternative characterization of rough system truth equationality, involving arbitrary $\mathbf{F}$-algebraic systems, or as a transfer theorem.

Theorem 1166 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly system truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in \widetilde{T}_\Sigma \quad \textit{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is roughly system truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly system truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rll}
\alpha_\Sigma(\phi) \in \widetilde{T}_{F(\Sigma)} & \text{iff} & \phi \in \alpha^{-1}_\Sigma(\widetilde{T}_{F(\Sigma)}) \\
& \text{iff} & \phi \in \widetilde{\alpha^{-1}_\Sigma(T_{F(\Sigma)})} \quad \text{(Theorem 377)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(\alpha^{-1}(T)) \quad \text{(hypothesis)} \\
& \text{iff} & \tau^\flat_\Sigma[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\
& \text{iff} & \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 95)}
\end{array}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.5 Narrow System Truth Equationality

Finally, we discuss *narrow system truth equationality*, the weakest of all rough/narrow truth equationality conditions. As the terminology suggests:

- It is in the same relation to narrow system c-reflectivity as rough system truth equationality is to rough system c-reflectivity;
- It is in the same relation to narrow truth equationality and narrow left truth equationality as rough system truth equationality is to rough truth equationality and rough left truth equationality, respectively.

In a nutshell, narrow system truth equationality is defined analogously to system truth equationality, but care is taken to bypass theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **narrowly system truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \le \Delta^{\mathcal{F}/\Omega(T)}.$$

Once more, since, by Proposition 369, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\widetilde{T}) = \Omega(T)$, $\Omega(T)$ is compatible with $\widetilde{T}$ and, hence, the preceding definition makes sense. The collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ is referred to as a set of **witnessing equations** (of/for the narrow system truth equationality of $\mathcal{I}$).

As in Proposition 1096, we get the following alternative characterization.

Proposition 1167 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a collection of natural transformations in $N^\flat$, with a single distinguished argument. $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in \widetilde{T}_\Sigma \quad \textit{iff} \quad \tau^\flat_\Sigma[\phi] \le \Omega(T).$$

Proof: Suppose that $\mathcal{I}$ is narrowly truth equational and let $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rll}
\phi \in \widetilde{T}_\Sigma & \text{iff} & \phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{(Proposition 369 and compatibility)}\\
& \text{iff} & \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \le \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by hypothesis)}\\
& \text{iff} & \tau^\flat_\Sigma[\phi]/\Omega(T) \le \Delta^{\mathcal{F}/\Omega(T)} \quad \text{(by definition)}\\
& \text{iff} & \tau^\flat_\Sigma[\phi] \le \Omega(T).
\end{array}$$

Suppose, conversely, that the displayed condition holds. Let $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}\phi/\Omega_\Sigma(T) \in \widetilde{T}_\Sigma/\Omega_\Sigma(T) & \text{iff} & \phi \in \widetilde{T}_\Sigma \quad \text{(Proposition 369 and compatibility)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(by hypothesis)}\\ & \text{iff} & \tau^\flat_\Sigma[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)}\\ & \text{iff} & \tau^{\mathcal{F}/\Omega(T)}_\Sigma[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}. \quad \text{(definition)}\end{array}$$

Therefore, $\mathcal{I}$ is narrowly system truth equational. ∎

It is not difficult to see that an alternative way to express narrow system truth equationality is to assert the same condition that defines system truth equationality, excluding, however, those theory systems with at least one empty component.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall from Chapter 6 that we denote by $\mathrm{ThSys}^{\not\varnothing}(\mathcal{I})$ the collection of all theory systems T of $\mathcal{I}$, such that $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}^\flat|$:

$$\mathrm{ThSys}^{\not\varnothing}(\mathcal{I}) = \{T \in \mathrm{ThSys}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma \neq \varnothing)\}.$$

Recall, also, that, if $\mathcal{I}$ has theorems, then $\mathrm{ThSys}^{\not\varnothing}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$. In particular, this is case if $\mathcal{I}$ happens to be system truth equational.

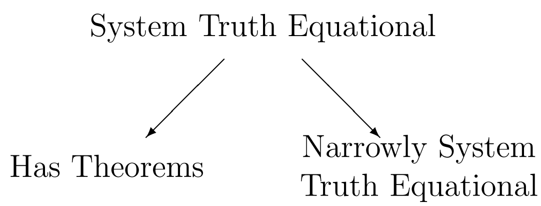
Proposition 1168 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ a collection of natural transformations in $N^\flat$, with a single distinguished argument. $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$, if and only if, for all $T \in \mathrm{ThSys}^{\not\varnothing}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThSys}^{\not\varnothing}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then $\widetilde{T} = T \in \mathrm{ThSys}(\mathcal{I})$, whence, taking into account Proposition 1167, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$.

Suppose, conversely, that the displayed condition holds. Consider $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, since, by definition of $\widetilde{T}$, we have $\widetilde{T} \in \mathrm{ThSys}^{\not\varnothing}(\mathcal{I})$, we get, by hypothesis, $\phi \in \widetilde{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(\widetilde{T})$, whence, using Proposition 369, we conclude that $\phi \in \widetilde{T}_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Therefore, $\mathcal{I}$ is narrowly system truth equational. ∎

As a corollary, we obtain the following key relationship between narrow system truth equationality and system truth equationality, paralleling the one established between system truth equationality and rough system truth equationality in Corollary 1152.



Corollary 1169 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system truth equational if and only if it is narrowly system truth equational with theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$, and that it has theorems. Availability of theorems implies that $\mathrm{ThSys}^{\nmid}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$. Thus, by Proposition 1168, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is system truth equational, with the same witnessing equations $\tau^\flat$.

Assume, conversely, that $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThSys}(\mathcal{I})$, and, hence, a fortiori, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Hence, again by Proposition 1168, $\mathcal{I}$ is narrowly system truth equational. Finally, by Theorem 872, $\mathcal{I}$ is system c-reflective and, by Proposition 243, it is system reflective and, therefore, system injective. Thus, it must have theorems. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 1159, of rough system truth equationality in terms of the solubility of the rough system core for the case of narrow system truth equationality.

Narrow system truth equationality allows the following expression for all theory systems with nonempty components, forming an analog of Proposition 1153.

Proposition 1170 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is narrowly system truth equational, with witnessing equations* $\tau^\flat$*;*

(ii) For all $T \in \mathrm{ThSys}(\mathcal{I})$*, such that* $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$*,* $\widetilde{T} = \tau^\flat(\Omega(T))$*;*

(iii) For all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,* $T = \tau^\flat(\Omega(T))$*.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$, and let $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rll} \phi \in \tau^\flat_\Sigma(\Omega(T)) & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(T) \quad \text{(definition)} \\ & \text{iff} & \phi \in \widetilde{T}_\Sigma. \quad \text{(hypothesis and Proposition 1167)} \end{array}$$

This proves Condition (ii). If Condition (ii) holds and $T \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$, then $\widetilde{T} = T \in \mathrm{ThSys}(\mathcal{I})$, whence, by hypothesis, $T = \widetilde{T} = \tau^\flat(\Omega(T))$. Thus, Condition (iii) holds. Finally, assume Condition (iii) holds. Then, by Proposition **??**, $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$. ■

Recall from Chapter 6 that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, $\mathcal{I}$ is called *narrowly system c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$,

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T\in\mathcal{T}} T \leq T'.$$

We are now able to show that narrow system truth equationality implies narrow system c-reflectivity. This is an analog of Theorem 1154.

Theorem 1171 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly system truth equational, then it is narrowly system c-reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{array}{rcll}
\bigcap_{T\in\mathcal{T}} T & = & \bigcap_{T\in\mathcal{T}} \tau^\flat(\Omega(T)) & \text{(Proposition 1170)}\\
& = & \tau^\flat(\bigcap_{T\in\mathcal{T}} \Omega(T)) & \text{(set theory)}\\
& \leq & \tau^\flat(\Omega(T')) & \text{(hypothesis)}\\
& = & T'. & \text{(Proposition 1170)}
\end{array}$$

Thus, $\mathcal{I}$ is narrowly system c-reflective. ■

In the context of narrow system truth equationality, the notion paralleling the rough system core, introduced in Section 14.3, is the *narrow system core*, a modification of the original definition of the system core from Chapter 11, which is defined by circumventing theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. The **narrow system core** $Z^{\mathcal{I}\nleq}$ of $\mathcal{I}$ is the collection

$$Z^{\mathcal{I}\nleq} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}(\mathcal{I}))(\widetilde{T} \in \mathrm{ThSys}(\mathcal{I}) \Rightarrow \sigma^\flat[\widetilde{T}] \leq \widehat{\Omega}^{\mathcal{I}}(\widetilde{T}))\}.$$

As before, an alternative characterization avoids $\widetilde{\ }$ at the expense of restricting quantification over $\mathrm{ThSys}^{\nleq}(\mathcal{I})$.

Proposition 1172 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Then*

$$Z^{\mathcal{I}\nleq} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}^{\nleq}(\mathcal{I}))(\sigma^\flat[T] \leq \widehat{\Omega}^{\mathcal{I}}(T))\}.$$

Proof: Inside this proof we set

$$M^{\mathcal{I}\nleq} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}^{\nleq}(\mathcal{I}))(\sigma^\flat[T] \leq \widehat{\Omega}^{\mathcal{I}}(T))\}.$$

Our goal is to show that $Z^{\mathcal{I}\nmid} = M^{\mathcal{I}\nmid}$. Suppose, first, that $\sigma^\flat \in Z^{\mathcal{I}\nmid}$ and let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Since $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we get $\widetilde{T} = T$. Thus, on the one hand, $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$ and, on the other, by hypothesis, $\phi \in \widetilde{T}_\Sigma$. Thus, since $\sigma^\flat \in Z^{\mathcal{I}\nmid}$, we get

$$\sigma^\flat_\Sigma[\phi] \le \widehat{\Omega}^{\mathcal{I}}(\widetilde{T}) = \widehat{\Omega}^{\mathcal{I}}(T).$$

This proves that $\sigma^\flat \in M^{\mathcal{I}\nmid}$. Assume, conversely, that $\sigma^\flat \in M^{\mathcal{I}\nmid}$ and let $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$. Since $\widetilde{T} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$ and $\sigma^\flat \in M^{\mathcal{I}\nmid}$, we get $\sigma^\flat_\Sigma[\phi] \le \widehat{\Omega}^{\mathcal{I}}(\widetilde{T})$, whence, $\sigma^\flat \in Z^{\mathcal{I}\nmid}$. This proves that $Z^{\mathcal{I}\nmid} = M^{\mathcal{I}\nmid}$. ■

From the definition, it is not difficult to see that any theory system T with all its components nonempty is always included in $Z^{\mathcal{I}\nmid}(\Omega(T))$. This forms an analog in the rough system context of Proposition 1155.

Proposition 1173 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,*

$$T \le Z^{\mathcal{I}\nmid}(\Omega(T)).$$

Proof: Suppose $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$, and $\sigma^\flat \in Z^{\mathcal{I}\nmid}$. Then, by Proposition **??**, $\sigma^\flat_\Sigma[\phi] \le \widehat{\Omega}^{\mathcal{I}}(T) \le \Omega(T)$. Hence, $Z^{\mathcal{I}\nmid}_\Sigma[\phi] \le \Omega(T)$. By definition, then, $\phi \in Z^{\mathcal{I}\nmid}_\Sigma(\Omega(T))$. Since Σ and $\phi \in T_\Sigma$ were arbitrary, we conclude that $T \le Z^{\mathcal{I}\nmid}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we say that the narrow system core $Z^{\mathcal{I}\nmid}$ of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The narrow system core $Z^{\mathcal{I}\nmid}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$Z^{\mathcal{I}\nmid}_\Sigma[\phi] \le \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

An alternative way to express solubility is to again expand the view to all theory systems, with nonempty components, at the balancing expense of adding rough equivalence representatives. We obtain, thus, an analog of Lemma 1103.

Lemma 1174 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $Z^{\mathcal{I}\nmid}$ *is soluble if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*, such that* $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\widetilde{T} = Z^{\mathcal{I}\nmid}(\Omega(T)).$$

Proof: $Z^{\mathcal{I}\nleq}$ is soluble if and only if, by definition and Proposition 1173, for all $T \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$, $T = Z^{\mathcal{I}\nleq}(\Omega(T))$. It is easy to see that this holds if and only if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{T} = Z^{\mathcal{I}\nleq}(\Omega(\widetilde{T}))$. And this is equivalent, by Proposition 369, to the statement that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{T} = Z^{\mathcal{I}\nleq}(\Omega(T))$. ■

As was the case with rough system truth equationality (see Lemma 1156), it turns out that, if a given π-institution is narrowly system truth equational, then any collection of witnessing equations must be included in the narrow system core of $\mathcal{I}$. That is, in case of narrow system truth equationality, the narrow system core is a candidate for the largest set of witnessing equations.

Lemma 1175 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. If $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$, then $\tau^\flat \subseteq Z^{\mathcal{I}\nleq}$.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Then, for all $T \leq T' \in \mathrm{ThSys}(\mathcal{I})$, we have $T' \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$ and $\phi \in T'_\Sigma$. Thus, by narrow system truth equationality and Proposition 1168, $\tau^\flat_\Sigma[\phi] \leq \Omega(T')$. Since T', with the postulated properties was arbitrary,

$$\tau^\flat_\Sigma[\phi] \leq \bigcap\{\Omega(T') : T \leq T' \in \mathrm{ThSys}(\mathcal{I})\} = \widehat{\Omega}^{\mathcal{I}}(T).$$

We conclude, using Proposition 1172, that $\tau^\flat \subseteq Z^{\mathcal{I}\nleq}$. ■

We are now ready to prove the equivalence between narrow system truth equationality and the solubility of the narrow system core, an analog of Theorem 1159. First, we show that narrow system truth equationality implies the solubility of the narrow system core. This forms an analog of Theorem 1157.

Theorem 1176 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. If $\mathcal{I}$ is narrowly system truth equational, then $Z^{\mathcal{I}\nleq}$ is soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $\tau^\flat$. Let $T \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $Z^{\mathcal{I}\nleq}_\Sigma[\phi] \leq \Omega(T)$. Then, by narrow system truth equationality and Lemma 1175, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Again, using narrow system truth equationality and Proposition 1168, we conclude that $\phi \in T_\Sigma$. This shows that $Z^{\mathcal{I}\nleq}$ is soluble. ■

Conversely, the solubility of the narrow system core of a π-institution implies narrow system truth equationality.

Theorem 1177 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}\nmid}$ *is soluble, then* $\mathcal{I}$ *is narrowly system truth equational, with witnessing equations* $Z^{\mathcal{I}\nmid}$*.*

Proof: Assume $Z^{\mathcal{I}\nmid}$ is soluble and let $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. By Proposition 1168, it suffices to show that

$$\phi \in T_\Sigma \quad \text{iff} \quad Z^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T).$$

If $\phi \in T_\Sigma$, then, by Proposition 1173, $\phi \in Z^{\mathcal{I}\nmid}_\Sigma(\Omega(T))$, i.e., $Z^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated solubility of $Z^{\mathcal{I}\nmid}$. Thus, $\mathcal{I}$ is indeed narrowly system truth equational, with witnessing equations $Z^{\mathcal{I}\nmid}$. ■

Theorems 1176 and 1177 provide the first characterization of narrow system truth equationality in terms of the solubility of the narrow system core. This parallels Theorem 1159, which asserted a similar characterization for rough system truth equationality in terms of the solubility of the rough system core of a π-institution.

$$\mathcal{I} \text{ Narrowly System Truth Equational } \longleftrightarrow\ Z^{\mathcal{I}\nmid} \text{ Soluble}$$

Theorem 1178 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly system truth equational if and only if* $Z^{\mathcal{I}\nmid}$ *is soluble.*

Proof: The "if" is by Theorem 1177. The "only if" by Theorem 1176. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow system core $Z^{\mathcal{I}\nmid}$ of $\mathcal{I}$ **narrowly defines theory systems** if, for al $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$,

$$T = Z^{\mathcal{I}\nmid}(\Omega(T)).$$

Another characterization of narrow system truth equationality, along the lines of Theorem 1160, asserts that it is equivalent to the narrow definability of the theory systems by the narrow system core.

$$\begin{array}{l}\mathcal{I} \text{ Narrowly System Truth Equational} \\ \qquad\qquad \longleftrightarrow\ Z^{\mathcal{I}\nmid} \text{ Narrowly Defines Theory Systems}\end{array}$$

Theorem 1179 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly system truth equational if and only if* $Z^{\mathcal{I}\nmid}$ *narrowly defines theory systems in* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational. By Theorem 1176, $Z^{\mathcal{I}\lightning}$ is soluble. Hence, by definition, for all $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, $Z^{\mathcal{I}\lightning}(\Omega(T)) \leq T$. Since, by Proposition 1173, the reverse inclusion always holds, we get, for all $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, $T = Z^{\mathcal{I}\lightning}(\Omega(T))$. Thus, $Z^{\mathcal{I}\lightning}$ narrowly defines theory systems in $\mathcal{I}$. Conversely, if, for all $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, $T = Z^{\mathcal{I}\lightning}(\Omega(T))$, then $Z^{\mathcal{I}\lightning}$ is soluble and, therefore, by Theorem 1178, $\mathcal{I}$ is narrowly system truth equational. ■

We establish, next, a connection between narrow system truth equationality and narrow system c-reflectivity by means of a variant of the systemic Suszko operator. This variant of the systemic Suszko operator, denoted $\widehat{\Omega}^{\mathcal{I}\lightning}$, is not necessarily identical to the systemic Suszko operator $\widehat{\Omega}^{\mathcal{I}}$ itself, unlike the version of the Suszko operator $\widetilde{\Omega}^{\mathcal{I}\lightning}$, defined in the preceding section, which was introduced only for convenience, but was actually shown to be equivalent to the original version $\widetilde{\Omega}^{\mathcal{I}}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define the **narrow systemic Suszko operator** $\widetilde{\Omega}^{\mathcal{I}\lightning}$ by setting, for all $T \in \mathrm{ThSys}(\mathcal{I})$,

$$\widehat{\Omega}^{\mathcal{I}\lightning}(T) = \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})\}.$$

Note that Lemma 1110 and, hence, a hypothetical analog of Corollary 1111, are not applicable in the case of theory systems, since, given $T \in \mathrm{ThSys}(\mathcal{I})$, it may not be the case that $\widetilde{T} \in \mathrm{ThSys}(\mathcal{I})$. On the other hand, as the following lemma shows, for all $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, $\widehat{\Omega}^{\mathcal{I}\lightning}(T) = \widehat{\Omega}^{\mathcal{I}}(T)$. So, for the case of theory systems, all of whose components are nonempty, the two operators do coincide.

Lemma 1180 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$*,*

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})\}.$$

Proof: Since $\{T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I}) : T \leq T'\} \subseteq \{T' \in \mathrm{ThSys}(\mathcal{I}) : T \leq T'\}$, we get

$$\widehat{\Omega}^{\mathcal{I}}(T) \leq \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})\}.$$

But, if $T \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, then, for all $T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$, we have $T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$. Thus, in this particular case, the two collections above are identical and, therefore, equality holds between the two sides in the displayed formula, which proves the lemma. ■

In analogy with the case of rough system truth equationality, we may introduce the notion of *adequacy* of the narrow system core, which will help in characterizing the relationship between narrow system truth equationality and narrow system c-reflectivity. The following proposition, a "narrow" analog of Proposition 1161, justifies the notion of adequacy that will follow.

Proposition 1181 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \Omega(T)\} \leq \widehat{\Omega}^{\mathcal{I}\sharp}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThSys}^{\sharp}(\mathcal{I})$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{implies} & Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \quad (\text{Definition of } Z^{\mathcal{I}\sharp}) \\ & \text{implies} & Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \Omega(T). \quad (T \in \mathrm{ThSys}^{\sharp}(\mathcal{I})) \end{array}$$

Hence,

$$\begin{array}{l} \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \Omega(T)\} \\ \quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T)\} \\ \quad \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ \quad = \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\ \quad = \widetilde{\Omega}^{\mathcal{I}\sharp}(C(\overrightarrow{\phi})). \end{array}$$

This is the displayed formula in the statement. ∎

If the reverse inclusion of that proven in Proposition 1181 holds, then we say that the narrow system core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow system core $Z^{\mathcal{I}\sharp}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}\sharp}(C(\overrightarrow{\phi})) \leq \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \Omega(T)\}.$$

We can show, in analogy with Corollary 1162, that the solubility of the narrow system core implies its adequacy.

Corollary 1182 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}\sharp}$ *is soluble, then it is adequate.*

Proof: Suppose $Z^{\mathcal{I}\sharp}$ is soluble and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll} \widehat{\Omega}^{\mathcal{I}\sharp}(C(\overrightarrow{\phi})) & = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T\} \\ & & (\text{definition of } \widehat{\Omega}^{\mathcal{I}\sharp}) \\ & = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\ & & (T \in \mathrm{ThSys}(\mathcal{I})) \\ & = & \bigcap\{\Omega(T) : T \in \mathrm{ThSys}^{\sharp}(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}\sharp}[\phi] \leq \Omega(T)\}. \\ & & (\text{Solubility of } Z^{\mathcal{I}\sharp}) \end{array}$$

Thus, $Z^{\mathcal{I}\sharp}$ is adequate. ∎

In order to prove a partial converse of Corollary 1182, we will employ the following characterization of narrow system c-reflectivity.

Lemma 1183 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly system c-reflective if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$ *and all* $T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,*

$$\widehat{\Omega}^{\mathcal{I}\nmid}(T) \leq \Omega(T') \quad \textit{implies} \quad T \leq T'.$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system c-reflective and let $T \in \mathrm{ThSys}(\mathcal{I})$ and $T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, such that $\widehat{\Omega}^{\mathcal{I}\nmid}(T) \leq \Omega(T')$. Then, by definition,

$$\bigcap\{\Omega(T'') : T \leq T'' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})\} \leq \Omega(T').$$

By narrow system c-reflectivity, $\bigcap\{T'' : T \leq T'' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})\} \leq T'$. Thus, $T \leq T'$.

Suppose, conversely, that the displayed condition in the statement holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nmid}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, since $\mathcal{T} \subseteq \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we get that

$$\bigcap\{\Omega(T) : \bigcap \mathcal{T} \leq T'' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})\} \leq \Omega(T').$$

By definition, then, $\widehat{\Omega}^{\mathcal{I}\nmid}(\bigcap \mathcal{T}) \leq \Omega(T')$, whence, by hypothesis, $\bigcap \mathcal{T} \leq T'$. This shows that $\mathcal{I}$ is narrowly system c-reflective. ■

We prove, next, a partial converse of Corollary 1182, under the additional assumption that the π-institution $\mathcal{I}$ under consideration is narrowly system c-reflective. This constitutes an analog of Proposition 1163.

Proposition 1184 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a narrowly system c-reflective* π*-institution based on* $\mathbf{F}$*. If* $Z^{\mathcal{I}\nmid}$ *is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly system c-reflective and $Z^{\mathcal{I}\nmid}$ is adequate. Let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $Z^{\mathcal{I}\nmid}_\Sigma[\phi] \leq \Omega(T)$. By the postulated adequacy of $Z^{\mathcal{I}\nmid}$, we get that $\widehat{\Omega}^{\mathcal{I}\nmid}(C(\overrightarrow{\phi})) \leq \Omega(T)$. By narrow system truth equationality and Lemma 1183, $C(\overrightarrow{\phi}) \leq T$. Therefore, $\phi \in T_\Sigma$. We conclude that $Z^{\mathcal{I}\nmid}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating narrow system truth equationality with narrow system c-reflectivity, an analog of Theorem 1164, which characterized rough system truth equationality in terms of rough system c-reflectivity and the adequacy of the rough system core.

Narrow System Truth Equationality
= $Z^{\mathcal{I}\nmid}$ Soluble
= $Z^{\mathcal{I}\nmid}$ Narrowly Defines Theory Systems
= Narrow System c-Reflectivity
+ $Z^{\mathcal{I}\nmid}$ Adequate

Theorem 1185 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly system truth equational if and only if it is narrowly system c-reflective and has an adequate narrow system core.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system truth equational. By Theorem 1171, it is narrowly system c-reflective. By Theorem 1176, its narrow system core is soluble. Thus, by Corollary 1182, its narrow system core is also adequate.

Assume, conversely, that $\mathcal{I}$ is narrowly system c-reflective and has an adequate narrow system core. Then, by Proposition 1184, its narrow system core is soluble. Hence, by Theorem 1177, $\mathcal{I}$ is narrowly system truth equational. ■

Based on Proposition 1152 and Theorem 468, it is not difficult to show, in an analog of Corollary 1165, that the characterization theorem, Theorem 887, of system truth equationality in terms of system c-reflectivity and the adequacy of the system core, can be inferred from Theorem 1185.

Corollary 1186 (Theorem 887) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: $\mathcal{I}$ is system truth equational if and only if, by Proposition 1152, it is narrowly system truth equational and has theorems, if and only if, by Theorem 1185, it is narrowly system c-reflective, with an adequate narrow system core and has theorems, if and only if, by Theorem 468 and the definitions of system core and narrow system core, it is system c-reflective and has an adequate system core. ■

Finally, we prove an analog of Theorem 1166, which may be perceived either as an alternative characterization of narrow system truth equationality, involving arbitrary $\mathbf{F}$-algebraic systems, or as a transfer theorem.

Theorem 1187 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is narrowly system truth equational, with witnessing equations* $\tau^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiSys}^{\mathcal{I}\sharp}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is narrowly system truth equational.

Suppose, conversely, that $\mathcal{I}$ is narrowly system truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiSys}^{\mathcal{I}\natural}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll}\alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \le \Omega(\alpha^{-1}(T)) \\ & & \text{(Lemma 6 and hypothesis)} \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \le \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(Proposition 24)} \\ & \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \le \Omega^{\mathcal{A}}(T). \quad \text{(Lemma 95)}\end{array}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.6 Availability of Natural Theorems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that, by convention, if $\mathcal{I}$ has theorems, then, for every $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathcal{I}$ has a Σ-theorem, i.e., there exists $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\varnothing)$.

On the other hand, recall from Section 2.6 that we say that a π-institution $\mathcal{I}$ has *natural theorems* if there exists a $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$,

$$\vartheta_\Sigma^\flat(\vec{\phi}) \in C_\Sigma(\varnothing).$$

Furthermore, recall that we denote by $\mathrm{NThm}(\mathcal{I})$ the collection of natural theorems of $\mathcal{I}$.

It is straightforward that having natural theorems is a stronger property than having theorems.

Lemma 1188 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has natural theorems, then it has theorems.*

Proof: Suppose $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$ is a natural theorem. Let $\Sigma \in |\mathbf{Sign}^\flat|$. By convention $\mathrm{SEN}^\flat(\Sigma) \neq \varnothing$. Let $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$. Then, we get $\vartheta_\Sigma^\flat(\vec{\phi}) \in \mathrm{Thm}_\Sigma(\mathcal{I})$. This shows that $\mathcal{I}$ has theorems. ■

On the other hand, it is easy to find examples of π-institutions with theorems that do not possess natural theorems. For example, every π-institution with at least one non-trivial set of sentences $\mathrm{SEN}^\flat(\Sigma)$, containing both a Σ-theorem and a Σ-non theorem, and with a trivial category of natural transformations, cannot have natural theorems. This follows from the fact that, under these circumstances, no projection natural transformation can be a natural theorem and projection natural transformations are the only ones available because of the triviality of $N^\flat$.

Another useful observation is that every π-institution with natural theorems has at least one at-most-unary natural theorem.

Lemma 1189 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *has natural theorems, then it has at least one at-most-unary natural theorem.*

Proof: Suppose $\mathcal{I}$ has natural theorems and let $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ be a natural theorem in $N^\flat$. If $k = 0$ or 1, then there is nothing to prove. If $k > 1$, then we define $\vartheta'^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\vartheta'^\flat_\Sigma(\phi) = \vartheta^\flat_\Sigma(\underbrace{\phi, \phi, \dots, \phi}_{k}).$$

Since $\vartheta'^\flat = \vartheta \circ \langle p^{1,0}, p^{1,0}, \dots, p^{1,0}\rangle$ and $\vartheta^\flat$ is in $N^\flat$, we get that $\vartheta'^\flat$ is in $N^\flat$ also. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\vartheta'^\flat_\Sigma(\phi) = \vartheta^\flat_\Sigma(\phi, \dots, \phi) \in \mathrm{Thm}_\Sigma(\mathcal{I}).$$

Hence $\vartheta'^\flat$ is a unary natural theorem. ∎

We have the following characterization of natural theorems involving the local Frege operator.

Theorem 1190 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *a natural transformation in* $N^\flat$*. Then the following conditions are equivalent:*

(i) $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *is a natural theorem;*

(ii) For every $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi \in T_\Sigma \quad \textit{iff} \quad \langle \phi, \vartheta^\flat_\Sigma(\vec{\chi})\rangle \in \lambda_\Sigma(T);$$

(iii) For every $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad \langle \phi, \vartheta^\flat_\Sigma(\vec{\chi})\rangle \in \lambda_\Sigma(\mathrm{Thm}(\mathcal{I})).$$

Proof:

(i)⇒(ii) Assume that $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is a natural theorem. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$.

- Suppose $\phi \in T_\Sigma$. Then, since $\vartheta^\flat_\Sigma(\vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by definition of $\lambda(T)$, $\langle \phi, \vartheta^\flat_\Sigma(\vec{\chi})\rangle \in \lambda_\Sigma(T)$.

- On the other hand, assume $\langle\phi,\vartheta^\flat_\Sigma(\vec{\chi})\rangle\in\lambda_\Sigma(T)$. Since $\vartheta^\flat_\Sigma(\vec{\chi})\in \mathrm{Thm}_\Sigma(\mathcal{I})\subseteq T_\Sigma$, we get, by the definition of $\lambda(T)$, $\phi\in T_\Sigma$.

(ii)⇒(iii) Trivial.

(iii)⇒(i) Suppose that (iii) holds. Let $\Sigma\in|\mathbf{Sign}^\flat|$, $\phi\in\mathrm{SEN}^\flat(\Sigma)$ and $\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$.

- If $\phi\in\mathrm{Thm}_\Sigma(\mathcal{I})$, then, by hypothesis, $\langle\phi,\vartheta^\flat_\Sigma(\vec{\chi})\rangle\in\lambda_\Sigma(\mathrm{Thm}(\mathcal{I}))$, whence, $\vartheta^\flat_\Sigma(\vec{\chi})\in\mathrm{Thm}_\Sigma(\mathcal{I})$.
- If $\phi\notin\mathrm{Thm}_\Sigma(\mathcal{I})$, then, by hypothesis, $\langle\phi,\vartheta^\flat_\Sigma(\vec{\chi})\rangle\notin\lambda_\Sigma(\mathrm{Thm}(\mathcal{I}))$. Thus, $\theta^\flat_\Sigma(\vec{\chi})\in\mathrm{Thm}_\Sigma(\mathcal{I})$.

We conclude that, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$, $\vartheta^\flat_\Sigma(\vec{\chi})\in\mathrm{Thm}_\Sigma(\mathcal{I})$. Therefore, $\vartheta^\flat$ is a natural theorem.

■

We provide two additional equivalent conditions in the theorem following the next lemma.

Lemma 1191 *Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I}=\langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$, and $\vartheta^\flat:(\mathrm{SEN}^\flat)^k\to\mathrm{SEN}^\flat$ a natural transformation in $N^\flat$. If $\vartheta^\flat$ is a natural theorem, then, for every $\mathbf{F}$-algebraic system $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$, all $\Sigma\in|\mathbf{Sign}|$ and all $\vec{\chi}\in\mathrm{SEN}(\Sigma)$, $\vartheta_\Sigma(\vec{\chi})\in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)$, i.e., ϑ is a natural theorem of $\langle\mathcal{A},C^{\mathcal{I},\mathcal{A}}\rangle$.*

Proof: Since $\vartheta^\flat$ is a natural theorem, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$,

$$\vartheta_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))=\alpha_\Sigma(\vartheta^\flat_\Sigma(\vec{\chi}))\in\alpha_\Sigma(\mathrm{Thm}_\Sigma(\mathcal{I}))\subseteq C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\varnothing).$$

By the surjectivity of $\langle F,\alpha\rangle$ the conclusion follows. ■

Theorem 1192 *Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I}=\langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$, and $\vartheta^\flat:(\mathrm{SEN}^\flat)^k\to\mathrm{SEN}^\flat$ a natural transformation in $N^\flat$. Then the following conditions are equivalent:*

(i) $\vartheta^\flat:(\mathrm{SEN}^\flat)^k\to\mathrm{SEN}^\flat$ *is a natural theorem;*

(ii) For every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma\in|\mathbf{Sign}|$ and all $\phi\in\mathrm{SEN}(\Sigma)$,

$$\phi\in T_\Sigma\quad\textit{iff}\quad(\forall\vec{\chi}\in\mathrm{SEN}(\Sigma))(\langle\phi,\vartheta_\Sigma(\vec{\chi})\rangle\in\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T));$$

(iii) For every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $\Sigma\in|\mathbf{Sign}|$ and all $\phi\in\mathrm{SEN}(\Sigma)$,

$$\phi\in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)\quad\textit{iff}\quad(\forall\vec{\chi}\in\mathrm{SEN}(\Sigma))(\langle\phi,\vartheta_\Sigma(\vec{\chi})\rangle\in\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(C^{\mathcal{I},\mathcal{A}}(\varnothing))).$$

Proof:

(i)⇒(ii) Assume that $\vartheta^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ is a natural theorem and let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. By Lemma 1191, for all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, $\vartheta^\flat_\Sigma(\vec{\chi}) \in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)$.

- If $\phi \in T_\Sigma$, then, clearly, for all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, and all $T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\phi \in T'_\Sigma$ and $\vartheta_\Sigma(\vec{\chi}) \in T'_\Sigma$. Hence, $\langle \phi, \vartheta_\Sigma(\vec{\chi})\rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$.
- If, for all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, $\langle \phi, \vartheta_\Sigma(\vec{\chi})\rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$, then, in particular, for all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, $\langle \phi, \vartheta_\Sigma(\vec{\chi})\rangle \in \lambda^{\mathcal{A}}_\Sigma(T)$. Since $\vartheta_\Sigma(\vec{\chi}) \in T_\Sigma$, we conclude that $\phi \in T_\Sigma$.

(ii)⇒(iii) Trivial.

(iii)⇒(iv) Suppose that (iii) holds. Consider, first, the trivial algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with the single signature object $*$ and such that $\mathrm{SEN}(*) = \{0\}$. Then, we have $\langle 0, \vartheta_\Sigma(\vec{0})\rangle = \langle 0,0\rangle \in \{\langle 0,0\rangle\} = \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_*(\varnothing)$. If $\varnothing \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, then this would imply, by hypothesis, that $0 \in \varnothing$, a contradiction. Thus, $\varnothing \notin \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$. This shows that $\mathcal{I}$ has theorems.

Let, now, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma)$. Take a theorem $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, by hypothesis, $\langle t, \vartheta^\flat_\Sigma(\vec{\chi})\rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(\mathrm{Thm}(\mathcal{I})) \subseteq \lambda_\Sigma(\mathrm{Thm}(\mathcal{I}))$. Thus, since $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$, we must have $\vartheta^\flat_\Sigma(\vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathcal{I})$. But $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$ were arbitrary, whence, we conclude that $\vartheta^\flat$ is a natural theorem.

■

We saw that availability of natural theorems is a strictly stronger condition that availability of theorems. We have the following theorem, which follows from preceding results.

Theorem 1193 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an* $\mathbf{F}$*-algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *has natural theorems, then there exists* $\tau : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, such that, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in T_\Sigma \quad \textit{iff}, \quad \text{for all } \vec{\chi} \in \mathrm{SEN}(\Sigma), \tau_\Sigma(\phi, \vec{\chi}) \subseteq \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T);$$

(b) If the condition in the conclusion of (a) holds, then $\mathcal{I}$ *has theorems.*

Proof:

(a) Suppose $\mathcal{I}$ has natural theorems and let $\vartheta^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ be a natural theorem. Then, we define $\tau^\flat : (\mathrm{SEN}^\flat)^{k+1} \to (\mathrm{SEN}^\flat)^2$, by setting

$$\tau^\flat := \{p^{k+1,0} \approx \vartheta^\flat \circ \langle p^{k+1,1}, \dots, p^{k+1,k}\rangle\}.$$

Then the conclusion follows from Theorem 1192.

(b) Suppose that the conclusion of Part (a) holds. Consider the trivial algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with the single signature object $*$ and such that $\mathrm{SEN}(*) = \{0\}$. If $\mathcal{I}$ does not have theorems, then $\varnothing \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $0 \notin \varnothing$, we must have, by hypothesis, $\langle 0, 0\rangle = \langle 0, \vartheta_\Sigma(\vec{0})\rangle \notin \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_*(\varnothing) = \{\langle 0, 0\rangle\}$, a contradiction. Therefore, $\mathcal{I}$ has theorems.

■

We may think of a π-institution that has theorems, but not natural theorems, as having a syntactic deficiency, i.e., not having enough natural transformations in its category of natural transformations to express theoremhood. So in an analogous way with the one used to formulate similar properties through the Leibniz property of the reflexive core and the adequacy of the Suszko core, we make the following definition, taking cue from Theorem 1190.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. The **Frege core** $F^{\mathcal{I}}$ of $\mathcal{I}$ is defined by

$$\begin{array}{rcl} F^{\mathcal{I}} & = & \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)) \\ & & (T_\Sigma \approx \sigma^\flat_\Sigma(\vec{\chi}) \subseteq \widetilde{\lambda}^{\mathcal{I}}_\Sigma(T))\}. \end{array}$$

It is not difficult to show that, in case $\mathcal{I}$ has theorems, $F^{\mathcal{I}} = \mathrm{NThm}(\mathcal{I})$.

Proposition 1194 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has theorems, then $F^{\mathcal{I}} = \mathrm{NThm}(\mathcal{I})$.*

Proof: Suppose that $\mathcal{I}$ has theorems.

Assume $\sigma^\flat \in F^{\mathcal{I}}$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$. Since $\mathcal{I}$ has theorems, there exists $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, by hypothesis and the definition of $F^{\mathcal{I}}$,

$$\langle t, \sigma^\flat_\Sigma(\vec{\chi})\rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(\mathrm{Thm}(\mathcal{I})) \subseteq \lambda_\Sigma(\mathrm{Thm}(\mathcal{I})).$$

Thus, since $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $\sigma^\flat_\Sigma(\vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Since $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$ were arbitrary, $\sigma^\flat \in \mathrm{NThm}(\mathcal{I})$. Therefore, we get that $F^{\mathcal{I}} \subseteq \mathrm{NThm}(\mathcal{I})$.

Suppose, conversely, that $\sigma^\flat \in \mathrm{NThm}(\mathcal{I})$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $T \leq T' \in \mathrm{ThFam}(\mathcal{I})$. Then, we get $\phi \in T'_\Sigma$ and $\sigma^\flat_\Sigma(\vec{\chi}) \in T'_\Sigma$, whence

$$\phi \in T'_\Sigma \quad \text{iff} \quad \sigma^\flat_\Sigma(\vec{\chi}) \in T'_\Sigma.$$

That is, for all $T \leq T' \in \mathrm{ThFam}(\mathcal{I})$, $\langle \phi, \sigma^\flat_\Sigma(\vec{\chi})\rangle \in \lambda_\Sigma(T)$. Hence, $\langle \phi, \sigma^\flat_\Sigma(\vec{\chi})\rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(T)$. This shows that $\sigma^\flat \in F^{\mathcal{I}}$, whence $\mathrm{NThm}(\mathcal{I}) \subseteq F^{\mathcal{I}}$. ■

In the remainder of the section, we show that a property analogous to adequacy, coupled with possession of theorems, guarantees the existence of natural theorems. The following lemma partly justifies the definition of adequacy.

Proposition 1195 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap\{\lambda(T) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\} \leq \widetilde{\lambda}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. By the definition of the Frege core, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{implies} \quad \phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \widetilde{\lambda}^{\mathcal{I}}_\Sigma(T) \subseteq \lambda_\Sigma(T).$$

Therefore, we get

$$\begin{array}{l}\{T \in \mathrm{ThFam}(\mathcal{I}) : \phi \in T_\Sigma\} \\ \quad \subseteq \{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\}.\end{array}$$

This, now, yields

$$\bigcap\{\lambda(T) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\} \leq \widetilde{\lambda}^{\mathcal{I}}(C(\phi)),$$

i.e., the displayed formula in the statement. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that the Frege core $F^{\mathcal{I}}$ is **adequate** if the reverse inclusion of the one proved in Proposition 1195 holds, i.e., if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\lambda}(C(\phi)) \leq \bigcap\{\lambda(T) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\}.$$

Theorem 1196 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has natural theorems if and only if it has theorems and its Frege core is adequate.*

Proof: If $\mathcal{I}$ has natural theorems, then, by Lemma 1188, it has theorems. Moreover, by Proposition 1194, $F^{\mathcal{I}} = \mathrm{NThm}(\mathcal{I})$. Now consider $\tau^\flat \in \mathrm{NThm}(\mathcal{I})$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T)$. Since $F^{\mathcal{I}} = \mathrm{NThm}(\mathcal{I})$, we get $F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$. Thus, $\phi \in T_\Sigma$. This shows that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{r}\{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\} \\ \leq \{T \in \mathrm{ThFam}(\mathcal{I}) : \phi \in T_\Sigma\}.\end{array}$$

This proves that $F^{\mathcal{I}}$ is adequate.

Assume, conversely, that $\mathcal{I}$ has theorems and $F^{\mathcal{I}}$ is adequate.

Note that, if $\mathrm{Thm}(\mathcal{I}) = \mathrm{SEN}^\flat$, then $p^{1,0} : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ is a natural theorem. So we may assume that $\overline{\varnothing} \lneq \mathrm{Thm}(\mathcal{I}) \lneq \mathrm{SEN}^\flat$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$ and $\phi \in \mathrm{SEN}^\flat(\Sigma) \backslash \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, we get

$$\langle \phi, t \rangle \in \lambda_\Sigma(C(\phi)) \quad \text{but} \quad \langle \phi, t \rangle \notin \lambda_\Sigma(\mathrm{Thm}(\mathcal{I})).$$

Thus, if $F^{\mathcal{I}} = \varnothing$, then

$$\mathrm{Thm}(\mathcal{I}) \in \{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\}.$$

So $\langle \phi, t\rangle \notin \bigcap\{\lambda_\Sigma(T) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\}$. Since $\langle \phi, t\rangle \in \bigcap\{\lambda_\Sigma(T) : \phi \in T_\Sigma\}$, we get that

$$\widetilde{\lambda}(C(\phi)) \nleq \bigcap\{\lambda(T) : (\forall \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(\phi \approx F^{\mathcal{I}}_\Sigma(\vec{\chi}) \subseteq \lambda_\Sigma(T))\},$$

contrary to the postulated adequacy of $F^{\mathcal{I}}$. ■

We close the section by showing that having natural theorems is a property that transfers from a π-institution to all $\mathcal{I}$-gmatrix families.

Theorem 1197 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has natural theorems if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*, the* $\mathcal{I}$*-gmatrix* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ *has natural theorems.*

Proof: The "if" is clear by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$ and taking into account the fact that $C^{\mathcal{I},\mathcal{F}} = C$. The "only if" was proven in Lemma 1191. ■

Chapter 15

The Syntactic Leibniz Hierarchy: Basement II

15.1 Syntactic Narrow Family Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **roughly/narrowly family monotone** if, for all $T, T' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

In this section we introduce and study a syntactic analog of this concept.

First, we relativize family reflexivity, family symmetry, family transitivity, family compatibility and family modus ponens to $\mathrm{ThFam}^{\nmid}(\mathcal{I})$.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Moreover, suppose that $I^\flat \subseteq N^\flat$ is a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **roughly family reflexive** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi, \phi] \leq \widetilde{T};$$
- $I^\flat$ is **narrowly family reflexive** if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi, \phi] \leq T.$$

As the following lemma establishes rough and narrow family reflexivity are identical properties.

Lemma 1198 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a family of natural transformations in $N^\flat$, with two distinguished arguments. $I^\flat$ is roughly family reflexive if and only if it is narrowly family reflexive.*

Proof: Suppose, first, that $I^\flat$ is roughly family reflexive and consider $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we have $\widetilde{T} = T$, whence, by rough family reflexivity, $I^\flat_\Sigma[\phi, \phi] \leq \widetilde{T} = T$. Thus, $I^\flat$ is narrowly family reflexive.

Suppose, conversely, that $I^\flat$ is narrowly family reflexive and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since $\widetilde{T} \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we get, by narrow family reflexivity, $I^\flat_\Sigma[\phi, \phi] \leq \widetilde{T}$. Thus, $I^\flat$ is roughly family reflexive. ■

Let, again, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **roughly family symmetric** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi,\psi] \le \widetilde{T} \quad \text{implies} \quad I^\flat_\Sigma[\psi,\phi] \le \widetilde{T};$$
- $I^\flat$ is **narrowly family symmetric** if, for all $T \in \mathrm{ThFam}^{\not\sim}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi,\psi] \le T \quad \text{implies} \quad I^\flat_\Sigma[\psi,\phi] \le T.$$

Similarly to rough and narrow family reflexivity, rough and narrow family symmetry coincide.

Lemma 1199 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a family of natural transformations in $N^\flat$, with two distinguished arguments. $I^\flat$ is roughly family symmetric if and only if it is narrowly family symmetric.*

Proof: Suppose, first, that $I^\flat$ is roughly family symmetric and consider $T \in \mathrm{ThFam}^{\not\sim}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi,\psi] \le T$. Since $T \in \mathrm{ThFam}^{\not\sim}(\mathcal{I})$, we have $\widetilde{T} = T$, whence, by hypothesis, $I^\flat_\Sigma[\phi,\psi] \le \widetilde{T}$. Applying rough family symmetry, we get $I^\flat_\Sigma[\psi,\phi] \le \widetilde{T} = T$. Thus, $I^\flat$ is narrowly family symmetric.

Suppose, conversely, that $I^\flat$ is narrowly family symmetric and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi,\psi] \le \widetilde{T}$. Since $\widetilde{T} \in \mathrm{ThFam}^{\not\sim}(\mathcal{I})$, we get, by narrow family symmetry, $I^\flat_\Sigma[\psi,\phi] \le \widetilde{T}$. Thus, $I^\flat$ is roughly family symmetric. ■

Let, once more, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **roughly family transitive** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi,\psi] \cup I^\flat_\Sigma[\psi,\chi] \le \widetilde{T} \quad \text{implies} \quad I^\flat_\Sigma[\phi,\chi] \le \widetilde{T};$$
- $I^\flat$ is **narrowly family transitive** if, for all $T \in \mathrm{ThFam}^{\not\sim}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,
$$I^\flat_\Sigma[\phi,\psi] \cup I^\flat_\Sigma[\psi,\chi] \le T \quad \text{implies} \quad I^\flat_\Sigma[\phi,\chi] \le T.$$

Rough and narrow family transitivity also coincide.

Lemma 1200 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a family of natural transformations in $N^\flat$, with two distinguished arguments. $I^\flat$ is roughly family transitive if and only if it is narrowly family transitive.*

Proof: Similar to the proof of Lemma 1199. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **roughly family compatible** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\sigma^\flat \in N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$\bigcup_{i<k} \overleftrightarrow{I^\flat}_\Sigma[\phi_i, \psi_i] \leq \widetilde{T} \quad \text{implies} \quad I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \leq \widetilde{T};$$
- $I^\flat$ is **narrowly family compatible** if, for all $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, all $\sigma^\flat \in N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$\bigcup_{i<k} \overleftrightarrow{I^\flat}_\Sigma[\phi_i, \psi_i] \leq T \quad \text{implies} \quad I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \leq T.$$

Rough and narrow family transitivity also coincide.

Lemma 1201 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a family of natural transformations in $N^\flat$, with two distinguished arguments. $I^\flat$ is roughly family compatible if and only if it is narrowly family compatible.*

Proof: Similar to the proof of Lemma 1199. ∎

Finally, we define the property of possessing the rough and the narrow family modus ponens. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ has the **rough family MP** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in \widetilde{T}_\Sigma \quad \text{and} \quad I^\flat_\Sigma[\phi, \psi] \leq \widetilde{T} \quad \text{imply} \quad \psi \in \widetilde{T}_\Sigma;$$
- $I^\flat$ has the **narrow family MP** if, for all $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{and} \quad I^\flat_\Sigma[\phi, \psi] \leq T \quad \text{imply} \quad \psi \in T_\Sigma.$$

As with all preceding properties, the rough and narrow family MP turn out to be identical properties.

Lemma 1202 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat \subseteq N^\flat$ a family of natural transformations in $N^\flat$, with two distinguished arguments. $I^\flat$ has the rough family MP if and only if it has the narrow family MP.*

Proof: The proof again follows the lines of the proof of Lemma 1199, but we describe it also in detail.

Suppose, first, that $I^\flat$ has the rough family MP and let $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $I^\flat_\Sigma[\phi,\psi] \leq T$. Again, by hypothesis, $\widetilde{T} = T$, whence, we get $\phi \in \widetilde{T}_\Sigma$ and $I^\flat_\Sigma[\phi,\psi] \leq \widetilde{T}$. Thus, by rough family MP, we get that $\psi \in \widetilde{T}_\Sigma$, i.e., $\psi \in T_\Sigma$. Thus, $I^\flat$ has the narrow family MP.

Assume, conversely, that $I^\flat$ has the narrow family MP and consider $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$ and $I^\flat_\Sigma[\phi,\psi] \leq \widetilde{T}$. Since $\widetilde{T} \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, we may apply narrow family MP to conclude that $\psi \in \widetilde{T}_\Sigma$. This proves that $I^\flat$ has the rough family MP. ■

We say that $\mathcal{I}$ is **syntactically roughly/narrowly family monotone** if there exists $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that $I^\flat$ satisfies:

- narrow family reflexivity;
- narrow family transitivity;
- narrow family compatibility; and
- narrow family MP.

In that case, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic rough/narrow family monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly family monotone π-institution, with witnessing transformations $I^\flat$, then $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T, for all $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$. This forms a "narrow" analog of Proposition 790.

Proposition 1203 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is syntactically narrowly family monotone, with witnessing transformations* $I^\flat$, *then, for all* $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, $\overleftrightarrow{I^\flat}(T)$ *is a congruence system on* $\mathbf{F}$ *compatible with* T.

Proof: The proof follows along the lines of the proof of Proposition 790. So we give an outline. Let $T \in \mathrm{ThFam}^{\nsim}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$. The narrow family reflexivity of $I^\flat$ ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The fact that $\overleftrightarrow{I^\flat}$ is the symmetrization of $I^\flat$ ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The narrow family transitivity of $I^\flat$ guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Suppose, next, that $\sigma^\flat \in N^\flat$, $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$. Then, the narrow family compatibility of $I^\flat$ ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, then

$\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle\in I^\flat_\Sigma(T)$. Thus, $\overleftrightarrow{I}^\flat(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I}^\flat(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I}^\flat(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I}^\flat(T)$ is compatible with T. Assume that $\phi\in T_\Sigma$ and $\langle\phi,\psi\rangle\in\overleftrightarrow{I}^\flat{}_\Sigma(T)$. Since $I^\flat\subseteq\overleftrightarrow{I}^\flat$, we get, by the narrow family MP of $I^\flat$, that $\psi\in T_\Sigma$. Thus, $\overleftrightarrow{I}^\flat(T)$ is also compatible with T. ■

Proposition 1203 shows that $\overleftrightarrow{I}^\flat$ defines Leibniz congruence systems of theory families in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$. Following similar terminology adopted in Chapter 14, we say that $I^\flat$ **roughly** or **narrowly defines Leibniz congruence systems** of theory families in $\mathcal{I}$ if, for all $T\in\mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$\overleftrightarrow{I}^\flat(T)=\Omega(T).$$

Then, in what is an analog of Corollary 791, we obtain

Corollary 1204 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is syntactically narrowly family monotone, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *narrowly defines Leibniz congruence systems of theory families in* $\mathcal{I}$.

Proof: By Proposition 1203 and Corollary 98. ■

Corollary 1204 allows establishing the fact that syntactic narrow family monotonicity implies (semantic) narrow family monotonicity. This forms an analog of Theorem 792.

Theorem 1205 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is syntactically narrowly family monotone, then it is narrowly family monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly family monotone with witnessing transformations $I^\flat$. Let $T,T'\in\mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $T\le T'$. Then

$$\begin{array}{rcll}\Omega(T)&=&\overleftrightarrow{I}^\flat(T)&\text{(by Corollary 1204)}\\&\le&\overleftrightarrow{I}^\flat(T')&\text{(by Lemma 94)}\\&=&\Omega(T').&\text{(by Corollary 1204)}\end{array}$$

Thus, $\mathcal{I}$ is narrowly family monotone. ■

We now introduce the notion of the rough/narrow reflexive core of a π-institution $\mathcal{I}$ in a way analogous to the reflexive core, which was introduced in Chapter 11. Its introduction will enable us to provide a characterization of the syntactical narrow family monotonicity property and to establish a relationship between this property and its semantic counterpart.

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I}=\langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$.

- The **rough reflexive core** of $\mathcal{I}$ is the collection

$$\begin{array}{rcl}\widetilde{R}^{\mathcal{I}} & = & \{\rho^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ & & (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \le \widetilde{T})\};\end{array}$$

- The **narrow reflexive core** of $\mathcal{I}$ is the collection

$$\begin{array}{rcl}R^{\mathcal{I}\natural} & = & \{\rho^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}^\natural(\mathcal{I}))(\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ & & (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \le T)\}.\end{array}$$

These two notions are identical, as shown in the following proposition, and this justifies the usage of the terms rough and narrow reflexive core interchangeably in this context.

Proposition 1206 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then* $\widetilde{R}^{\mathcal{I}} = R^{\mathcal{I}\natural}$*.*

Proof: On the one hand, if $\rho^\flat \in \widetilde{R}^{\mathcal{I}}$, $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, then, by the definition of the rough reflexive core, $\rho^\flat_\Sigma[\phi,\phi] \le \widetilde{T} = T$, where the equality follows from the assumption that $T \in \mathrm{ThFam}^\natural(\mathcal{I})$. This shows that $\rho^\flat \in R^{\mathcal{I}\natural}$. On the other hand, if $\rho^\flat \in R^{\mathcal{I}\natural}$, $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, then, since $\widetilde{T} \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get by the definition of $R^{\mathcal{I}\natural}$, $\rho^\flat_\Sigma[\phi,\phi] \le \widetilde{T}$. This shows that $\rho^\flat \in \widetilde{R}^{\mathcal{I}}$. ■

Given any theory family in $\mathrm{ThFam}^\natural(\mathcal{I})$, the relation system $R^{\mathcal{I}\natural}(T)$ is a reflexive relation system on $\mathbf{F}$. This forms an analog of Lemma 773.

Lemma 1207 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}^\natural(\mathcal{I})$*,* $R^{\mathcal{I}\natural}(T)$ *is a reflexive relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$. By Lemma 93, $R^{\mathcal{I}\natural}(T)$ is a relation system on $\mathbf{F}$. For reflexivity, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. By the definition of the narrow reflexive core, $R^{\mathcal{I}\natural}_\Sigma[\phi,\phi] \le T$. Thus, $\langle\phi,\phi\rangle \in R^{\mathcal{I}\natural}_\Sigma(T)$ and, therefore, $R^{\mathcal{I}\natural}(T)$ is reflexive. ■

As in Lemma 775, it may also be established that $R^{\mathcal{I}\natural}(T)$ is a symmetric relation system on $\mathbf{F}$, for all $T \in \mathrm{ThFam}^\natural(\mathcal{I})$.

Lemma 1208 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}^\natural(\mathcal{I})$*,* $R^{\mathcal{I}\natural}(T)$ *is a symmetric relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$. Again, Lemma 93 shows that $R^{\mathcal{I}\natural}(T)$ is a relation system. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi,\psi\rangle \in R^{\mathcal{I}\natural}_\Sigma(T)$. Equivalently, $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T$. Consider any $\rho^\flat \in R^{\mathcal{I}\natural}$. By the definition of

$R^{\mathcal{I}\natural}$, we get that $\overline{\rho^\flat} \in R^{\mathcal{I}\natural}$. Therefore, by the hypothesis, $\overline{\rho^\flat}_\Sigma[\phi,\psi] \le T$. But this gives $\rho^\flat_\Sigma[\psi,\phi] \le T$. Since this holds for all $\rho^\flat \in R^{\mathcal{I}\natural}$, we conclude that $R^{\mathcal{I}\natural}_\Sigma[\psi,\phi] \le T$. Hence, $\langle\psi,\phi\rangle \in R^{\mathcal{I}\natural}_\Sigma(T)$. Therefore, $R^{\mathcal{I}\natural}(T)$ is a symmetric relation system on $\mathbf{F}$. ■

Continuing the study of sequence of properties of $R^{\mathcal{I}\natural}(T)$, we show that, for all theory families $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $R^{\mathcal{I}\natural}(T)$ has the compatibility property in $\mathbf{F}$.

Lemma 1209 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Then, for all $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $R^{\mathcal{I}\natural}(T)$ has the compatibility property in $\mathbf{F}$.*

Proof: Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$. We rely on Corollary 12. Let $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi,\psi\rangle \in R^{\mathcal{I}\natural}_\Sigma(T)$ or, equivalently, $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T$. Let $\rho^\flat : (\mathrm{SEN}^\flat)^n \to \mathrm{SEN}^\flat$ be arbitrary in $R^{\mathcal{I}\natural}$. We consider the natural transformation $\rho'^\flat : (\mathrm{SEN}^\flat)^{n+k} \to \mathrm{SEN}^\flat$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\zeta,\eta,\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, by

$$\rho'^\flat_\Sigma(\zeta,\eta,\vec{\chi},\vec{\xi}) = \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta,\vec{\chi}),\sigma^\flat_\Sigma(\eta,\vec{\chi}),\vec{\xi}).$$

Note that, since $\sigma^\flat \in N^\flat$, $\rho^\flat \in N^\flat$ and

$$\begin{aligned}\rho'^\flat \;=\; \rho^\flat \circ \langle &\sigma^\flat \circ \langle p^{n+k,0}, p^{n+k,2},\dots,p^{n+k,k}\rangle, \sigma^\flat \circ \langle p^{n+k,1},p^{n+k,2},\dots,p^{n+k,k}\rangle,\\ &p^{n+k,k+1},\dots,p^{n+k,n+k-1}\rangle,\end{aligned}$$

we get that $\rho'^\flat \in N^\flat$. Moreover, for all $T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\zeta,\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}\rho'^\flat_\Sigma(\zeta,\zeta,\vec{\chi},\vec{\xi}) &= \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta,\vec{\chi}),\sigma^\flat_\Sigma(\zeta,\vec{\chi}),\vec{\xi}) \quad \text{(by definition of } \rho'^\flat)\\ &\in T'_\Sigma. \quad (\text{since } \rho^\flat \in R^{\mathcal{I}\natural}).\end{aligned}$$

Thus, by the definition of the narrow reflexive core, we get that $\rho'^\flat \in R^{\mathcal{I}\natural}$.

Now since $\rho'^\flat \in R^{\mathcal{I}\natural}$ and, by hypothesis, $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}),\vec{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\phi,\vec{\chi})),\mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\psi,\vec{\chi})),\vec{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho^\flat_\Sigma[\sigma^\flat_\Sigma(\phi,\vec{\chi}),\sigma^\flat_\Sigma(\psi,\vec{\chi})] \le T.$$

Since this holds for all $\rho^\flat \in R^{\mathcal{I}\natural}$, we get that $R^{\mathcal{I}\natural}_\Sigma[\sigma^\flat_\Sigma(\phi,\vec{\chi}),\sigma^\flat_\Sigma(\psi,\vec{\chi})] \le T$ or, equivalently, $\langle\sigma^\flat_\Sigma(\phi,\vec{\chi}),\sigma^\flat_\Sigma(\psi,\vec{\chi})\rangle \in R^{\mathcal{I}\natural}_\Sigma(T)$. Therefore, $R^{\mathcal{I}\natural}(T)$ has the congruence compatibility property in $\mathbf{F}$. ■

We now show, in an analog of Theorem 799, that possession of the narrow family modus ponens by the narrow reflexive core intrinsically characterizes syntactic narrow family monotonicity. We start by showing that possession of the narrow family MP by the narrow reflexive core is necessary for syntactic narrow family monotonicity. This forms an analog of Theorem 796.

Theorem 1210 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly family monotone, then* $R^{\mathcal{I}\nmid}$ *has the narrow family MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly family monotone with witnessing transformations $I^\flat$. Since, by definition, $I^\flat$ is narrowly family reflexive, we get, by definition of $R^{\mathcal{I}\nmid}$, $I^\flat \subseteq R^{\mathcal{I}\nmid}$. Thus, since $I^\flat$ has narrow family MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}\nmid}$ also satisfies the narrow family MP. ∎

Possession of narrow family MP by $R^{\mathcal{I}\nmid}$ implies that $R^{\mathcal{I}\nmid}$ has the narrow family transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 797.

Proposition 1211 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}\nmid}$ *has the narrow family MP, then it also has the narrow family transitivity in* $\mathcal{I}$*.*

Proof: Suppose that $R^{\mathcal{I}\nmid}$ has the narrow family MP and let $T \in \mathrm{ThFam}^\nmid(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in R^{\mathcal{I}\nmid}_\Sigma(T)$. This means that $R^{\mathcal{I}\nmid}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}\nmid}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 1209, we get that, for all $\rho^\flat \in R^{\mathcal{I}\nmid}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$R^{\mathcal{I}\nmid}_{\Sigma'}[\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}), \\ \rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R^{\mathcal{I}\nmid}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}\nmid}$ has the narrow family MP. Therefore, for all $\rho^\flat \in R^{\mathcal{I}\nmid}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R^{\mathcal{I}\nmid}_\Sigma[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in R^{\mathcal{I}\nmid}_\Sigma(T)$ and, hence, $R^{\mathcal{I}\nmid}$ is narrowly family transitive in $\mathcal{I}$. ∎

We are now ready to show a converse of Theorem 1210, i.e., that possession of the narrow family MP by $R^{\mathcal{I}\nmid}$ suffices to establish the syntactic narrow family monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}\nmid}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 798.

Theorem 1212 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}\nleq}$ *has the narrow family MP, then* $\mathcal{I}$ *is syntactically narrowly family monotone, with witnessing transformations* $R^{\mathcal{I}\nleq}$*.*

Proof: By Lemma 1207, $R^{\mathcal{I}\nleq}$ is narrowly family reflexive in $\mathcal{I}$. By Lemma 1208, $R^{\mathcal{I}\nleq}$ is narrowly family symmetric in $\mathcal{I}$. By hypothesis and Proposition 1211, it is narrowly family transitive in $\mathcal{I}$. By Lemma 1209 it has the narrow family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow family MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations $R^{\mathcal{I}\nleq}$. ∎

Theorems 1210 and 1212 provide the promised characterization of syntactic narrow family monotonicity in terms of the narrow family MP of the narrow reflexive core.

$$\begin{array}{c} \mathcal{I} \text{ is Syntactically Narrow} \\ \text{Family Monotone} \end{array} \longleftrightarrow \begin{array}{c} R^{\mathcal{I}\nleq} \text{ has Narrow Family} \\ \text{Modus Ponens} \end{array}.$$

Theorem 1213 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly family monotone if and only if* $R^{\mathcal{I}\nleq}$ *has the narrow family MP in* $\mathcal{I}$*.*

Proof: Theorem 1210 gives the "only if" and the "if" is by Theorem 1212. ∎

A related alternative characterization asserts that syntactic narrow family monotonicity amounts to the narrow definability of Leibniz congruence systems of theory families by the narrow reflexive core. This result forms an analog of Theorem 801.

$$\begin{array}{c} \mathcal{I} \text{ is Syntactically Narrow} \\ \text{Family Monotone} \end{array} \longleftrightarrow \begin{array}{c} R^{\mathcal{I}\nleq} \text{ Defines Leibniz Congruence} \\ \text{Systems of Theory Families} \end{array}.$$

Theorem 1214 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly family monotone if and only if, for all* $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}\nleq}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly family monotone, then, by Theorem 1210, $R^{\mathcal{I}\nleq}$ has the narrow family MP in $\mathcal{I}$. Thus, by Theorem 1212, $R^{\mathcal{I}\nleq}$ is a family of witnessing transformations for the syntactic narrow family monotonicity of $\mathcal{I}$. Thus, by Corollary 1204, for all $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Omega(T) = R^{\mathcal{I}\nleq}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}\natural}$ is narrowly family reflexive, narrowly family transitive and has the narrow family compatibility property and the narrow family MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly family monotone. ∎

In the case of syntactic protoalgebraicity, in Chapter 11, it was shown that the property that separates syntactic protoalgebraicity from protoalgebraicity is the Leibniz compatibility property with respect to the theory family generated by the reflexive core, i.e., the property that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])).$$

The task of characterizing those π-institutions that are syntactically narrowly family monotone among those that are narrowly family monotone is more involved. The additional complications arise from the fact that the class of theory families $\mathrm{ThFam}^{\natural}(\mathcal{I})$ may not be, in general, closed under (signature-wise) intersections and, hence, may not possess a least element. Therefore, to pinpoint syntactic narrow family monotonicity inside the class of narrow family monotone π-institutions, we need to devise a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow reflexive core.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we interject a small discussion. Recall that a π-institution $\mathcal{I}$ is *protoalgebraic* if its Leibniz operator is monotone on theory families. Recall, also, that its reflexive core $R^{\mathcal{I}}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])).$$

If a π-institution is protoalgebraic and has a Leibniz reflexive core, then it satisfies the global family modus ponens. This was shown in Chapter 11 using the following method. Considering $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$, we get

- $\langle\phi,\psi\rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi]))$ first, by applying the Leibniz property;
- $\Omega(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) \leq \Omega(T)$, by applying the hypothesis that $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$ and the postulated protoalgebraicity of $\mathcal{I}$.

However, in case of narrow family monotonicity, the plausibility of $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]$ having some empty components makes it likely that, in the second stage, narrow family monotonicity may not be applicable to ensure the inclusion $\Omega(C(R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])) \leq \Omega(T)$.

An obvious remedy is to restrict attention to those π-institutions in which $C(R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]) \in \mathrm{ThFam}^{\natural}(\mathcal{I})$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, and leave the Leibniz property unaltered. A more relaxed approach is to assume that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, the poset

$$[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]) \coloneqq \{T \in \mathrm{ThFam}^\natural(\mathcal{I}) : R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T\}$$

satisfies the descending chain condition and to postulate that every minimal element $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$ satisfies $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.

- For $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, define

$$[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]) \coloneqq \{T \in \mathrm{ThFam}^\natural(\mathcal{I}) : R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T\};$$

- For $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\mathcal{I}$ is called $\langle\Sigma,\phi,\psi\rangle$-**reflexively covered** if, for every theory family $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, there exists minimal $T' \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, such that $T' \le T$;
- $\mathcal{I}$ is called **reflexively covered** if it is $\langle\Sigma,\phi,\psi\rangle$-reflexively covered, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

Given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we write

$$\min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$$

for the collection of minimal elements in $[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow reflexive core $R^{\mathcal{I}\natural}$ of $\mathcal{I}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in \min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(T).$$

We show, in an analog of Proposition 785, that, if $R^{\mathcal{I}\natural}$ has the narrow family MP, then it is Leibniz. In fact, the proof demonstrates that, under the narrow family MP, a stronger property than that of being Leibniz holds; more concretely, that for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(T).$$

Proposition 1215 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\natural}$ has the narrow family MP, then for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$.*

Proof: Suppose $R^{\mathcal{I}\natural}$ has the narrow family MP and let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \le T$. To verify that $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$, we use Theorem 19. Let $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and

$\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, such that $\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$. Since $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, by Lemma 1209,

$$R^{\mathcal{I}\nleq}_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}\nleq}$ has the narrow family MP, we obtain

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

Hence, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$ and, therefore, $R^{\mathcal{I}\nleq}$ is Leibniz. ∎

Corollary 1216 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\nleq}$ has the narrow family MP, then it is Leibniz.*

Proof: Directly by Proposition 1215. ∎

In the opposite direction, when dealing with reflexively covered π-institutions, we may show that narrow family monotonicity combined with the Leibniz property of the narrow reflexive core imply that the narrow reflexive core has the narrow family modus ponens in $\mathcal{I}$.

Proposition 1217 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively covered, narrowly family monotone π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\nleq}$ is Leibniz, then it has the narrow family MP in $\mathcal{I}$.*

Proof: Let $\mathcal{I}$ be a reflexively covered π-institution. Suppose that $\mathcal{I}$ is narrowly family monotone and that $R^{\mathcal{I}\nleq}$ is Leibniz. Let $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}\nleq}_\Sigma[\phi, \psi] \leq T$. Since $\mathcal{I}$ is reflexively covered, there exists $T' \in \min[R^{\mathcal{I}\nleq}_\Sigma[\phi, \psi]]$, such that $T' \leq T$. Now we have

$$\begin{array}{rcll} \langle \phi, \psi \rangle & \in & \Omega_\Sigma(T') & (\text{since } R^{\mathcal{I}\nleq} \text{ is Leibniz and } T' \in \min[R^{\mathcal{I}\nleq}_\Sigma[\phi, \psi]]) \\ & \subseteq & \Omega_\Sigma(T). & (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly family monotone}) \end{array}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T, that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}\nleq}$ has the narrow family MP in $\mathcal{I}$. ∎

Thus, at least for reflexively covered π-institutions, it is possible to show that the class of syntactically narrowly monotone ones inside the class of the narrowly monotone ones can be characterized exactly by the Leibniz property of the narrow reflexive core. This forms a partial analog of Theorem 805 in the narrow context.

Theorem 1218 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a reflexively covered* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically narrowly family monotone if and only if it is narrowly family monotone and has a Leibniz narrow reflexive core.*

Proof: Let $\mathcal{I}$ be a reflexively covered π-institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly family monotone. Then it is narrowly family monotone by Theorem 1205. Moreover, its narrow reflexive core has the narrow family MP by Theorem 1210 and, hence, by Corollary 1216, its narrow reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly family monotone with a Leibniz narrow reflexive core. Then, by Proposition 1217, its narrow reflexive core has the narrow family MP and, therefore, by Theorem 1212, $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations $R^{\mathcal{I}\nmid}$. ∎

15.2 Syntactic Narrow System Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **narrowly system monotone** if, for all $T, T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$,

$$T \le T' \quad \text{implies} \quad \Omega(T) \le \Omega(T').$$

In this section, in analogy with Section 15.1, we introduce and study a syntactic analog of this concept.

First, the concepts of narrow family reflexivity, narrow family symmetry, narrow family transitivity, narrow family compatibility and narrow family modus ponens can all be relativized to $\mathrm{ThSys}^{\nmid}(\mathcal{I})$.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Moreover, suppose that $I^\flat \subseteq N^\flat$ is a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **narrowly system reflexive** if, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \phi] \le T;$$

- $I^\flat$ is **narrowly system symmetric** if, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \psi] \le T \quad \text{implies} \quad I^\flat_\Sigma[\psi, \phi] \le T;$$

- $I^\flat$ is **narrowly system transitive** if, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \psi] \cup I^\flat_\Sigma[\psi, \chi] \le T \quad \text{implies} \quad I^\flat_\Sigma[\phi, \chi] \le T;$$

- $I^\flat$ is **narrowly system compatible** if, for all $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$, all $\sigma^\flat \in N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcup_{i<k} \overleftrightarrow{I^\flat}_\Sigma[\phi_i, \psi_i] \leq T \quad \text{implies} \quad I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \leq T;$$

- $I^\flat$ has the **narrow system MP** if, for all $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{and} \quad I^\flat_\Sigma[\phi, \psi] \leq T \quad \text{imply} \quad \psi \in T_\Sigma.$$

We say that $\mathcal{I}$ is **syntactically narrowly system monotone** if there exists $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that $I^\flat$ satisfies:

- narrow system reflexivity;
- narrow system transitivity;
- narrow system compatibility; and
- narrow system MP.

In that case, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic narrow system monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly system monotone π-institution, with witnessing transformations $I^\flat$, then $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$ compatible with T, for all $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$. This forms a system analog of Proposition 1203.

Proposition 1219 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly system monotone, with witnessing transformations* $I^\flat$*, then, for all* $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$*,* $\overleftrightarrow{I^\flat}(T)$ *is a congruence system on* $\mathbf{F}$ *compatible with* T*.*

Proof: The proof is similar to that of Proposition 1203. Let $T \in \mathrm{ThSys}^\nmid(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$. The narrow system reflexivity of $I^\flat$ ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The fact that $\overleftrightarrow{I^\flat}$ is the symmetrization of $I^\flat$ ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The narrow system transitivity of $I^\flat$ guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Suppose, next, that $\sigma^\flat \in N^\flat$, $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$. Then, the narrow system compatibility of $I^\flat$ ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, then $\langle \sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi}) \rangle \in I^\flat_\Sigma(T)$. Thus, $\overleftrightarrow{I^\flat}(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I^\flat}(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I^\flat}(T)$ is compatible with T. Assume that $\phi \in T_\Sigma$ and $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Since $I^\flat \subseteq \overleftrightarrow{I^\flat}$, we get, by the narrow system MP of $I^\flat$, that $\psi \in T_\Sigma$. Thus, $\overleftrightarrow{I^\flat}(T)$ is also compatible with T. ∎

Proposition 1219 shows that $\overleftrightarrow{I^\flat}$ defines Leibniz congruence systems of theory systems in $\mathrm{ThSys}^{\nmid}(\mathcal{I})$. Again, following terminology adopted in Section 15.1, we say that $I^\flat$ **narrowly defines Leibniz congruence systems** of theory systems in $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$,

$$\overleftrightarrow{I^\flat}(T) = \Omega(T).$$

Then, in what is an analog of Corollary 1204, we obtain

Corollary 1220 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly system monotone, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *narrowly defines Leibniz congruence systems of theory systems in* $\mathcal{I}$*.*

Proof: By Proposition 1219 and Corollary 98. ∎

Corollary 1220 shows that syntactic narrow system monotonicity implies (semantic) narrow system monotonicity. This forms an analog of Theorem 1205.

Theorem 1221 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly system monotone, then it is narrowly system monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly system monotone with witnessing transformations $I^\flat$. Let $T, T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{array}{rcll} \Omega(T) & = & \overleftrightarrow{I^\flat}(T) & \text{(by Corollary 1220)} \\ & \leq & \overleftrightarrow{I^\flat}(T') & \text{(by Lemma 94)} \\ & = & \Omega(T'). & \text{(by Corollary 1220)} \end{array}$$

Thus, $\mathcal{I}$ is narrowly system monotone. ∎

We now introduce the notion of the narrow reflexive system core of a π-institution $\mathcal{I}$ in a way analogous to the narrow reflexive core, which was introduced in Section 15.1. Its introduction will enable us to provide a characterization of the syntactical narrow system monotonicity property and to establish a relationship between this property and its semantic counterpart.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The **narrow reflexive system core** of $\mathcal{I}$ is the collection

$$\begin{aligned} R^{\mathcal{I}s} = \{\rho^\flat \in N^\flat : (\forall T \in \mathrm{ThSys}^{\nmid}(\mathcal{I}))(\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi,\phi] \leq T)\}. \end{aligned}$$

Given any theory system in $\mathrm{ThSys}^{\nmid}(\mathcal{I})$, the relation system $R^{\mathcal{I}s}(T)$ is a reflexive relation system on $\mathbf{F}$. This forms an analog of Lemma 1207.

Lemma 1222 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,* $R^{\mathcal{I}s}(T)$ *is a reflexive relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$. By Lemma 93, $R^{\mathcal{I}s}(T)$ is a relation system on $\mathbf{F}$. For reflexivity, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. By the definition of the narrow reflexive system core, $R^{\mathcal{I}s}_\Sigma[\phi,\phi] \leq T$. Thus, $\langle \phi,\phi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$ and, therefore, $R^{\mathcal{I}s}(T)$ is reflexive. ■

As in Lemma 1208, we establish that $R^{\mathcal{I}s}(T)$ is a symmetric relation system on $\mathbf{F}$, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$.

Lemma 1223 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,* $R^{\mathcal{I}s}(T)$ *is a symmetric relation system on* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$. Again, Lemma 93 shows that $R^{\mathcal{I}s}(T)$ is a relation system. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi,\psi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$. Equivalently, $R^{\mathcal{I}s}_\Sigma[\phi,\psi] \leq T$. Consider any $\rho^\flat \in R^{\mathcal{I}s}$. By the definition of $R^{\mathcal{I}s}$, we get that $\overline{\rho^\flat} \in R^{\mathcal{I}s}$. Therefore, by the hypothesis, $\overline{\rho^\flat}_\Sigma[\phi,\psi] \leq T$. But this gives $\rho^\flat_\Sigma[\psi,\phi] \leq T$. Since this holds for all $\rho^\flat \in R^{\mathcal{I}s}$, we conclude that $R^{\mathcal{I}s}_\Sigma[\psi,\phi] \leq T$. Hence, $\langle \psi,\phi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$. Therefore, $R^{\mathcal{I}s}(T)$ is a symmetric relation system on $\mathbf{F}$. ■

We now show that, for all theory systems $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $R^{\mathcal{I}s}(T)$ has the compatibility property in $\mathbf{F}$. This forms an analog of Lemma 1209.

Lemma 1224 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,* $R^{\mathcal{I}s}(T)$ *has the compatibility property in* $\mathbf{F}$*.*

Proof: Let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$. We rely on Corollary 12. Let $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ is in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi,\psi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$ or, equivalently, $R^{\mathcal{I}s}_\Sigma[\phi,\psi] \leq T$. Let $\rho^\flat : (\mathrm{SEN}^\flat)^n \to \mathrm{SEN}^\flat$ be arbitrary in $R^{\mathcal{I}s}$. We consider the natural transformation $\rho'^\flat : (\mathrm{SEN}^\flat)^{n+k} \to \mathrm{SEN}^\flat$, defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\zeta,\eta,\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, by

$$\rho'^\flat_\Sigma(\zeta,\eta,\vec{\chi},\vec{\xi}) = \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta,\vec{\chi}),\sigma^\flat_\Sigma(\eta,\vec{\chi}),\vec{\xi}).$$

Note that, since $\sigma^\flat \in N^\flat$, $\rho^\flat \in N^\flat$ and

$$\rho'^\flat = \rho^\flat \circ \langle \sigma^\flat \circ \langle p^{n+k,0}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \sigma^\flat \circ \langle p^{n+k,1}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, p^{n+k,k+1}, \dots, p^{n+k,n+k-1} \rangle,$$

we get that $\rho'^\flat \in N^\flat$. Moreover, for all $T' \in \mathrm{ThSys}^\nmid(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\zeta, \vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rcll} \rho'^\flat_\Sigma(\zeta, \zeta, \vec{\chi}, \vec{\xi}) & = & \rho^\flat_\Sigma(\sigma^\flat_\Sigma(\zeta, \vec{\chi}), \sigma^\flat_\Sigma(\zeta, \vec{\chi}), \vec{\xi}) & \text{(by definition of } \rho'^\flat) \\ & \in & T'_\Sigma. \quad (\text{since } \rho^\flat \in R^{\mathcal{I}s}). & \end{array}$$

Thus, by the definition of the narrow reflexive system core, we get that $\rho'^\flat \in R^{\mathcal{I}s}$.

Now since $\rho'^\flat \in R^{\mathcal{I}s}$ and, by hypothesis, $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \vec{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\phi, \vec{\chi})), \mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\psi, \vec{\chi})), \vec{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho^\flat_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \leq T.$$

Since this holds for all $\rho^\flat \in R^{\mathcal{I}s}$, we get that $R^{\mathcal{I}s}_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi})] \leq T$ or, equivalently, $\langle \sigma^\flat_\Sigma(\phi, \vec{\chi}), \sigma^\flat_\Sigma(\psi, \vec{\chi}) \rangle \in R^{\mathcal{I}s}_\Sigma(T)$. Therefore, $R^{\mathcal{I}s}(T)$ has the congruence compatibility property in $\mathbf{F}$. ∎

We now show, in an analog of Theorem 1213, that possession of the narrow system modus ponens by the narrow reflexive system core intrinsically characterizes syntactic narrow system monotonicity. We start by showing that possession of the narrow system MP by the narrow reflexive core is necessary for syntactic narrow system monotonicity. This forms an analog of Theorem 1210.

Theorem 1225 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly system monotone, then $R^{\mathcal{I}s}$ has the narrow system MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly system monotone with witnessing transformations $I^\flat$. Since, by definition, $I^\flat$ is narrowly system reflexive, we get, by definition of $R^{\mathcal{I}s}$, $I^\flat \subseteq R^{\mathcal{I}s}$. Thus, since $I^\flat$ has the narrow system MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}s}$ also satisfies the narrow system MP. ∎

If $R^{\mathcal{I}s}$ has the narrow system MP, then it has the narrow system transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 1211.

Proposition 1226 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $R^{\mathcal{I}s}$ *has the narrow system MP, then it also has the narrow system transitivity in* $\mathcal{I}$.

Proof: Suppose that $R^{\mathcal{I}s}$ has the narrow system MP and let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$. This means that $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}s}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 1224, we get that, for all $\rho^\flat \in R^{\mathcal{I}s}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$R^{\mathcal{I}s}_{\Sigma'}[\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}), \\ \rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}s}$ has the narrow system MP. Therefore, for all $\rho^\flat \in R^{\mathcal{I}s}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R^{\mathcal{I}s}_\Sigma[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in R^{\mathcal{I}s}_\Sigma(T)$ and, hence, $R^{\mathcal{I}s}$ is narrowly system transitive in $\mathcal{I}$. ■

We are now ready to show a converse of Theorem 1225, i.e., that possession of the narrow system MP by $R^{\mathcal{I}s}$ suffices to establish the syntactic narrow system monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}s}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 1212.

Theorem 1227 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $R^{\mathcal{I}s}$ *has the narrow system MP, then* $\mathcal{I}$ *is syntactically narrowly system monotone, with witnessing transformations* $R^{\mathcal{I}s}$.

Proof: By Lemma 1222, $R^{\mathcal{I}s}$ is narrowly system reflexive in $\mathcal{I}$. By Lemma 1223, $R^{\mathcal{I}s}$ is narrowly system symmetric in $\mathcal{I}$. By hypothesis and Proposition 1226, it is narrowly system transitive in $\mathcal{I}$. By Lemma 1224 it has the narrow system compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow system MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations $R^{\mathcal{I}s}$. ■

Theorems 1225 and 1227 provide the promised characterization of syntactic narrow system monotonicity in terms of the narrow system MP of the narrow reflexive system core.

$$\begin{array}{c}\mathcal{I}\text{ is Syntactically Narrow}\\ \text{System Monotone}\end{array} \longleftrightarrow \begin{array}{c}R^{\mathcal{I}s}\text{ has Narrow System}\\ \text{Modus Ponens}\end{array}.$$

Theorem 1228 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly system monotone if and only if* $R^{\mathcal{I}s}$ *has the narrow system MP in* $\mathcal{I}$*.*

Proof: Theorem 1225 gives the "only if" and the "if" is by Theorem 1227. ■

A related alternative characterization asserts that syntactic narrow system monotonicity amounts to the narrow definability of Leibniz congruence systems of theory systems by the narrow reflexive system core. This result forms an analog of Theorem 1214.

$$\begin{array}{c}\mathcal{I} \text{ is Syntactically Narrow}\\ \text{System Monotone}\end{array} \longleftrightarrow \begin{array}{c}R^{\mathcal{I}s} \text{ Defines Leibniz Congruence}\\ \text{Systems of Theory Systems}\end{array}.$$

Theorem 1229 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly system monotone if and only if, for all* $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*,*

$$\Omega(T) = R^{\mathcal{I}s}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly system monotone, then, by Theorem 1225, $R^{\mathcal{I}s}$ has the narrow system MP in $\mathcal{I}$. Thus, by Theorem 1227, $R^{\mathcal{I}s}$ is a family of witnessing transformations for the syntactic narrow system monotonicity of $\mathcal{I}$. Thus, by Corollary 1220, for all $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Omega(T) = R^{\mathcal{I}s}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}s}$ is narrowly system reflexive, narrowly system transitive and has the narrow system compatibility property and the narrow system MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly system monotone. ■

To prove an analog of Theorem 1218, which, in a certain restricted sense characterizes syntactic narrow family monotonicity inside the class of narrow family monotone π-institutions, we create a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow reflexive system core. Once more, the difficulty in this case, similarly with that described in some detail in Section 15.1, arises from the fact that $\mathrm{ThSys}^{\nmid}(\mathcal{I})$ may not be, in general, closed under signature-wise intersections.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we elaborate further on the relevant discussion initiated in Section 15.1. Recall that a π-institution $\mathcal{I}$ is *prealgebraic* if its Leibniz operator is monotone on theory systems. Recall, also, once more, that its reflexive core $R^{\mathcal{I}}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

If a π-institution is prealgebraic and has a Leibniz reflexive core, then it satisfies the global system modus ponens. This was shown in Chapter 11 using the following method. Considering $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$, we get

- $\langle\phi,\psi\rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi,\psi]))$ first, by applying the Leibniz property;
- $\Omega(C(R^{\mathcal{I}}_\Sigma[\phi,\psi])) \leq \Omega(T)$, by applying the hypothesis that $R^{\mathcal{I}}_\Sigma[\phi,\psi] \leq T$ and the postulated prealgebraicity of $\mathcal{I}$ and observing at the same time that $C(R^{\mathcal{I}}_\Sigma[\phi,\psi]) \in \mathrm{ThSys}(\mathcal{I})$, since $R^{\mathcal{I}}_\Sigma[\phi,\psi]$ is a sentence system.

However, in case of narrow system monotonicity, the plausibility of $R^{\mathcal{I}s}_\Sigma[\phi,\psi]$ having some empty components makes it likely that, in the second stage, narrow system monotonicity may not be applicable to ensure the inclusion $\Omega(C(R^{\mathcal{I}s}_\Sigma[\phi,\psi])) \leq \Omega(T)$. To deal with this plausibility, we assume, in a similar way as before, that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, the poset

$$[R^{\mathcal{I}s}_\Sigma[\phi,\psi]) \coloneqq \{T \in \mathrm{ThSys}^{\not\emptyset}(\mathcal{I}) : R^{\mathcal{I}s}_\Sigma[\phi,\psi] \leq T\}$$

satisfies the descending chain condition and to postulate that every minimal element $T \in [R^{\mathcal{I}s}_\Sigma[\phi,\psi])$ satisfies $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.

- For $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, define
$$[R^{\mathcal{I}s}_\Sigma[\phi,\psi]) \coloneqq \{T \in \mathrm{ThSys}^{\not\emptyset}(\mathcal{I}) : R^{\mathcal{I}s}_\Sigma[\phi,\psi] \leq T\};$$
- For $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\mathcal{I}$ is called **$\langle\Sigma,\phi,\psi\rangle$-reflexively system covered** if, for every theory system $T \in [R^{\mathcal{I}s}_\Sigma[\phi,\psi])$, there exists minimal $T' \in [R^{\mathcal{I}s}_\Sigma[\phi,\psi])$, such that $T' \leq T$;
- $\mathcal{I}$ is called **reflexively system covered** if it is $\langle\Sigma,\phi,\psi\rangle$-reflexively system covered, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$.

Given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, we write

$$\min[R^{\mathcal{I}s}_\Sigma[\phi,\psi])$$

for the collection of minimal elements in $[R^{\mathcal{I}s}_\Sigma[\phi,\psi])$.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow reflexive system core $R^{\mathcal{I}s}$ of $\mathcal{I}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in \min[R^{\mathcal{I}s}_\Sigma[\phi,\psi])$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(T).$$

We show, in an analog of Proposition 1215, that, if $R^{\mathcal{I}s}$ has the narrow system MP, then it is Leibniz. In fact, the proof demonstrates that, under the narrow system MP, a stronger property than that of being Leibniz holds; more concretely, that for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in [R^{\mathcal{I}s}_\Sigma[\phi, \psi])$ (and not only for $T \in \min[R^{\mathcal{I}s}_\Sigma[\phi, \psi]))$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

Proposition 1230 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}s}$ *has the narrow system MP, then for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ *and all* $T \in [R^{\mathcal{I}s}_\Sigma[\phi, \psi])$*,* $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$*.*

Proof: Suppose $R^{\mathcal{I}s}$ has the narrow system MP and let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$. To verify that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, we use Theorem 19. Let $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, such that $\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$. Since $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, by Lemma 1224,

$$R^{\mathcal{I}s}_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}s}$ has the narrow system MP, we obtain

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

Hence, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. ■

Corollary 1231 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}s}$ *has the narrow system MP, then it is Leibniz.*

Proof: Directly by Proposition 1230. ■

In the opposite direction, when dealing with reflexively system covered π-institutions, we may show that narrow system monotonicity combined with the Leibniz property of the narrow reflexive system core imply that the narrow reflexive system core has the narrow system modus ponens in $\mathcal{I}$. The following proposition forms an analog of Proposition 1217 in the system context.

Proposition 1232 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a reflexively system covered, narrowly system monotone* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}s}$ *is Leibniz, then it has the narrow system MP in* $\mathcal{I}$*.*

Proof: Let $\mathcal{I}$ be a reflexively system covered π-institution. Suppose that $\mathcal{I}$ is narrowly system monotone and that $R^{\mathcal{I}s}$ is Leibniz. Let $T \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$. Since $\mathcal{I}$ is reflexively system covered, there exists $T' \in \min[R^{\mathcal{I}s}_\Sigma[\phi, \psi])$, such that $T' \leq T$. Now we have

$$\begin{array}{lll}\langle \phi, \psi \rangle & \in & \Omega_\Sigma(T') \quad (\text{since } R^{\mathcal{I}s} \text{ is Leibniz and } T' \in \min[R^{\mathcal{I}s}_\Sigma[\phi, \psi])) \\ & \subseteq & \Omega_\Sigma(T). \quad (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly system monotone})\end{array}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T, that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}s}$ has the narrow system MP in $\mathcal{I}$. ∎

Thus, at least for reflexively system covered π-institutions, it is possible to show that the class of syntactically narrowly system monotone ones inside the class of the narrowly system monotone ones can be characterized exactly by the Leibniz property of the narrow reflexive system core. This forms a partial analog of Theorem 1218.

Theorem 1233 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively system covered π-institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly system monotone if and only if it is narrowly system monotone and has a Leibniz narrow reflexive system core.*

Proof: Let $\mathcal{I}$ be a reflexively system covered π-institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly system monotone. Then it is narrowly system monotone by Theorem 1221. Moreover, its narrow reflexive system core has the narrow system MP by Theorem 1225 and, hence, by Corollary 1231, its narrow reflexive system core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly system monotone with a Leibniz narrow reflexive system core. Then, by Proposition 1232, its narrow reflexive system core has the narrow system MP and, therefore, by Theorem 1227, $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations $R^{\mathcal{I}s}$. ∎

15.3 Syntactic Narrow Right Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $I^\flat \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments. Recall from Proposition 99, that, for all $T \in \mathrm{SenFam}(\mathbf{F})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \psi] \leq T \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T}. \tag{15.1}$$

Let, now, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We may attempt to define "syntactic narrow left monotonicity" as the existence of a collection

$I^\flat \subseteq N^\flat$, with two distinguished arguments, such that, for all $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi,\psi] \leq \overleftarrow{T} \quad \text{iff} \quad \langle \phi,\psi\rangle \in \Omega_\Sigma(T).$$

Because of the the preceding remark, however, this condition would amount exactly to defining syntactic narrow family monotonicity. On the other hand, syntactic narrow system monotonicity is equivalent, again based on the remark above, to asserting the existence of $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that, for all $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, with $\overleftarrow{T} \in \mathrm{ThSys}^{\not\,}(\mathcal{I})$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi,\psi] \leq T \quad \text{iff} \quad \langle \phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T}).$$

If we drop the restriction that $\overleftarrow{T}$ be in $\mathrm{ThSys}^{\not\,}(\mathcal{I})$, thus allowing the condition above to be imposed on the wider class of all $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, we obtain a concept slightly more general that syntactic narrow system monotonicity, which we term *syntactic narrow right monotonicity*. We study this notion in more detail in this section, following the study of syntactic narrow family (and system) monotonicity, carried out in the preceding sections of the chapter.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is **narrowly right monotone** if, for all $T, T' \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$

In this section, following the work on syntactic narrow family monotonicity of Section 15.1, we introduce and study a syntactic analog of narrow right monotonicity.

First, the concepts of narrow system reflexivity, narrow system symmetry, narrow system transitivity, narrow system compatibility and narrow system modus ponens are recast to accommodate theory systems that arise by applying the arrow operator $\leftarrow$ on theory families in $\mathrm{ThFam}^{\not\,}(\mathcal{I})$. Note that such theory systems include, of course, all theory systems in $\mathrm{ThSys}^{\not\,}(\mathcal{I})$, since these arise by applying the arrow operator on themselves.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Moreover, suppose that $I^\flat \subseteq N^\flat$ is a collection of natural transformations in $N^\flat$, with two distinguished arguments.

- $I^\flat$ is **narrowly right reflexive** if, for all $T \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi,\phi] \leq \overleftarrow{T};$$

- $I^\flat$ is **narrowly right symmetric** if, for all $T \in \mathrm{ThFam}^{\nsucc}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T} \quad \text{implies} \quad I^\flat_\Sigma[\psi, \phi] \leq \overleftarrow{T};$$

- $I^\flat$ is **narrowly right transitive** if, for all $T \in \mathrm{ThFam}^{\nsucc}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma[\phi, \psi] \cup I^\flat_\Sigma[\psi, \chi] \leq \overleftarrow{T} \quad \text{implies} \quad I^\flat_\Sigma[\phi, \chi] \leq \overleftarrow{T};$$

- $I^\flat$ is **narrowly right compatible** if, for all $T \in \mathrm{ThFam}^{\nsucc}(\mathcal{I})$, all $\sigma^\flat \in N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\bigcup_{i<k} \overleftrightarrow{I^\flat}_\Sigma[\phi_i, \psi_i] \leq \overleftarrow{T} \quad \text{implies} \quad I^\flat_\Sigma[\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})] \leq \overleftarrow{T};$$

- $I^\flat$ has the **narrow right MP** if, for all $T \in \mathrm{ThFam}^{\nsucc}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{and} \quad I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T} \quad \text{imply} \quad \psi \in \overleftarrow{T}_\Sigma.$$

Note that, because of Equivalence (15.1), narrow right reflexivity, narrow right symmetry, narrow right transitivity and narrow right compatibility are equivalent, respectively, to narrow family reflexivity, narrow family symmetry, narrow family transitivity and narrow family compatibility. They are simply recast involving the arrow operator, but the change is inessential. On the other hand, narrow right modus ponens is an essentially different property than narrow family modus ponens and it is the critical property that differentiates syntactic narrow right monotonicity from syntactic narrow family monotonicity.

Note, also, that, based on Equivalence (15.1), for all $T \in \mathrm{ThFam}^{\nsucc}(\mathcal{I})$,

$$I^\flat(T) = I^\flat(\overleftarrow{T}).$$

We say that $\mathcal{I}$ is **syntactically narrowly right monotone** if there exists $I^\flat \subseteq N^\flat$, with two distinguished arguments, such that $I^\flat$ satisfies:

- narrow right reflexivity;
- narrow right transitivity;
- narrow right compatibility; and
- narrow right MP.

In that case, we call $I^\flat$ a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic narrow right monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly right monotone π-institution, with witnessing transformations $I^\flat$, then $\overleftrightarrow{I^\flat}(T)$ $(:= \overleftrightarrow{I^\flat}(\overleftarrow{T}))$ is a congruence system on $\mathbf{F}$ compatible with $\overleftarrow{T}$, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$. This forms a system analog of Proposition 1203.

Proposition 1234 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly right monotone, with witnessing transformations* $I^\flat$*, then, for all* $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$*,* $\overleftrightarrow{I^\flat}(T)$ *is a congruence system on* $\mathbf{F}$ *compatible with* $\overleftarrow{T}$*.*

Proof: The proof is similar to that of Proposition 1203. Let $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$. The narrow right reflexivity of $I^\flat$ ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The fact that $\overleftrightarrow{I^\flat}$ is the symmetrization of $I^\flat$ ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. The narrow right transitivity of $I^\flat$ guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$.

Suppose, next, that $\sigma^\flat \in N^\flat$, $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$. Then, the narrow right compatibility of $I^\flat$ ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$, then $\langle \sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi}) \rangle \in I^\flat_\Sigma(T)$. Thus, $\overleftrightarrow{I^\flat}(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I^\flat}(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I^\flat}(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I^\flat}(T)$ is compatible with $\overleftarrow{T}$. Assume that $\phi \in \overleftarrow{T}_\Sigma$ and $\langle \phi, \psi \rangle \in \overleftrightarrow{I^\flat}_\Sigma(T)$. Since $I^\flat \subseteq \overleftrightarrow{I^\flat}$, we get, by the narrow right MP of $I^\flat$, that $\psi \in \overleftarrow{T}_\Sigma$. Thus, $\overleftrightarrow{I^\flat}(T)$ is also compatible with $\overleftarrow{T}$. ■

Proposition 1234 shows that $\overleftrightarrow{I^\flat}$ defines Leibniz congruence systems of those theory systems of the form $\overleftarrow{T}$, for $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$. We say that $I^\flat$ **narrowly defines Leibniz congruence systems** of theory families in $\mathcal{I}$ **up to arrow** if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$\overleftrightarrow{I^\flat}(T) = \Omega(\overleftarrow{T}).$$

Then, in what is an analog of Corollary 1204, we obtain

Corollary 1235 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly right monotone, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *narrowly defines Leibniz congruence systems of theory families in* $\mathcal{I}$ *up to arrow.*

Proof: By Proposition 1219 and Corollary 98. ∎

This corollary has as immediate consequence the fact that syntactic narrow right monotonicity implies (semantic) narrow right monotonicity. This forms an analog of Theorem 1205.

Theorem 1236 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly right monotone, then it is narrowly right monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly right monotone with witnessing transformations $I^\flat$. Let $T, T' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{array}{rcll} \Omega(\overleftarrow{T}) & = & \overleftrightarrow{I}^\flat(T) & \text{(by Corollary 1235)} \\ & \leq & \overleftrightarrow{I}^\flat(T') & \text{(by Lemma 94)} \\ & = & \Omega(\overleftarrow{T'}). & \text{(by Corollary 1235)} \end{array}$$

Thus, $\mathcal{I}$ is narrowly right monotone. ∎

We now introduce the notion of the narrow reflexive system core of a π-institution $\mathcal{I}$ in a way analogous to the narrow reflexive core, which was introduced in Section 15.1. Its introduction will enable us to provide a characterization of the syntactical narrow system monotonicity property and to establish a relationship between this property and its semantic counterpart.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall from Section 15.1 that the **narrow reflexive core** of $\mathcal{I}$ is the collection

$$\begin{array}{rcl} R^{\mathcal{I}\nmid} & = & \{\rho^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}^{\nmid}(\mathcal{I}))(\forall \Sigma \in |\mathbf{Sign}^\flat|) \\ & & \qquad (\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\rho^\flat_\Sigma[\phi, \phi] \leq T)\}. \end{array}$$

Recall, also, from Lemmas 1207, 1208 and 1209, that, given any theory family in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$, the relation system $R^{\mathcal{I}\nmid}(T)$ is a reflexive and symmetric relation system on $\mathbf{F}$ that has the congruence compatibility property in $\mathbf{F}$.

We now show, in an analog of Theorem 1213, that possession of the narrow right modus ponens by the narrow reflexive core intrinsically characterizes syntactic narrow right monotonicity. We start by showing that possession of the narrow right MP by the narrow reflexive core is necessary for syntactic narrow right monotonicity. This forms an analog of Theorem 1210.

Theorem 1237 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically narrowly right monotone, then* $R^{\mathcal{I}\nmid}$ *has the narrow right MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly right monotone with witnessing transformations $I^\flat$. Since, by definition, $I^\flat$ is narrowly right reflexive, which is equivalent to being narrowly family reflexive, we get, by definition of $R^{\mathcal{I}\nleq}$, $I^\flat \subseteq R^{\mathcal{I}\nleq}$. Thus, since $I^\flat$ has the narrow right MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}\nleq}$ also satisfies the narrow right MP. ■

If $R^{\mathcal{I}\nleq}$ has the narrow right MP, then it has the narrow right transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 1211.

Proposition 1238 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $R^{\mathcal{I}\nleq}$ *has the narrow right MP, then it also has the narrow right transitivity in* $\mathcal{I}$.

Proof: Suppose that $R^{\mathcal{I}\nleq}$ has the narrow right MP and let $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in R^{\mathcal{I}\nleq}_\Sigma(T)$. This means that $R^{\mathcal{I}\nleq}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}\nleq}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 1224, we get that, for all $\rho^\flat \in R^{\mathcal{I}\nleq}$, and all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$R^{\mathcal{I}\nleq}_{\Sigma'}[\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}), \\ \rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R^{\mathcal{I}\nleq}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}\nleq}$ has the narrow right MP. Therefore, for all $\rho^\flat \in R^{\mathcal{I}\nleq}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\rho^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R^{\mathcal{I}\nleq}_\Sigma[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in R^{\mathcal{I}\nleq}_\Sigma(T)$ and, hence, $R^{\mathcal{I}\nleq}$ is narrowly right transitive in $\mathcal{I}$. ■

We are now ready to show a converse of Theorem 1237, i.e., that possession of the narrow right MP by $R^{\mathcal{I}\nleq}$ suffices to establish the syntactic narrow right monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}\nleq}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 1212.

Theorem 1239 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $R^{\mathcal{I}\nleq}$ *has the narrow right MP, then* $\mathcal{I}$ *is syntactically narrowly right monotone, with witnessing transformations* $R^{\mathcal{I}\nleq}$.

Proof: By Lemma 1207, $R^{\mathcal{I}\nleq}$ is narrowly right reflexive in $\mathcal{I}$. By Lemma 1208, $R^{\mathcal{I}\nleq}$ is narrowly right symmetric in $\mathcal{I}$. By hypothesis and Proposition 1238, it is narrowly right transitive in $\mathcal{I}$. By Lemma 1209 it has the narrow right compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow right MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations $R^{\mathcal{I}\nleq}$. ■

Theorems 1237 and 1239 provide the promised characterization of syntactic narrow right monotonicity in terms of the narrow right MP of the narrow reflexive core.

$$\begin{array}{c}\mathcal{I} \text{ is Syntactically Narrow}\\ \text{Right Monotone}\end{array} \longleftrightarrow \begin{array}{c}R^{\mathcal{I}\natural} \text{ has Narrow Right}\\ \text{Modus Ponens}\end{array}.$$

Theorem 1240 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly right monotone if and only if* $R^{\mathcal{I}\natural}$ *has the narrow right MP in* $\mathcal{I}$*.*

Proof: Theorem 1237 gives the "only if" and the "if" is by Theorem 1239. ■

A related alternative characterization asserts that syntactic narrow right monotonicity amounts to the narrow definability of Leibniz congruence systems of theory families up to arrow by the narrow reflexive core. This result forms an analog of Theorem 1214.

$$\begin{array}{c}\mathcal{I} \text{ is Syntactically Narrow}\\ \text{Right Monotone}\end{array} \longleftrightarrow \begin{array}{c}R^{\mathcal{I}\natural} \text{ Defines Leibniz Congruence Systems}\\ \text{of Theory Families up to Arrow}\end{array}$$

Theorem 1241 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly right monotone if and only if, for all* $T \in \mathrm{ThFam}^{\natural}(\mathcal{I})$*,*

$$\Omega(\overleftarrow{T}) = R^{\mathcal{I}\natural}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly right monotone, then, by Theorem 1237, $R^{\mathcal{I}\natural}$ has the narrow right MP in $\mathcal{I}$. Thus, by Theorem 1239, $R^{\mathcal{I}\natural}$ is a family of witnessing transformations for the syntactic narrow right monotonicity of $\mathcal{I}$. Thus, by Corollary 1235, for all $T \in \mathrm{ThFam}^{\natural}(\mathcal{I})$, $\Omega(\overleftarrow{T}) = R^{\mathcal{I}\natural}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}\natural}$ is narrowly right reflexive, narrowly right transitive and has the narrow right compatibility property and the narrow right MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly right monotone. ■

To prove an analog of Theorem 1218, which, in a sense analogous to that seen for syntactic narrow family monotonicity, characterizes syntactic narrow right monotonicity inside the class of narrow right monotone π-institutions, we create a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow reflexive core. Once more, the difficulty in this case, similarly with that described in some detail in Section 15.1, arises from the fact that $\mathrm{ThFam}^{\natural}(\mathcal{I})$ may not be, in general, closed under signature-wise intersections.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we reembark, once more, on a discussion initiated in Section 15.1 and revisit some of the points with relevance in treating the "right" case.

Recall, again, the definition of prealgebraicity and the Leibniz property of the reflexive core of a π-institution. Also recall the method employed to show that, if a π-institution is prealgebraic and has a Leibniz reflexive core, then it satisfies the global system modus ponens, which is done by first applying the Leibniz property and then prealgebraicity. However, in case of narrow right monotonicity, the plausibility of $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]$ having some empty components makes it likely that, when one attempts to apply narrow right monotonicity in place of prealgebraicity in the second stage of the argument outlined above, its application in order to derive the inclusion $\Omega(C(R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])) \leq \Omega(\overleftarrow{T})$ may not be possible. To deal with this plausibility, we assume, in a similar way as before, that the π-institution under consideration is reflexively covered and postulate that every minimal element $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$ satisfies $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. For $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, recall the notation

$$[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]) \coloneqq \{T \in \mathrm{ThFam}^\natural(\mathcal{I}) : R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \leq T\}.$$

Recall, also that $\mathcal{I}$ is said to be *reflexively covered* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, it is $\langle\Sigma,\phi,\psi\rangle$-reflexively covered, i.e., for every theory family $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, there exists minimal $T' \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, such that $T' \leq T$. Recall, furthermore, that, given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, we write $\min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$ for the collection of minimal elements in $[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that the narrow reflexive core $R^{\mathcal{I}\natural}$ of $\mathcal{I}$ is **right Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in \min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$,

$$\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T}).$$

We show, in an analog of Proposition 1215, that, if $R^{\mathcal{I}\natural}$ has the narrow right MP, then it is right Leibniz. In fact, the proof demonstrates that, under the narrow right MP, a stronger property than that of being right Leibniz holds; more concretely, that for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$ (not only for $T \in \min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$), $\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T})$.

Proposition 1242 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\natural}$ has the narrow right MP, then for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in [R^{\mathcal{I}\natural}_\Sigma[\phi,\psi])$, $\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T})$.*

Proof: Suppose $R^{\mathcal{I}\natural}$ has the narrow right MP and let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \leq T$. To verify that $\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T})$, we use Theorem 19. Let $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, such that $\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in \overleftarrow{T}_{\Sigma'}$. Since $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, by Lemma 1209,

$$R^{\mathcal{I}\natural}_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}\natural}$ has the narrow right MP, we obtain

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \in \overleftarrow{T}_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in \overleftarrow{T}_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \in \overleftarrow{T}_{\Sigma'}.$$

Hence, by Theorem 19, $\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T})$. ■

Corollary 1243 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\natural}$ has the narrow right MP, then it is right Leibniz.*

Proof: Directly by Proposition 1242. ■

To prove a converse, we restrict attention to reflexively covered π-institutions. Inside this class, we may show that narrow right monotonicity combined with the right Leibniz property of the narrow reflexive core imply that the narrow reflexive core has the narrow right modus ponens in $\mathcal{I}$. The following proposition forms an analog of Propositions 1217 and 1232 in the "right" context.

Proposition 1244 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a reflexively covered, narrowly right monotone π-institution based on $\mathbf{F}$. If $R^{\mathcal{I}\natural}$ is right Leibniz, then it has the narrow right MP in $\mathcal{I}$.*

Proof: Let $\mathcal{I}$ be a reflexively covered π-institution. Suppose that $\mathcal{I}$ is narrowly right monotone and that $R^{\mathcal{I}\natural}$ is right Leibniz. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \overleftarrow{T}_\Sigma$ and $R^{\mathcal{I}\natural}_\Sigma[\phi,\psi] \leq T$. Since $\mathcal{I}$ is reflexively covered, there exists $T' \in \min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]]$, such that $T' \leq T$. Now we have

$$\begin{array}{lll}\langle\phi,\psi\rangle & \in & \Omega_\Sigma(\overleftarrow{T'}) \quad (\text{since } R^{\mathcal{I}\natural} \text{ is right Leibniz and } T' \in \min[R^{\mathcal{I}\natural}_\Sigma[\phi,\psi]])\\ & \subseteq & \Omega_\Sigma(\overleftarrow{T}). \quad (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly right monotone})\end{array}$$

Therefore, since $\phi \in \overleftarrow{T}_\Sigma$, we get, by the compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, that $\psi \in \overleftarrow{T}_\Sigma$. We conclude that $R^{\mathcal{I}\natural}$ has the narrow right MP in $\mathcal{I}$. ■

Thus, at least for reflexively covered π-institutions, it is possible to show that the class of syntactically narrowly right monotone ones inside the class of the narrowly right monotone ones can be characterized exactly by the right Leibniz property of the narrow reflexive core. This forms a partial analog of Theorems 1218 and 1233.

Theorem 1245 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a reflexively covered* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically narrowly right monotone if and only if it is narrowly right monotone and has a right Leibniz narrow reflexive core.*

Proof: Let $\mathcal{I}$ be a reflexively covered π-institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly right monotone. Then it is narrowly right monotone by Theorem 1236. Moreover, its narrow reflexive core has the narrow right MP by Theorem 1237 and, hence, by Corollary 1243, its narrow reflexive core is right Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly right monotone with a right Leibniz narrow reflexive core. Then, by Proposition 1244, its narrow reflexive core has the narrow right MP and, therefore, by Theorem 1239, $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations $R^{\mathcal{I}\natural}$. ■

Chapter 16

The Syntactic Leibniz Hierarchy: Attic I

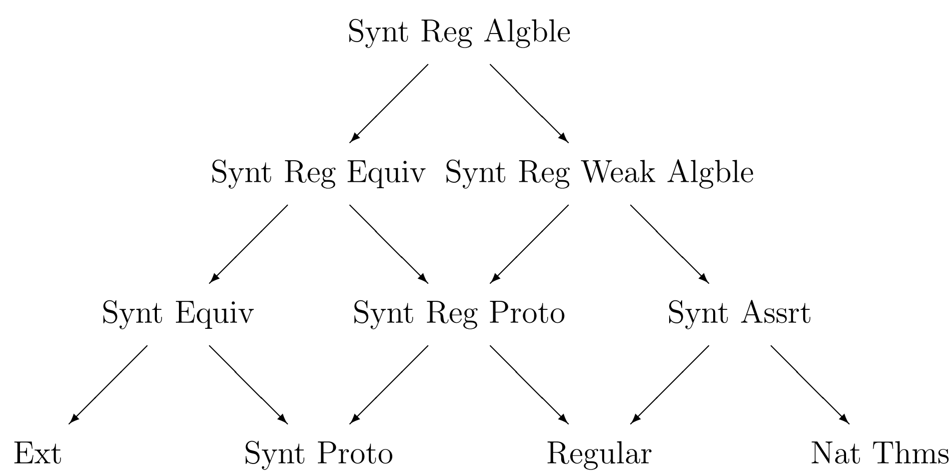
16.1 Introduction

In this chapter our goal is to develop a hierarchy analogous to the one developed in Chapter 8, but on the syntactic side. The key on the semantic side, developed in Chapter 8, was the property of regularity of a π-institution. The family version of the property asserts that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, $\mathcal{I}$ is *family regular* if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

By combining this property with pre- or proto-algebraicity, on the one hand, and with the existence of theorems, on the other, which subsumes complete reflectivity, one obtains various classes in the regular (weak) (pre)algebraizability hierarchy, which were studied in some detail in Chapter 8.

In this chapter, as our interest shifts to the syntactic side, the role played by of pre- and proto-algebraicity is assumed by syntactic pre- and proto-algebraicity, respectively, and the existence of theorems is replaced by the existence of natural theorems. By adding these features to regularity, one obtains the classes of the syntactically regularly (weakly) (pre)algebraizable π-institutions, which dominate, in general, the corresponding semantic classes. Roughly speaking, the hierarchy that we are aiming for here has the general shape depicted in the accompanying diagram. Of course various classes are present at each level, since the properties shown have various flavors, or versions, that may be used at each of the combinations depicted.



16.2 Regularity of Transformations

To prepare us for the main developments, we start by looking closely at the various versions of the regularity property of a family of natural transformations in a given π-institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Moreover, let $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ be a collection of natural transformations in $N^\flat$, having two distinguished arguments. We define the following properties:

- $I^\flat$ has the **family regularity in** $\mathcal{I}$, or is **family regular in** $\mathcal{I}$, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I^\flat_\Sigma[\phi, \psi] \leq T;$$
- $I^\flat$ has the **left regularity in** $\mathcal{I}$, or is **left regular in** $\mathcal{I}$, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in \overleftarrow{T}_\Sigma \quad \text{implies} \quad I^\flat_\Sigma[\phi, \psi] \leq T;$$
- $I^\flat$ has the **right regularity in** $\mathcal{I}$, or is **right regular in** $\mathcal{I}$, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T};$$
- $I^\flat$ has the **system regularity in** $\mathcal{I}$, or is **system regular in** $\mathcal{I}$, if, for all $T \in \mathrm{ThSys}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I^\flat_\Sigma[\phi, \psi] \leq T.$$

Recalling that, by Proposition 99, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we have
$$I^\flat_\Sigma[\phi, \psi] \leq T \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T},$$
it is easy to see that the four properties defined above collapse in pairs and, therefore, there are only two distinct ones. This is detailed in the following:

Proposition 1246 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a collection of natural transformations in $N^\flat$, with two distinguished arguments.*

(a) $I^\flat$ is family regular in $\mathcal{I}$ if and only if it is right regular in $\mathcal{I}$;

(b) $I^\flat$ is system regular in $\mathcal{I}$ if and only if it is left regular in $\mathcal{I}$.

Proof: By Proposition 99, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we have
$$I^\flat_\Sigma[\phi, \psi] \leq T \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T}.$$

Thus, taking into account the definitions of family and right regularity, the equivalence of Part (a) becomes clear. We turn now to Part (b).

Assume, first, that $I^\flat$ is left regular in $\mathcal{I}$ and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, $\overleftarrow{T} = T$, whence, by hypothesis, $\phi, \psi \in \overleftarrow{T}_\Sigma$. Thus, by left regularity, $I^\flat_\Sigma[\phi, \psi] \le T$. This shows that $I^\flat$ has the system regularity in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ is system regular in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Since $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get, by system regularity, $I^\flat_\Sigma[\phi, \psi] \le \overleftarrow{T}$. Therefore, by Proposition 99, $I^\flat_\Sigma[\phi, \psi] \le T$, showing that $I^\flat$ has the left regularity in $\mathcal{I}$. ∎

Based on Proposition 1246, we use the term **family regular** to refer to family/right regularity and the term **system regular** for system/left regularity. As far as the relation between these two distinct properties, it is straightforward to see that, as is typical with almost all properties studied in the monograph, system regularity is weaker than family regularity.

Proposition 1247 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a collection of natural transformations in $N^\flat$, having two distinguished arguments. If $I^\flat$ is family regular in $\mathcal{I}$, then it is system regular in $\mathcal{I}$.*

Proof: This is clear from the definitions, since the condition defining system regularity is a specialization of that defining family regularity, where T is allowed to range over theory systems only. ∎

Thus, the following hierarchy of regularity properties emerges.

$I^\flat$ Family/Right Regular

↓

$I^\flat$ System/Left Regular

It is also easy to see that, in case $\mathcal{I}$ is systemic, the two properties of being family and system regular are identified.

Proposition 1248 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a collection of natural transformations in $N^\flat$. If $\mathcal{I}$ is systemic, then $I^\flat$ is system regular if and only if it is family regular in $\mathcal{I}$.*

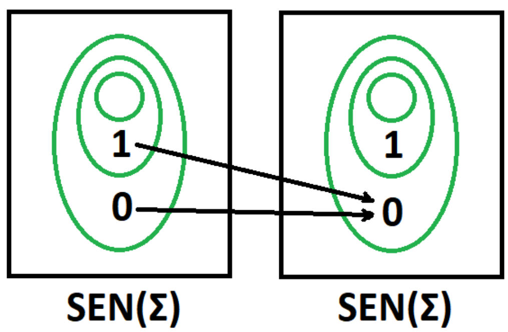
Proof: If $\mathcal{I}$ is systemic, then $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, whence the two conditions defining family and system regularity are identical. ∎

And it is not difficult to show that this hierarchy does not collapse, in general.

Example 1249 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the clone of natural transformations generated by the binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, specified by*

$$\sigma^\flat_\Sigma(x, y) = 0, \quad \textit{for all } x, y \in \mathrm{SEN}^\flat(\Sigma).$$



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ *has three theory families* $\overline{\varnothing}$, $\{\{1\}\}$ *and* $\mathrm{SEN}^\flat$*, but only two theory systems,* $\overline{\varnothing}$ *and* $\mathrm{SEN}^\flat$*. Consider* $I^\flat = \{\sigma^\flat\}$*. Since, the only theory systems are* $\overline{\varnothing}$ *and* $\mathrm{SEN}^\flat$*,* $I^\flat$ *is trivially system regular. On the other hand, for* $T = \{\{1\}\}$*, we get,* $1 \in T_\Sigma$*, but* $I^\flat_\Sigma[1, 1] = \{\{0\}\} \not\leq \{\{1\}\}$*, whence* $I^\flat$ *is not family regular in* $\mathcal{I}$*.*

We close the section by showing that the two versions of regularity transfer from the family $I^\flat$ to $I^\mathcal{A}$, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$.

Proposition 1250 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a collection of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) $I^\flat$ *is family regular in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $I^\mathcal{A}$ *is family regular in* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$*;*

(b) $I^\flat$ *is system regular in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $I^\mathcal{A}$ *is system regular in* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$*.*

Proof:

(a) The "if" follows easily by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and recalling from Lemma 51 that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$.

Assume, conversely, that $I^\flat$ is family regular in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then, $\phi, \psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. By Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, whence, by the postulated family regularity of $I^\flat$ in $\mathcal{I}$, we get that $I^\flat_\Sigma[\phi, \psi] \leq \alpha^{-1}(T)$. Thus, by Lemma 95, we get $I^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, if $\phi, \psi \in T_\Sigma$, then $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$. Therefore, $I^{\mathcal{A}}$ is family regular in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

(b) This follows along very similar lines.

■

16.3 Syntactic Regular PreAlgebraicity

In the next result, we connect the property of regularity of a collection of natural transformations with the property of regularity of a π-institution $\mathcal{I}$, studied in Chapter 8. More specifically, we show that, in case the π-institution under consideration is syntactically pre- (proto-)algebraic with $I^\flat$ a collection of witnessing transformations, then family (system) regularity of $I^\flat$ is equivalent to $\mathcal{I}$ being family (system) regular. Since the combination of syntactic pre- and proto-algebraicity with regularity turns out to be an important property in its own right, we give it a name, partly inspired by the results that follow. Recall that there are two kinds of syntactic monotonicity, namely syntactic prealgebraicity and syntactic protoalgebraicity, and two kinds of regularity properties of collections of natural transformations, namely family regularity and system regularity. Thus, by combining syntactic monotonicity properties with regularity properties, we obtain, a priori, four versions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is said to be **syntactically family regularly protoalgebraic** if it is syntactically protoalgebraic, with a witnessing collection $I^\flat$ of transformations, which is family regular in $\mathcal{I}$;

- $\mathcal{I}$ is said to be **syntactically system regularly protoalgebraic** if it is syntactically protoalgebraic, with a witnessing collection $I^\flat$ of transformations, which is system regular in $\mathcal{I}$;

- $\mathcal{I}$ is said to be **syntactically family regularly prealgebraic** if it is syntactically prealgebraic, with a witnessing collection $I^\flat$ of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly prealgebraic** if it is syntactically prealgebraic, with a witnessing collection $I^\flat$ of transformations, which is system regular in $\mathcal{I}$.

The definitions are partially justified by the following propositions that relate them to the semantical notions of family, right, left and system regularity.

Proposition 1251 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically protoalgebraic* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$*.*

(a) $\mathcal{I}$ *is family regular if and only if* $I^\flat$ *is family regular in* $\mathcal{I}$*;*

(b) $\mathcal{I}$ *is left regular if and only if* $I^\flat$ *is system regular in* $\mathcal{I}$*.*

Proof: Let $\mathcal{I}$ be a syntactically protoalgebraic π-institution, with witnessing transformations $I^\flat$.

(a) This part is easy to see, since, by syntactic protoalgebraicity, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq T.$$

(b) Suppose, first, that $\mathcal{I}$ is left regular and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \mathrm{ThSys}(\mathcal{I})$, $\phi, \psi \in \overleftarrow{T}_\Sigma$. By the left regularity of $\mathcal{I}$, we get $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, whence, by syntactic protoalgebraicity, $I^\flat_\Sigma[\phi, \psi] \leq T$. This shows that $I^\flat$ is system regular in $\mathcal{I}$.

Assume, conversely, that $I^\flat$ is system regular in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, since $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, by the system regularity of $I^\flat$, $I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T} \leq T$, whence, by syntactic protoalgebraicity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is left regular.

■

Proposition 1252 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically prealgebraic* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$*.*

(a) $\mathcal{I}$ *is right regular if and only if* $I^\flat$ *is family regular in* $\mathcal{I}$*;*

(b) $\mathcal{I}$ is system regular if and only if $I^\flat$ is system regular in $\mathcal{I}$.

Proof: Let $\mathcal{I}$ be a syntactically prealgebraic π-institution, with witnessing transformations $I^\flat$.

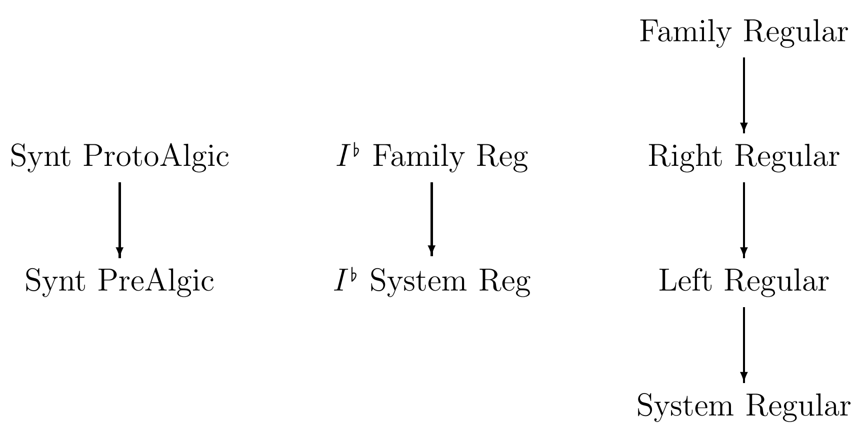
(a) Suppose, first, that $\mathcal{I}$ is right regular and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. By the right regularity of $\mathcal{I}$, we get $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$, whence, since $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get, by syntactic prealgebraicity, $I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T} \leq T$. This shows that $I^\flat$ is family regular in $\mathcal{I}$.

Assume, conversely, that $I^\flat$ is family regular in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by the family regularity of $I^\flat$, $I^\flat_\Sigma[\phi, \psi] \leq T$. Hence, by Proposition 99, we get $I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T}$. Since $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, by syntactic prealgebraicity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. Therefore, $\mathcal{I}$ is right regular.

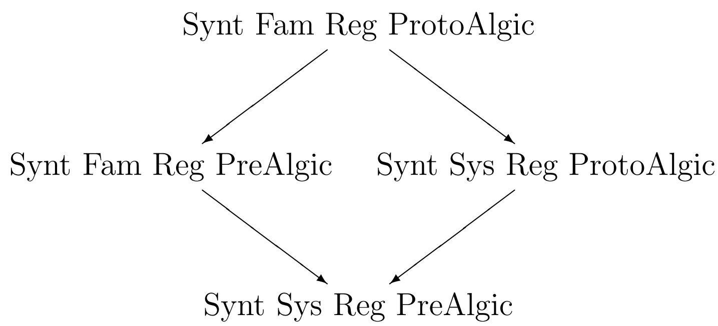
(b) This part is straightforward, since, by syntactic prealgebraicity, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$ if and only if $I^\flat_\Sigma[\phi, \psi] \leq T$.

■

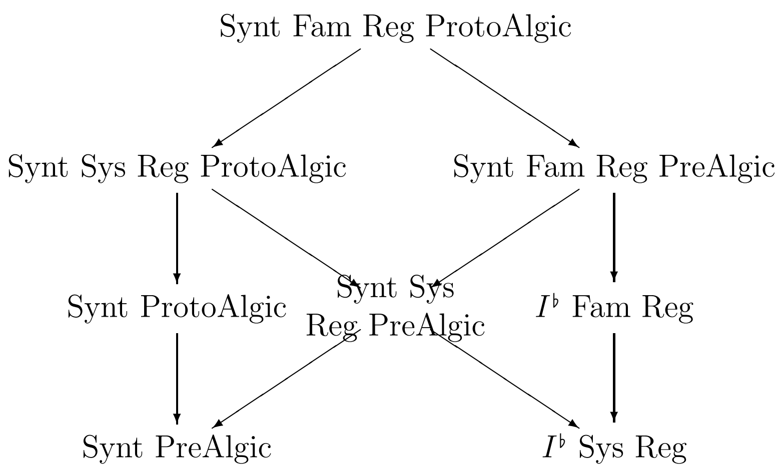
Propositions 1251 and 1252 may be viewed as partial justifications for the definitions of syntactic regular pre- and proto-algebraicity Moreover, recalling the following hierarchies of syntactic pre- and protoalgebraicity, of the regularity properties of $I^\flat$ and of semantic regularity,



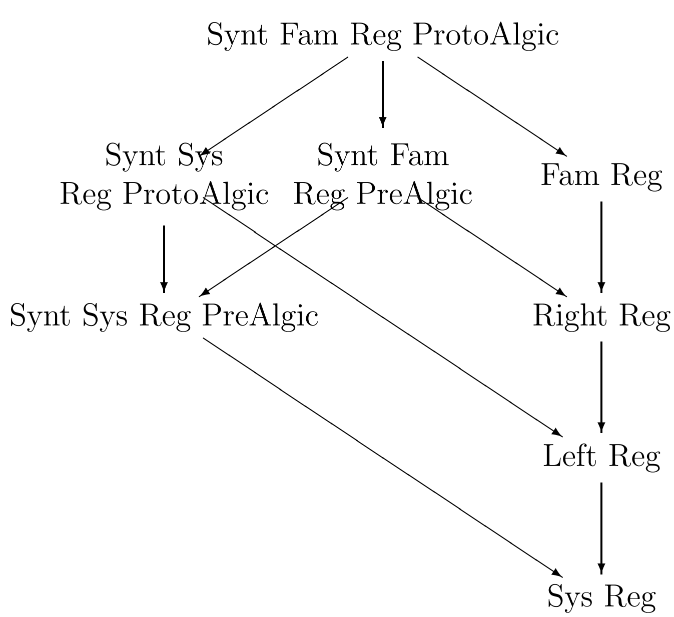
the following hierarchy of syntactic classes of regularly pre- and protoalgebraic π-institutions emerges.



Furthermore, these four classes relate with their immediate subordinate properties on the syntactic side, as shown in the following diagram



and with the four semantic regularity classes, as revealed by Propositions 1251 and 1252, as shown in the following diagram.



Theorem 584, which provided a characterization of both family and of system regularity in terms of the Suszko operator and of a system version of the Suszko operator, respectively, gives rise to the following characterizations of family and system regularity of witnessing collections of natural transformations for the proto- and pre-algebraicity, respectively, of a π-institution.

Corollary 1253 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a collection of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is syntactically protoalgebraic, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *is family regular in* $\mathcal{I}$ *if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi, \psi));$$

(ba) If $\mathcal{I}$ *is syntactically prealgebraic, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *is system regular in* $\mathcal{I}$ *if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)).$$

Proof: Part (a) follows by combining Part (a) of Proposition 1251 with the characterization of family regularity given in Theorem 584. Similarly, Part (b) follows by combing Part (b) of Proposition 1252 with the characterization of system regularity given in Theorem 584. ■

The next results form transfer theorems, asserting that all four types of syntactic regularity, studied here, transfer from a π-institution to all its generalized matrix families/systems. We start with the two types obtained by strengthening syntactic protoalgebraicity.

Theorem 1254 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically family (system, respectively) regularly protoalgebraic, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *(and all* $T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, respectively), all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

- $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$ *iff* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$*;*
- $\phi, \psi \in T_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$ *(*$\phi, \psi \in T'_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$*, respectively).*

Proof: $\mathcal{I}$ is syntactically regularly protoalgebraic if and only if, by definition, it is syntactically protoalgebraic, with witnessing transformations $I^\flat$, which are family regular, if and only if, by Theorem 810 and Proposition 1250, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is syntactically protoalgebraic, with witnessing transformations $I^{\mathcal{A}}$, which are family regular in $\langle\mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$, if and only if, for every **F**-algebraic system $\mathcal{A}$, the two conditions asserted in the statement hold.

The case of system regularity may be treated similarly. ■

We close with the two types that only require syntactic prealgebraicity.

Theorem 1255 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically family (system, respectively) regularly prealgebraic with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$*, if and only if, for every* **F***-algebraic system* $\mathcal{A} = \langle\mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and* $T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

- $\langle\phi, \psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T')$ *iff* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$*;*
- $\phi, \psi \in T_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$ *(*$\phi, \psi \in T'_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$*, respectively).*

Proof: Similar to the proof of Theorem 1254. ■

16.4 Syntactic Regular (Pre-)Equivalentiality

Syntactic regular pre- and proto-algebraicity were defined by combining syntactic pre- and proto-algebraicity, respectively, with versions of regularity. If we upgrade syntactic pre- and proto-algebraicity to syntactic preequivalentiality and equivalentiality, respectively, then we obtain, analogously, versions of syntactic regular preequivalentiality and syntactic regular equivalentiality, respectively.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on **F**.

- $\mathcal{I}$ is said to be **syntactically family regularly equivalential** if it is syntactically equivalential, with a witnessing collection $I^\flat$ of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly equivalential** if it is syntactically equivalential, with a witnessing collection $I^\flat$ of transformations, which is system regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically family regularly preequivalential** if it is syntactically preequivalential, with a witnessing collection $I^\flat$ of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly preequivalential** if it is syntactically preequivalential, with a witnessing collection $I^\flat$ of transformations, which is system regular in $\mathcal{I}$.

Analogs of Propositions 1251 and 1252 may be proven. They follow the same lines of proof, the only difference being that the witnessing collections of transformations we are dealing with in this case, as opposed to the cases of syntactic pre- and proto-algebraicity, are parameter free.

Corollary 1256 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically equivalential* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$.

(a) *$\mathcal{I}$ is family regular if and only if $I^\flat$ is family regular in $\mathcal{I}$;*

(b) *$\mathcal{I}$ is left regular if and only if $I^\flat$ is system regular in $\mathcal{I}$.*

Proof: By Proposition 1251, taking into account the fact that syntactic equivalentiality is equivalent to syntactic protoalgebraicity via a parameter free collection of transformations. ■

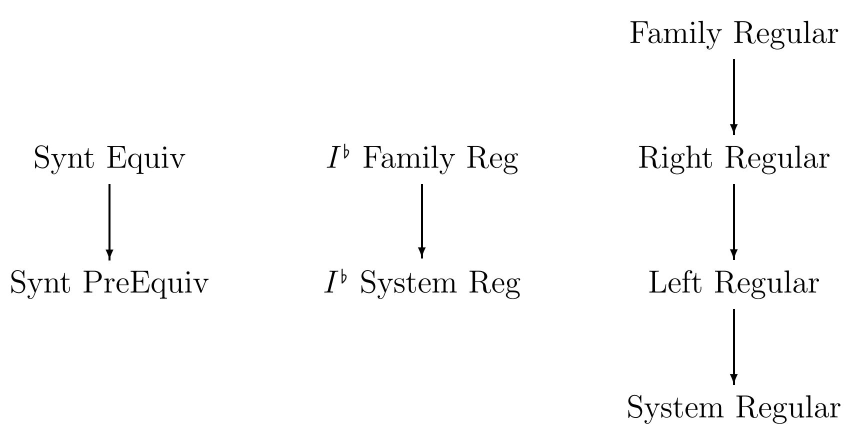
Corollary 1257 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically preequivalential* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$.

(a) *$\mathcal{I}$ is right regular if and only if $I^\flat$ is family regular in $\mathcal{I}$;*

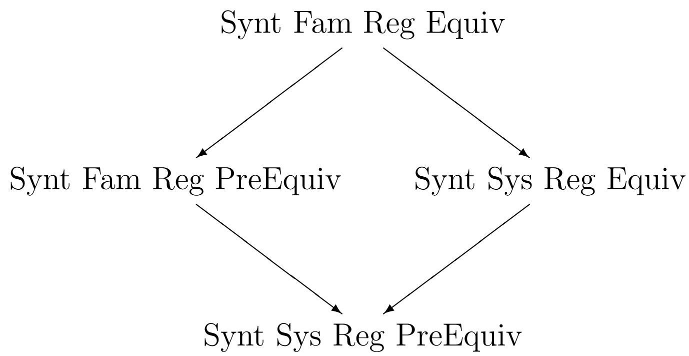
(b) *$\mathcal{I}$ is system regular if and only if $I^\flat$ is system regular in $\mathcal{I}$.*

Proof: By Proposition 1252, taking into account the fact that syntactic preequivalentiality is equivalent to syntactic prealgebraicity via a parameter free collection of transformations. ■

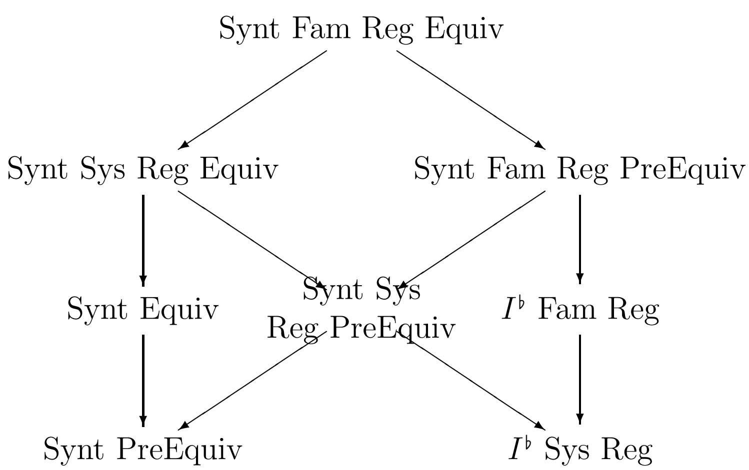
Recalling the following hierarchies of syntactic (pre)equivalentiality, of the regularity properties of $I^\flat$ and of semantic regularity,



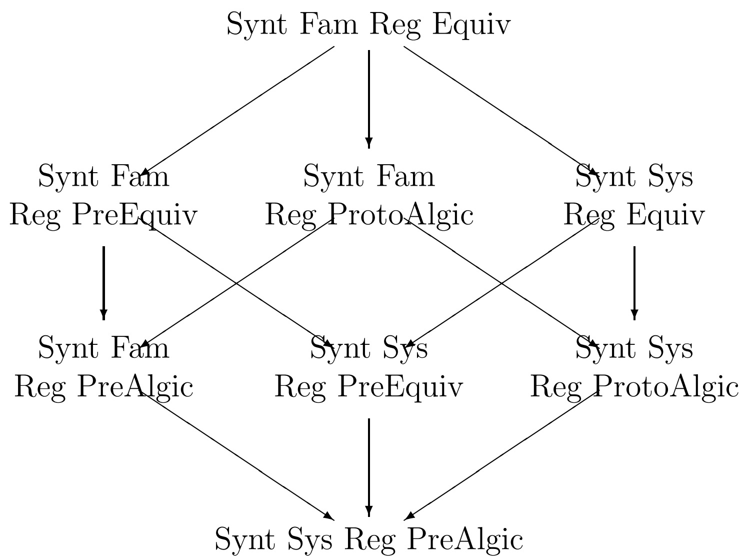
the following hierarchy of syntactic classes of regularly (pre)equivalential π-institutions arises.



Furthermore, these four classes relate to their immediate subordinate properties on the syntactic side, as shown in the following diagram



Moreover, from the fact that syntactic equivalentiality is equivalent to syntactic protoalgebraicity, with a parameter free witnessing collection of transformations, and, similarly for preequivalentiality and prealgebraicity, we get, immediately from the definitions. the following hierarchy of classes of π-institutions involving syntactic regular pre- and proto-algebraicity and syntactic regular (pre)equivalentiality.



An analog to Corollary 1253 adjusts its contents to address the special case in which the collection $I^\flat$ witnessing syntactic pre- or proto-algebraicity is parameter free, thus giving rise, instead, to syntactic preequivalentiality or equivalentiality, respectively.

Corollary 1258 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *a collection of natural transformations in* $N^\flat$ *(with both arguments distinguished).*

(a) If $\mathcal{I}$ *is syntactically equivalential, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *is family regular in* $\mathcal{I}$ *if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*
$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi, \psi));$$

(b) If $\mathcal{I}$ *is syntactically preequivalential, with witnessing transformations* $I^\flat$*, then* $I^\flat$ *is system regular in* $\mathcal{I}$ *if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*
$$\langle \phi, \psi \rangle \in \widehat{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)).$$

Proof: Each part is a consequence of the corresponding part of Corollary 1253 and the fact that $I^\flat$ is assumed to be parameter free. ■

Finally, the transfer theorems for syntactic regular pre- and proto-algebraicity, Theorems 1254 and 1255, may also be easily adapted to provide analogous transfer theorems for syntactic regular equivalentiality and preequivalentiality, respectively.

Corollary 1259 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically family (system, respectively) regularly equivalential, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^2 \to$

$\mathrm{SEN}^\flat$, *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *(and all* $T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, *respectively), all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

- $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$ *iff* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$;
- $\phi, \psi \in T_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$ *(*$\phi, \psi \in T'_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$, *respectively).*

Proof: Directly from Theorem 1254. ■

We close with the two types that only require syntactic preequivalentiality.

Corollary 1260 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically family (system, respectively) regularly pre-equivalential with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$, *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and* $T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, *all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

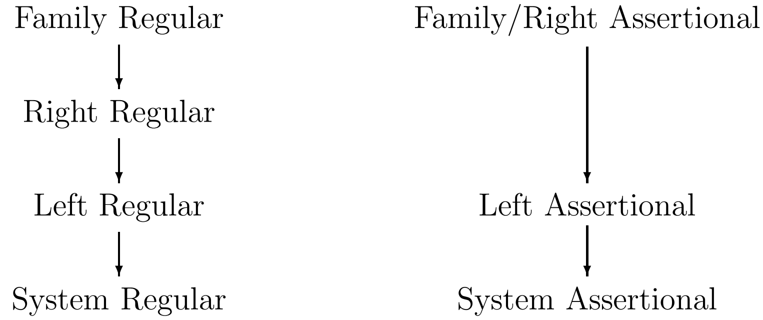
- $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T')$ *iff* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$;
- $\phi, \psi \in T_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T$ *(*$\phi, \psi \in T'_\Sigma$ *implies* $I^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T'$, *respectively).*

Proof: Follows from Theorem 1255. ■

16.5 Syntactic Assertionality

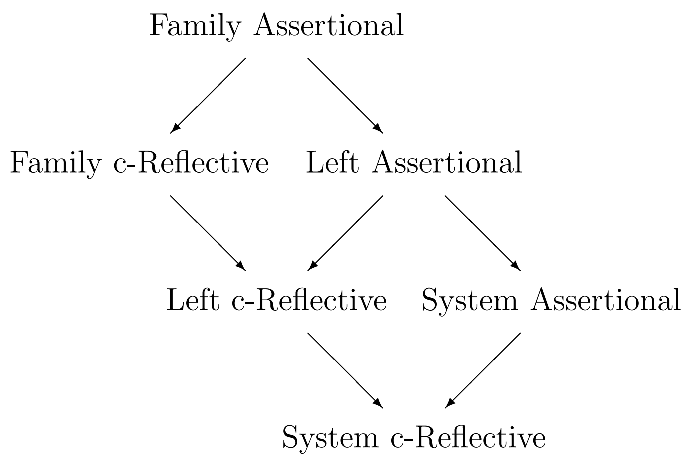
In this section, we study some of the consequences of adding to the various versions of semantic regularity, studied in detail in Section 8.2, the property of having natural theorems.

Recall, first, from Section 8.2, that there are four distinct types of semantic regularity, namely, family, right, left and system, which form the hierarchy depicted in the left diagram (obtained in Section 8.2).



If to the various regularity conditions, one adds the existence of theorems, then one obtains the semantic assertionality classes, which were studied in detail in Section 8.3, where it was shown that they form the hierarchy depicted in the diagram on the right.

Additionally, it was shown in Section 8.3 that these three assertionality classes dominate, respectively, the three corresponding complete reflectivity classes. This is shown in the third diagram, reproduced here from Section 8.3.



In this section, we study the classes arising by adding to the various flavors of semantic regularity the property of possessing natural theorems. Since the property of possessing natural theorems is strictly stronger that having theorems, there are, in accordance with the results recalled from Section 8.3 above, only three potentially different classes of π-institutions arising. These, of course, dominate the corresponding assertionality classes. The π-institution members of these classes are termed *syntactically assertional*. A strong motivation for introducing these three classes lies in the fact that lifting the possession of theorems to that of the existence of natural theorems, in tandem with semantic regularity, is enough to allow passing from the semantic classes of completely reflective π-institutions to the corresponding syntactic classes of truth equational π-institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically family assertional** if it is family regular and has natural theorems;
- $\mathcal{I}$ is **syntactically left assertional** if it is left regular and has natural theorems;
- $\mathcal{I}$ is **syntactically right assertional** if it is right regular and has natural theorems;

- $\mathcal{I}$ is **syntactically system assertional** if it is system regular and has natural theorems.

First, it is easy to see that syntactic family and syntactic right assertionality coincide.

Proposition 1261 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically family assertional if and only if it is syntactically right assertional.*

Proof: $\mathcal{I}$ is syntactically family assertional iff, by definition, it is family assertional and has natural theorems iff, by Proposition 591, it is right assertional and has natural theorems iff, by definition, it is syntactically right assertional. ■

Given Proposition 1261, asserting that syntactic family and syntactic right assertionality coincide, we may establish the hierarchy of syntactic assertionality classes.

Proposition 1262 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is syntactically family/right assertional, then it is syntactically left assertional;*

(b) If $\mathcal{I}$ *is syntactically left assertional, then it is syntactically system assertional.*

Proof: If $\mathcal{I}$ is syntactically family assertional, then it is, by definition, family assertional and has natural theorems, whence, by Proposition 592, it is left assertional and has natural theorems, i.e., it is syntactically left assertional. Similarly, if $\mathcal{I}$ is syntactically left assertional, then it is, by definition, left assertional and has natural theorems, whence, by Proposition 592, it is system assertional and has natural theorems, i.e., it is syntactically system assertional. ■

Proposition 1262 establishes the following hierarchy of **syntactic assertionality** classes, paralleling the corresponding semantic hierarchy established in Section 8.3.

Syntactically Family/Right Assertional

↓

Syntactically Left Assertional

↓

Syntactically System Assertional

It is not difficult to see that the bottom classes of the hierarchy collapse, if restricted to stable π-institutions, and that the entire hierarchy collapses when considering only systemic π-institutions.

Proposition 1263 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is stable and syntactically system assertional, then it is syntactically left assertional;*

(b) If $\mathcal{I}$ *is systemic and syntactically system assertional, then it is syntactically family assertional.*

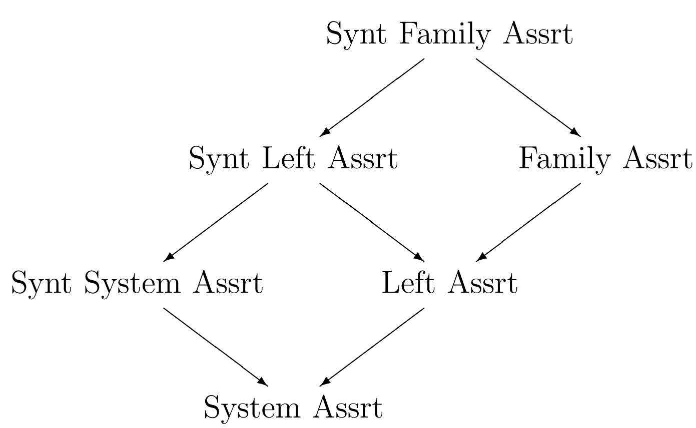
Proof: The first statement follows directly from Proposition 579, whereas the second implication is a consequence of Proposition 580. ■

We formalize, next, a result, which is straightforward, establishing the close interrelationships between the syntactic and semantic assertionality classes.

Proposition 1264 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically family (respectively left, system) assertional if and only if it is family (respectively left, system) assertional and has natural theorems.*

Proof: These equivalences follow by the definitions involved, since existence of natural theorems implies having theorems, as was shown in Lemma 1188. ■

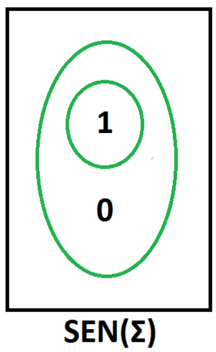
Thus, Proposition 1264 establishes the following relationships between the semantic assertionality and the corresponding syntactic assertionality classes.



It is not difficult to show, by providing an example, that the syntactic classes are properly included in the semantic ones. More precisely, we provide an example of a π-institution which is family assertional but fails to be syntactically system assertional. Thus, it belongs to all three semantic assertionality classes but in none of the three syntactic assertionality steps of the hierarchy.

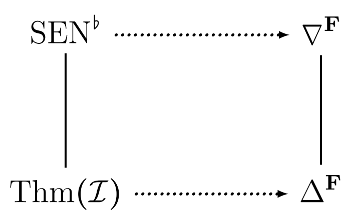
Example 1265 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$*.*

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, which are also theory systems. Moreover,* $\Omega(\mathrm{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ *and* $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$*.*



Clearly, $\mathcal{I}$ *is family regular, i.e., for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, and all* $x, y \in \{0,1\}$*, if* $x, y \in T_\Sigma$*, then* $\langle x, y \rangle \in \Omega_\Sigma(T)$*. Further, obviously,* $\mathcal{I}$ *has theorems. Finally, since there are no nontrivial natural transformations in* $N^\flat$*,* $\mathcal{I}$ *does not have natural theorems. Therefore,* $\mathcal{I}$ *is family assertional but it fails to be syntactically system assertional.*

A corollary of the connections established in Proposition 1264 and the characterizations of semantic assertionality classes, given in Proposition 588, provides similar characterizations of the three syntactic assertionality classes.

Corollary 1266 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution having natural theorems and* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *a natural theorem.*

(a) *$\mathcal{I}$ is syntactically family assertional if and only if, for all* $T \in \text{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$;

(b) *$\mathcal{I}$ is syntactically left assertional if and only if, for all* $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \tau/\Omega(T)$;

(c) *$\mathcal{I}$ is syntactically system assertional if and only if, for all* $T \in \text{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$.

Proof: By combining Propositions 1264 and 588. ∎

We conclude the section by establishing the relationships between the three syntactic assertionality classes and the three truth equationality classes, introduced and studied in detail in Chapter 11.

Theorem 1267 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$.

(a) *If $\mathcal{I}$ is syntactically family assertional, with a natural theorem* $\tau : \text{SEN}^\flat \to \text{SEN}^\flat$, *then it is family truth equational, with witnessing equation* $\iota \approx \tau$;

(b) *If $\mathcal{I}$ is syntactically left assertional, with a natural theorem* $\tau : \text{SEN}^\flat \to \text{SEN}^\flat$, *then it is left truth equational, with witnessing equation* $\iota \approx \tau$;

(c) *If $\mathcal{I}$ is syntactically system assertional, with a natural theorem* $\tau : \text{SEN}^\flat \to \text{SEN}^\flat$, *then it is system truth equational, with witnessing equation* $\iota \approx \tau$.

Proof: We prove Part (a). The other parts can be proven similarly. Suppose that $\mathcal{I}$ is syntactically family assertional, with $\tau : \text{SEN}^\flat \to \text{SEN}^\flat$ a natural theorem. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \text{SEN}^\flat(\Sigma)$. To show that $\mathcal{I}$ is family truth equational, with witnessing equation $\iota \approx \tau$, we must establish the equivalence

$$\phi \in T_\Sigma \quad \text{iff} \quad (\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T).$$

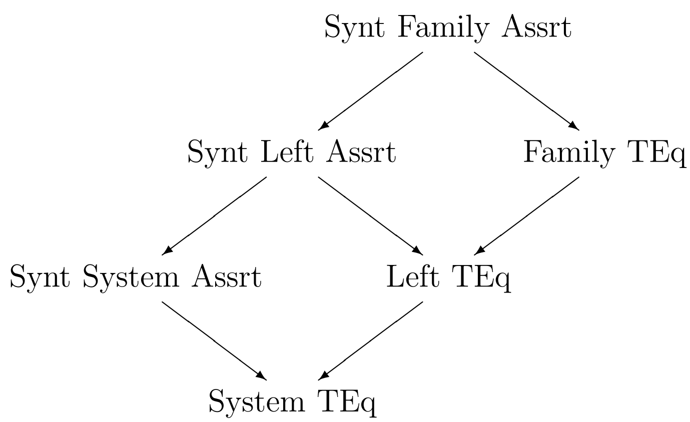
Suppose, first, that $\phi \in T_\Sigma$. Since τ is a natural theorem, we also have $\tau_\Sigma(\phi) \in T_\Sigma$. Thus, by family regularity (part of syntactic family assertionality), $\langle \phi, \tau_\Sigma(\phi) \rangle \in \Omega_\Sigma(T)$. But $\Omega(T)$ is a congruence system on $\mathbf{F}$, whence, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\langle \text{SEN}^\flat(f)(\phi), \tau_{\Sigma'}(\text{SEN}^\flat(f)(\phi)) \rangle \in \Omega_{\Sigma'}(T),$$

i.e., $(\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T)$.

Assume, conversely, that $(\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T)$. In particular, $\langle \phi, \tau_\Sigma(\phi) \rangle \in \Omega_\Sigma(T)$. However, since τ is a natural theorem, $\tau_\Sigma(\phi) \in T_\Sigma$. Therefore, by the compatibility of $\Omega(T)$ with T, we get that $\phi \in T_\Sigma$. ∎

Theorem 1267 establishes the following mixed hierarchy of syntactic assertionality and truth equationality classes.



It is not difficult to see that the syntactic assertionality classes are properly included in the corresponding truth equationality classes. This is accomplished by exhibiting a π-institution which is family truth equational but fails to be syntactically system assertional.

Example 1268 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone generated by the unary natural transformations* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, specified by*

$$\sigma^\flat_\Sigma(0) = 0, \quad \sigma^\flat_\Sigma(1) = 1, \quad \sigma^\flat_\Sigma(2) = 0,$$

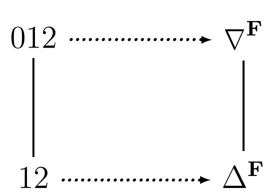
  and $\tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by*

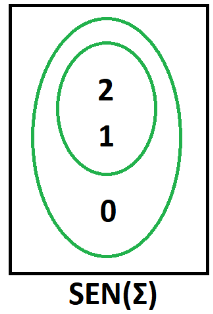
$$\tau^\flat_\Sigma(0) = 2, \quad \tau^\flat_\Sigma(1) = 1, \quad \tau^\flat_\Sigma(2) = 2.$$

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



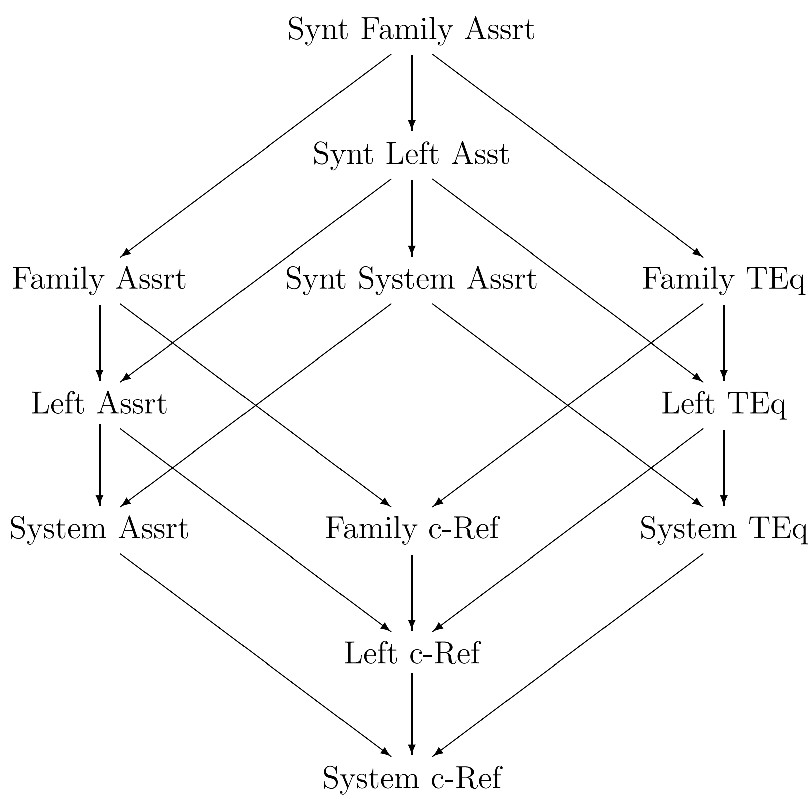


It is not difficult to check that $\mathcal{I}$ *is family truth equational, with witnessing equation* $\iota \approx \tau^\flat$.

On the other hand, $\mathcal{I}$ *is not system regular, since, for* $T = \{\{1,2\}\}$, *we have* $1,2 \in T_\Sigma$, *but* $\langle 1,2\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$.

Thus, $\mathcal{I}$ *belongs to all three truth equationality classes, but does not satisfy any of the three regularity conditions and, hence, belongs to none of the three syntactic assertionality classes.*

Finally, if we add the corresponding semantic classes of those depicted in the preceding diagram, we get a bigger view of the hierarchy consisting of assertionality (semantic and syntactic) and of complete reflectivity (semantic) and truth equationality (syntactic) classes.



Finally, based on previously established results, we can easily show that the three types of syntactic assertionality transfer from a π-institution to all its generalized matrix families. This constitutes an analog of Theorem 599 in the syntactic context.

Theorem 1269 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically family (respectively, left, system) assertional if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\langle \mathbf{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ *is syntactically family (respectively, left, system) assertional.*

Proof: This follows by putting together Theorem 585, asserting that regularity transfers, and Theorem 1197, asserting that the existence of natural theorems transfers. ■

16.6 Syntactic RW Prealgebraizability

In this section, we deal with three versions of syntactic regular weak prealgebraizability. These arise by combining syntactic prealgebraicity with each of the three versions of syntactic assertionality.

Definition 1270 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **syntactically regularly weakly family prealgebraizable***, or* **syntactically RWF prealgebraizable** *for short, if it is syntactically prealgebraic and syntactically family assertional;*
- $\mathcal{I}$ *is* **syntactically regularly weakly left prealgebraizable***, or* **syntactically RWL prealgebraizable** *for short, if it is syntactically prealgebraic and syntactically left assertional;*
- $\mathcal{I}$ *is* **syntactically regularly weakly system prealgebraizable***, or* **syntactically RWS prealgebraizable** *for short, if it is syntactically prealgebraic and syntactically system assertional.*

Based on the syntactic assertionality hierarchy established in Proposition 1262, we have the following

Proposition 1271 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is syntactically regularly weakly family prealgebraizable, then it is syntactically regularly weakly left prealgebraizable;*

(b) *If $\mathcal{I}$ is syntactically regularly weakly left prealgebraizable, then it is syntactically regularly weakly system prealgebraizable.*

Proof: Straightforward by combining Definition 1270 and Proposition 1262. ■

Proposition 1271 establishes the syntactic regular weak prealgebraizability hierarchy depicted in the following diagram.

Syntactic Regular Weak Family Prealgebraizable

↓

Syntactic Regular Weak Left Prealgebraizable

↓

Syntactic Regular Weak System Prealgebraizable

Being very close to the apex of the Leibniz hierarchy, just below the other classes that are studied in detail in the remaining sections of the present chapter, it compares favorably (meaning is stronger) to many of the other classes, semantic and syntactic introduced so far.

First, we look at the extant relationships between syntactic regular weak prealgebraizability classes and the four syntactic regular prealgebraicity classes of Section 16.3. It turns out that syntactic regular weak family prealgebraizability implies syntactic family regular protoalgebraicity and that syntactically regular weak system prealgebraizability implies syntactic system regular prealgebraicity. The only implication one can draw from the middle class of syntactically regular weak left prealgebraizability is the trivial one of being syntactically prealgebraic and left regular, which, strictly speaking, lies outside the syntactic hierarchy of Section 16.3.

Proposition 1272 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *If $\mathcal{I}$ is syntactically RWF prealgebraizable, then it is syntactically family regularly protoalgebraic;*

(b) *If $\mathcal{I}$ is syntactically RWS prealgebraizable, then it is syntactically system regularly prealgebraic.*

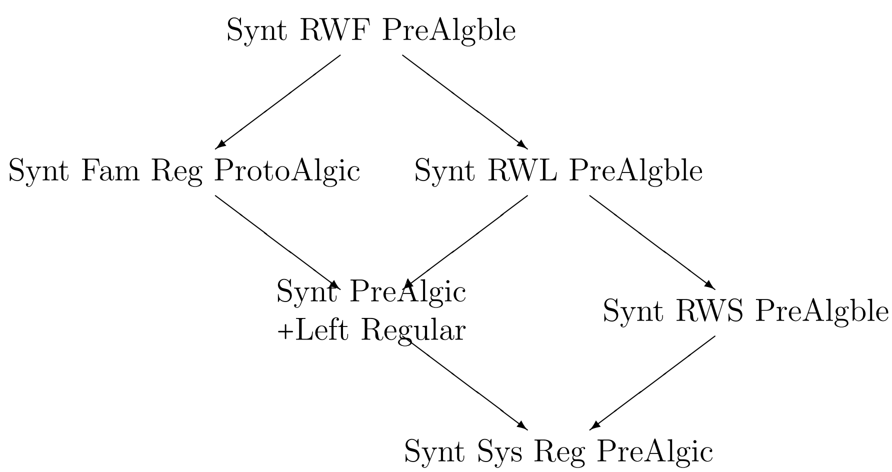
Proof:

(a) Suppose that $\mathcal{I}$ is syntactically RWF prealgebraizable. Note that, by definition, $\mathcal{I}$ is syntactically family assertional, i.e., it is family regular and has natural theorems. Thus, by Theorem 1267, it is family truth equational. Thus, by Theorem 829, it is family c-reflective, whence, by Proposition 237, it is systemic. Thus, since, by definition, it is syntactically prealgebraic, it must be syntactically protoalgebraic. This proves that it is syntactically family regularly protoalgebraic.

(b) By definition $\mathcal{I}$ is syntactically system assertional, whence it is system regular. And it is syntactically prealgebraic, also by definition. Thus, it is syntactically system regularly prealgebraic.

■

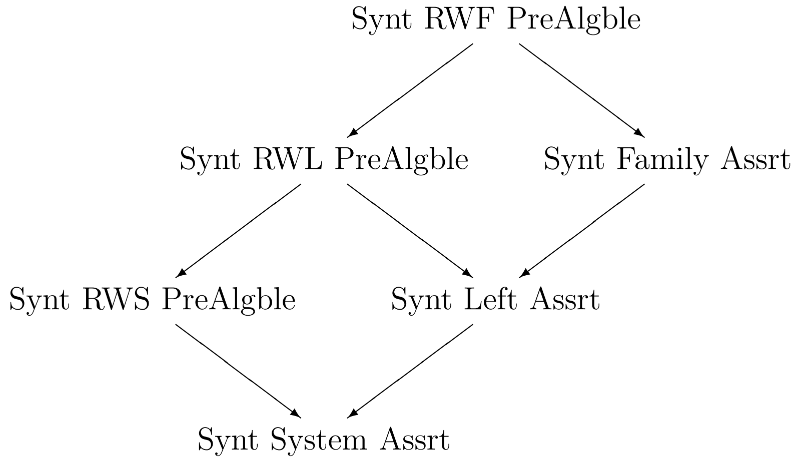
Thus, according to Proposition 1272, we get the mixed hierarchy depicted in the diagram.



As far as relationships between the syntactic regular weak prealgebraizability hierarchy and the syntactic assertionality hierarchy are concerned, we have, directly by definition, the following inclusions.

Proposition 1273 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is syntactically regularly weakly family (left, system, respectively) prealgebraizable, then it is syntactically family (left, system, respectively) assertional.*

Proof: Directly from Definition 1270. ■



Finally we look at closer relationships with other classes that are placed relatively high in the Leibniz hierarchy. Still staying with syntactically defined classes, we have the following relationships between the classes in the syntactic regular weak prealgebraizability hierarchy and the classes in the syntactic weak prealgebraizability hierarchy, which were defined in Chapter 12.

Proposition 1274 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

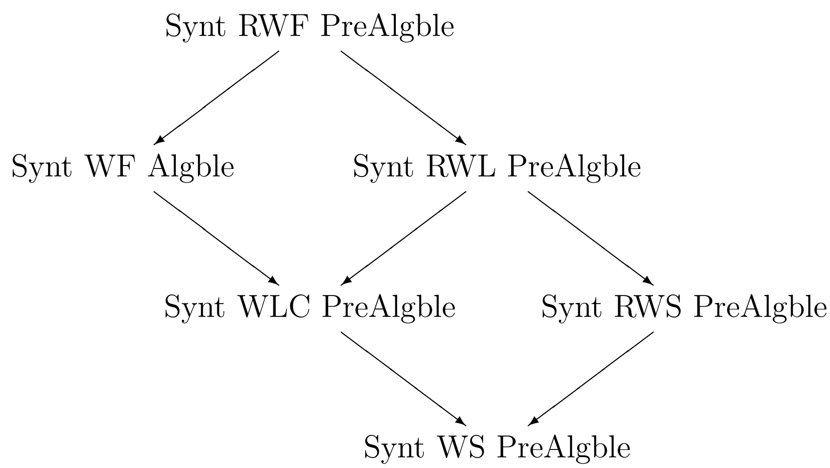
(a) If $\mathcal{I}$ *is syntactically regularly weakly family prealgebraizable, then it is syntactically weakly family algebraizable;*

(b) If $\mathcal{I}$ *is syntactically regularly weakly left prealgebraizable, then it is syntactically weakly left c-reflective prealgebraizable;*

(c) If $\mathcal{I}$ *is syntactically regularly weakly system prealgebraizable, then it is syntactically weakly system prealgebraizable.*

Proof: We only prove Part (a). Parts (b) and (c) can be proven similarly and are easier. Suppose $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then, it is, by definition syntactically family assertional. Thus, by Theorem 1267, it is family truth equational and, therefore, systemic. Thus, on the one hand, $\mathcal{I}$ is syntactically prealgebraic, and, hence, by systemicity, syntactically protoalgebraic, and, on the other, it is family truth equational. Therefore, it is syntactically weakly family algebraizable. ■

Proposition 1274, establishes the following hierarchy of syntactically regularly weakly prealgebraizable and syntactically weakly prealgebraizable π-institutions.



Finally, we reach across to bridge the gap between syntactically and semantically defined prealgebraizability classes. We establish relationaships that govern the syntactic regular weak prealgebraizability classes and the regular weak prealgebraizability classes that were defined in Chapter 8.

Proposition 1275 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

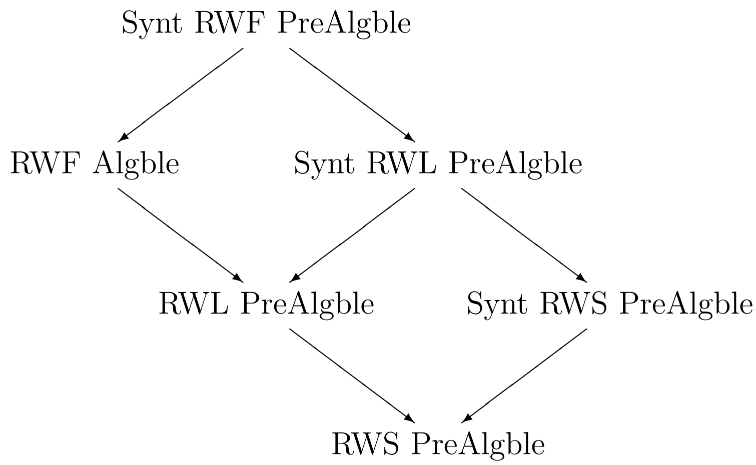
(a) If $\mathcal{I}$ *is syntactically regularly weakly family prealgebraizable, then it is regularly weakly family algebraizable;*

(b) If $\mathcal{I}$ *is syntactically regularly weakly left prealgebraizable, then it is regularly weakly left prealgebraizable;*

(c) If $\mathcal{I}$ *is syntactically regularly weakly system prealgebraizable, then it is regularly weakly system prealgebraizable.*

Proof: This follows from the facts that, on the one hand, syntactic prealgebraicity implies prealgebraicity and, on the other hand, syntactic family (left, system, respectively) assertionality implies family (left, system, respectively) assertionality. ∎

Proposition 1275 gives rise to the following mixed, semantic and syntactic, hierarchy of regularly weakly prealgebraizable π-institutions.



Based on existing results, we can show that all three kinds of syntactic regular weak prealgebraizability transfer from theory families/systems to filter families/systems over arbitrary **F**-algebraic systems. This is the syntactic analog of Theorem 609, which asserted that regular weak prealgebraizability properties transfer from a π-institution to all its generalized matrix families.

Theorem 1276 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically regularly weakly family (left, system, respectively) prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the* $\mathcal{I}$*-gmatrix family* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ *is syntactically regularly weakly family (left, system, respectively) prealgebraizable.*

Proof: By Theorem 789, syntactic prealgebraicity transfers. By Theorem 585, the three regularity properties transfer. Finally, by Theorem 1197, the property of possessing natural theorems also transfers. Thus, the properties of being syntactically regularly weakly family, left and system prealgebraizable all transfer from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$. ■

Finally, we adapt previously obtained results characterizing regular weak prealgebraizability to obtain similar characterizations of syntactic regular weak prealgebraizability in terms of mappings between posets of filter families/systems (including theory families/systems) and congruence systems. Essentially, to the characterizations obtained in Theorems 610, 611 and 612, we add the conditions of having enough natural transformations so that syntactic prealgebraicity is ensured and also the existence of natural theorems so that truth equationality is obtained, rather than having only complete reflectivity.

Theorem 1277 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly weakly family prealgebraizable;*

(ii) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism,* $\mathcal{I}$ *has a Leibniz reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $T = \tau/\Omega(T)$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}}\rangle$*.*

Proof: By Theorem 1299, $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the π-institution $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ is also syntactically regularly weakly family prealgebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i)$\Leftrightarrow$(ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then it is, by definition, syntactically prealgebraic. Moreover, it is, by definition, syntactically family assertional. Thus, it has a natural theorem τ and it is, by Theorem 1267, family truth equational. Thus, by Theorem 829, it is family c-reflective and, hence, by Proposition 237, systemic. This implies that it is syntactically protoalgebraic and family truth equational. Using Theorem 610, we conclude that Ω is an order isomorphism. By Theorem 788, it has a Leibniz reflexive core and, by Corollary 1266, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$.

Assume, conversely, that the postulated conditions hold. By Proposition 1275, $\mathcal{I}$ is regularly weakly family prealgebraizable. Hence it is protoalgebraic, which, together with the postulated Leibniz property of the reflexive core, gives, by Corollary 809, that it is syntactically protoalgebraic. Further, by hypothesis and Corollary 1266, it is syntactically family assertional. Thus, by definition, it is syntactically regularly weakly family prealgebraizable. ■

Analogous characterization theorems may be provided for syntactical regular weak left and system prealgebraizability. The proofs are analogous and are omitted.

Theorem 1278 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly weakly left prealgebraizable;*

(ii) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order embedding,* $\mathcal{I}$ *has a Leibniz reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\overleftarrow{T} = \tau/\Omega(T)$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}}\rangle$*.*

Theorem 1279 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly weakly system prealgebraizable;*

(ii) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order embedding,* $\mathcal{I}$ *has a Leibniz reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $T = \tau/\Omega(T)$*;*

(iii) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}} \rangle$*.*

16.7 Syntactic RW Algebraizability

In this section, we deal with three versions of syntactic regular weak algebraizability. These arise by combining syntactic protoalgebraicity with each of the three versions of syntactic assertionality.

Definition 1280 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **syntactically regularly weakly family algebraizable***, or* **syntactically RWF algebraizable** *for short, if it is syntactically protoalgebraic and syntactically family assertional;*
- $\mathcal{I}$ *is* **syntactically regularly weakly left algebraizable***, or* **syntactically RWL algebraizable** *for short, if it is syntactically protoalgebraic and syntactically left assertional;*
- $\mathcal{I}$ *is* **syntactically regularly weakly system algebraizable***, or* **syntactically RWS algebraizable** *for short, if it is syntactically protoalgebraic and syntactically system assertional.*

One of the immediate consequences of family assertionality is that the π-institution under consideration must be systemic and, therefore, that pre- and protoalgebraicity coincide. This reasoning has been applied a few times already in the preceding section. It shows that syntactic regular weak family algebraizability coincides with syntactic weak family prealgebraizability.

Proposition 1281 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically regularly weakly family algebraizable if and only if it is syntactically regularly weakly family prealgebraizable.*

Proof: Suppose $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then, by definition, it is family assertional. Thus, by Theorem 1267, it is family truth equational. Hence, by Theorem 829, it is family completely reflective and, hence, by Proposition 237, it is systemic. Since, by definition, it is syntactically prealgebraic, it is, by systemicity, syntactically protoalgebraic. Therefore, being syntactically protoalgebraic and syntactically family assertional, it is syntactically regularly weakly family algebraizable. The reverse implication is trivial. So, equivalence of the two conditions is established. ■

The second important observation that one can make is that syntactic regular weak left and system algebraizability coincide. This is due to the fact that protoalgebraicity implies stability.

Proposition 1282 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically regularly weakly left algebraizable if and only if it is syntactically regularly weakly system algebraizable.*

Proof: It is easy to see that the left version implies the system version. This follows directly from the fact that syntactic left assertionality implies syntactic system assertionality, established in Proposition 1262. For the converse, assume that $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then it is, by definition, syntactically protoalgebraic. This implies, by Theorem 805, that it is protoalgebraic. Hence, by Theorem 175, it is stable. Now, also by definition, $\mathcal{I}$ is syntactically system assertional. Thus, by Proposition 1263, it is syntactically left assertional. Being syntactically protoalgebraic and syntactically left assertional, $\mathcal{I}$ is, by definition, syntactically regularly weakly left algebraizable. ■

Based on the syntactic assertionality hierarchy established in Proposition 1262, we have the following

Corollary 1283 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically regularly weakly family algebraizable, then it is syntactically regularly weakly system algebraizable.*

Proof: Straightforward by combining Definition 1280 and Proposition 1262. ■

Proposition 1283 establishes the syntactic regular weak algebraizability hierarchy depicted in the following diagram.

Syntactic Regular Weak Family Algebraizable

↓

Syntactic Regular Weak System Algebraizable

It is easy to see how the two classes introduced in this section fit within a mixed syntactic regular weak (pre)algebraizability hierarchy. Given Proposition 1281, which showed that the top classes in each of the two hierarchies coincide, the picture is completed by the following easy consequence of the definitions involved.

Proposition 1284 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically regularly weakly system algebraizable, then it is syntactically regularly weakly left prealgebraizable.*

Proof: If $\mathcal{I}$ is syntactically regularly weakly system algebraizable, then, by Proposition 1282, it is syntactically regularly weakly left algebraizable, whence, since syntactic protoalgebraicity implies syntactic prealgebraicity, we conclude that $\mathcal{I}$ is syntactically regularly weakly left algebraizable. ∎

Thus, the following diagram presents the complete picture consisting of the four syntactic regular weak (pre)algebraizability classes of π-institutions. Compare this with the identical hierarchy revealed on the semantic side in Section 8.5.

Syntactic RWF (Pre)Algebraizable

↓

Syntactic RWS Algebraizable

↓

Syntactic RWL Prealgebraizable

↓

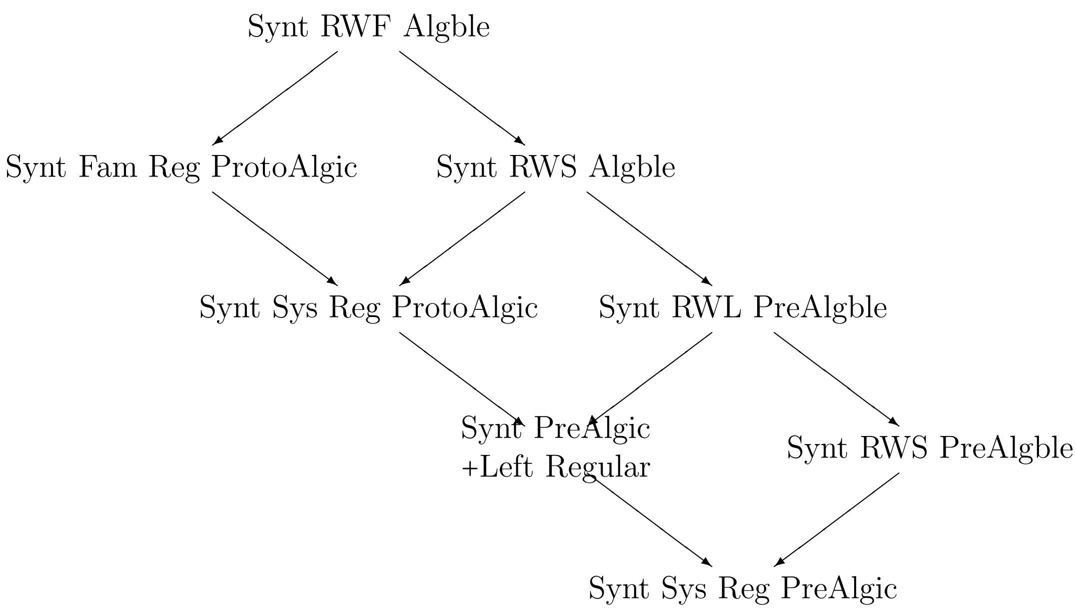
Syntactic RWS Prealgebraizable

To complete the puzzle of the relationships between syntactic regular weak prealgebraizability and syntactic regular pre- and protoalgebraicity classes, it suffices to observe that syntactic regular weak system algebraizability implies, rather trivially, syntactic system regular protoalgebraicity.

Proposition 1285 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically RWS algebraizable, then it is syntactically system regularly protoalgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically RWS algebraizable. Note that, by definition, $\mathcal{I}$ is syntactically system assertional, and syntactically protoalgebraic. Hence, it is syntactically system regularly protoalgebraic. ∎

Thus, according to both Proposition 1272 and Proposition 1285, we get the following hierarchy, which completes the diagram given in the preceding section after Proposition 1272.

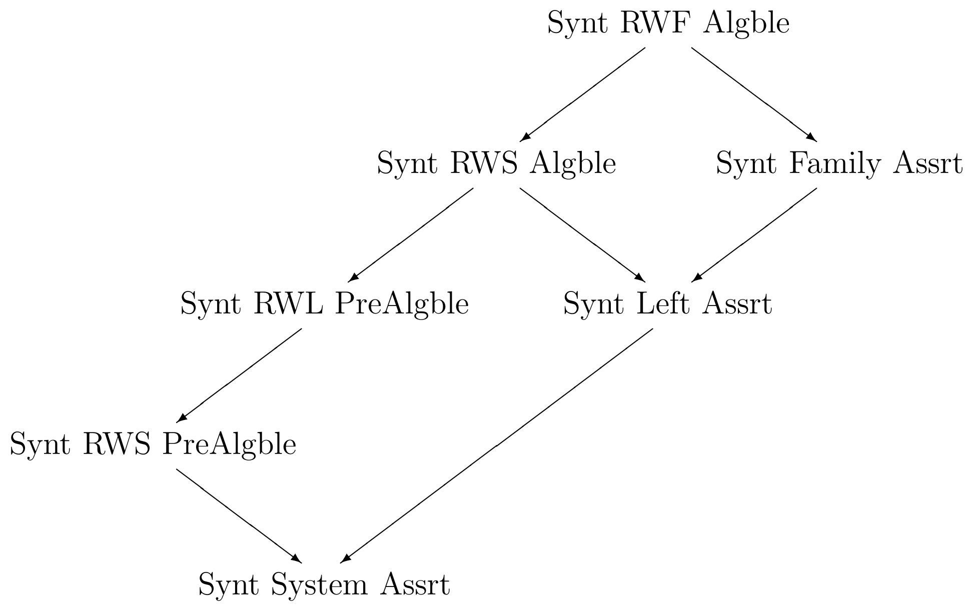


As far as relationships between the syntactic regular weak prealgebraizability hierarchy and the syntactic assertionality hierarchy are concerned, the picture is completed by realizing that syntactic regular weak system algebraizability implies syntactic left assertionality.

Corollary 1286 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically RWS algebraizable, then it is syntactically left assertional.*

Proof: The conclusion follows directly by Proposition 1282. ∎

Thus, according to Corollary 1286, and the hierarchy obtained in the preceding section, the interactions with syntactic assertionality properties are as shown in the diagram.

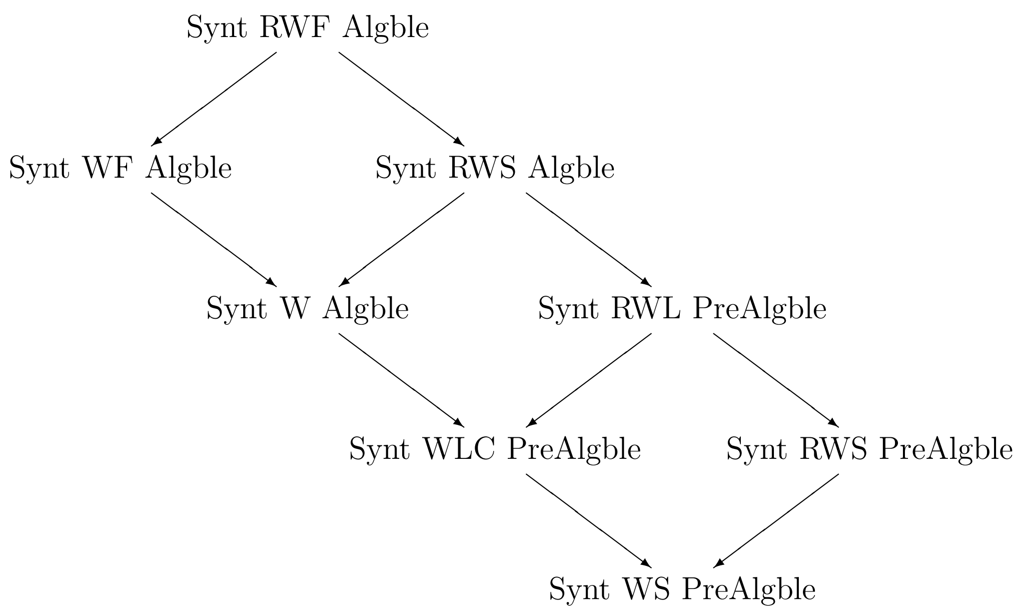


Finally we look at completing the hierarchy diagrams examining the relationships with other classes that are placed relatively high in the Leibniz hierarchy. Staying with syntactically defined classes, we have the following extra relationship between syntactically regularly weakly system algebraizable π-institutions and syntactically weakly (system) algebraizable ones.

Proposition 1287 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically regularly weakly system algebraizable, then it is syntactically weakly (system) algebraizable.*

Proof: Suppose $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then, it is, by definition syntactically protoalgebraic and system assertional. Thus, by Theorem 1267, it is syntactically protoalgebraic and system truth equational. Therefore, it is, by definition, syntactically weakly (system) algebraizable. ■

Proposition 1287, in conjunction with Proposition 1274, completes the hierarchy of syntactically regularly weakly (pre)algebraizable and syntactically weakly (pre)algebraizable π-institutions, part of which was shown following Proposition 1274.

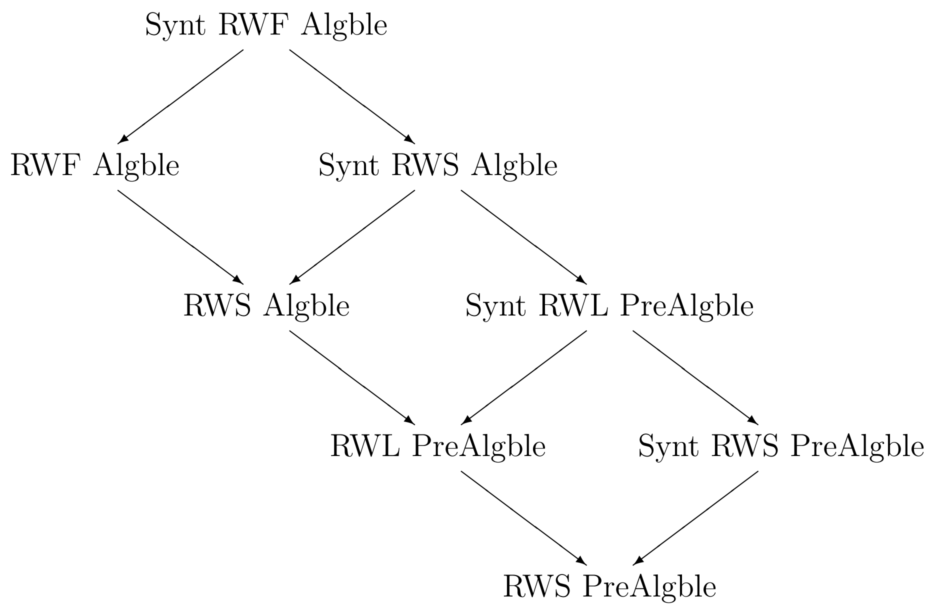


Finally, we revisit the relationships between syntactically and semantically defined (pre)algebraizability classes. We show that syntactic regular weak system algebraizability implies regular weak system algebraizability. This completes the picture established in Proposition 1275.

Proposition 1288 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically regularly weakly system algebraizable, then it is regularly weakly system algebraizable.*

Proof: This follows from the facts that, on the one hand, by Theorem 805, syntactic protoalgebraicity implies protoalgebraicity and, on the other hand, by Proposition 1264, syntactic system assertionality implies system assertionality. ■

Propositions 1275 and 1288 give rise to the following mixed, semantic and syntactic, hierarchy of regularly weakly (pre)algebraizable π-institutions, which completes the hierarchy shown after Proposition 1275.



As was the case with the three syntactic regular weak prealgebraizability classes, we may show that syntactic regular weak system algebraizability also transfers from theory families/systems to filter families/systems over arbitrary **F**-algebraic systems. This completes Transfer Theorem 1276.

Theorem 1289 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is syntactically regularly weakly system algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the* $\mathcal{I}$*-gmatrix family* $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ *is syntactically regularly weakly system algebraizable.*

Proof: By Theorem 810, syntactic protoalgebraicity transfers. By Theorem 585, system regularity transfers. Finally, by Theorem 1197, the property of possessing natural theorems also transfers. Thus, syntactic regular weak system algebraizability transfers from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$, for all **F**-algebraic systems $\mathcal{A}$. This establishes the theorem. ■

Finally, we adapt previously obtained results characterizing syntactic regular weak prealgebraizability to obtain a similar characterization of syntactic regular weak system algebraizability in terms of mappings between posets of filter families/ systems (including theory families/systems) and congruence systems. This completes Theorem 1277.

Theorem 1290 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly weakly system algebraizable;*

(ii) $\mathcal{I}$ *is stable,* $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism,* $\mathcal{I}$ *has a Leibniz reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $T = \tau/\Omega(T)$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}} \rangle$*.*

Proof: By Theorem 1289, $\mathcal{I}$ is syntactically regularly weakly system algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the π-institution $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is also syntactically regularly weakly system algebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i)⇔(ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then, it is, in particular, by Proposition 1288, regularly weakly system algebraizable, and, by definition, syntactically protoalgebraic and syntactically system assertional. By Theorem 624, $\mathcal{I}$ is stable, $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an order isomorphism and, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$, where τ is a natural theorem, whose existence is guaranteed by syntactic assertionality. Finally, syntactic protoalgebraicity implies, by Theorem 805, that $\mathcal{I}$ has a Leibniz reflexive core.

Assume, conversely, that the postulated conditions hold. By Theorem 624, $\mathcal{I}$ is regularly weakly system algebraizable. Hence it is protoalgebraic, which, together with the postulated Leibniz property of the reflexive core, gives, by Theorem 805, that it is syntactically protoalgebraic. Further, since it is regularly weakly system algebraizable, it is, in particular, system regular and, by hypothesis, has natural theorems. Thus, it is syntactically system assertional. Hence, being syntactically protoalgebraic and syntactically system assertional, it is, by definition, syntactically regularly weakly system algebraizable. ∎

16.8 Syntactic Regular (Pre)Algebraizability

In this section, we deal with the four versions of syntactic regular (pre)algebraizability, corresponding to the four versions of syntactic regular weak (pre)algebraizability that were studied in the preceding two sections. These arise by combining syntactic (pre)equivalentiality with each of the three versions of syntactic assertionality. They give rise to a four-element linear hierarchy that parallels that of syntactically regularly weakly (pre)algebraizable π-institutions and lies directly above it. The four classes, introduced and studied in the present section, lie at the very apex of the Leibniz hierarchies that were studied in detail in the monograph, and which form the backbone of the field of categorical abstract algebraic logic.

A priori, one may define six different classes of syntactically regularly (pre)algebraizable π-institutions. Three of these classes use syntactic preequivalentiality.

Definition 1291 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

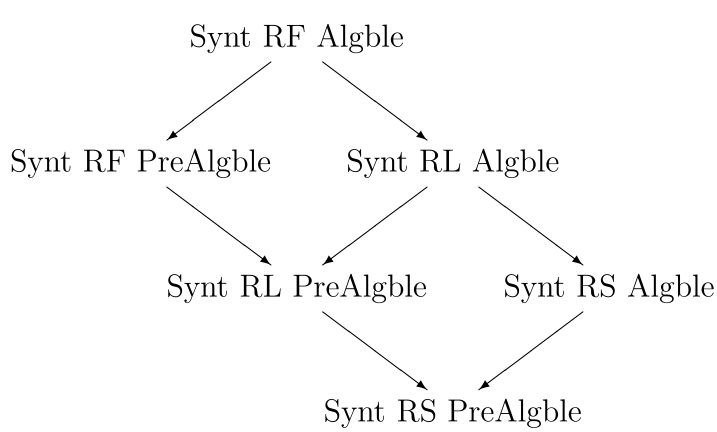
- $\mathcal{I}$ *is* **syntactically regularly family prealgebraizable***, or* **syntactically RF prealgebraizable** *for short, if it is syntactically preequivalential and syntactically family assertional;*
- $\mathcal{I}$ *is* **syntactically regularly left prealgebraizable***, or* **syntactically RL prealgebraizable** *for short, if it is syntactically preequivalential and syntactically left assertional;*
- $\mathcal{I}$ *is* **syntactically regularly system prealgebraizable***, or* **syntactically RS prealgebraizable** *for short, if it is syntactically preequivalential and syntactically system assertional.*

Three more classes use syntactic equivalentiality.

Definition 1292 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **syntactically regularly family algebraizable***, or* **syntactically RF algebraizable** *for short, if it is syntactically equivalential and syntactically family assertional;*
- $\mathcal{I}$ *is* **syntactically regularly left algebraizable***, or* **syntactically RL algebraizable** *for short, if it is syntactically equivalential and syntactically left assertional;*
- $\mathcal{I}$ *is* **syntactically regularly system algebraizable***, or* **syntactically RS algebraizable** *for short, if it is syntactically equivalential and syntactically system assertional.*

We can show that similar relationships to those holding between the syntactic regular weak (pre)algebraizability classes are valid in this case also, leading to the collapsing of the six-class hierarchy (which, a priori, would look as in the accompanying figure)



to only four classes forming a linear hierarchy.

The top classes of syntactically regularly family prealgebraizable and algebraizable π-institutions coincide. Moreover, in the algebraizability case, syntactic regular left algebraizability turns out to be identical with syntactic regular system algebraizability. These relationships are presented formally in the following proposition.

Proposition 1293 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is syntactically regularly family prealgebraizable if and only if it is syntactically regularly family algebraizable;*

(b) $\mathcal{I}$ *is syntactically regularly left algebraizable if and only if it is syntactically regularly system algebraizable.*

Proof:

(a) Of course the right-to-left implication is trivial, since, by definition (see Section 13.2 and 13.3), syntactic equivalentiality implies syntactic preequivalentiality. On the other hand, by Theorem 1267, syntactic family assertionality implies family truth equationality, which, in turn, implies, by Theorem 829, family c-reflectivity and, hence, by Lemma 233, systemicity. Thus, under the given hypothesis, syntactic preequivalentiality coincides with syntactic equivalentiality.

(b) Again, since it is obvious that syntactical regular left algebraizability implies syntactical system algebraizability, in view of the fact (Proposition 1262) that syntactical left assertionality implies syntactical system assertionality, one must focus on the reverse implication. However, syntactic system algebraizability entails syntactic protoalgebraicity, which implies, by Theorem 792, protoalgebraicity, which, in turn, by Lemma 170, implies stability. And under stability, by Proposition 1263, syntactic left assertionality and syntactic system assertionality coincide. ■

Now the following implications are straightforward and establish the hierarchy obtained from the preceding diagram, if one takes into account the pairwise identification of classes proven in Proposition 1293.

Proposition 1294 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is syntactically regularly family (pre)algebraizable, then it is syntactically regularly system (left) algebraizable;*

(b) If $\mathcal{I}$ *is syntactically regularly system (left) algebraizable, then it is syntactically regularly left prealgebraizable;*

(c) *If $\mathcal{I}$ is syntactically regularly left prealgebraizable, then it is syntactically regularly system prealgebraizable.*

Proof: Part (a) relies on the fact that, by Proposition 1262, syntactic family assertionality is stronger than syntactic system assertionality. Part (b) relies on the fact that syntactic equivalentiality implies syntactic preequivalentiality. Finally, Part (c) is a direct consequence of syntactic system assertionality being dominated by syntactic left assertionality (Proposition 1262). ■

Proposition 1294, which takes into account the identifications of Proposition 1293, establishes the syntactic regular (pre)algebraizability hierarchy depicted in the following diagram.

Syntactic Regular Family Algebraizable

↓

Syntactic Regular System Algebraizable

↓

Syntactic Regular Left Prealgebraizable

↓

Syntactic Regular System Prealgebraizable

We look, next, at the relationships between syntactic regular (pre)algebraizability classes and the four syntactic regular (pre)equivalentiality classes of Section 16.4. Syntactic regular family algebraizability implies syntactic family regular equivalentiality, syntactic regular system algebraizability implies syntactic system regular equivalentiality and syntactic regular system prealgebraizability implies syntactic system regular preequivalentiality. However, from syntactic regular left prealgebraizability we can only make the trivial deduction of syntactic preequivalentiality and left regularity. Strictly speaking, the combination of these two properties does not form a class in the syntactic hierarchy of Section 16.4.

Proposition 1295 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

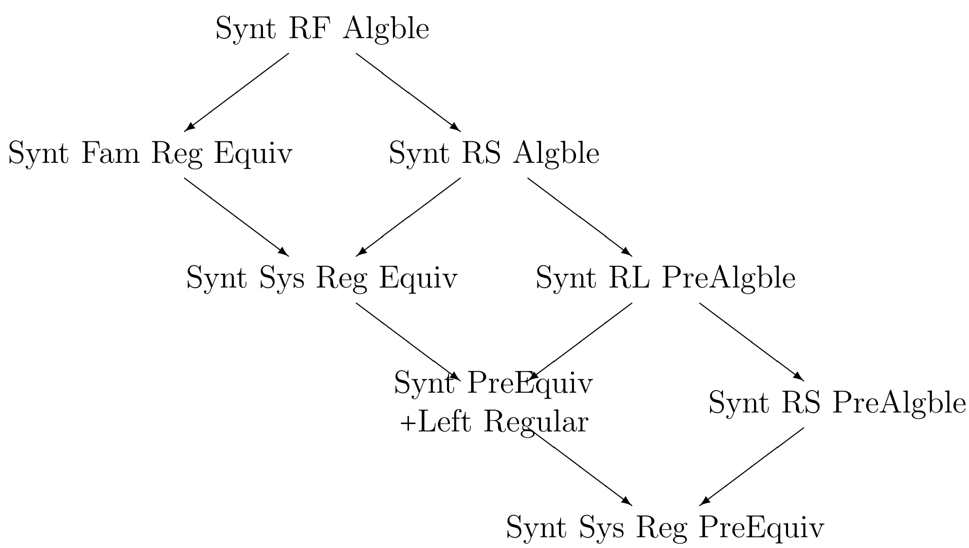
(a) *If $\mathcal{I}$ is syntactically RF algebraizable, then it is syntactically family regularly equivalential;*

(b) *If $\mathcal{I}$ is syntactically RS algebraizable, then it is syntactically system regularly equivalential;*

(c) *If $\mathcal{I}$ is syntactically RS prealgebraizable, then it is syntactically system regularly preequivalential.*

Proof: For Part (a) observe that, by definition, $\mathcal{I}$ is syntactically equivalential and syntactically family assertional, which implies that it is family regular. Thus, it is syntactically family regularly equivalential. Similarly, for Part (b), $\mathcal{I}$ is, by definition, syntactically equivalential and syntactically system assertional, which implies system regularity. Thus, it is syntactically system regularly equivalential. Finally, in Part (c), $\mathcal{I}$ is, by definition, syntactically preequivalential and syntactically system assertional, whence, once more, it is also syntactically system regular. Hence, it is syntactically system regularly preequivalential. ∎

Thus, according to Proposition 1295, we get the mixed hierarchy depicted in the diagram.



We do not dwell on relationships between the syntactic regular (pre)algebraizability classes and the syntactic assertionlity classes, since those are direct consequences of the relationships, already established in the preceding section, between syntactic regular weak (pre)algebraizability classes and the syntactic assertionality classes, once the following, also easily obtainable, relations between syntactic regular (pre)algebraizability classes and syntactic regular weak (pre)algebraizability classes are established.

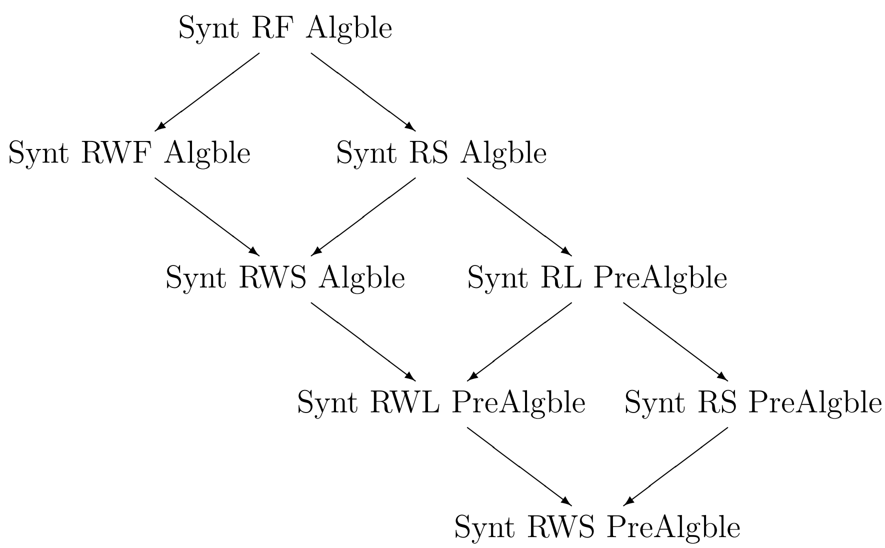
Proposition 1296 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *If $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable, then it is syntactically regularly weakly family (system, respectively) algebraizable;*

(b) *If $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable, then it is syntactically regularly weakly left (system, respectively) prealgebraizable.*

Proof: Directly from the definitions involved. ∎

Thus, we get a comprehensive picture of the syntactic regular prealgebraizability hierarchy, including both weak and "strong" (meaning non-weak) classes.



Finally we look at the relationships with other classes that are placed just below syntactically regularly (pre)algebraizable π-institutions, namely, the classes in the syntactic (pre)algebraizablity hierarchy and those in the (semantic) regular (pre)algebraizability hierarchy. The former hierarchy was studied in detail in Chapter 12, whereas the latter was studied in Chapter 8. Starting with the relationships between the syntactic regular (pre)algebraizability and the syntactic (pre)algebraizability classes, we get the following

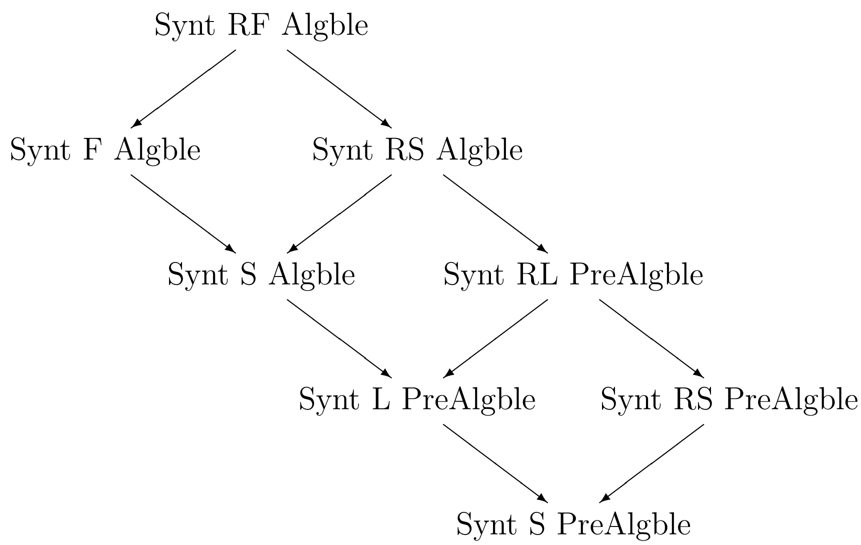
Proposition 1297 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$.

(a) *If $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable, then it is syntactically family (system, respectively) algebraizable;*

(b) *If $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable, then it is syntactically left (system, respectively) prealgebraizable.*

Proof: Part (a) follows from the fact that syntactic family and system assertionality imply, respectively, family and system truth equationality. Part (b), similarly, follows from the fact that syntactic left and system assertionality imply, respectively, left and system truth equationality. All the aforementioned implications, forming the key to the inclusions in the statement, are the subject of Theorem 1267. ■

Proposition 1297, establishes the following mixed hierarchy of syntactically regularly (pre)algebraizable and syntactically (pre)algebraizable π-institutions.



We close with the relationships between syntactically and semantically defined regular (pre)algebraizability classes.

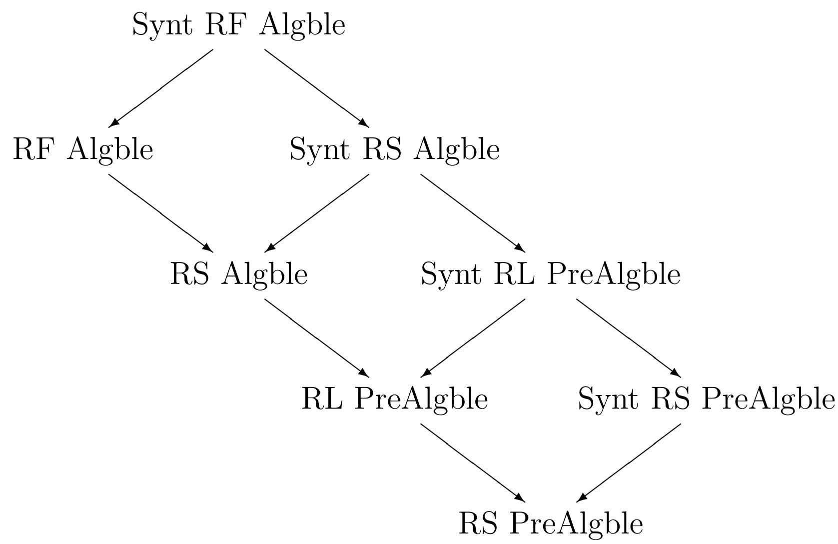
Proposition 1298 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is syntactically regularly family (system, respectively) algebraizable, then it is regularly family (system, respectively) algebraizable;*

(b) If $\mathcal{I}$ *is syntactically regularly left (system, respectively) prealgebraizable, then it is regularly left (system, respectively) prealgebraizable.*

Proof: This follows from the facts that, on the one hand, syntactic pre- and protoalgebraicity imply respectively pre- and protoalgebraicity, and, on the other hand, syntactic family (left, system, respectively) assertionality implies family (left, system, respectively) assertionality. The former implications are established in Theorems 771 and 792. The latter are by Proposition 1264. ■

Proposition 1298 gives rise to the following mixed, semantic and syntactic, hierarchy of regularly (pre)algebraizable π-institutions.



As was the case with syntactic regular weak (pre)algebraizability, all four flavors of syntactic regular (pre)algebraizability transfer from theory families/systems to filter families/systems over arbitrary $\mathbf{F}$-algebraic systems. This is a "strong" analog of Theorems 1276 and 1289, which asserted that syntactic regular weak (pre)algebraizability properties transfer from a π-institution to all its generalized matrix families.

Theorem 1299 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$-gmatrix family $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is syntactically regularly family (system, respectively) algebraizable;

(b) $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$-gmatrix family $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is syntactically regularly left (system, respectively) prealgebraizable.

Proof: By Theorems 955 and 972, syntactic preequivalentiality and syntactic equivalentiality transfer. By Theorem 585, the three regularity properties transfer. Finally, by Theorem 1197, the property of possessing natural theorems also transfers. Thus, all four syntactic regular (pre)algebraizability properties transfer from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$. ■

Finally, we obtain characterizations of syntactically regular (pre)algebraizability in terms of mappings between posets of filter families/ systems (including theory families/systems) and congruence systems.

Theorem 1300 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly family algebraizable;*

(ii) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism commuting with inverse logical extensions,* $\mathcal{I}$ *has a Leibniz binary reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $T = \tau/\Omega(T)$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}} \rangle$*.*

Proof: By Theorem 1299, $\mathcal{I}$ is syntactically regularly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the π-institution $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is also syntactically regularly family algebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i)$\Leftrightarrow$(ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly family algebraizable. Then it is, by definition, syntactically equivalential and syntactically family assertional. Thus, it has a natural theorem τ, it is family regular and it is, by Theorem 1267, family truth equational. Using Corollary 649, we conclude that Ω is an order isomorphism commuting with inverse logical extensions, by Theorem 983, that it has a Leibniz binary reflexive core and, by Corollary 1266, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$.

Assume, conversely, that the postulated conditions hold. By Corollary 649, $\mathcal{I}$ is regularly family algebraizable. Hence it is equivalential, whence, together with the postulated Leibniz property of the binary reflexive core, we obtain, by Corollary 983, that it is syntactically equivalential. Further, by hypothesis and Corollary 1266, it is syntactically family assertional. Thus, by definition, it is syntactically regularly family algebraizable. ∎

Theorem 1301 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly system algebraizable;*

(ii) $\mathcal{I}$ *is stable,* $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism commuting with inverse logical extensions,* $\mathcal{I}$ *has a Leibniz binary reflexive core and a natural theorem* $\tau : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, such that, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*,* $T = \tau/\Omega(T)$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the clauses of Part (ii) hold for the* π*-institution* $\langle \mathcal{A}.C^{\mathcal{I},\mathcal{A}} \rangle$*.*

Proof: Similar to that of Theorem 1300. ■

Analogous characterization theorems may be provided for the syntactic regular prealgebraizability properties. The proofs are also similar and are, therefore, omitted.

Theorem 1302 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is syntactically regularly left prealgebraizable;*

Chapter 17

The Syntactic Leibniz Hierarchy: Attic II

17.1 Finitary Companions Revisited

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall from Chapter 9 the construction of the *finitary companion* $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$ of $\mathcal{I}$. It is defined, by setting, for all $\Sigma in|\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$C^f_\Sigma(\Phi) = \bigcup\{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\},$$

where $\subseteq_f$ denotes the finite subset relation. It was shown in Corollary 653 that $\mathcal{I}^f$ is the largest finitary π-institution based on $\mathbf{F}$ that lies below $\mathcal{I}$ is the $\leq$ ordering. Furthermore, even though it is obvious, based on $\mathcal{I}^f \leq \mathcal{I}$, that $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$, Proposition 655 provided a characterization of those sentence families of $\mathbf{F}$ that are theory families of $\mathcal{I}^f$. More concretely, it asserted that $T \in \mathrm{ThFam}(\mathcal{I}^f)$ if and only if it is the union of a directed locally finitely generated collection of theory families of $\mathcal{I}$.

Turning now to the Leibniz hierarchy, some of the semantic aspects of which, in relation to finitarity, were studied in some detail in Chapter 9, it was proven in Lemma 656 that protoalgebraicity is inherited by $\mathcal{I}$ from $\mathcal{I}^f$, i.e., if $\mathcal{I}^f$ is protoalgebraic, then so is $\mathcal{I}$ itself. This is a rather simple consequence of the fact that $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$.

Recall from Chapter 11 the definition of the *reflexive core* $R^{\mathcal{I}}$ of a π-institution $\mathcal{I}$. It consists of all natural transformations $\rho^\flat$ in $N^\flat$, with two distinguished arguments, having the property that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\rho^\flat_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I}).$$

It is not very difficult to show that the reflexive core of the finitary companion $\mathcal{I}^f$ of a π-institution $\mathcal{I}$ is included in that of $\mathcal{I}$.

Lemma 1304 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$R^{\mathcal{I}^f} \subseteq R^{\mathcal{I}}.$$

Proof: Suppose $\rho^\flat \in R^{\mathcal{I}^f}$ and consider $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{rcll}\rho^\flat_\Sigma[\phi, \phi] & \leq & \mathrm{Thm}(\mathcal{I}^f) & (\rho^\flat \in R^{\mathcal{I}^f}) \\ & \leq & \mathrm{Thm}(\mathcal{I}). & (\mathrm{Thm}(\mathcal{I}) \in \mathrm{ThFam}(\mathcal{I}^f))\end{array}$$

Thus, by definition, $\rho^\flat \in R^{\mathcal{I}}$. It follows that $R^{\mathcal{I}^f} \subseteq R^{\mathcal{I}}$. ■

Recall that the reflexive core $R^{\mathcal{I}}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])).$$

From the fact that $R^{\mathcal{I}^f} \subseteq R^{\mathcal{I}}$ it follows at once that, if $\mathcal{I}^f$ is protoalgebraic and $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$, then $R^{\mathcal{I}}$ is Leibniz in $\mathcal{I}$.

Proposition 1305 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f$ *is protoalgebraic and* $R^{\mathcal{I}^f}$ *is Leibniz in* $\mathcal{I}^f$*, then so is* $R^{\mathcal{I}}$ *in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}^f$ is protoalgebraic and $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. We then have

$$\begin{array}{lll}\langle \phi, \psi \rangle & \in & \Omega_\Sigma(C^f(R^{\mathcal{I}^f}_\Sigma[\phi, \psi])) \quad (R^{\mathcal{I}^f} \text{ Leibniz in } \mathcal{I}^f) \\ & \subseteq & \Omega_\Sigma(C^f(R^{\mathcal{I}}_\Sigma[\phi, \psi])) \quad (\text{Lemma 1304 and hypothesis}) \\ & \subseteq & \Omega_\Sigma(C(R^{\mathcal{I}}_\Sigma[\phi, \psi])). \quad (\text{Corollary 653 and hypothesis})\end{array}$$

Therefore, $R^{\mathcal{I}}$ is Leibniz in $\mathcal{I}$. ∎

We can now show that syntactic protoalgebraicity is inherited by a π-institution $\mathcal{I}$ from its finitary companion $\mathcal{I}^f$. This forms an analog in the syntactic context of Lemma 656.

Theorem 1306 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f$ *is syntactically protoalgebraic, then so is* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is syntactically protoalgebraic. By Theorem 805, it is protoalgebraic and its reflexive core $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$. Therefore, by Lemma 656, $\mathcal{I}$ is protoalgebraic and, by Proposition 1305, $R^{\mathcal{I}}$ is Leibniz in $\mathcal{I}$. Therefore, again by Theorem 805, $\mathcal{I}$ is syntactically protoalgebraic. ∎

Recalling Theorem 799, which characterizes syntactic protoalgebraicity in terms of the global family modus ponens property of the reflexive core, we derive the following

Corollary 1307 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}^f}$ *has the global family MP in* $\mathcal{I}^f$*, then* $R^{\mathcal{I}}$ *has the global family MP in* $\mathcal{I}$*.*

Proof: If $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$, then, by Theorem 799, $\mathcal{I}^f$ is syntactically protoalgebraic. Thus, by Theorem 1306, $\mathcal{I}$ is syntactically protoalgebraic, whence, again by Theorem 799, applied in the opposite direction, $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. ∎

Alternatively, instead of deriving the implication in Corollary 1307 by applying Theorem 1306, we may prove it first and then use Theorem 799 to establish that syntactic protoalgebraicity of $\mathcal{I}^f$ implies the syntactic protoalgebraicity of $\mathcal{I}$. We outline this reasoning also, at the expense of having to repeat Corollary 1307 and Theorem 1306.

Lemma 1308 (Corollary 1307) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $R^{\mathcal{I}^f}$ *has the global family MP in* $\mathcal{I}^f$*, then* $R^{\mathcal{I}}$ *has the global family MP in* $\mathcal{I}$*.*

Proof: Suppose $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\phi \in T_\Sigma \quad \text{and} \quad R^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T.$$

By Lemma 1304, we get

$$\phi \in T_\Sigma \quad \text{and} \quad R^{\mathcal{I}^f}_\Sigma[\phi, \psi] \leq T.$$

But $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$ and $R^{\mathcal{I}^f}$ is assumed to have the global family MP in $\mathcal{I}^f$. Thus, $\psi \in T_\Sigma$. This proves that $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. ■

Corollary 1309 (Theorem 1306) *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is syntactically protoalgebraic, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is syntactically protoalgebraic. Then, by Theorem 799, $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$. Thus, by Lemma 1308, $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. Hence, again by applying Theorem 799, only now in the reverse direction, $\mathcal{I}$ is syntactically protoalgebraic. ■

A similar work can be undertaken concerning truth equationality, based on an analog of Lemma 657, but referring to family c-reflectivity, which can be proved in a similar fashion as Lemma 657. We now provide the details.

It is straightforward to see, first of all, that family complete reflectivity is also inherited by $\mathcal{I}$ itself by its finitary companion.

Lemma 1310 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is family c-reflective, then so is $\mathcal{I}$.*

Proof: If $\mathcal{I}^f$ is family c-reflective, then, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I}^f)$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

In particular, the condition holds if quantification is restricted over the collection $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$. Therefore, $\mathcal{I}$ is family c-reflective. ■

It is not very hard either to see that the the Suszko core of the finitary companion $\mathcal{I}^f$ of a π-institution $\mathcal{I}$ is contained in the Suszko core of $\mathcal{I}$ itself, just as was the case with the reflexive core. Recall that the Suszko core $S^{\mathcal{I}}$ of a π-institution $\mathcal{I}$ consists of those natural transformations $\sigma^\flat$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\sigma^\flat[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

This means, of course, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{implies} \quad \sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

Lemma 1311 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$S^{\mathcal{I}^f} \subseteq S^{\mathcal{I}}.$$

Proof: Suppose that $\sigma^\flat \in S^{\mathcal{I}^f}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Then, since $\sigma^\flat \in S^{\mathcal{I}^f}$ and $T \in \mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$, we get $\sigma^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}^f}(T) \leq \widetilde{\Omega}^{\mathcal{I}}(T)$, where the second inclusion follows from the fact that $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$. Therefore, we conclude that $\sigma^\flat \in S^{\mathcal{I}}$. Hence, $S^{\mathcal{I}^f} \subseteq S^{\mathcal{I}}$. ■

With this result available, we can see that, if $\mathcal{I}^f$ is family c-reflective and its Suszko core is adequate, then the Suszko core of $\mathcal{I}$ is also adequate. Recall that adequacy of the Suszko core $S^{\mathcal{I}}$ means that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}.$$

Recall also, that the right-to-left inclusion always holds. So the definition is tantamount to the assertion that the left-to-right inclusion also holds.

Proposition 1312 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f$ *is family c-reflective and* $S^{\mathcal{I}^f}$ *is adequate in* $\mathcal{I}^f$*, then so is* $S^{\mathcal{I}}$ *in* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is family c-reflective and that $S^{\mathcal{I}^f}$ is adequate. Then, by Theorem 847, $\mathcal{I}^f$ is truth equational, whence, by Theorem 840, for all $T \in \mathrm{ThFam}(\mathcal{I}^f)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S^{\mathcal{I}^f}_\Sigma[\phi] \leq \Omega(T).$$

Consider $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{lll}
\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) & = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } \phi \in T_\Sigma\} \\
& & (\text{Definition of } \widetilde{\Omega}^{\mathcal{I}}) \\
& = & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } S^{\mathcal{I}^f}_\Sigma[\phi] \leq \Omega(T)\} \\
& & (\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f) \text{ and displayed equivalence}) \\
& \leq & \bigcap\{\Omega(T) : T \in \mathrm{ThFam}(\mathcal{I}) \text{ and } S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)\}. \\
& & (\text{Lemma 1311})
\end{array}$$

Thus, by definition, $S^{\mathcal{I}}$ is also adequate in $\mathcal{I}$. ■

We can now show that truth equationality is inherited by a π-institution $\mathcal{I}$ from its finitary companion $\mathcal{I}^f$. This forms an analog of Lemma 1306.

Theorem 1313 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f$ *is truth equational, then so is* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is truth equational. By Theorem 847, it is family c-reflective and its Suszko core $S^{\mathcal{I}^f}$ is adequate in $\mathcal{I}^f$. Therefore, by Lemma 1310, $\mathcal{I}$ is family c-reflective and, by Proposition 1312, $S^{\mathcal{I}}$ is adequate in $\mathcal{I}$. Therefore, again by Theorem 847, $\mathcal{I}$ is truth equational. ∎

Theorem 840 characterized truth equationality in terms of the solubility property of the Suszko core. In fact, the solubility of the Suszko core is the condition asserting that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

Since the reverse implication always holds, the condition is equivalent to the assertion that, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T).$$

Corollary 1314 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $S^{\mathcal{I}^f}$ *is soluble in* $\mathcal{I}^f$*, then* $S^{\mathcal{I}}$ *is soluble in* $\mathcal{I}$*.*

Proof: If $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$, then, by Theorem 838, $\mathcal{I}^f$ is truth equational. Thus, by Theorem 1313, $\mathcal{I}$ is also truth equational, whence, again by Theorem 838, applied in the opposite direction, $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. ∎

Once more, as was the case with syntactic protoalgebraicity, instead of deriving the implication in Corollary 1314 by applying Theorem 1313, we may prove it first and then use Theorem 838 to establish that truth equationality of $\mathcal{I}^f$ implies truth equationality of $\mathcal{I}$.

Lemma 1315 (Corollary 1314) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $S^{\mathcal{I}^f}$ *is soluble in* $\mathcal{I}^f$*, then* $S^{\mathcal{I}}$ *is soluble in* $\mathcal{I}$*.*

Proof: Suppose $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $S^{\mathcal{I}}_\Sigma[\phi] \leq \Omega(T)$. hence, by Lemma 1311, we get $S^{\mathcal{I}^f}_\Sigma[\phi] \leq \Omega(T)$. But $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$ and $S^{\mathcal{I}^f}$ is assumed to be soluble in $\mathcal{I}^f$. Thus, $\phi \in T_\Sigma$. This proves that $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. ∎

Corollary 1316 (Theorem 1313) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f$ *is truth equational, then so is* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is truth equational. Then, by Theorem 838, $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$. Thus, by Lemma 1315, $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. Hence, again by applying Theorem 838, only now in the reverse direction, $\mathcal{I}$ is truth equational. ∎

We conclude the section by synthesizing Theorems 1306 and 1313. Recall that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is syntactically weakly family algebraizable if it is

- protoalgebraic;
- family c-reflective;
- $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified, i.e., has a Leibniz reflexive core and an adequate Suszko core.

By Theorem 913, $\mathcal{I}$ is syntactically weakly family algebraizable if and only if it is syntactically protoalgebraic and family truth equational. Thus, we get

Theorem 1317 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is syntactically weakly family algebraizable, then so is $\mathcal{I}$.*

Proof: If $\mathcal{I}^f$ is syntactically weakly family algebraizable, then, by Theorem 913, it is syntactically protoalgebraic and family truth equational. Hence, by Theorems 1306 and 1313, $\mathcal{I}$ possesses the same properties. Therefore, applying again Theorem 913 in the reverse direction, we conclude that $\mathcal{I}$ is also syntactically weakly family algebraizable. ∎

In Section 9.4, we saw that the continuity of the Leibniz operator is one of the key properties when studying finitarity conditions. Lemma 660 showed that, if $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous, then $\mathcal{I}$ is protoalgebraic. That is asserting the continuity of the Leibniz operator strengthens protoalgebraicity. Additionally, it was proven in Lemma 661 that, if $\mathbf{Sign}^\flat$ is finite, then continuity of Ω also ensures that the finitary companion $\mathcal{I}^f$ of $\mathcal{I}$ is also protoalgebraic.

We begin, here, our parallel treatment on the syntactic side by showing that, maintaining the finiteness of $\mathbf{Sign}^\flat$, the condition that $\mathcal{I}$ be syntactically protoalgebraic, with a finite collection of parameter-free witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$, constitutes an additional strengthening on protoalgebraicity, on top of the continuity of Ω.

Proposition 1318 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, with a finite parameter-free collection $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ of witnessing transformations, then $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π-institution based on $\mathbf{F}$, with a finite parameter-free collection $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ of witnessing transformations. Suppose $\{T^i : i \in I\}$ is a directed collection of theory families of $\mathcal{I}$, such that $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\langle \phi, \psi \rangle \in \Omega_\Sigma(\bigcup_{i\in I} T^i) & \text{iff} & I^\flat_\Sigma[\phi,\psi] \leq \bigcup_{i\in I} T^i \\ & \text{iff} & I^\flat_\Sigma[\phi,\psi] \leq T^i, \text{ some } i \in I, \\ & \text{iff} & \langle \phi, \psi \rangle \in \Omega_\Sigma(T^i), \text{ some } i \in I, \\ & \text{iff} & \langle \phi, \psi \rangle \in \bigcup_{i\in I} \Omega_\Sigma(T^i).\end{array}$$

Note that the second equivalence employs both the fact that $\mathbf{Sign}^\flat$ is finite and the fact that $I^\flat$ is finite and parameter-free. Thus, $\Omega(\bigcup_{i\in I} T^i) = \bigcup_{i\in I} \Omega(T^i)$ and, hence, Ω is indeed continuous. ■

We next see that this stronger condition than the continuity of the Leibniz operator suffices to ensure that $\mathcal{I}^f$ is also syntactically protoalgebraic, with the same collection of witnessing transformations. Thus, the following proposition may be viewed as a syntactic analog of Lemma 661.

Proposition 1319 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is syntactically protoalgebraic, with a finite and parameter-free collection* $I^\flat$ *of witnessing transformations, then* $\mathcal{I}^f$ *is also syntactically protoalgebraic, with the same collection of witnessing transformations.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π-institution, with a finite and parameter-free collection $I^\flat$ of witnessing transformations. Let $T \in \mathrm{ThFam}(\mathcal{I}^f)$. Then, by Proposition 655, there exists a directed locally finitely generated collection $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T = \bigcup_{i\in I} T^i$. Now we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\langle \phi, \psi \rangle \in \Omega_\Sigma(T) & \text{iff} & \langle \phi, \psi \rangle \in \Omega_\Sigma(\bigcup_{i\in I} T^i) \\ & \text{iff} & \langle \phi, \psi \rangle \in \bigcup_{i\in I} \Omega_\Sigma(T^i) \quad \text{(Proposition 1318)} \\ & \text{iff} & \langle \phi, \psi \rangle \in \Omega_\Sigma(T^i), \text{ some } i \in I, \\ & \text{iff} & \overleftrightarrow{I}^\flat_\Sigma[\phi, \psi] \leq T^i, \text{ some } i \in I, \\ & \text{iff} & \overleftrightarrow{I}^\flat_\Sigma[\phi, \psi] \leq \bigcup_{i\in I} T^i \\ & \text{iff} & \overleftrightarrow{I}^\flat_\Sigma[\phi, \psi] \leq T.\end{array}$$

Again, note that the one-before-the-last equivalence employs both the fact that $\mathbf{Sign}^\flat$ is finite and the fact that $I^\flat$ is finite and parameter-free. Therefore, by Corollary 791, $\mathcal{I}^f$ is also syntactically protoalgebraic, with the same collection $I^\flat$ of witnessing transformations. ■

Suppose, now, that $\mathbf{Sign}^\flat$ is finite and $\mathcal{I}$ is weakly family algebraizable, so that $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ be defined. An analog of Proposition 1318 asserts that, if $\mathcal{I}$ is truth equational, with a finite and parameter-free witnessing family $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of equations, then the inverse Leibniz operator Ω^{-1} is continuous. Thus, under these hypotheses, the truth equationality of $\mathcal{I}$ via a finite, parameter-free collection of witnessing equations is stronger than the continuity of Ω^{-1}.

Proposition 1320 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is truth equational, with a finite parameter-free collection* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of witnessing equations, then* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *is continuous.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a weakly family algebraizable π-institution, which is, in addition, truth equational, with a finite parameter-free collection $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of witnessing equations. Let $\{\theta^i : i \in I\}$ be a directed collection of $\mathcal{I}^*$-congruence systems, such that $\bigcup_{i \in I} \theta^i \in \mathrm{ConSys}^*(\mathcal{I})$. Now we get, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in \Omega_\Sigma^{-1}(\bigcup_{i \in I} \theta^i) & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \bigcup_{i \in I} \theta^i \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \theta^i, \text{ some } i \in I, \\ & \text{iff} & \phi \in \Omega_\Sigma^{-1}(\theta^i), \text{ some } i \in I, \\ & \text{iff} & \phi \in \bigcup_{i \in I} \Omega_\Sigma^{-1}(\theta^i). \end{array}$$

Thus, Ω^{-1} is indeed continuous. ■

Recall from Theorem 663 that given a weakly family algebraizable π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F}$ over a finite category of signatures, the continuity of both $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ and $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ are sufficient to ensure that $\mathcal{I}^f$ is also weakly family algebraizable. In Propositions 1318 and 1320, by comparison, it was shown that the continuities of Ω and Ω^{-1} are strengthened by assuming, respectively, that $\mathcal{I}$ is syntactically protoalgebraic, with a finite, parameter-free witnessing family of transformations, and that $\mathcal{I}$ is family truth equational, with a finite, parameter-free witnessing family of equations. We show, next, in an analog of Theorem 663, that imposing these two stronger conditions on $\mathcal{I}$ suffices to ensure that syntactic strong algebraizability transfers from $\mathcal{I}$ to its finitary companion $\mathcal{I}^f$.

Proposition 1321 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π-institution, with a finite parameter-free collection $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ of witnessing transformations. If $\mathcal{I}$ is family truth equational, with a finite and parameter-free collection $\tau^\flat$ of witnessing equations, then $\mathcal{I}^f$ is also family truth equational, with the same collection of witnessing equations.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\mathbf{Sign}^\flat$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a weakly family algebraizable π-institution, which is family truth equational, with a finite and parameter-free collection $I^\flat$ of witnessing equations. Let $T \in \mathrm{ThFam}(\mathcal{I}^f)$. Then, by Proposition 655, there exists a directed locally finitely generated collection $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T = \bigcup_{i \in I} T^i$. Now we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & \phi \in \bigcup_{i \in I} T_\Sigma^i \\ & \text{iff} & \phi \in T_\Sigma^i, \text{ some } i \in I, \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(T^i), \text{ some } i \in I, \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \bigcup_{i \in I} \Omega(T^i) \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(\bigcup_{i \in I} T^i) \quad \text{(Proposition 1318)} \\ & \text{iff} & \tau_\Sigma^\flat[\phi] \leq \Omega(T). \end{array}$$

Again, note that the fourth equivalence employs both the fact that $\mathbf{Sign}^\flat$ is finite and the fact that $\tau^\flat$ is finite and parameter-free. We conclude that $\mathcal{I}^f$ is also family truth equational, with the same collection $\tau^\flat$ of witnessing equations. ■

Putting together Propositions we finally obtain the promised analog of Theorem 663.

Theorem 1322 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution, via a conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$ *consisting of finite and parameter-free collections of transformations. Then* $\mathcal{I}^f$ *is also syntactically strongly family algebraizable, via the same conjugate pair of transformations.*

Proof: We simply put together Propositions 1319 and 1321. ■

17.2 Natural Finitarity

This section deals with concepts analogous to those studied in Section 9.4, but in the syntactic, rather than in the semantic, context. In the semantic context, the four key ingredients of our study were the finitarity of the π-institutions involved as well as the continuity of the Leibniz operator and its inverse. Recall that for the inverse to be defined in the context under consideration, the general underlying hypothesis that the π-institution $\mathcal{I}$ be weakly family algebraizable was adhered to. In the present, syntactic, context, we assume that $\mathcal{I}$ is syntactically strongly family algebraizable, that is, syntactically family algebraizable via a conjugate pair $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$, where both $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ and $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ are parameter-free witnessing collections of equations and of transformations, respectively. The four notions involved are the properties of $\mathcal{I}$ and $\mathcal{Q}^{\mathsf{K}}$ being naturally finitary, a strengthening of finitarity, and those of $\tau^\flat$ and $I^\flat$ being finite, also strengthening the continuity of the Leibniz operator and its inverse operator. But let us embark on the developments so as to clarify these introductory remarks and to make the concepts and the details involved precise.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is *finitary* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in C_\Sigma(\Phi')$. Equivalently, $\mathcal{I}$ is finitary if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$C_\Sigma(\Phi) = \bigcup\{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\}.$$

We say that $\mathcal{I}$ is **naturally finitary** if it is finitary and, in addition, the following condition holds:

(NATFIN) If, for some collections $\mu, \nu : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$, such that $|\mu| < \infty$, it holds that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}]),$$

then, there exists a finite subset $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}]).$$

It is not difficult to see that, if $\mathcal{I}$ is naturally finitary, the implication resulting from (NATFIN) by replacing the two inclusions by equalities of closure families also holds.

Lemma 1323 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is naturally finitary, then, for all $\mu, \nu : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu_\Sigma[\vec{\phi}])$, there exists a finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu'_\Sigma[\vec{\phi}])$.*

Proof: Suppose $\mathcal{I}$ is naturally finitary and let $\mu, \nu : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu_\Sigma[\vec{\phi}])$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}])$. Thus, by natural finitarity, there exists a finite subset $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}])$. But, then, we obtain, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\nu_\Sigma[\vec{\phi}]) = C(\mu_\Sigma[\vec{\phi}]) \leq C(\nu'_\Sigma[\vec{\phi}]) \leq C(\nu_\Sigma[\vec{\phi}]).$$

We conclude that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu'_\Sigma[\vec{\phi}])$. ■

Starting to take advantage of natural finitarity, we show that it allows to draw the conclusion that, in case of syntactic family algebraizability, the existence of a finite witnessing family of transformations ensures that every witnessing family possesses a finite witnessing subfamily. More precisely, we have

Lemma 1324 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a naturally finitary π-institution based on $\mathbf{F}$. Suppose $\mathcal{I}$ is syntactically family algebraizable, with equivalent guasivariety K. If $\mathcal{I}$ has a finite witnessing family $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ of transformations, then every witnessing family $J^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ possesses a finite witnessing subfamily $J'^\flat$.*

Proof: Suppose that $\mathcal{I}$ is naturally finitary and syntactically family algebraizable, with equivalent guasivariety K. Let $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ be a finite set of witnessing transformations and $J^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ a family of witnessing transformations. By Theorem 912, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(I^\flat_\Sigma[\phi,\psi]) = C(J^\flat_\Sigma[\phi,\psi]).$$

Since $\mathcal{I}$ is naturally finitary and, by hypothesis, $|I^\flat| < \infty$, we get, by Lemma 1323, that there exists finite $J'^\flat \subseteq J^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(J'^\flat_\Sigma[\phi,\psi]) = C(I^\flat_\Sigma[\phi,\psi]).$$

Thus, applying Proposition 903, we conclude that $J'^\flat$ is also a witnessing family of transformations. ■

Dually, we may also prove a corresponding result concerning the witnessing equations for the truth equationality of $\mathcal{I}$.

Lemma 1325 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution based on* $\mathbf{F}$*, with equivalent guasivariety* K*. If* $\mathcal{Q}^\mathsf{K}$ *is naturally finitary and* $\mathcal{I}$ *has a finite witnessing family* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of equations, then every witnessing family* $\rho^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of equations possesses a finite witnessing subfamily* $\rho'^\flat$*.*

Proof: Follows along the lines of the proof of Lemma 1324. Suppose that $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent guasivariety K, such that $\mathcal{Q}^\mathsf{K}$ is naturally finitary. Let $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ be a finite set of witnessing equations and $\rho^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ a family of witnessing equations. By Theorem 912, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^\mathsf{K}(\tau^\flat_\Sigma[\phi]) = D^\mathsf{K}(\rho^\flat_\Sigma[\phi]).$$

Since $\mathcal{Q}^\mathsf{K}$ is naturally finitary and, by hypothesis, $|\tau^\flat| < \infty$, we get, by Lemma 1323, that there exists finite $\rho'^\flat \subseteq \rho^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^\mathsf{K}(\rho'^\flat_\Sigma[\phi]) = D^\mathsf{K}(\tau^\flat_\Sigma[\phi]).$$

Thus, applying Proposition 903, we conclude that $\rho'^\flat$ is also a witnessing family of equations. ■

We now establish a theorem to the effect that, under natural finitarity and syntactic strong family algebraizability, every witnessing family of equations contains a finite witnessing subfamily. This is the first main result in a series of finitarity results that we aim to prove in the present section, with the ultimate goal of obtaining a hierarchy on the syntactic side, analogous to that obtained on the semantic side at the end of Section 9.4.

Theorem 1326 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a naturally finitary, syntactically strongly family algebraizable* π*-institution, with equivalent guasivariety* K*. Then every witnessing collection* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of equations contains a finite subcollection* $\tau'^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$*, which is also a witnessing collection.*

Proof: Suppose $\mathcal{I}$ is naturally finitary and syntactically strongly family algebraizable, with equivalent guasivariety K. Let $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ be a collection of witnessing equations. Then, by definition, there exists a collection $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\iota_\Sigma[\phi]) = C(\phi) = C(I^\flat[\tau^\flat_\Sigma[\phi]]).$$

Since $\mathcal{I}$ is naturally finitary, there exist finite $I'^\flat \subseteq I^\flat$ and $\tau'^\flat \subseteq \tau^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\phi) = C(I'^\flat[\tau'^\flat_\Sigma[\phi]]).$$

Thus, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\phi) = C(I^\flat[\tau'^\flat_\Sigma[\phi]]).$$

Thus, since, by the properties of $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$,

$$\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E) \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq C(I^\flat_\Sigma[E]),$$

we get, by Proposition 903, that $\tau'^\flat$ is a witnessing family of equations. ■

Dually, we may prove that, under syntactic strong family algebraizability and natural finitarity of the algebraic counterpart $\mathcal{Q}^{\mathsf{K}}$, every witnessing family of transformations contains a finite witnessing subfamily.

Theorem 1327 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution, with equivalent guasivariety* K*, such that* $\mathcal{Q}^{\mathsf{K}}$ *is naturally finitary. Then every witnessing collection* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *of transformations contains a finite subcollection* $I'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, which is also a witnessing collection.*

Proof: Suppose $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent guasivariety K, such that $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary. Let $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ be a collection of witnessing transformations. Then, by definition, there exists a collection $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathsf{K}}(\langle p^{2,0}, p^{2,1}\rangle_\Sigma[\phi, \psi]) = D^{\mathsf{K}}(\phi \approx \psi) = D^{\mathsf{K}}(\tau^\flat[I^\flat_\Sigma[\phi, \psi]]).$$

Since $\mathcal{I}$ is naturally finitary, there exist finite $I'^\flat \subseteq I^\flat$ and $\tau'^\flat \subseteq \tau^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathsf{K}}(\phi \approx \psi) = D^{\mathsf{K}}(\tau'^\flat[I'^\flat_\Sigma[\phi, \psi]]).$$

Thus, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$D^{\mathsf{K}}(\phi \approx \psi) = D^{\mathsf{K}}(\tau^\flat[I'^\flat_\Sigma[\phi, \psi]]).$$

Thus, since, by the properties of $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq D^{\mathsf{K}}(\tau^\flat_\Sigma[\Phi]),$$

we get, by Proposition 903, that $I'^\flat$ is also a witnessing family of transformations. ■

The following proposition asserts that, under similar hypotheses, but adding finiteness of the signature category, the finitarity of $\mathcal{I}$ and of the witnessing collection $I^\flat$ imply the finitarity of the algebraic counterpart $\mathcal{Q}^{\mathsf{K}}$.

Proposition 1328 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary, syntactically family algebraizable* π*-institution, with equivalent guasivariety* K*. If* $\mathcal{I}$ *has a finite witnessing set* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *of transformations, then its algebraic counterpart* $\mathcal{Q}^{\mathsf{K}}$ *is also finitary.*

Proof: Suppose $\mathcal{I}$ is a finitary π-institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically family algebraizable, with equivalent guasivariety K and that it has a finite witnessing collection $I^\flat$ of transformations. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that

$$\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E).$$

Since $I^\flat$ is a witnessing collection of transformations,

$$I^\flat_\Sigma[\phi, \psi] \leq C(I^\flat_\Sigma[E]).$$

Since $\mathbf{Sign}^\flat$ is finite and $I^\flat$ is finite, we get, by the finitarity of $\mathcal{I}$ that there exists finite $E' \subseteq E$, such that $I^\flat_\Sigma[\phi, \psi] \leq C(I^\flat_\Sigma[E'])$. Thus, again by the fact that $I^\flat$ is a set of witnessing transformations, we obtain $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E')$. Thus, $\mathcal{Q}^{\mathsf{K}}$ is indeed finitary. ■

A similar result can also be established when focus is shifted from finitarity to natural finitarity.

Proposition 1329 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a naturally finitary, syntactically family algebraizable* π*-institution, with equivalent guasivariety* K*. If* $\mathcal{I}$ *has a finite witnessing set* $I^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *of transformations, then its algebraic counterpart* $\mathcal{Q}^{\mathsf{K}}$ *is also naturally finitary.*

Proof: Suppose $\mathcal{I}$ is a naturally finitary π-institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically family algebraizable, with equivalent guasivariety K and that it has a finite witnessing collection $I^\flat$ of transformations. By Proposition 1328, we know that $\mathcal{Q}^\mathsf{K}$ is finitary. Let $\mu,\nu : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ be collections of natural transformations in $N^\flat$, with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq D^\mathsf{K}(\nu_\Sigma[\vec{\phi}]).$$

Since $I^\flat$ is a witnessing collection of transformations, we get, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat[\mu_\Sigma[\vec{\phi}]] \leq C(I^\flat[\nu_\Sigma[\vec{\phi}]]).$$

But both μ and $I^\flat$ are finite and, also, $\mathbf{Sign}^\flat$ is assumed to be finite. Hence, since $\mathcal{I}$ is naturally finitary, there exists finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat[\mu_\Sigma[\vec{\phi}]] \leq C(I^\flat[\nu'_\Sigma[\vec{\phi}]]).$$

Therefore, again by the fact that $I^\flat$ is a set of witnessing transformations, we obtain, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq D^\mathsf{K}(\nu'_\Sigma[\vec{\phi}]).$$

Thus, $\mathcal{Q}^\mathsf{K}$ is indeed naturally finitary. ∎

We turn, next, to results dual to those established in Propositions 1328 and 1329. We start with a dual to Proposition 1328 to the effect that, if $\mathcal{Q}^\mathsf{K}$ is finitarty and $\mathcal{I}$ has a finite witnessing collection of equations, then $\mathcal{I}$ is itself finitary.

Proposition 1330 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution, with equivalent guasivariety* K*. If* $\mathcal{Q}^\mathsf{K}$ *is finitary and* $\mathcal{I}$ *has a finite witnessing set* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of equations, then* $\mathcal{I}$ *is also finitary.*

Proof: Suppose $\mathcal{I}$ is a π-institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent guasivariety K, such that $\mathcal{Q}^\mathsf{K}$ is finitary, and that it has a finite witnessing collection $\tau^\flat$ of equations. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that

$$\phi \in C_\Sigma(\Phi).$$

Since $\tau^\flat$ is a witnessing collection of equations,

$$\tau^\flat_\Sigma[\phi] \leq D^\mathsf{K}(\tau^\flat_\Sigma[\Phi]).$$

Since $\mathbf{Sign}^\flat$ is finite and $\tau^\flat$ is finite, we get, by the finitarity of $\mathcal{Q}^\mathsf{K}$ that there exists finite $\Phi' \subseteq \Phi$, such that $\tau^\flat_\Sigma[\phi] \leq D^\mathsf{K}(\tau^\flat_\Sigma[\Phi'])$. Thus, again by the fact that $\tau^\flat$ is a set of witnessing equations, we obtain $\phi \in C_\Sigma(\Phi')$. Thus, $\mathcal{I}$ is indeed finitary. ■

A dual of Proposition 1329 addresses the case of natural finitarity.

Proposition 1331 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution, with equivalent guasivariety* K*. If* $\mathcal{Q}^\mathsf{K}$ *is naturally finitary and* $\mathcal{I}$ *has a finite witnessing set* $\tau^\flat : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of equations, then* $\mathcal{I}$ *is also naturally finitary.*

Proof: Suppose $\mathcal{I}$ is a π-institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent guasivariety K, such that $\mathcal{Q}^\mathsf{K}$ is naturally finitary, and that it has a finite witnessing collection $\tau^\flat$ of equations. Let $\mu, \nu : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ be collections of natural transformations in $N^\flat$, with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}]).$$

Since $\tau^\flat$ is a witnessing collection of equations, we get, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\tau^\flat[\mu_\Sigma[\vec{\phi}]] \leq D^\mathsf{K}(\tau^\flat[\nu_\Sigma[\vec{\phi}]]).$$

But both μ and $\tau^\flat$ are finite and, also, $\mathbf{Sign}^\flat$ is assumed to be finite. Hence, since $\mathcal{Q}^\mathsf{K}$ is naturally finitary, there exists finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\tau^\flat[\mu_\Sigma[\vec{\phi}]] \leq D^\mathsf{K}(\tau^\flat[\nu'_\Sigma[\vec{\phi}]]).$$

Therefore, again by the fact that $\tau^\flat$ is a set of witnessing equations, we obtain, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}]).$$

Thus, $\mathcal{I}$ is naturally finitary. ■

Finally, we present a syntactic analog of Corollary 668, which summarizes the conclusions drawn from the study of the various finitarity properties, at the center of the investigations carried out in the present chapter.

Corollary 1332 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically strongly family algebraizable* π*-institution, via the conjugate pair* $(\tau^\flat, I^\flat) : \mathcal{I} \rightleftarrows \mathcal{Q}^\mathsf{K}$*.*

(a) If both $\tau^\flat$ *and* $I^\flat$ *are finite, then* $\mathcal{I}$ *is naturally finitary if and only if* $\mathcal{Q}^\mathsf{K}$ *is naturally finitary;*

(b) *If $\mathcal{I}$ is naturally finitary, then $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary if and only if $I^\flat$ can be taken to be finite;*

(c) *If $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary, then $\mathcal{I}$ is naturally finitary if and only if $\tau^\flat$ can be taken to be finite.*

In each case, if the equivalent alternatives hold, then all four "finitarity" conditions hold.

Proof:

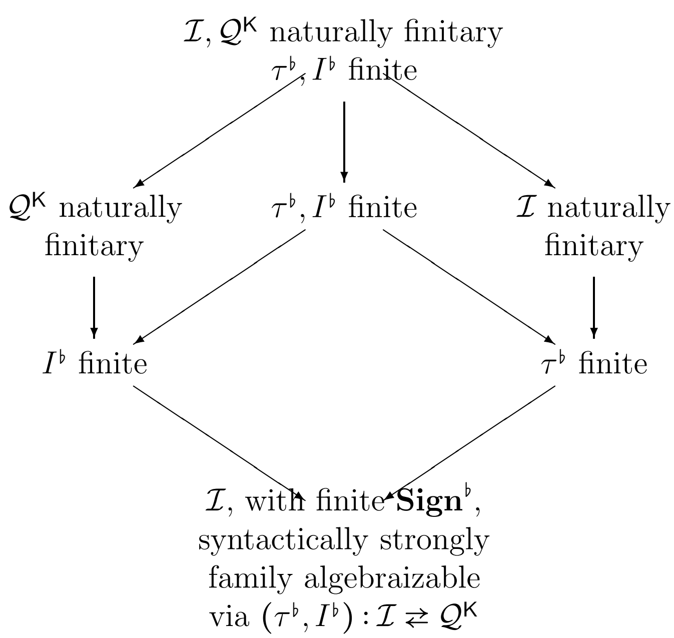
(a) Suppose both $\tau^\flat$ and $I^\flat$ are finite. If $\mathcal{I}$ is naturally finitary, then, by Proposition 1329, $\mathcal{Q}^{\mathsf{K}}$ is also naturally finitary. If, on the other hand, $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary, then, by Proposition 1331, $\mathcal{I}$ is naturally finitary.

(b) Assume that $\mathcal{I}$ is naturally finitary. If $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary, then, by Theorem 1327, $I^\flat$ may be taken to be finite. If, on trhe other hand, $I^\flat$ can be taken to be finite, then, by Proposition 1329, $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary.

(c) Assume $\mathcal{Q}^{\mathsf{K}}$ is naturally finitary. If $\mathcal{I}$ is naturally finitary, then, by Theorem 1326, $\tau^\flat$ may be taken to be finite. If, on the other hand, $\tau^\flat$ may be taken to be finite, then, by Proposition 1331, $\mathcal{I}$ is naturally finitary.

■

In summary, Corollary 1332 establishes the hierarchy depicted below, which parallels in the syntactic context the hierarchy pictured at the end of Chapter 9, concerning the semantic side.



Chapter 18

Properties of Selected Classes

18.1 Protoalgebraic π-Institutions

18.1.1 The Correspondence Theorem

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **protoalgebraic** if the Leibniz operator is monotone on theory families, i.e., if, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

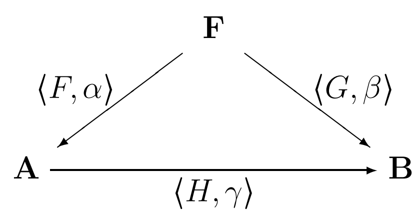
Recall, also, that, by Theorem 175, every protoalgebraic π-institution is stable and that, moreover, by Theorem 179, $\mathcal{I}$ is protoalgebraic if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \leq T' \quad \text{implies} \quad \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T').$$

The π-institution $\mathcal{I}$ has the **compatibility property** if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, and all $\theta \in \mathrm{ConSys}(\mathbf{A})$,

$$\theta \text{ compatible with } T \quad \text{implies} \quad \theta \text{ compatible with } T'.$$

The π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ has the **filter correspondence property** if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, and surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$, with $H : \mathbf{Sign} \to \mathbf{Sign}'$ an isomorphism,



and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\gamma^{-1}(\widehat{\gamma}(T) \vee T') = T \vee \gamma^{-1}(T'),$$

where $\widehat{\gamma}(T) = C^{\mathcal{I},\mathcal{B}}(\gamma(T))$ is the least $\mathcal{I}$-filter family on $\mathcal{B}$ that includes $\gamma(T)$.

Our goal is to show that both the compatibility property and the filter correspondence property characterize protoalgebraic π-institutions. We start with a lemma to the effect that, for every $\mathcal{I}$-filter family T of $\mathcal{A}$, if the kernel of $\langle H, \gamma \rangle$ happens to be compatible with T, then $\gamma(T)$ is already an $\mathcal{I}$-filter family of $\mathcal{B}$ and, therefore, $\widehat{\gamma}(T) = \gamma(T)$.

Lemma 1333 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$-algebraic systems, and $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with $H : \mathbf{Sign} \to \mathbf{Sign}'$ an isomorphism. If $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\mathrm{Ker}(\langle H, \gamma \rangle)$ is compatible with T, then $\widehat{\gamma}(T) = \gamma(T)$.*

Proof: By definition, $\gamma(T) \leq \widehat{\gamma}(T)$ always holds. To show the reverse inequality, it suffices to show that $\gamma(T)$, under the hypothesis of the compatibility of $\mathrm{Ker}(\langle H,\gamma\rangle)$ with T, is an $\mathcal{I}$-filter family of $\mathcal{B}$. So assume $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, and let $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, such that

$$\beta_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

This gives

$$\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))) \subseteq \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

By the postulated compatibility of $\mathrm{Ker}(\langle H,\gamma\rangle)$ with T, we obtain

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}.$$

Since $\phi \in C_\Sigma(\Phi)$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}.$$

Thus, $\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))) \in \gamma_{F(\Sigma')}(T_{F(\Sigma')})$, and, therefore,

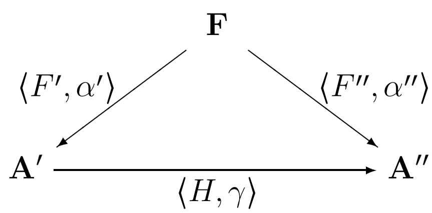
$$\beta_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

This shows that $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, hence, $\widehat{\gamma}(T) = \gamma(T)$. ∎

Next, we give an equivalent formulation of the Filter Correspondence Property.

Proposition 1334 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has the filter correspondence property iff*

> *for all* $\mathcal{I}$*-matrix families* $\mathfrak{A} = \langle \mathcal{A}', T'\rangle$, $\mathfrak{A}'' = \langle \mathcal{A}'', T''\rangle$ *and strict surjective matrix morphism* $\langle H,\gamma\rangle : \mathfrak{A}' \to \mathfrak{A}''$*, with* $H : \mathbf{Sign}' \to \mathbf{Sign}''$ *an isomorphism,*



$$T = \gamma^{-1}(\gamma(T)), \quad \textit{for all } T' \leq T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}').$$

Proof: Suppose, first, that $\mathcal{I}$ has the Filter Correspondence Property and consider $\mathcal{I}$-matrix families $\mathfrak{A} = \langle \mathcal{A}', T'\rangle$, $\mathfrak{A}'' = \langle \mathcal{A}'', T''\rangle$, a strict surjective matrix morphism $\langle H,\gamma\rangle:\mathfrak{A}'\to\mathfrak{A}''$, with $H:\mathbf{Sign}'\to\mathbf{Sign}''$ an isomorphism, and $T'\leq T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$. Then we have

$$\begin{array}{rcll}\gamma^{-1}(\gamma(T)) & \leq & \gamma^{-1}(\widehat{\gamma}(T)\vee T'') & (\gamma(T)\leq\widehat{\gamma}(T))\\ & = & T\vee\gamma^{-1}(T'') & \text{(Filter Correspondence)}\\ & = & T\vee T' & (\langle H,\gamma\rangle\text{ strict})\\ & = & T. & (T'\leq T\text{ by hypothesis})\end{array}$$

Thus, the displayed property holds. Assume, conversely, that the displayed property holds. We must show that $\mathcal{I}$ has the Filter Correspondence Property. So suppose that $\mathcal{A}=\langle\mathbf{A}',\langle F',\alpha'\rangle\rangle$, $\mathcal{A}''=\langle\mathbf{A}'',\langle F'',\alpha''\rangle\rangle$ are $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle:\mathcal{A}'\to\mathcal{A}''$ a surjective morphism, with $H:\mathbf{Sign}'\to\mathbf{Sign}''$ an isomorphism, and let $T'\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$ and $T''\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}'')$. Our goal is to show that

$$\gamma^{-1}(\widehat{\gamma}(T')\vee T'')=T'\vee\gamma^{-1}(T'').$$

Notice that $\langle H,\gamma\rangle:\langle\mathcal{A}',\gamma^{-1}(T'')\rangle\to\langle\mathcal{A}'',T''\rangle$ is a strict surjective morphism, with H an isomorphism, and $\gamma^{-1}(T'')\leq T'\vee\gamma^{-1}(T'')$. Thus, we fit the setup of the hypothesis, which allows us to conclude that

$$\gamma^{-1}(\gamma(T'\vee\gamma^{-1}(T'')))=T'\vee\gamma^{-1}(T'').$$

So, it suffices, in turn, to show that $\widehat{\gamma}(T')\vee T''=\gamma(T'\vee\gamma^{-1}(T''))$ and, since, $\mathrm{Ker}(\langle H,\gamma\rangle)$ is compatible with T' (having $\gamma^{-1}(\gamma(T'))=T'$, by hypothesis), it suffices, by Lemma 1333, to show that

$$\gamma(T')\vee T''=\gamma(T'\vee\gamma^{-1}(T'')).$$

The left to right inclusion is obvious, since $\gamma(T'),T''\leq\gamma(T'\vee\gamma^{-1}(T''))$. Conversely, note that, taking into account the hypothesis, $T',\gamma^{-1}(T'')\leq\gamma^{-1}(\gamma(T')\vee T'')$. Therefore, $T'\vee\gamma^{-1}(T'')\leq\gamma^{-1}(\gamma(T')\vee T'')$ and, therefore, $\gamma(T'\vee\gamma^{-1}(T''))\leq\gamma(T')\vee T''$ and, hence, the right to left inclusion also holds. Thus, the Filter Correspondence Property holds. ■

Now we proceed with the formulation and proof of the main theorem.

Theorem 1335 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is protoalgebraic;*

(ii) $\mathcal{I}$ *has the compatibility property;*

(iii) $\mathcal{I}$ *has the filter correspondence property.*

Proof:

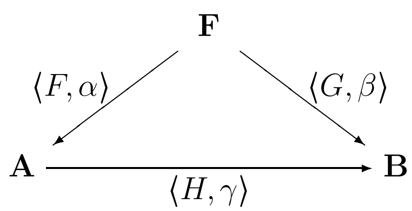
(i)⇒(ii) Suppose $\mathcal{I}$ is protoalgebraic and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system, $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \le T'$, and $\theta \in \mathrm{ConSys}(\mathbf{A})$, such that θ is compatible with T. Then we have

$$\begin{array}{rcll} \theta & \le & \Omega(T) & \text{(by the compatibility of } \theta \text{ with } T) \\ & \le & \Omega(T'). & \text{(by protoalgebraicity)} \end{array}$$

We conclude that θ is also compatible with T' and, hence, $\mathcal{I}$ has the compatibility property.

(ii)⇒(i) Suppose that $\mathcal{I}$ has the compatibility property and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \le T'$. Then $\Omega(T) \in \mathrm{ConSys}(\mathbf{A})$ and, by the definition of a Leibniz congruence system, it is compatible with T. Now it follows by the compatibility property, that $\Omega(T)$ is also compatible with T'. Hence $\Omega(T) \le \Omega(T')$. We conclude that $\mathcal{I}$ is protoalgebraic.

(ii)⇒(iii) Suppose that $\mathcal{I}$ has the compatibility property and consider $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle$, a commutative triangle



with $H : \mathbf{Sign} \to \mathbf{Sign}'$ an isomorphism, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Note that it is always the case that

$$T \vee \gamma^{-1}(T') \le \gamma^{-1}(\widehat{\gamma}(T) \vee T').$$

Thus, it suffices to show that, under the hypothesis of compatibility, the reverse inclusion also holds.

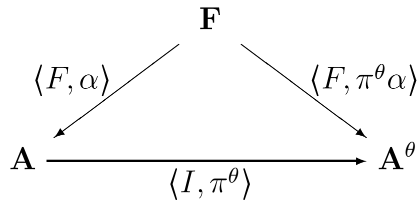
Consider, temporarily, $X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\gamma^{-1}(T') \le X$. Since $\mathrm{Ker}(\langle H, \gamma\rangle)$ is compatible with $\gamma^{-1}(T')$, by the postulated compatibility property, it is also compatible with X. Thus, by Lemma 1333, $\widehat{\gamma}(X) = \gamma(X)$. Moreover, we have $T' \le \gamma(X) = \widehat{\gamma}(X)$.

Now set $X = T \vee \gamma^{-1}(T')$ and reason as follows:

$$\begin{array}{rcll} \gamma^{-1}(\widehat{\gamma}(T) \vee T') & \le & \gamma^{-1}(\widehat{\gamma}(X) \vee T') & (T \le X) \\ & = & \gamma^{-1}(\widehat{\gamma}(X)) & (T' \le \widehat{\gamma}(X)) \\ & = & \gamma^{-1}(\gamma(X)) & (\widehat{\gamma}(X) = \gamma(X)) \\ & = & X. & (\mathrm{Ker}(\langle H, \gamma\rangle) \text{ compatible with } X) \end{array}$$

So we get $\gamma^{-1}(\widehat{\gamma}(T) \vee T') = T \vee \gamma^{-1}(T')$ and $\mathcal{I}$ has the correspondence property.

(iii)⇒(ii) Suppose that $\mathcal{I}$ has the correspondence property and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, and $\theta \in \mathrm{ConSys}(\mathbf{A})$, such that θ is compatible with T. We look at the commutative diagram



and calculate

$$\begin{array}{rcl}(\pi^\theta)^{-1}(\widehat{\pi^\theta}(T')) & = & (\pi^\theta)^{-1}(\widehat{\pi^\theta}(T') \vee \widehat{\pi^\theta}(T)) \quad (T \leq T') \\ & = & T' \vee (\pi^\theta)^{-1}(\widehat{\pi^\theta}(T)) \quad \text{(correspondence property)} \\ & \leq & T' \vee T \quad (\theta \text{ compatible with } T) \\ & = & T'. \quad (T \leq T')\end{array}$$

Thus, θ is also compatible with T' and $\mathcal{I}$ has the compatibility property. ■

As a consequence we obtain the *Correspondence Theorem*, which asserts that, under the same hypothesis, $\langle H, \gamma \rangle$ induces an order isomorphism between the principal filter of the lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ generated by $\gamma^{-1}(T')$ and the principal filter of the lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$ generated by T'.

Theorem 1336 (Correspondence Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$*. Let, also,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ *be* $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* $H : \mathbf{Sign} \to \mathbf{Sign}'$ *an isomorphism, and* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$*. Then,* $Y \mapsto \gamma^{-1}(Y)$*,* $T' \leq Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$*, defines an order isomorphism* $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$*.*

Proof: $\gamma^{-1} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \to \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$ is well defined by Corollary 55 and it is clearly monotone. Furthermore, $\widehat{\gamma} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')} \to \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is also well-defined and monotone. So it suffices to show that, for all $T' \leq Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, $\widehat{\gamma}(\gamma^{-1}(Y)) = Y$ and that, for all $\gamma^{-1}(T') \leq X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\gamma^{-1}(\widehat{\gamma}(X)) = X$.

First, for $T' \leq Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, since $\langle H, \gamma \rangle$ is surjective, $\gamma(\gamma^{-1}(Y)) = Y$ and, therefore, $\widehat{\gamma}(\gamma^{-1}(Y)) = Y$, since $Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. For the other equation, if $\gamma^{-1}(T') \leq X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have,

$$\begin{array}{rcl}\gamma^{-1}(\widehat{\gamma}(X)) & = & \gamma^{-1}(\widehat{\gamma}(X) \vee T') \quad (\gamma^{-1}(T') \leq X \Rightarrow T' \leq \widehat{\gamma}(X)) \\ & = & X \vee \gamma^{-1}(T') \quad \text{(correspondence property)} \\ & = & X. \quad (\gamma^{-1}(T') \leq X)\end{array}$$

So $\gamma^{-1} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$. ■

18.1.2 The Homomorphism Theorem

We show that, in the case of protoalgebraic π-institutions $\mathcal{I}$, every surjective morphism of $\mathcal{I}$-matrix families gives rise to a corresponding surjective morphism between their reductions. This establishes a "reduction" functor and, moreover, gives rise to a version of the Homomorphism Theorem of Universal Algebra.

Recall that, given a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and an $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we denote by $\mathfrak{A}^*$ the reduction of $\mathfrak{A}$, i.e.,

$$\mathfrak{A}^* = \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle.$$

Moreover, extending this notation, given $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, we set

$$\phi^* = \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \mathrm{SEN}^*(\Sigma).$$

Theorem 1337 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π-institution based on $\mathbf{F}$. Further, let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$, be $\mathbf{F}$-algebraic systems, $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$ be $\mathcal{I}$-matrix families and $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{A}'$ a surjective morphism. Then, there exists a surjective morphism $\langle H, \gamma^* \rangle : \mathfrak{A}^* \to \mathfrak{A}'^*$, given, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by*

$$\gamma^*_\Sigma(\phi^*) = \gamma_\Sigma(\phi)^*.$$

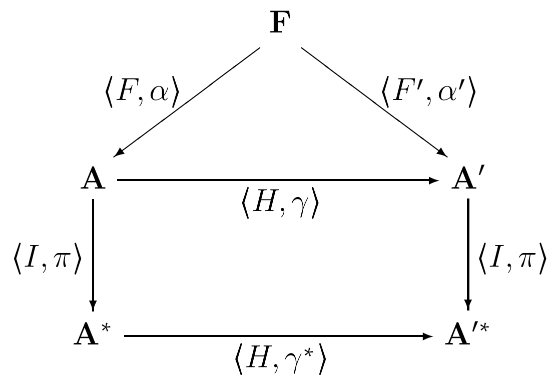
Proof: First, we show that, for all $\Sigma \in |\mathbf{Sign}|$, $\gamma^*_\Sigma : \mathrm{SEN}^*(\Sigma) \to \mathrm{SEN}'^*(H(\Sigma))$ is well-defined. Indeed, suppose $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi^* = \psi^*$, i.e., $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$. Then, since $T \leq \gamma^{-1}(T')$, we get, by protoalgebraicity, $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))$, whence, by Proposition 24, $\langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))$, and, hence, $\langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}'}_{H(\Sigma)}(T')$, or, equivalently, $\gamma_\Sigma(\phi)^* = \gamma_\Sigma(\psi)^*$.

Next we see that $\gamma^* : \mathrm{SEN}^* \to \mathrm{SEN}'^* \circ H$ is a natural transformation. To this end, let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{ccc}
\mathrm{SEN}^*(\Sigma) & \xrightarrow{\gamma^*_\Sigma} & \mathrm{SEN}'^*(H(\Sigma)) \\
\mathrm{SEN}^*(f) \downarrow & & \downarrow \mathrm{SEN}'^*(H(f)) \\
\mathrm{SEN}^*(\Sigma') & \xrightarrow[\gamma^*_{\Sigma'}]{} & \mathrm{SEN}'^*(H(\Sigma'))
\end{array}$$

$$\begin{array}{rcl}
\mathrm{SEN}'^*(H(f))(\gamma^*_\Sigma(\phi^*)) & = & \mathrm{SEN}'^*(H(f))(\gamma_\Sigma(\phi)^*) \\
& = & \mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi))^* \\
& = & \gamma_{\Sigma'}(\mathrm{SEN}(f)(\phi))^* \\
& = & \gamma^*_{\Sigma'}(\mathrm{SEN}(f)(\phi)^*) \\
& = & \gamma^*_{\Sigma'}(\mathrm{SEN}^*(f)(\phi^*)).
\end{array}$$

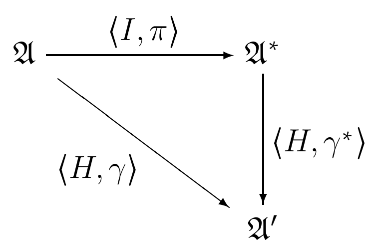
Surjectivity of $\langle H,\gamma^*\rangle : \mathcal{A}^* \to \mathcal{A}'^*$ follows from the fact that $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{A}'$ is surjective. So it suffices to show that $\langle F',\pi\alpha'\rangle = \langle H,\gamma^*\rangle \circ \langle F,\pi,\alpha\rangle$ and that $\langle H,\gamma^*\rangle : \mathfrak{A}^* \to \mathfrak{A}'^*$ is a matrix family morphism. The first equation follows from the fact that the upper triangle of the diagram commutes by hypothesis and the rectangle commutes by the definition of $\langle H,\gamma^*\rangle$.



To finish the proof, we calculate, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi^* \in T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)$ if and only if, by compatibility, $\phi \in T_\Sigma$ implies, by hypothesis, $\phi \in \gamma_\Sigma^{-1}(T'_{H(\Sigma)})$ if and only if $\gamma_\Sigma(\phi) \in T'_{H(\Sigma)}$ if and only if, by compatibility, $\gamma_\Sigma(\phi)^* \in T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T')$ if and only if, by the definition of γ^*, $\gamma^*_\Sigma(\phi^*) \in T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T')$ if and only if $\phi^* \in (\gamma^*_\Sigma)^{-1}(T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))$. ■

We also have the following construction.

Corollary 1338 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$*. Let, also* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F',\alpha'\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$*, be* $\mathbf{F}$*-algebraic systems,* $\mathfrak{A} = \langle \mathcal{A}, T\rangle$ *an* $\mathcal{I}$*-matrix family and* $\mathfrak{A}' = \langle \mathcal{A}', T'\rangle$ *a reduced* $\mathcal{I}$*-matrix family and* $\langle H,\gamma\rangle : \mathfrak{A} \to \mathfrak{A}'$ *a surjective morphism.*



There exists a unique surjective morphism $\langle H,\gamma^*\rangle : \mathfrak{A}^* \to \mathfrak{A}'$ *that makes the triangle commute.*

Proof: By Theorem 1337, there exists a surjective matrix morphism $\langle H,\gamma^*\rangle :$

$\mathfrak{A}^* \to \mathfrak{A}'^*$, such that the following rectangle commutes:

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle I,\pi\rangle} & \mathfrak{A}^* \\ {\scriptstyle\langle H,\gamma\rangle}\downarrow & & \downarrow{\scriptstyle\langle H,\gamma^*\rangle} \\ \mathfrak{A}' & \xrightarrow[\langle I,\pi\rangle]{} & \mathfrak{A}'^* \end{array}$$

But, by hypothesis, $\mathfrak{A}'$ is reduced, whence $\mathfrak{A}'^* = \mathfrak{A}'$ and $\langle I,\pi\rangle = \langle I,\iota\rangle : \mathfrak{A}' \to \mathfrak{A}'^*$ is the identity morphism. We now obtain the triangle depicted in the diagram of the statement. ■

Let us denote by $\mathbf{MatFam}(\mathcal{I})$ the category of $\mathcal{I}$-matrix families with surjective matrix morphisms between them and, similarly, $\mathbf{MatFam}^*(\mathcal{I})$ the category of reduced $\mathcal{I}$-matrix families with surjective matrix morphisms between them. Then, based on Theorem 1337, we obtain the following functor.

Theorem 1339 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$^* : \mathbf{MatFam}(\mathcal{I}) \to \mathbf{MatFam}^*(\mathcal{I})$$

is a functor. The subcategory $\mathbf{MatFam}^*(\mathcal{I})$ *is a reflective subcategory of* $\mathbf{MatFam}(\mathcal{I})$ *with* * *a reflector from* $\mathbf{MatFam}(\mathcal{I})$ *to* $\mathbf{MatFam}^*(\mathcal{I})$*.*

Proof: Given $\mathcal{A} \in \mathrm{MatFam}(\mathcal{I})$, it is easy to see that $\langle I,\iota^*\rangle : \mathfrak{A}^* \to \mathfrak{A}^*$ is the identity matrix morphism. For the composition property, assume $\mathfrak{A}$, $\mathfrak{A}'$, $\mathfrak{A}'' \in \mathrm{MathFam}(\mathcal{I})$, and $\langle G,\beta\rangle : \mathfrak{A} \to \mathfrak{A}'$, $\langle H,\gamma\rangle : \mathfrak{A}' \to \mathfrak{A}''$ be matrix morphisms. Then, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rcl} (\gamma_{G(\Sigma)} \circ \beta_\Sigma)^*(\phi^*) & = & \gamma_{G(\Sigma)}(\beta_\Sigma(\phi))^* \\ & = & \gamma^*_{G(\Sigma)}(\beta_\Sigma(\phi)\star) \\ & = & \gamma^*_{G(\Sigma)}(\beta^*_\Sigma(\phi^*)). \end{array}$$

Thus, $(\langle H,\gamma\rangle \circ \langle G,\beta\rangle)^* = \langle H,\gamma\rangle^* \circ \langle G,\beta\rangle^*$. Therefore, $^* : \mathbf{MatFam}(\mathcal{I}) \to \mathbf{MatFam}^*(\mathcal{I})$ is a functor.

As far a s reflectivity is concerned, for every $\mathfrak{A} \in \mathrm{MatFam}^*(\mathcal{I})$, we consider the natural quotient morphism $\langle I,\pi\rangle : \mathfrak{A} \to \mathfrak{A}^*$. Given reduced $\mathfrak{B} \in \mathrm{MatFam}^*(\mathcal{I})$ and a surjective morphism $\langle H,\gamma\rangle : \mathfrak{A} \to \mathfrak{B}$, the surjective morphism $\langle H,\gamma^*\rangle : \mathfrak{A}^* \to \mathfrak{B}$ of Corollary 1338 is the unique surjective morphism such that the following diagram commutes.

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle I,\pi\rangle} & \mathfrak{A}^* \\ & {\scriptstyle\langle H,\gamma\rangle}\searrow & \downarrow{\scriptstyle\langle H,\gamma^*\rangle} \\ & & \mathfrak{B} \end{array}$$

Thus, $\mathbf{MatFam}^*(\mathcal{I})$ is a reflective subcategory of $\mathbf{MatFam}(\mathcal{I})$ with * a reflector from $\mathbf{MatFam}(\mathcal{I})$ to $\mathbf{MatFam}^*(\mathcal{I})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Given an $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we denote by $\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A})$ the principal filter of the complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ generated by the $\mathcal{I}$-filter family T:

$$\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : T \leq T'\}.$$

Recall that this set is also denoted by $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$, without explicit reference to the matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$.

The Correspondence Theorem allows us to prove the following.

Theorem 1340 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π-institution based on $\mathbf{F}$. For every $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}) \cong \mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}^*).$$

Proof: By The Correspondence Theorem 1336, with $\mathcal{B} = \mathcal{A}/\Omega^{\mathcal{A}}(T)$, $\langle H, \gamma \rangle = \langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$ and $T' = T/\Omega^{\mathcal{A}}(T)$, we get

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))^{T/\Omega^{\mathcal{A}}(T)} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\pi^{-1}(T/\Omega^{\mathcal{A}}(T))}.$$

But this amounts to $\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}^*) \cong \mathbf{FiFam}(\mathfrak{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Consider $\mathbf{F}$-matrix families $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $\mathfrak{B} = \langle \mathcal{B}, T' \rangle$ and a surjective matrix morphism $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{B}$. By definition, we have $T \leq \gamma^{-1}(T')$. We call $\gamma^{-1}(T')$ the **filter kernel** of $\langle H, \gamma \rangle$. By the inclusion relation above, we can see that, if $\mathfrak{B} \in \mathrm{MatFam}(\mathcal{I})$, then $\gamma^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$.

Given $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $X \in \mathrm{SenFam}(\mathcal{A})$, such that $T \leq X$, we define

$$\mathfrak{A}/X := \langle \mathcal{A}, X \rangle^* = \langle \mathcal{A}/\Omega^{\mathcal{A}}(X), X/\Omega^{\mathcal{A}}(X) \rangle.$$

We call $\mathfrak{A}/X$ the **quotient of $\mathfrak{A}$ by X**. We note that, if $\mathfrak{A} \in \mathrm{MatFam}(\mathcal{I})$, then

$$X \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) \quad \text{iff} \quad \mathfrak{A}/X \in \mathrm{MatFam}^*(\mathcal{I}).$$

The following is an analog in the context of $\mathcal{I}$-matrix families of the Homomorphism Theorem of Universal Algebra.

Theorem 1341 (Homomorphism Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π-institution based on $\mathbf{F}$. Let also $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle \in \mathrm{MatFam}(\mathcal{I})$ and $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{A}'$ a surjective morphism.*

(i) *There exists a strict surjective morphism* $\langle H, \gamma' \rangle : \mathfrak{A}/\gamma^{-1}(T') \to \mathfrak{A}'^*$ *with isomorphic components;*

(ii) *If* $X \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ *and* $X \le \gamma^{-1}(T')$, *then, there exists a surjective morphism* $\langle H, \gamma^X \rangle : \mathfrak{A}/X \to \mathfrak{A}'^*$, *such that*

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle H,\gamma\rangle} & \mathfrak{A}' \\ {\scriptstyle \langle I,\pi^X\rangle}\downarrow & & \downarrow{\scriptstyle \langle I,\pi\rangle} \\ \mathfrak{A}/X & \xrightarrow[\langle H,\gamma^X\rangle]{} & \mathfrak{A}'^* \end{array}$$

$\langle H, \gamma^X \rangle \circ \langle I, \pi^X \rangle = \langle I, \pi \rangle \circ \langle H, \gamma \rangle$.

Proof:

(i) First, note that $\gamma^{-1}(T') \le \gamma^{-1}(T')$, whence, $\langle H, \gamma \rangle : \langle \mathcal{A}, \gamma^{-1}(T') \rangle \to \mathfrak{A}'$ is also a surjective matrix morphism. Thus, taking into account that $T \le \gamma^{-1}(T')$, we get, by Theorem 1337, a surjective matrix morphism $\langle H, \gamma^* \rangle : \mathfrak{A}/\gamma^{-1}(T') \to \mathfrak{A}'^*$, such that the following diagram commutes.

$$\begin{array}{ccc} \langle \mathcal{A}, \gamma^{-1}(T') \rangle & \xrightarrow{\langle H,\gamma\rangle} & \mathfrak{A}' \\ {\scriptstyle \langle I,\pi\rangle}\downarrow & & \downarrow{\scriptstyle \langle I,\pi\rangle} \\ \mathfrak{A}/\gamma^{-1}(T') & \xrightarrow[\langle H,\gamma^*\rangle]{} & \mathfrak{A}'^* \end{array}$$

It remains to show that, for every $\Sigma \in |\mathbf{Sign}|$,

$$\gamma^*_\Sigma : \mathrm{SEN}^{\gamma^{-1}(T')}(\Sigma) \to \mathrm{SEN}'^*(H(\Sigma))$$

is a bijection and that $\langle H, \gamma^* \rangle$ is strict. To see that γ^*_Σ is a bijection, let $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that

$$\gamma^*_\Sigma(\phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))) = \gamma^*_\Sigma(\psi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))).$$

Then, by the commutativity of the rectangle,

$$\gamma_\Sigma(\phi)/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T') = \gamma_\Sigma(\psi)/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T').$$

This gives that $\langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))$. Thus, $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))$ and, hence,

$$\phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T')) = \phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T')).$$

Therefore, $\gamma^*_\Sigma : \mathrm{SEN}^{\gamma^{-1}(T')}(\Sigma) \to \mathrm{SEN}'^*(H(\Sigma))$ is a bijection, for all $\Sigma \in |\mathbf{Sign}|$.

To prove strictness, assume $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T')) \in \gamma^{*-1}_\Sigma(T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))$. Then $\gamma^*_\Sigma(\phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))) \in T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T')$. Hence, by the definition of γ^*, we get $\gamma_\Sigma(\phi)^* \in T'_{H(\Sigma)}/\Omega^{\mathcal{A}'}_{H(\Sigma)}(T')$. By compatibility, we obtain $\gamma_\Sigma(\phi) \in T'_{H(\Sigma)}$, whence $\phi \in \gamma^{-1}_\Sigma(T'_{H(\Sigma)})$. This, finally, yields

$$\phi/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T')) \in \gamma^{-1}_\Sigma(T'_{H(\Sigma)})/\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T')),$$

proving strictness.

(ii) This part is proven by the following diagram chase:

$$\begin{array}{ccccc}
\mathfrak{A} & & \xrightarrow{\langle H,\gamma\rangle} & & \mathfrak{A}' \\
\langle I,\pi^X\rangle \downarrow & & & & \downarrow \langle I,\pi\rangle \\
\mathfrak{A}/X & \xrightarrow[\langle I,\pi\rangle]{} & \mathfrak{A}/\gamma^{-1}(T') & \xrightarrow[\langle H,\gamma'\rangle]{} & \mathfrak{A}'^*
\end{array}$$

where $\langle I,\pi\rangle : \mathfrak{A}/X \to \mathfrak{A}/\gamma^{-1}(T')$ is the canonical projection morphism, defined because of the hypothesis $X \le \gamma^{-1}(T')$ and protoalgebraicity, and

$$\langle H,\gamma'\rangle : \mathfrak{A}/\gamma^{-1}(T') \to \mathfrak{A}'^*$$

is the morphism obtained in Part (i).

■

18.2 Pointed Classes of Algebraic Systems

Proposition 1342 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a protoalgebraic π-institution based on $\mathbf{F}$, having theorems. Then the following conditions are equivalent:*

(i) $\mathcal{I}$ is family regular;

(ii) For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in T_\Sigma$, $T_\Sigma = \phi/\Omega_\Sigma(T)$;

(iii) For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t/\Omega_\Sigma(T)$;

(iv) For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and some $\phi \in T_\Sigma$, $T_\Sigma = \phi/\Omega_\Sigma(T)$;

(v) For all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and some $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t/\Omega_\Sigma(T)$.

Proof:

(i)⇒(ii) Suppose $\mathcal{I}$ is family regular and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in T_\Sigma$. Then, we have, for all $\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll} \psi \in T_\Sigma \quad \text{iff} & \phi, \psi \in T_\Sigma & (\phi \in T_\Sigma) \\ \text{iff} & C(\phi,\psi) \le T & (\text{definition of } C(\phi,\psi)) \\ \text{implies} & \Omega_\Sigma(C(\phi,\psi)) \le \Omega_\Sigma(T) & (\mathcal{I} \text{ protoalgebraic}) \\ \text{implies} & \langle \phi,\psi\rangle \in \Omega_\Sigma(T) & (\mathcal{I} \text{ family regular}) \\ \text{iff} & \psi \in \phi/\Omega_\Sigma(T). & (\text{definition of } \phi/\Omega_\Sigma(T)) \end{array}$$

On the other hand, if $\psi \in \phi/\Omega_\Sigma(T)$, then, since $\phi \in T_\Sigma$, by the compatibility of $\Omega(T)$ with T, $\psi \in T_\Sigma$. Thus, we conclude that $T_\Sigma = \phi/\Omega_\Sigma(T)$.

(ii)⇒(iii) Suppose (ii) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, since $\mathrm{Thm}(\mathcal{I}) \le T$, we get that $t \in T_\Sigma$ and, hence, by hypothesis, $T_\Sigma = t/\Omega_\Sigma(T)$.

(iii)⇒(iv) Assume (iii) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. Since $\mathcal{I}$ has theorems, there exists $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, $t \in T_\Sigma$ and, by hypothesis, $T_\Sigma = t/\Omega_\Sigma(T)$.

(iv)⇒(v) Assume (iv) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. Then, by hypothesis, there exists $\phi \in T_\Sigma$, such that $T_\Sigma = \phi/\Omega_\Sigma(T)$. Moreover, $\mathcal{I}$ has theorems, whence, there exists $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, we have $t \in T_\Sigma = \phi/\Omega_\Sigma(T)$, whence $\langle \phi, t\rangle \in \Omega_\Sigma(T)$ and, therefore, $T_\Sigma = \phi/\Omega_\Sigma(T) = t/\Omega_\Sigma(T)$.

(v)⇒(i) Assume that (v) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in T_\Sigma$. By hypothesis, for some $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t/\Omega_\Sigma(T)$. Hence, $\phi,\psi \in t/\Omega_\Sigma(T)$, i.e., $\langle \phi,t\rangle \in \Omega_\Sigma(T)$ and $\langle t,\psi\rangle \in \Omega_\Sigma(T)$. By transitivity, $\langle \phi,\psi\rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is family regular.

■

We show now that a protoalgebraic family assertional π-institution $\mathcal{I}$ is weakly family algebraizable.

Theorem 1343 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic π-institution based on* $\mathbf{F}$. *If $\mathcal{I}$ is family assertional, then it is weakly family algebraizable.*

Proof: By Definition 613, protoalgebraicity and family assertionality are equivalent to regular weak family algebraizability. By Proposition 620, this entails weak family algebraizability.

More directly, assume $\mathcal{I}$ is family assertional. Since it is protoalgebraic, by hypothesis, it suffices to show that $\mathcal{I}$ is family injective. To this end, let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$,

$$T_\Sigma = t/\Omega_\Sigma(T) = t/\Omega_\Sigma(T') = T'_\Sigma.$$

Therefore $T = T'$. Hence $\mathcal{I}$ is family injective and, therefore, it is weakly family algebraizable. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a class of $\mathbf{F}$-algebraic systems. We say that K is $\top^\flat$-**pointed** if, for all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathsf{K}$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$,

$$\top^{\mathcal{A}}_\Sigma(\vec{\phi}) = \top^{\mathcal{A}}_\Sigma(\vec{\psi}).$$

K is called **pointed** if it is $\top^\flat$-pointed with respect to some $\top^\flat$ in $N^\flat$.

If a class K is pointed, then, for every $\mathcal{A} \in \mathsf{K}$, we write $\top^{\mathcal{A}} = \{\top^{\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, where $\top^{\mathcal{A}}_\Sigma \coloneqq \top^{\mathcal{A}}_\Sigma(\vec{\phi})$, for some $\vec{\phi} \in \mathrm{SEN}(\Sigma)$, this value being independent of the choice of $\vec{\phi} \in \mathrm{SEN}(\Sigma)$.

We focus now on protoalgebraic, family regular π-institutions that have natural theorems. Recall that this means that there exists a natural transformation $\top^\flat$ in $N^\flat$, such that $\top^\flat$ is evaluated to a theorem in every signature and at all tuples of sentences. Of course, by definition, all π-institutions that fit this description are regularly weakly family algebraizable. We show that for such π-institutions, the class $\mathrm{AlgSys}^*(\mathcal{I})$ of their reduced algebraic systems is a pointed class of $\mathbf{F}$-algebraic systems, where any natural theorem may serve as the "point".

Proposition 1344 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic family regular π-institution based on $\mathbf{F}$, having natural theorems. Then, the class $\mathrm{AlgSys}^*(\mathcal{I})$ is a pointed class of $\mathbf{F}$-algebraic systems.*

Proof: Suppose $\mathcal{I}$ is protoalgebraic and family regular, with a natural theorem $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$, i.e., such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\top^\flat_\Sigma(\vec{\phi}) \in \mathrm{Thm}_\Sigma(\mathcal{I})$. By family regularity, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, $\langle \top^\flat_\Sigma(\vec{\phi}), \top^\flat_\Sigma(\vec{\psi}) \rangle \in \Omega_\Sigma(\mathrm{Thm}(\mathcal{I}))$. Now, let $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. Thus, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Therefore, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, we get, by what was shown above and protoalgebraicity, and taking into account Lemma 51, $\langle \top^\flat_\Sigma(\vec{\phi}), \top^\flat_\Sigma(\vec{\psi}) \rangle \in \Omega_\Sigma(\alpha^{-1}(T))$, whence, by Proposition 24, $\langle \top^\flat_\Sigma(\vec{\phi}), \top^\flat_\Sigma(\vec{\psi}) \rangle \in \alpha^{-1}_\Sigma(\Omega^{\mathcal{A}}_{F(\Sigma)}(T))$. Thus,

$$\langle \alpha_\Sigma(\top^\flat_\Sigma(\vec{\phi})), \alpha_\Sigma(\top^\flat_\Sigma(\vec{\psi})) \rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T) = \Delta^{\mathcal{A}}_{F(\Sigma)},$$

i.e., since $\top^\flat$ is a natural transformation, $\top^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) = \top^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\psi}))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathrm{AlgSys}^*(\mathcal{I})$ is a pointed class of $\mathbf{F}$-algebraic systems, with any natural theorem serving as the "point" natural transformation. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$ and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems. We say that K

is **relatively point regular** if, for every $\theta,\theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$,

$$\top^\flat/\theta = \top^\flat/\theta' \quad \text{implies} \quad \theta = \theta'.$$

It is not difficult to show that the defining property transfers from K-congruence systems on $\mathcal{F}$ to K-congruence systems on every $\mathbf{F}$-algebraic system, under the proviso that K be an abstract class.

Lemma 1345 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *a natural transformation in* $N^\flat$*, and* K *a* $\top^\flat$*-pointed abstract class of* $\mathbf{F}$*-algebraic systems. If* K *is relatively point regular, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $\theta,\theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$*,*

$$\top^{\mathcal{A}}/\theta = \top^{\mathcal{A}}/\theta' \quad \textit{implies} \quad \theta = \theta'.$$

Proof: Suppose $\mathcal{A}$ is an $\mathbf{F}$-algebraic system, $\theta,\theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, such that $\top^{\mathcal{A}}/\theta = \top^{\mathcal{A}}/\theta'$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\langle \phi, \top^\flat_\Sigma\rangle \in \alpha_\Sigma^{-1}(\theta_{F(\Sigma)}) & \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\top^\flat_\Sigma)\rangle \in \theta_{F(\Sigma)}\\ & \text{iff} & \langle \alpha_\Sigma(\phi), \top^{\mathcal{A}}_{F(\Sigma)}\rangle \in \theta_{F(\Sigma)}\\ & \text{iff} & \langle \alpha_\Sigma(\phi), \top^{\mathcal{A}}_{F(\Sigma)}\rangle \in \theta'_{F(\Sigma)}\\ & \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\top^\flat_\Sigma)\rangle \in \theta'_{F(\Sigma)}\\ & \text{iff} & \langle \phi, \top^\flat_\Sigma\rangle \in \alpha_\Sigma^{-1}(\theta'_{F(\Sigma)}).\end{array}$$

Thus, $\top^\flat/\alpha^{-1}(\theta) = \top^\flat/\alpha^{-1}(\theta')$. Since K is abstract and $\mathcal{A}/\theta, \mathcal{A}/\theta' \in \mathsf{K}$, we get that $\mathcal{F}/\alpha^{-1}(\theta), \mathcal{F}/\alpha^{-1}(\theta') \in \mathsf{K}$. It follows that $\alpha^{-1}(\theta), \alpha^{-1}(\theta') \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$. Since K is relatively point regular, by definition, $\alpha^{-1}(\theta) = \alpha^{-1}(\theta')$. Therefore, by surjectivity of $\langle F, \alpha\rangle$, $\theta = \theta'$. ∎

Moreover, we can show that, for a protoalgebraic family regular π-institution $\mathcal{I}$, having natural theorems, the associated class $\mathrm{AlgSys}^*(\mathcal{I})$ of its reduced algebraic systems is a relatively point regular class.

Proposition 1346 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic family regular* π*-institution based on* $\mathbf{F}$*, having natural theorems. Then, the class* $\mathrm{AlgSys}^*(\mathcal{I})$ *is a relatively point regular class of* $\mathbf{F}$*-algebraic systems.*

Proof: We know, by Proposition 1344, that $\mathrm{AlgSys}^*(\mathcal{I})$ is pointed, with any natural theorem $\top^\flat$ serving as a "point". Consider $\theta,\theta' \in \mathrm{ConSys}^*(\mathcal{I})$, such that $\top^\flat/\theta = \top^\flat/\theta'$. Since $\theta,\theta' \in \mathrm{ConSys}^*(\mathcal{I})$, there exist $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\theta = \Omega(T)$ and $\theta' = \Omega(T')$. But then, since $\mathcal{I}$ is protoalgebraic and family regular, with theorems, we get, by Proposition 1342,

$$\begin{array}{rcll}\theta & = & \Omega(T) & \\ & = & \Omega(\top^\flat/\Omega(T)) & \text{(Proposition 1342)}\\ & = & \Omega(\top^\flat/\theta) & \\ & = & \Omega(\top^\flat/\theta') & \text{(hypothesis)}\\ & = & \Omega(\top^\flat/\Omega(T')) & \\ & = & \Omega(T') & \text{(Proposition 1342)}\\ & = & \theta'. & \end{array}$$

Hence $\mathrm{AlgSys}^*(\mathcal{I})$ is indeed relatively point regular. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems. Define on $\mathbf{F}$ the family $C^{\mathsf{K},\top} = \{C^{\mathsf{K},\top}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$C^{\mathsf{K},\top}_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)),$$

be given, for all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, by

$$\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi) \quad \text{iff} \quad \phi \approx \top^\flat_\Sigma \in C^{\mathsf{K}}_\Sigma(\Phi \approx \top^\flat_\Sigma),$$

i.e., $\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi)$ if and only if, for all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathsf{K}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma')}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) = \top^{\mathcal{A}}_{F(\Sigma')}.$$

In the next proposition, it is shown that $C^{\mathsf{K},\top}$ is a closure system on $\mathbf{F}$. In this way the pointed class K of $\mathbf{F}$-algebraic systems defines a bona fide π-institution based on $\mathbf{F}$.

Proposition 1347 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems. $C^{\mathsf{K},\top}$ is a closure system on $\mathbf{F}$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$. It is obvious from the definition that

$$C^{\mathsf{K},\top}_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$$

is inflationary and monotone. To show that it is also idempotent, let $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathsf{K},\top}_\Sigma(C^{\mathsf{K},\top}_\Sigma(\Phi))$. Thus, we have, by definition, for all $\mathcal{A} \in \mathsf{K}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(C^{\mathsf{K},\top}_\Sigma(\Phi))) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma')}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) = \top^{\mathcal{A}}_{F(\Sigma')}.$$

But, also by definition, we have, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma')}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(C^{\mathsf{K},\top}_\Sigma(\Phi))) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma')}\}.$$

Therefore, we get that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma')}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) = \top^{\mathcal{A}}_{F(\Sigma')},$$

showing that $\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi)$.

It remains, finally, to show that $C^{\mathsf{K},\top}$ is structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi)$. Consider $\mathcal{A} \in \mathsf{K}$, such that, for all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{\ f\ } \Sigma' \xrightarrow{\ g\ } \Sigma''$$

$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\Phi))) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma'')}\}$. This gives $\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\Phi)) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma'')}\}$, whence, by hypothesis, $\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi)) = \top^{\mathcal{A}}_{F(\Sigma'')}$. Thus, for all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$, $\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\phi))) = \top^{\mathcal{A}}_{F(\Sigma'')}$. We conclude that $\mathrm{SEN}^\flat(f)(\phi) \in C^{\mathsf{K},\top}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$ and, therefore, $C^{\mathsf{K},\top}$ is also structural. ■

Based on Proposition 1347, it makes sense, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems, to define the **assertional π-institution of K** as the pair

$$\mathcal{I}^{\mathsf{K},\top} = \langle \mathbf{F}, C^{\mathsf{K},\top} \rangle.$$

We have seen in Proposition 1346 that, if $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a protoalgebraic and family regular π-institution, having natural theorems, then its class $\mathrm{AlgSys}^*(\mathcal{I})$ of reduced $\mathbf{F}$-algebraic systems is a relatively point regular class. We show next, in a form of converse, that if K is a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems, then the assertional π-institution $\mathcal{I}^{\mathsf{K},\top}$, associated with K, is a protoalgebraic family regular π-institution that has natural theorems.

First, we establish possession of natural theorems, under the assumption that K is pointed.

Proposition 1348 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a pointed class of $\mathbf{F}$-algebraic systems. Then $\mathcal{I}^{\mathsf{K},\top}$ has natural theorems.*

Proof: Let K be a pointed class of $\mathbf{F}$-algebraic systems. Since K is pointed, there exists $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\top^{\mathcal{A}}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))) = \top^{\mathcal{A}}_{F(\Sigma')}.$$

This implies that $\alpha_{\Sigma'}(\top^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))) = \top^{\mathcal{A}}_{F(\Sigma')}$ and, hence, we obtain $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\top^\flat_\Sigma(\vec{\phi}))) = \top^{\mathcal{A}}_{F(\Sigma')}$. Thus, by definition, $\top^\flat_\Sigma(\vec{\phi}) \in C^{\mathsf{K},\top}_\Sigma(\varnothing)$ and, therefore, $\top^\flat$ is a natural theorem. ■

Next, we turn to proving family regularity, again under the assumption of pointedness.

Proposition 1349 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a pointed class of $\mathbf{F}$-algebraic systems. Then $\mathcal{I}^{\mathsf{K},\top}$ is a family regular π-institution.*

Proof: Let K be a pointed class of $\mathbf{F}$-algebraic systems. We know, by Proposition 1348, that $\mathcal{I}^{\mathsf{K},\top}$ has a natural theorem $\top^\flat$, where $\top^\flat$ is a point in K. We show that $\mathcal{I}^{\mathsf{K},\top}$ is family regular. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, we have

$$\mathrm{SEN}^\flat(f)(\phi) \approx \top^\flat_{\Sigma'}, \mathrm{SEN}^\flat(f)(\psi) \approx \top^\flat_{\Sigma'} \in C^{\mathsf{K}}_{\Sigma'}(\phi \approx \top^\flat_\Sigma, \psi \approx \top^\flat_\Sigma).$$

This implies that, for all $\sigma^\flat$ in $N^\flat$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \approx \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in C^{\mathsf{K}}_{\Sigma'}(\phi \approx \top^\flat_\Sigma, \psi \approx \top^\flat_\Sigma).$$

Now we get

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \approx \top^\flat_{\Sigma'} \in C^{\mathsf{K}}_{\Sigma'}(\phi \approx \top^\flat_\Sigma, \psi \approx \top^\flat_\Sigma) \\ \qquad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \approx \top^\flat_{\Sigma'} \in C^{\mathsf{K}}_{\Sigma'}(\phi \approx \top^\flat_\Sigma, \psi \approx \top^\flat_\Sigma).\end{array}$$

Hence, by definition,

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in C^{\mathsf{K},\top}_{\Sigma'}(\phi, \psi) \\ \qquad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in C^{\mathsf{K},\top}_{\Sigma'}(\phi, \psi).\end{array}$$

Therefore, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_\Sigma(C(\phi, \psi))$. ■

Before establishing protoalgebraicity, we need a couple of lemmas. We show, first, that, if K is a pointed class, then all theory families of $\mathcal{I}^{\mathsf{K},\top}$ are fully determined by the corresponding Leibniz class of the point.

Lemma 1350 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with a natural transformation $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a pointed class of $\mathbf{F}$-algebraic systems. Then, for all $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$,*

$$T = \top^\flat / \Omega(T).$$

Proof: Let K be a pointed class of $\mathbf{F}$-algebraic systems, $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$.

- Suppose $\phi \in \top^\flat_\Sigma / \Omega_\Sigma(T)$. This means that $\langle \phi, \top^\flat_\Sigma \rangle \in \Omega_\Sigma(T)$. But, by definition, $\top^\flat_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I}^{\mathsf{K},\top}) \subseteq T_\Sigma$, whence, by the compatibility property of $\Omega(T)$ with T, we get that $\phi \in T_\Sigma$.

- Suppose $\phi \in T_\Sigma$. Then $\phi \approx \top^\flat_\Sigma \in C^{\mathsf{K}}_\Sigma(T \approx \top^\flat)$. This implies that, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \approx \top^\flat_{\Sigma'} \in C^{\mathsf{K}}_{\Sigma'}(T \approx \top^\flat) \\ \qquad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\top^\flat_\Sigma), \vec{\chi}) \approx \top^\flat_{\Sigma'} \in C^{\mathsf{K}}_{\Sigma'}(T \approx \top^\flat).\end{array}$$

  This is, by definition, equivalent to the statement that, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in C^{\mathsf{K},\top}_{\Sigma'}(T) \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\top^\flat_\Sigma), \vec{\chi}) \in C^{\mathsf{K},\top}_{\Sigma'}(T).$$

  We conclude that $\langle \phi, \top^\flat_\Sigma \rangle \in \Omega_\Sigma(T)$, i.e., that $\phi \in \top^\flat_\Sigma / \Omega_\Sigma(T)$.

Thus, we get that $T = \top^\flat/\Omega(T)$. ■

Next, we show that, if K is a relatively point regular guasivariety, then, for every theory family of $\mathcal{I}^{\mathsf{K},\top}$, the quotient of $\mathcal{F}$ by the Leibniz congruence system of T, belongs to K and, therefore, for every theory family T of $\mathcal{I}^{\mathsf{K},\top}$, the Leibniz congruence system $\Omega(T)$ is a K-congruence system on $\mathcal{F}$.

Lemma 1351 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with a natural transformation* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a relatively point regular guasivariety of* $\mathbf{F}$*-algebraic systems. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$*,* $\mathcal{F}/\Omega(T) \in \mathsf{K}$*.*

Proof: Suppose that K is a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i \in I$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\langle\{\phi_i \approx \psi_i : i \in I\}, \phi \approx \psi\rangle \in \mathrm{GEq}_\Sigma(\mathsf{K}).$$

This is equivalent to the statement $\langle\phi, \psi\rangle \in \Theta^{\mathsf{K},\mathcal{F}}_\Sigma(\{\langle\phi_i, \psi_i\rangle : i \in I\})$. Since $\Theta^{\mathsf{K},\mathcal{F}}(\{\langle\phi_i, \psi_i\rangle : i \in I\}) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ and K is relatively point regular, $\Theta^{\mathsf{K},\mathcal{F}}(\{\langle\phi_i, \psi_i\rangle : i \in I\})$ is completely determined by its $\top^\flat$-equivalence class. So it suffices to consider guasiequations of the form

$$\langle\{\phi_i \approx \top^\flat_\Sigma : i \in I\}, \phi \approx \top^\flat_\Sigma\rangle \in \mathrm{GEq}_\Sigma(\mathsf{K}).$$

Now, let $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$, such that $\langle\phi_i, \top^\flat_\Sigma\rangle \in \Omega_\Sigma(T)$, for all $i \in I$. Then, taking into account Lemma 1350, $\phi_i \in \top^\flat_\Sigma/\Omega_\Sigma(T) = T_\Sigma$, for all $i \in I$. Therefore, by definition, $\phi_i \approx \top^\flat_\Sigma \in C^{\mathsf{K}}_\Sigma(T \approx \top^\flat)$, for all $i \in I$. Since, by hypothesis, $\langle\{\phi_i \approx \top^\flat_\Sigma : i \in I\}, \phi \approx \top^\flat_\Sigma\rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$, we get $\phi \approx \top^\flat_\Sigma \in C^{\mathsf{K}}_\Sigma(T \approx \top^\flat)$, i.e., $\phi \in C^{\mathsf{K},\top}_\Sigma(T)$. Since $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$, $\phi \in T_\Sigma = \top^\flat_\Sigma/\Omega_\Sigma(T)$. Therefore, $\langle\phi, \top^\flat_\Sigma\rangle \in \Omega_\Sigma(T)$. We conclude that $\mathcal{F}/\Omega(T)$ satisfies all guasiequations of K and, hence, since K is a guasivariety, $\mathcal{F}/\Omega(T) \in \mathsf{K}$. ■

Finally, we establish protoalgebraicity of $\mathcal{I}^{\mathsf{K},\top}$, under the hypotheses that K is a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems.

Proposition 1352 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a relatively point regular guasivariety of* $\mathbf{F}$*-algebraic systems. Then* $\mathcal{I}^{\mathsf{K},\top}$ *is a protoalgebraic* π*-institution.*

Proof: Let K be a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems. We know, by Proposition 1348, that $\mathcal{I}^{\mathsf{K},\top}$ has a natural theorem $\top^\flat$, where $\top^\flat$ is a point in K, and, by Proposition 1349, that $\mathcal{I}^{\mathsf{K},\top}$ is a family regular π-institution.

Now we show that $\mathcal{I}^{\mathsf{K},\top}$ is protoalgebraic. Suppose that $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \le T'$. Then, by Lemma 1350, we get $\top^\flat/\Omega(T) \le \top^\flat/\Omega(T')$. Since, by Lemma 1351, $\Omega(T)$ and $\Omega(T')$ are K-congruence systems on $\mathcal{F}$ and K is relatively point regular, they are completely determined (generated) by their $\top^\flat$-classes and, hence, we get $\Omega(T) \le \Omega(T')$. Thus, $\mathcal{I}^{\mathsf{K},\top}$ is protoalgebraic. ■

We show, next, that, for a protoalgebraic family regular π-institution $\mathcal{I}$, having natural theorems, the assertional π-institution of its class $\mathrm{AlgSys}^*(\mathcal{I})$ of reduced $\mathbf{F}$-algebraic systems coincides with $\mathcal{I}$.

Theorem 1353 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a family regular protoalgebraic* π*-institution based on* $\mathbf{F}$*, having a natural theorem* $\top$*. Then*

$$\mathcal{I}^{\mathrm{AlgSys}^*(\mathcal{I}),\top} = \mathcal{I}.$$

Proof: Set, for brevity in the course of this proof, $\mathsf{K} := \mathrm{AlgSys}^*(\mathcal{I})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi) & \text{iff} & \phi \approx \top^\flat_\Sigma \in C^{\mathsf{K}}_\Sigma(\Phi \approx \top^\flat_\Sigma)\\ & \text{iff} & \text{for all } T \in \mathrm{ThFam}(\mathcal{I}), \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\ & & \mathrm{SEN}^\flat(f)(\Phi) \approx \top^\flat_{\Sigma'} \in \Omega_{\Sigma'}(T)\\ & & \qquad\qquad \text{implies } \mathrm{SEN}^\flat(f)(\phi) \approx \top^\flat_{\Sigma'} \in \Omega_{\Sigma'}(T)\\ & \text{iff} & \text{for all } T \in \mathrm{ThFam}(\mathcal{I}), \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\ & & \mathrm{SEN}^\flat(f)(\Phi) \in T_{\Sigma'} \text{ implies } \mathrm{SEN}^\flat(f)(\phi) \in T_{\Sigma'}\\ & \text{iff} & \phi \in C_\Sigma(\Phi).\end{array}$$

We conclude that $C^{\mathsf{K},\top} = C$ and, therefore, $\mathcal{I}^{\mathrm{AlgSys}^*(\mathcal{I}),\top} = \mathcal{I}$. ■

Moreover, starting with a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems, the class of all reduced $\mathbf{F}$-algebraic systems of its assertional π-institution coincides with the original class.

Theorem 1354 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a relatively point regular guasivariety of* $\mathbf{F}$*-algebraic systems. Then*

$$\mathrm{AlgSys}^*(\mathcal{I}^{\mathsf{K},\top}) = \mathsf{K}.$$

Proof: Let K be a relatively point regular guasivariety of $\mathbf{F}$-algebraic systems. Assume that $\mathcal{A} \in \mathsf{K}$ and consider $\{\top^\mathcal{A}\} := \{\top^\mathcal{A}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|} \in \mathrm{SenFam}(\mathcal{A})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathsf{K},\top}_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq \{\top^\mathcal{A}_{F(\Sigma)}\}$, we get, by the definition of $C^{\mathsf{K},\top}$, $\alpha_\Sigma(\phi) = \top^\mathcal{A}_{F(\Sigma)}$. Therefore, $\{\top^\mathcal{A}\} \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$. Moreover, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll}\langle \phi, \top^\mathcal{A}_\Sigma\rangle \in \Omega^\mathcal{A}_\Sigma(\{\top^\mathcal{A}\}) & \text{iff} & \phi = \top^\mathcal{A}_\Sigma \quad \text{(Lemma 1350)}\\ & \text{iff} & \langle \phi, \top^\mathcal{A}_\Sigma\rangle \in \Delta^\mathcal{A}_\Sigma.\end{array}$$

Thus, $\top^\mathcal{A}/\Omega^\mathcal{A}(\{\top^\mathcal{A}\}) = \top^\mathcal{A}/\Delta^\mathcal{A}$. Therefore, by relative point regularity, we obtain $\Omega^\mathcal{A}(\{\top^\mathcal{A}\}) = \Delta^\mathcal{A}$. This yields $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I}^{\mathsf{K},\top})$.

Assume, conversely, that $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I}^{\mathsf{K},\top})$. Then, by definition, there exists $T \in \mathrm{FiFam}^{\mathcal{I}^{\mathsf{K},\top}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Suppose that $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that

$$\langle \Phi \approx \top^\flat_\Sigma, \phi \approx \top^\flat_\Sigma \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$$

and $\alpha_\Sigma(\Phi) \subseteq \{\top^{\mathcal{A}}_{F(\Sigma)}\}$. Then, since $T \in \mathrm{FiFam}^{\mathcal{I}^{\mathsf{K},\top}}(\mathcal{A})$, $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Hence, $\Phi \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since $T \in \mathrm{ThFam}^{\mathcal{I}^{\mathsf{K},\top}}(\mathcal{A})$, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$, whence, by Lemma 1350, $\alpha^{-1}(T) = \top^\flat/\Omega(\alpha^{-1}(T))$. Thus, we get $\Phi \subseteq \top^\flat_\Sigma/\Omega_\Sigma(\alpha^{-1}(T))$. Hence, $\Phi \approx \top^\flat_\Sigma \in \Omega_\Sigma(\alpha^{-1}(T))$. By Lemma 1351, $\Omega(\alpha^{-1}(T)) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$, whence, since $\langle \Phi \approx \top^\flat_\Sigma, \phi \approx \top^\flat_\Sigma \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$, $\phi \approx \top^\flat_\Sigma \in \Omega_\Sigma(\alpha^{-1}(T))$. By Proposition 24, $\phi \approx \top^\flat_\Sigma \in \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T))$, i.e., $\alpha_\Sigma(\phi) \approx \top^{\mathcal{A}}_{F(\Sigma)} \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T) = \Delta^{\mathcal{A}}_{F(\Sigma)}$. Thus, $\alpha_\Sigma(\phi) = \top^{\mathcal{A}}_{F(\Sigma)}$. We conclude that $\langle \Phi \approx \top^\flat_\Sigma, \phi \approx \top^\flat_\Sigma \rangle \in \mathrm{GEq}_\Sigma(\mathcal{A})$. Since $\mathcal{A}$ satisfies all guasiequations in $\mathrm{GEq}(\mathsf{K})$ and K is, by hypothesis, a guasivariety, we get that $\mathcal{A} \in \mathsf{K}$. Therefore, $\mathrm{AlgSys}^*(\mathcal{I}^{\mathsf{K},\top}) = \mathsf{K}$. ■

Now we can formulate the main theorems of the section.

Theorem 1355 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is protoalgebraic family regular, with natural theorems, if and only if it is the assertional* π*-institution of a relatively point regular guasivariety of* $\mathbf{F}$*-algebraic systems.*

More precisely, $\mathcal{I}$ *is protoalgebraic family regular, with natural theorems, if and only if* $\mathrm{AlgSys}^*(\mathcal{I})$ *is a relatively point regular guasivariety and* $\mathcal{I} = \mathcal{I}^{\mathrm{AlgSys}^*(\mathcal{I}),\top}$*, where* $\top^\flat$ *is any natural theorem.*

Proof: Suppose $\mathcal{I}$ is protoalgebraic family regular, with natural theorems. Then, by Proposition 1346, $\mathrm{AlgSys}^*(\mathcal{I})$ is a relatively point regular class of $\mathbf{F}$-algebraic systems and, by protoalgebraicity, Proposition 68 and Theorem **??**, it is a guasivariety. Moreover, by Theorem 1353, $\mathcal{I} = \mathcal{I}^{\mathrm{AlgSys}^*(\mathcal{I}),\top}$.

Assume, conversely, that $\mathcal{I}^{\mathsf{K},\top}$ is the assertional π-institution of a relatively point regular guasivariety K of $\mathbf{F}$-algebraic systems. Then, by Proposition 1349, it is family regular, by Proposition 1352, it is protoalgebraic and, by Proposition 1348, it has natural theorems. ■

Theorem 1356 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*. Then, there exists a one to one correspondence between relatively point regular guasivarieties, with point* $\top^\flat$*, and family regular protoalgebraic* π*-institutions, with a natural theorem* $\top^\flat$*.*

Every relatively point regular guasivariety with point $\top^\flat$ *determines a unique family regular protoalgebraic* π*-institution with natural theorems, its assertional* π*-institution.*

Every family regular protoalgebraic π-institution with natural theorems is the assertional π-institution of a unique relatively point regular guasivariety, the guasivariety $\mathrm{AlgSys}^*(\mathcal{I})$ *of all its reduced* $\mathbf{F}$*-algebraic systems.*

For each family regular protoalgebraic π-institution, with a natural theorem $\top^\flat$, we have $\mathcal{I} = \mathcal{I}^{\mathrm{AlgSys}^*(\mathcal{I}),\top}$ and, conversely, for every relatively point regular guasivariety K, with point $\top^\flat$, we have $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I}^{\mathsf{K},\top})$.

Proof: This is a recap of Theorems 1353 and 1354. ■

Chapter 19

Full Models of π-Institutions

19.1 π-Structures Revisited

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system. An $N^\flat$-**structure** is a pair $\mathbb{L} = \langle \mathbf{A}, D \rangle$, where $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ is an $N^\flat$-algebraic system and $D : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ is a closure (operator) family (not necessarily a system, i.e., not necessarily structural) on $\mathbf{A}$. An $\mathbf{F}$-**structure** is a pair $\mathbb{L} = \langle \mathcal{A}, D \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$-algebraic system and $D : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ is a closure family on $\mathcal{A}$.

We give a condition pinpointing exactly when a closure family is a closure system and, as a consequence, when a π-structure becomes a π-institution.

Proposition 1357 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system and* $D : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ *a closure family on* SEN. *Then* D *is a closure system, if and only if, for all* $\Sigma, \Sigma' \in |\mathbf{Sign}|$ *and all* $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathrm{SEN}(f)^{-1}(\mathcal{D}_{\Sigma'}) \subseteq \mathcal{D}_\Sigma$.

Proof: Suppose, first, that D is structural and let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $X' \subseteq \mathrm{SEN}(\Sigma')$, such that $D_{\Sigma'}(X') = X'$. Then we have

$$\begin{array}{rcl}\mathrm{SEN}(f)(D_\Sigma(\mathrm{SEN}(f)^{-1}(X'))) & \subseteq & D_{\Sigma'}(\mathrm{SEN}(f)(\mathrm{SEN}(f)^{-1}(X'))) \\ & \subseteq & D_{\Sigma'}(X') \\ & = & X'.\end{array}$$

So $D_\Sigma(\mathrm{SEN}(f)^{-1}(X')) \subseteq \mathrm{SEN}(f)^{-1}(X')$ and $\mathrm{SEN}(f)^{-1}(X') \in \mathcal{D}_\Sigma$.

Suppose, conversely, that, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathrm{SEN}(f)^{-1}(\mathcal{D}_{\Sigma'}) \subseteq \mathcal{D}_\Sigma$. Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathrm{Sign}(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\Phi)$. Let $T' \in \mathcal{D}_{\Sigma'}$, such that $\mathrm{SEN}(f)(\Phi) \subseteq T'$. Thus, $\Phi \subseteq \mathrm{SEN}(f)^{-1}(T')$. By hypothesis, $\mathrm{SEN}(f)^{-1}(T') \in \mathcal{D}_\Sigma$, whence, since $\phi \in D_\Sigma(\Phi)$ and $\Phi \subseteq \mathrm{SEN}(f)^{-1}(T')$, we get that $\phi \in \mathrm{SEN}(f)^{-1}(T')$ and, therefore, $\mathrm{SEN}(f)(\phi) \in T'$. We conclude that $\mathrm{SEN}(f)(\phi) \in D_{\Sigma'}(\mathrm{SEN}(f)(\Phi))$. Thus, D is a structural closure family on SEN. ■

Let $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two $N^\flat$-structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$, and consider an $N^\flat$-algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$. We say that

> $\langle F, \alpha \rangle$ is a **logical morphism from $\mathbb{L}$ to $\mathbb{L}'$** , denoted $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$, if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,
>
> $$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)),$$
>
> or, equivalently, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,
>
> $$\alpha_\Sigma(D_\Sigma(\Phi)) \subseteq D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Proposition 1358 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ *be two* $N^\flat$*-structures, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$, *and consider an* $N^\flat$*-algebraic system morphism* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$. $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a logical morphism if and only if, for every* $T' \in \mathrm{ThFam}(\mathbb{L}')$, $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$.

Proof: Suppose, first, that $\langle F,\alpha\rangle : \mathbb{L}\rangle\!\!-\mathbb{L}'$ is a logical morphism and let $T' \in \mathrm{ThFam}(\mathbb{L}')$, $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)}))$. Then, we have

$$\begin{array}{rcl}\alpha_\Sigma(\phi) & \in & \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)})))\\ & \subseteq & D'_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)})))\\ & \subseteq & D'_{F(\Sigma)}(T'_{F(\Sigma)})\\ & = & T'_{F(\Sigma)}.\end{array}$$

Therefore, $\phi \in \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$ and we conclude that $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$.

Suppose, conversely, that, for every $T' \in \mathrm{ThFam}(\mathbb{L}')$, we have $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi\cup\{\phi\} \subseteq \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\Phi)$. Then, for all $T' \in \mathrm{ThFam}(\mathbb{L}')$, such that $\alpha_\Sigma(\Phi) \subseteq T'_{F(\Sigma)}$, we get $\Phi \subseteq \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$. Since $\phi \in D_\Sigma(\Phi)$ and, by hypothesis, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathbb{L})$, we get $\phi \in \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$. Hence, $\alpha_\Sigma(\phi) \in T'_{F(\Sigma)}$. Since $T' \in \mathrm{ThFam}(\mathbb{L}')$ was arbitrary, we conclude that $\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Thus, $\langle F,\alpha\rangle : \mathbb{L}\rangle\!\!-\mathbb{L}'$ is a logical morphism. ∎

Let $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ be two $N^\flat$-structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$, and consider an $N^\flat$-algebraic system morphism $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$. We say that

> $\langle F,\alpha\rangle$ is a **bilogical morphism from $\mathbb{L}$ to $\mathbb{L}'$** , denoted $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$, if $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$ is surjective and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,
>
> $$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)),$$
>
> or, equivalently, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,
>
> $$\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Proposition 1359 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ *be two* $N^\flat$*-structures, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$*, and consider a surjective* $N^\flat$*-algebraic system morphism* $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$. $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a bilogical morphism if and only if* $\mathrm{ThFam}(\mathbb{L}) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$.

Proof: Suppose, first, that $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism. Then, by Proposition 1358, if $T' \in \mathrm{ThFam}(\mathbb{L}')$, then $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$, whence $\alpha^{-1}(\mathrm{ThFam}(\mathbb{L}')) \subseteq \mathrm{ThFam}(\mathbb{L})$. To show the converse, suppose that $T \in \mathrm{ThFam}(\mathbb{L})$. For every $\Sigma' \in |\mathbf{Sign}'|$, choose $\Sigma \in |\mathbf{Sign}|$, such that $F(\Sigma) = \Sigma'$ and let $T'_{\Sigma'} = D'_{\Sigma'}(\alpha_\Sigma(T_\Sigma))$. Then set

$$T' = \{T'_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}'|}.$$

Clearly, $T' \in \mathrm{ThFam}(\mathbb{L}')$ and, since $\langle F,\alpha\rangle$ is a bilogical morphism, $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$. But we also have. for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha_\Sigma^{-1}(T'_{F(\Sigma)}) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(T_\Sigma))) = D_\Sigma(T_\Sigma) = T_\Sigma.$$

Therefore, we conclude that $\mathrm{ThFam}(\mathbb{L}) \subseteq \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$.

Suppose, conversely, that $\mathrm{ThFam}(\mathbb{L}) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$. We have $\phi \in D_\Sigma(\Phi)$ iff, for all $T \in \mathrm{ThFam}(\mathbb{L})$,

$$\Phi \subseteq T_\Sigma \quad \text{implies} \quad \phi \in T_\Sigma,$$

iff, for all $T' \in \mathrm{ThFam}(\mathbb{L}')$,

$$\Phi \subseteq \alpha_\Sigma^{-1}(T'_{F(\Sigma)}) \quad \text{implies} \quad \phi \in \alpha_\Sigma^{-1}(T'_{F(\Sigma)}),$$

iff, for all $T' \in \mathrm{ThFam}(\mathbb{L}')$,

$$\alpha_\Sigma(\Phi) \subseteq T'_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\phi) \in T'_{F(\Sigma)},$$

iff $\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Therefore, $\langle F,\alpha\rangle$ is a bilogical morphism. ∎

Let $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ be two $N^\flat$-structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$, and consider an $N^\flat$-algebraic system morphism $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$. We say that

> $\langle F,\alpha\rangle$ is an **α-isomorphism from $\mathbb{L}$ to $\mathbb{L}'$** , denoted $\langle F,\alpha\rangle : \mathbb{L} \vdash^\alpha \mathbb{L}'$, if it is a bilogical morphism $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$, such that, for all $\Sigma \in |\mathbf{Sign}|$, $\alpha_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SEN}'(F(\Sigma))$ is a bijection.

Finally, $\langle F,\alpha\rangle : \mathbb{L} \to \mathbb{L}'$ is an **isomorphism**, denoted $\langle F,\alpha\rangle : \mathbb{L} \cong \mathbb{L}'$, if it is an α-isomorphism and $F : \mathbf{Sign} \to \mathbf{Sign}'$ is also an isomorphism.

In most instances, when a result holds for $F : \mathbf{Sign} \to \mathbf{Sign}'$ an isomorphism, we will formulate it, for simplicity, for the identity functor $I_{\mathbf{Sign}} : \mathbf{Sign} \to \mathbf{Sign}$, which will be sufficient for most of our purposes.

The following is an important characterization result for bilogical morphisms containing many equivalent formulations.

Given an $N^\flat$-structure $\mathbb{L} = \langle \mathbf{A}, D\rangle$, a congruence system $\theta \in \mathrm{ConSys}(\mathbf{A})$ is called a **logical congruence system of** $\mathbb{L}$ if it is compatible with every theory family of $\mathbb{L}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi,\psi\rangle \in \theta_\Sigma \quad \text{implies} \quad D_\Sigma(\phi) = D_\Sigma(\psi).$$

If this is the case, we write $\theta \in \mathrm{ConSys}(\mathbb{L})$.

Proposition 1360 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ *be two* $N^\flat$*-structures, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$*, and consider a surjective* $N^\flat$*-algebraic system morphism* $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$*. Then the following are equivalent:*

(i) $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a bilogical morphism;*

(ii) *For all* $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \mathrm{SEN}(\Sigma)$, $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$*;*

(iii) *For all* $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \mathrm{SEN}(\Sigma)$, $\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ *and* $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$*;*

(iv) *For all* $\Sigma \in |\mathbf{Sign}|$, $\Psi \subseteq \mathrm{SEN}'(F(\Sigma))$, $D'_{F(\Sigma)}(\Psi) = \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\Psi)))$ *and* $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$*;*

(v) *For all* $\Sigma \in |\mathbf{Sign}|$, $\mathrm{Th}_{F(\Sigma)}(\mathbb{L}') = \alpha_\Sigma(\mathrm{Th}_\Sigma(\mathbb{L}))$ *and, also,* $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$*;*

(vi) $\mathrm{ThFam}(\mathbb{L}) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$.

Proof:

(i)⇒(ii) Suppose $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$. Then, we have

$$\begin{array}{lll}\phi \in D_\Sigma(\Phi) & \text{iff} & \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \\ & \text{iff} & \phi \in \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))).\end{array}$$

We conclude that $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$.

(ii)⇒(iii) Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \subseteq \mathrm{SEN}(\Sigma)$. Then, by the hypothesis (ii), $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$, whence, by surjectivity of $\langle F,\alpha\rangle$, $\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. For the second claim, suppose $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Then

$$\alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\phi))) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\psi))).$$

Thus, by hypothesis, $D_\Sigma(\phi) = D_\Sigma(\psi)$. It follows that $\mathrm{Ker}(\langle F,\alpha\rangle)$ is a logical congruence system of $\mathbb{L}$.

(iii)⇒(iv) Let $\Sigma \in |\mathbf{Sign}|$ and $\Psi \in \mathrm{SEN}'(F(\Sigma))$. Then we have

$$\begin{array}{rcl}D'_{F(\Sigma)}(\Psi) & = & D'_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(\Psi))) \\ & = & \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\Psi))).\end{array}$$

(iv)⇒(v) Let $\Sigma \in |\mathbf{Sign}|$ and assume, first, that $T' \in \mathrm{Th}_{F(\Sigma)}(\mathbb{L}')$. Then, we have

$$T' = D'_{F(\Sigma)}(T') = \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(T'))) \in \alpha_\Sigma(\mathrm{Th}_\Sigma(\mathbb{L})).$$

Suppose, conversely, that $T \in \mathrm{Th}_\Sigma(\mathbb{L})$. Then, we have

$$\begin{array}{rcl}D'_{F(\Sigma)}(\alpha_\Sigma(T)) & = & \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\alpha_\Sigma(T)))) \\ & = & \alpha_\Sigma(D_\Sigma(T)) \\ & = & \alpha_\Sigma(T).\end{array}$$

Therefore, $\alpha_\Sigma(T) \in \mathrm{Th}_{F(\Sigma)}(\mathbb{L}')$.

(v)⇒(vi) It suffices to show that, for all $\Sigma \in |\mathbf{Sign}|$, $\mathrm{Th}_\Sigma(\mathbb{L}) = \alpha_\Sigma^{-1}(\mathrm{Th}_{F(\Sigma)}(\mathbb{L}'))$.

Suppose, first, $T \in \mathrm{Th}_\Sigma(\mathbb{L})$. Then, by hypothesis, $\alpha_\Sigma(T) \in \mathrm{Th}_{F(\Sigma)}(\mathbb{L}')$. But, since $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$, we now get

$$T = \alpha_\Sigma^{-1}(\alpha_\Sigma(T)) \in \alpha_\Sigma^{-1}(\mathrm{Th}_{F(\Sigma)}(\mathbb{L}')).$$

Therefore, $\mathrm{Th}_\Sigma(\mathbb{L}) \subseteq \alpha_\Sigma^{-1}(\mathrm{Th}_{F(\Sigma)}(\mathbb{L}'))$.

Suppose, conversely, $T' \in \mathrm{Th}_{F(\Sigma)}(\mathbb{L}')$. Then, by hypothesis, there exists $T \in \mathrm{Th}_\Sigma(\mathbb{L})$, such that $T' = \alpha_\Sigma(T)$. Thus, since $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$, we now get

$$\alpha_\Sigma^{-1}(T') = \alpha_\Sigma^{-1}(\alpha_\Sigma(T)) = T \in \mathrm{Th}_\Sigma(\mathbb{L}).$$

We conclude that $\alpha_\Sigma^{-1}(\mathrm{Th}_{F(\Sigma)}(\mathbb{L}')) \subseteq \mathrm{Th}_\Sigma(\mathbb{L})$ and, hence, $\mathrm{ThFam}(\mathbb{L}) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$.

(vi)⇒(i) This is one part of Proposition 1359. ∎

A consequence of the preceding characterization is that, when the categories of signatures of the $N^\flat$-structures that are connected via a bilogical morphism are isomorphic, then the complete lattices of their theory families are order isomorphic.

Proposition 1361 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ *be two* $N^\flat$*-structures, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *and consider a surjective* $N^\flat$*-algebraic system morphism* $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$*. Then* $\langle F,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a bilogical morphism if and only if, for all* $\Sigma \in |\mathbf{Sign}|$*,* $\alpha_\Sigma : \mathbf{Th}_\Sigma(\mathbb{L}) \to \mathbf{Th}_{F(\Sigma)}(\mathbb{L}')$ *is an order isomorphism.*

Proof: First, by Part (v) of Proposition 1360, α is a well defined surjection from $\mathrm{Th}_\Sigma(\mathbb{L})$ onto $\mathrm{Th}_{F(\Sigma)}(\mathbb{L}')$. Second, by Part (ii) of Proposition 1360, it is an injection. Therefore, it is a bijection, whose inverse, also by Part (ii) of Proposition 1360, is α_Σ^{-1}. That both α_Σ and α_Σ^{-1} are order preserving is straightforward.

Conversely, note that Part (vi) of Proposition 1360 is automatically satisfied in case $\alpha_\Sigma : \mathbf{Th}_\Sigma(\mathbb{L}) \to \mathbf{Th}_{F(\Sigma)}(\mathbb{L}')$ is an order isomorphism, for all $\Sigma \in |\mathbf{Sign}|$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system and consider an $N^\flat$-algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$. Extending the concept and notation from the framework of closure systems and π-institutions, given two closure families D and D' on $\mathbf{A}$ and corresponding $N^\flat$-structures $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}, D'\rangle$, we write $D \le D'$ and $\mathbb{L} \le \mathbb{L}'$ to signify that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\Phi) \subseteq D'_\Sigma(\Phi).$$

Under this ordering, the collection of all closure families on the algebraic system $\mathbf{A}$ forms a complete lattice, which will be denoted by

$$\mathbf{ClFam}(\mathbf{A}) = \langle \mathrm{ClFam}(\mathbf{A}), \leq \rangle.$$

Given $D \in \mathrm{ClFam}(\mathbf{A})$ and corresponding $N^\flat$-structure $\mathbb{L} = \langle \mathbf{A}, D\rangle$, we write $\mathrm{ClFam}(\mathbb{L}) = \mathrm{ClFam}^D(\mathbf{A})$ to denote the principal filter of $\mathbf{ClFam}(\mathbf{A})$ generated by D, i.e., we set

$$\mathrm{ClFam}(\mathbb{L}) = \{D' \in \mathrm{ClFam}(\mathbf{A}) : D \leq D'\}.$$

Then, we have the following corollary, expressed partially in terms of the closed set families corresponding in the standard way with closure operator families.

Corollary 1362 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ be two $N^\flat$-structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle$. If $\langle I, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$, where $I : \mathbf{Sign} \to \mathbf{Sign}$ is the identity functor, is a bilogical morphism, then*

$$\mathcal{T} \mapsto \alpha(\mathcal{T}) := \{\alpha(T) : T \in \mathcal{T}\}$$

is an isomorphism between $\mathbf{ClFam}(\mathbb{L})$ and $\mathbf{ClFam}(\mathbb{L}')$.

Proof: Directly from Proposition 1361. ∎

Recall that given an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and a closure family $\mathcal{D}$ on $\mathbf{A}$, with corresponding $N^\flat$-structure $\mathbb{L} = \langle \mathbf{A}, \mathcal{D}\rangle$, and $T \in \mathrm{ThFam}(\mathbb{L})$, we denote by $\mathbb{L}^T = \langle \mathbf{A}, \mathcal{D}^T\rangle$ the $N^\flat$-structure whose theory families are those closure families of $\mathbb{L}$ that contain T. Moreover, we denote by $\widetilde{\Omega}(\mathbb{L}^T)$ or $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{D}^T)$ the Tarski congruence system of $\mathbb{L}^T$, i.e., the large congruence system on $\mathbf{A}$ compatible with all theory families in $\mathcal{D}^T$.

Connecting Tarski congruence systems and bilogical morphisms, we obtain the following:

Proposition 1363 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ be two $N^\flat$-structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$. If $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, then, for all $T' \in \mathrm{ThFam}(\mathbb{L}')$,*

$$\alpha^{-1}(\widetilde{\Omega}(\mathbb{L}'^{T'})) = \widetilde{\Omega}(\mathbb{L}^{\alpha^{-1}(T')}).$$

Proof: We have

$$\begin{array}{rcl}
\alpha^{-1}(\widetilde{\Omega}(\mathbb{L}'^{T'})) & = & \alpha^{-1}(\bigcap\{\Omega^{\mathbf{A}'}(T'') : T' \leq T'' \in \mathrm{ThFam}(\mathbb{L}')\}) \\
& = & \bigcap\{\alpha^{-1}(\Omega^{\mathbf{A}'}(T'')) : T' \leq T'' \in \mathrm{ThFam}(\mathbb{L}')\}) \\
& = & \bigcap\{\Omega^{\mathbf{A}}(\alpha^{-1}(T'')) : T' \leq T'' \in \mathrm{ThFam}(\mathbb{L}')\}) \\
& = & \bigcap\{\Omega^{\mathbf{A}}(T) : \alpha^{-1}(T') \leq T \in \mathrm{ThFam}(\mathbb{L})\}) \\
& = & \widetilde{\Omega}(\mathbb{L}^{\alpha^{-1}(T')}).
\end{array}$$

∎

In particular, we obtain

Corollary 1364 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ *be two* $N^\flat$*-structures, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$*. If* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a bilogical morphism, then*

$$\alpha^{-1}(\widetilde{\Omega}(\mathbb{L}')) = \widetilde{\Omega}(\mathbb{L}).$$

Proof: By Proposition 1361, we have that $\alpha^{-1}(\mathrm{Thm}(\mathbb{L}')) = \mathrm{Thm}(\mathbb{L})$. So the result follows by applying Proposition 1363 with $T' = \mathrm{Thm}(\mathbb{L}')$. ∎

We close the section by proving that two important properties of $N^\flat$-structures are preserved under bilogical morphisms.

First, we show that finitarity is preserved across bilogical morphisms. Given a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, an $N^\flat$-algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ and an $N^\flat$-structure $\mathbb{L} = \langle \mathbf{A}, D \rangle$, we say that $\mathbb{L}$ is **finitary** if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\Phi) = \bigcup \{D_\Sigma(\Psi) : \Psi \subseteq_f \Phi\},$$

where $\subseteq_f$ denoted the finite subset relation.

Proposition 1365 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ $N^\flat$*-structures, based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism. Then* $\mathbb{L}$ *is finitary if and only if* $\mathbb{L}'$ *is finitary.*

Proof: Since $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, it is surjective and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Now we have $\mathbb{L}$ finitary iff, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \phi \in D_\Sigma(\Psi), \text{ some } \Psi \subseteq_f \Phi,$$

iff, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\alpha_\Sigma(\phi) \subseteq D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \quad \text{implies} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Psi)), \text{ some } \Psi \subseteq_f \Phi,$$

which, taking into account the surjectivity of $\langle F, \alpha \rangle$, is equivalent to $\mathbb{L}'$ being finitary. ∎

Finally, we show that structurality is also preserved by bilogical morphisms.

Proposition 1366 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ $N^\flat$*-structures, based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism. Then* D *is structural if and only if* D' *is structural.*

Proof: Suppose, first, that D is structural. We will use Proposition 1357. Consider $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $T' \in \mathcal{D}'_{F(\Sigma')}$. Then we have

$$\begin{array}{rcl}
D'_{F(\Sigma)}(\mathrm{SEN}'(F(f))^{-1}(T')) & = & \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\mathrm{SEN}'(F(f))^{-1}(T')))) \\
& & \text{(Proposition 1360)}
\end{array}$$

$$\begin{array}{ccc}
\mathrm{SEN}(\Sigma) & \xrightarrow{\alpha_\Sigma} & \mathrm{SEN}'(F(\Sigma)) \\
{\scriptstyle \mathrm{SEN}(f)}\downarrow & & \downarrow{\scriptstyle \mathrm{SEN}'(F(f))} \\
\mathrm{SEN}(\Sigma') & \xrightarrow[\alpha_{\Sigma'}]{} & \mathrm{SEN}'(F(\Sigma'))
\end{array}$$

$$\begin{array}{rl}
= & \alpha_\Sigma(D_\Sigma(\mathrm{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T')))) \\
& \text{(Commutativity of Rectangle)} \\
= & \alpha_\Sigma(\mathrm{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T'))) \\
& \text{(Propositions 1360 and 1357)} \\
= & \alpha_\Sigma(\alpha_{\Sigma'}^{-1}(\mathrm{SEN}'(F(f))^{-1}(T'))) \\
& \text{(Commutativity of Rectangle)} \\
= & \mathrm{SEN}'(F(f))^{-1}(T'). \\
& \text{(Surjectivity of } \langle F, \alpha\rangle)
\end{array}$$

By Proposition 1357 and taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that D' is structural.

Assume, conversely, that D' is structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $T \in \mathcal{D}_{\Sigma'}$. Then, there exists, by Proposition 1360, $T' \in \mathcal{D}'_{F(\Sigma')}$, such that $T = \alpha_{\Sigma'}^{-1}(T')$. So we have

$$\begin{array}{rcl}
D_\Sigma(\mathrm{SEN}(f)^{-1}(T)) & = & D_\Sigma(\mathrm{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T'))) \\
& = & D_\Sigma(\alpha_\Sigma^{-1}(\mathrm{SEN}'(F(f))^{-1}(T'))) \\
& & \text{(Commutativity of Rectangle)} \\
& = & \alpha_\Sigma^{-1}(\mathrm{SEN}'(F(f))^{-1}(T')) \\
& & \text{(Propositions 1357 and 1360)} \\
& = & \mathrm{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T')) \\
& & \text{(Commutativity of Rectangle)} \\
& = & \mathrm{SEN}(f)^{-1}(T).
\end{array}$$

We conclude, using Proposition 1357, that D is structural. ∎

19.2 Quotients and Morphisms

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system and $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an $N^\flat$-algebraic system. Given a congruence system $\theta \in \mathrm{ConSys}(\mathbf{A})$, we may define the quotient $\mathbf{A}^\theta := \mathbf{A}/\theta$ and the quotient morphism $\langle I, \pi^\theta\rangle : \mathbf{A} \to \mathbf{A}^\theta$. Moreover, given an $N^\flat$-structure $\mathbb{L} = \langle \mathbf{A}, D\rangle$, we define on the quotient $\mathbf{A}^\theta$ the closure family $D^\theta : \mathcal{P}\mathrm{SEN}^\theta \to \mathcal{P}\mathrm{SEN}^\theta$ by stipulating that its corresponding closure family $\mathcal{D}^\theta \subseteq \mathcal{P}\mathrm{SEN}^\theta$ is given by

$$\mathcal{D}^\theta := \{T \in \mathrm{SenFam}(\mathbf{A}^\theta) : (\pi^\theta)^{-1}(T) \in \mathcal{D}\}.$$

It is not difficult to see that $\mathcal{D}^\theta$ is indeed a closure family on $\mathbf{A}^\theta$. Indeed, for all $T^i \in \mathcal{D}^\theta$, $i \in I$, we have

$$(\pi^\theta)^{-1}(\bigcap_{i\in I} T^i) = \bigcap_{i\in I} (\pi^\theta)^{-1}(T^i) \in \mathcal{D},$$

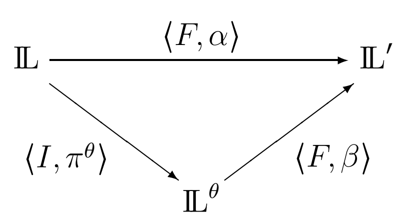
since $\mathcal{D}$ is, by hypothesis, a closure family on $\mathbf{A}$. The $N^\flat$-structure $\mathbb{L}^\theta = \langle \mathbf{A}^\theta, D^\theta\rangle$ is called the **quotient of** $\mathbb{L}$ **by** θ.

Consider, again, the quotient morphism $\langle I, \pi^\theta\rangle : \mathbf{A} \to \mathbf{A}^\theta$. It is not difficult to see either that $\langle I, \pi^\theta\rangle : \mathbb{L} \succ \mathbb{L}^\theta$ is a logical morphism. This simply follows from the definition of $\mathbb{L}^\theta$ and the characterization in Proposition 1358. This logical morphism is also termed the **quotient morphism** from $\mathbb{L}$ onto $\mathbb{L}^\theta$.

Suppose, now, that, in addition to being a congruence system on $\mathbf{A}$, θ is a logical congruence system of $\mathbb{L}$, $\theta \in \mathrm{ConSys}(\mathbb{L})$. An equivalent formalization is to say that $\theta \leq \widetilde{\Omega}(\mathbb{L})$. This hypothesis ensures that $\mathcal{D}^\theta = \pi^\theta(\mathcal{D})$ and that, moreover, $\mathrm{Ker}(\langle I, \pi^\theta\rangle) = \theta \in \mathrm{ConSys}(\mathbb{L})$. Therefore, by Part (v) of Proposition 1360, the quotient morphism $\langle I, \pi^\theta\rangle : \mathbb{L} \to \mathbb{L}^\theta$ becomes a bilogical morphism.

Having behind us this short introduction, we proceed to formulate and prove the Morphism Theorems, which correspond for $N^\flat$-structures to the Homomorphism, Second Isomorphism and Correspondence Theorems of Universal Algebra in forms reminiscent of the versions applicable in the context of abstract logics of abstract algebraic logic.

Theorem 1367 (Morphism Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *two* $N^\flat$*-algebraic systems, and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ *two* $N^\flat$*-structures. If* $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ *is a bilogical morphism, with* $\theta = \mathrm{Ker}(\langle F, \alpha\rangle)$*, then there exists an* α*-isomorphism* $\langle F, \beta\rangle : \mathbb{L}^\theta \vdash^\alpha \mathbb{L}'$*, that makes the following diagram commute*



Proof: Since $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we get that $\theta = \mathrm{Ker}(\langle F, \alpha\rangle)$ is a congruence system of $\mathbb{L}$. Thus, $\langle I, \pi^\theta\rangle : \mathbb{L} \vdash \mathbb{L}^\theta$ is also a bilogical morphism. Define $\langle F,\beta\rangle : \mathbf{A}^\theta \to \mathbf{A}'$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\beta_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\phi).$$

First, $\langle F,\beta\rangle$ is well-defined: This is straightforward, since, if $\langle\phi,\psi\rangle \in \theta_\Sigma = \mathrm{Ker}_\Sigma(\langle F,\alpha\rangle)$, then, by definition, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$.

Second, $\beta : \mathrm{SEN}^\theta \to \mathrm{SEN}' \circ F$ is natural: We have, for all $\Sigma,\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma,\Sigma')$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc}
\mathrm{SEN}^\theta(\Sigma) & \xrightarrow{\beta_\Sigma} & \mathrm{SEN}'(F(\Sigma)) \\
{\scriptstyle \mathrm{SEN}^\theta(f)}\downarrow & & \downarrow{\scriptstyle \mathrm{SEN}'(F(f))} \\
\mathrm{SEN}^\theta(\Sigma') & \xrightarrow[\beta_{\Sigma'}]{} & \mathrm{SEN}'(F(\Sigma'))
\end{array}$$

$$\begin{array}{lll}
\mathrm{SEN}'(F(f))(\beta_\Sigma(\phi/\theta_\Sigma)) & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) \\
& = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \\
& = & \beta_{\Sigma'}(\mathrm{SEN}(f)(\phi)/\theta_{\Sigma'}) \\
& = & \beta_{\Sigma'}(\mathrm{SEN}^\theta(f)(\phi/\theta_\Sigma)).
\end{array}$$

Third, $\langle F,\beta\rangle : \mathbf{A}^\theta \to \mathbf{A}'$ is surjective: This is also clear, based on the fact that $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$ is surjective.

Fourth, $\langle F,\beta\rangle : \mathbb{L}^\theta \vdash \mathbb{L}'$ is bilogical: Since surjectivity was pointed out above, we only have to show Part (iii) of Proposition 1360. First, note that $\mathrm{Ker}(\langle F,\beta\rangle) \in \mathrm{ConSys}(\mathbb{L}^\theta)$, since, for all $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, if $\langle\phi/\theta_\Sigma,\psi/\theta_\Sigma\rangle \in \mathrm{Ker}_\Sigma(\langle F,\beta\rangle)$, then $\beta_\Sigma(\phi/\theta_\Sigma) = \beta_\Sigma(\psi/\theta_\Sigma)$, whence $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Thus, since $\mathrm{Ker}(\langle F,\alpha\rangle) \in \mathrm{ConSys}(\mathbb{L})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$ and, hence, $D^\theta_\Sigma(\phi/\theta_\Sigma) = D^\theta_\Sigma(\psi/\theta_\Sigma)$. This proves that $\mathrm{Ker}(\langle F,\beta\rangle) \in \mathrm{ConSys}(\mathbb{L}^\theta)$. Finally, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll}
\beta_\Sigma(D^\theta_\Sigma(\Phi/\theta_\Sigma)) & = & \beta_\Sigma(D_\Sigma(\Phi)/\theta_\Sigma) \\
& = & \alpha_\Sigma(D_\Sigma(\Phi)) \\
& = & D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \\
& = & D'_{F(\Sigma)}(\beta_\Sigma(\Phi/\theta_\Sigma)).
\end{array}$$

This shows that both conditions in Part (iii) of Proposition 1360 are satisfied and, hence, $\langle F,\beta\rangle : \mathbb{L}^\theta \vdash \mathbb{L}'$ is a bilogical morphism.

Fifth, for all $\Sigma \in |\mathbf{Sign}|$ $\beta_\Sigma : \mathrm{SEN}^\theta(\Sigma) \to \mathrm{SEN}'(F(\Sigma))$ is injective. If $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\beta_\Sigma(\phi/\theta_\Sigma) = \beta_\Sigma(\psi/\theta_\Sigma)$, then $\alpha_\Sigma(\phi) = \beta_\Sigma(\phi)$, whence $\phi/\theta_\Sigma = \psi/\theta_\Sigma$. We now conclude that $\langle F,\beta\rangle : \mathbb{L}^\theta \vdash^\alpha \mathbb{L}'$ is an α-isomorphism.

Finally, the triangle commutes: This is clear, since, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\beta_\Sigma(\pi^\theta_\Sigma(\phi)) = \beta_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\phi)$. ■

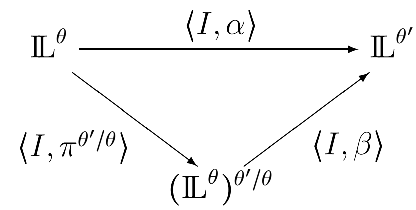
Theorem 1368 (Isomorphism Theorem) *Suppose* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *is a base algebraic system and* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *an* $N^\flat$*-algebraic system. If* $\mathbb{L} = \langle \mathbf{A}, D \rangle$ *is an* $N^\flat$*-structure and* $\theta, \theta' \in \mathrm{ConSys}(\mathbb{L})$*, such that* $\theta \leq \theta'$*, then* $\theta'/\theta \in \mathrm{ConSys}(\mathbb{L}^\theta)$ *and* $(\mathbb{L}^\theta)^{\theta'/\theta} \cong \mathbb{L}^{\theta'}$*.*

Proof: First, we show that $\theta'/\theta \in \mathrm{ConSys}(\mathbb{L}^\theta)$. To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \theta'_\Sigma/\theta_\Sigma$. Then $\langle \phi, \psi \rangle \in \theta'_\Sigma$, whence, since $\theta' \in \mathrm{ConSys}(\mathbb{L})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$. Hence, $D^\theta_\Sigma(\phi/\theta_\Sigma) = D^\theta_\Sigma(\psi/\theta_\Sigma)$. So $\theta'/\theta \in \mathrm{ConSys}(\mathbb{L}^\theta)$.

To finish the proof, we define $\langle I, \alpha \rangle : \mathbb{L}^\theta \vdash \mathbb{L}^{\theta'}$, by setting, for all $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$,

$$\alpha_\Sigma(\phi/\theta_\Sigma) = \phi/\theta'_\Sigma.$$

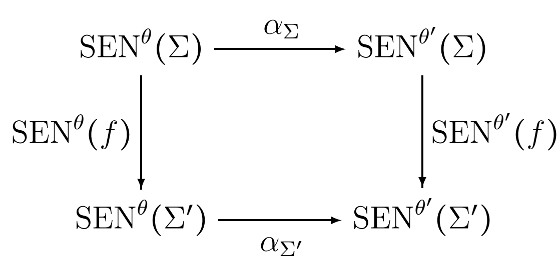
If we show that $\langle I, \alpha \rangle : \mathbb{L}^\theta \vdash \mathbb{L}^{\theta'}$ is a bilogical morphism, then, by noting that $\mathrm{Ker}(\langle I, \alpha \rangle) = \theta'/\theta$ and applying Theorem 1367,



we will have the sought after isomorphism $\langle I, \beta \rangle : (\mathbb{L}^\theta)^{\theta'/\theta} \cong \mathbb{L}^{\theta'}$.

First, $\langle I, \alpha \rangle : \mathrm{SEN}^\theta \to \mathrm{SEN}^{\theta'}$ is well-defined, since, for all $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, if $\langle \phi, \psi \rangle \in \theta_\Sigma$, then, by hypothesis, $\langle \phi, \psi \rangle \in \theta'_\Sigma$, showing that $\alpha_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\psi/\theta_\Sigma)$.

Second, $\alpha : \mathrm{SEN}^\theta \to \mathrm{SEN}^{\theta'}$ is natural, since, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}(\Sigma)$,



$$\begin{array}{rcl}
\mathrm{SEN}^{\theta'}(f)(\alpha_\Sigma(\phi/\theta_\Sigma)) & = & \mathrm{SEN}^{\theta'}(f)(\phi/\theta'_\Sigma) \\
 & = & \mathrm{SEN}(f)(\phi)/\theta'_{\Sigma'} \\
 & = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)/\theta_{\Sigma'}) \\
 & = & \alpha_{\Sigma'}(\mathrm{SEN}^\theta(\phi/\theta_\Sigma)).
\end{array}$$

Third, it is clear that $\langle I, \alpha \rangle : \mathbf{A}^\theta \to \mathbf{A}^{\theta'}$ is surjective. So it suffices now to show that the conditions in Part (iii) of Proposition 1360 are satisfied.

First, $\text{Ker}(\langle I,\alpha\rangle) = \theta'/\theta \in \text{ConSys}(\mathbb{L}^\theta)$, as was shown above. Finally, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$, we have

$$\begin{array}{rcl}\alpha_\Sigma(D^\theta_\Sigma(\Phi/\theta_\Sigma)) & = & \alpha_\Sigma(D_\Sigma(\Phi)/\theta_\Sigma)\\ & = & D_\Sigma(\Phi)/\theta'_\Sigma\\ & = & D^{\theta'}_\Sigma(\Phi/\theta'_\Sigma)\\ & = & D^{\theta'}_\Sigma(\alpha_\Sigma(\Phi/\theta_\Sigma)).\end{array}$$

Therefore, $\langle I,\alpha\rangle : \mathbb{L}^\theta \vdash \mathbb{L}^{\theta'}$ is indeed a bilogical morphism. ■

Theorem 1369 (Correspondence Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N\rangle$ *an* $N^\flat$*-algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *an* $N^\flat$*-structure and* $\theta \in \text{ConSys}(\mathbb{L})$. *Then* $\theta' \mapsto \theta'/\theta$ *defines an order isomorphism between the principal filter* $[\theta, \widetilde{\Omega}(\mathbb{L})]$ *in* $\mathbf{ConSys}(\mathbb{L})$ *and the complete lattice* $\mathbf{ConSys}(\mathbb{L}^\theta)$.

Proof: By Theorem 1368, the mapping $\theta' \mapsto \theta'/\theta$ is a well defined mapping from $[\theta, \widetilde{\Omega}(\mathbb{L})]$ into $\text{ConSys}(\mathbb{L}^\theta)$. The mapping is also one-to-one. To see this, assume $\theta'/\theta = \theta''/\theta$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \text{SEN}(\Sigma)$, such that $\langle \phi,\psi\rangle \in \theta'_\Sigma$. Then $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma\rangle \in \theta'_\Sigma/\theta_\Sigma = \theta''_\Sigma/\theta_\Sigma$ and, therefore, $\langle\phi,\psi\rangle \in \theta''_\Sigma$. Thus, $\theta' \leq \theta''$ and, hence, by symmetry, $\theta' = \theta''$. The mapping is also surjective. To prove surjectivity, Let $\eta \in \text{ConSys}(\mathbb{L}^\theta)$. Define $\theta' = \{\theta'_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\theta'_\Sigma = \{\langle\phi,\psi\rangle \in \text{SEN}(\Sigma)^2 : \langle \phi/\theta_\Sigma, \psi/\theta_\Sigma\rangle \in \eta_\Sigma\}.$$

It is easy to see that θ' is a congruence system on $\mathbf{A}$. It is also easy to see that $\theta \leq \theta'$. Furthermore, θ' is a congruence system of $\mathbb{L}$, since, if $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \text{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \theta'_\Sigma$, we get $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma\rangle \in \eta_\Sigma \in \text{ConSys}(\mathbb{L}^\theta)$, whence $D^\theta_\Sigma(\phi/\theta_\Sigma) = D^\theta_\Sigma(\psi/\theta_\Sigma)$, i.e., $D_\Sigma(\phi)/\theta_\Sigma = D_\Sigma(\psi)/\theta_\Sigma$ and, since $\theta \in \text{ConSys}(\mathbb{L})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$. Since $\theta' \mapsto \theta'/\theta = \eta$, it follows that the mapping is also surjective. Finally, it is obvious that both it and its inverse are monotone, which establishes that it is an order isomorphism. ■

The Correspondence Theorem implies immediately a relation between the quotient of a Tarski congruence system and the Tarski system of the corresponding quotient structure.

Corollary 1370 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N\rangle$ *an* $N^\flat$*-algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *an* $N^\flat$*-structure and* $\theta \in \text{ConSys}(\mathbb{L})$. *Then*

$$\widetilde{\Omega}(\mathbb{L}^\theta) = \widetilde{\Omega}(\mathbb{L})/\theta.$$

Proof: We take $\theta' = \widetilde{\Omega}(\mathbb{L})$ and apply the Correspondence Theorem 1369. ■

Corollary 1370 allows us also to conclude that the quotient of any $N^\flat$-structure by its Tarski congruence system has an identity Tarski congruence system. More precisely,

$$\widetilde{\Omega}(\mathbb{L}^{\widetilde{\Omega}(\mathbb{L})}) = \widetilde{\Omega}(\mathbb{L})/\widetilde{\Omega}(\mathbb{L}) = \Delta^{\mathbf{A}/\widetilde{\Omega}(\mathbb{L})}.$$

This leads to the definition of a reduced $N^\flat$-structure and of the reduction of an $N^\flat$-structure.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ an $N^\flat$-algebraic system and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ an $N^\flat$-structure. We call $\mathbb{L}$ **reduced** if $\widetilde{\Omega}(\mathbb{L}) = \Delta^{\mathbf{A}}$. More generally, we set $\mathbb{L}^* = \mathbb{L}^{\widetilde{\Omega}(\mathbb{L})}$ and call $\mathbb{L}^*$ the **reduction** of $\mathbb{L}$. Moreover, for a class L of $N^\flat$-structures, we set

$$\mathsf{L}^* = \{\mathbb{L}^* : \mathbb{L} \in \mathsf{L}\}.$$

By the comments following Corollary 1370, $\mathbb{L}^*$ is reduced for any $N^\flat$-structure $\mathbb{L}$. In case $\mathbb{L}$ is reduced to start with, then $\mathbb{L}^* \cong \mathbb{L}$ and, in this case, $\mathbb{L}^*$ will be identified with $\mathbb{L}$.

Another important consequence of the Correspondence Theorem is that reducing a quotient of a structure results in a reduced structure that is isomorphic (and, thus, can be identified) with the reduction of the originally given structure.

Proposition 1371 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ an $N^\flat$-algebraic system, $\mathbb{L} = \langle \mathbf{A}, D\rangle$ an $N^\flat$-structure and $\theta \in \mathrm{ConSys}(\mathbb{L})$. Then*

$$(\mathbb{L}^\theta)^* \cong \mathbb{L}^*.$$

Proof: We have

$$\begin{array}{rcl}(\mathbb{L}^\theta)^* & = & (\mathbb{L}^\theta)^{\widetilde{\Omega}(\mathbb{L}^\theta)} \quad \text{(Definition of Reduction)}\\ & = & (\mathbb{L}^\theta)^{\widetilde{\Omega}(\mathbb{L})/\theta} \quad \text{(Corollary 1370)}\\ & \cong & \mathbb{L}^{\widetilde{\Omega}(\mathbb{L})} \quad \text{(Theorem 1368)}\\ & = & \mathbb{L}^*. \quad \text{(Definition of Reduction)}\end{array}$$

■

Generalizing Proposition 1371, we can show that a similar relation holds between the reductions of two $N^\flat$-structures that are related via a bilogical morphism.

Proposition 1372 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ $N^\flat$-algebraic systems and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ and $\mathbb{L}' = \langle \mathbf{A}, D'\rangle$ $N^\flat$-structures, based on $\mathbf{A}$ and $\mathbf{A}'$, respectively. If there exists a bilogical morphism $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$, then there exists an α-isomorphism*

$$\mathbb{L}^* \vdash^\alpha \mathbb{L}'^*.$$

Proof: We define $\langle F, \beta\rangle : \mathbf{A}^* \to \mathbf{A}'^*$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\beta_\Sigma(\phi/\widetilde{\Omega}_\Sigma(\mathbb{L})) = \alpha_\Sigma(\phi)/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}'),$$

i.e., $\langle F, \beta\rangle$ is the morphism that makes the following rectangle commute

$$\begin{array}{ccc}
\mathbf{A} & \xrightarrow{\langle F,\alpha\rangle} & \mathbf{A}' \\
{\scriptstyle \langle I,\pi^{\widetilde{\Omega}(\mathbb{L})}\rangle}\downarrow & & \downarrow{\scriptstyle \langle I,\pi^{\widetilde{\Omega}(\mathbb{L}')}\rangle} \\
\mathbf{A}^* & \xrightarrow[\langle F,\beta\rangle]{} & \mathbf{A}'^*
\end{array}$$

First, $\langle I, \beta\rangle$ is well-defined: In fact, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi\rangle \in \widetilde{\Omega}_\Sigma(\mathbb{L})$, then, since, by Corollary 1364, $\Omega(\mathbb{L}) = \alpha^{-1}(\widetilde{\Omega}(\mathbb{L}'))$, we get that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')$.

Second $\beta : \mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})} \to \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')} \circ F$ is a natural transformation: Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \mathrm{SEN}(\Sigma)$. We have

$$\begin{array}{ccc}
\mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})}(\Sigma) & \xrightarrow{\beta_\Sigma} & \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(\Sigma)) \\
{\scriptstyle \mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})}(f)}\downarrow & & \downarrow{\scriptstyle \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(f))} \\
\mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})}(\Sigma') & \xrightarrow[\beta_{\Sigma'}]{} & \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(\Sigma'))
\end{array}$$

$$\begin{array}{l}
\mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(f))(\beta_\Sigma(\phi/\widetilde{\Omega}_\Sigma(\mathbb{L}))) \\
\quad = \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(f))(\alpha_\Sigma(\phi)/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')) \\
\quad = \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi))/\widetilde{\Omega}_{F(\Sigma')}(\mathbb{L}') \\
\quad = \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi))/\widetilde{\Omega}_{F(\Sigma')}(\mathbb{L}') \\
\quad = \beta_{\Sigma'}(\mathrm{SEN}(f)(\phi)/\widetilde{\Omega}_{\Sigma'}(\mathbb{L})) \\
\quad = \beta_{\Sigma'}(\mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})}(f)(\phi/\widetilde{\Omega}_\Sigma(\mathbb{L})).
\end{array}$$

Third, for every $\Sigma \in |\mathbf{Sign}|$, $\beta_\Sigma : \mathrm{SEN}^{\widetilde{\Omega}(\mathbb{L})}(\Sigma) \to \mathrm{SEN}'^{\widetilde{\Omega}(\mathbb{L}')}(F(\Sigma))$ is a bijection. Surjectivity is immediate and follows from the fat that both $\langle F, \alpha\rangle$ and $\langle I, \pi^{\widetilde{\Omega}(\mathbb{L}')}\rangle$ are surjective. For injectivity, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\beta_\Sigma(\phi/\widetilde{\Omega}_\Sigma(\mathbb{L})) = \beta_\Sigma(\psi/\widetilde{\Omega}_\Sigma(\mathbb{L}))$, then $\alpha_\Sigma(\phi)/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}') = \alpha_\Sigma(\psi)/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')$, whence

$$\langle \phi, \psi\rangle \in \alpha_\Sigma^{-1}(\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')) = \widetilde{\Omega}_\Sigma(\mathbb{L}).$$

This proves that β_Σ is indeed a bijection.

Finally, we use Part (iii) of Proposition 1360 to show that it is a bilogical morphism. Of course, since $\langle F, \beta\rangle$ has injective components, we get

$\mathrm{Ker}(\langle F,\beta\rangle) = \Delta^{\mathbf{A}^*}$ and, hence it is a congruence system of $\mathbb{L}^*$. Finally, if $\Sigma \in |\mathbf{Sign}|$ and $\Phi \subseteq \mathrm{SEN}(\Sigma)$, we have

$$\begin{array}{rcl}\beta_\Sigma(D^*_\Sigma(\Phi/\widetilde{\Omega}_\Sigma(\mathbb{L}))) & = & \beta_\Sigma(D_\Sigma(\Phi)/\widetilde{\Omega}_\Sigma(\mathbb{L}))\\ & = & \alpha_\Sigma(D_\Sigma(\Phi))/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')\\ & = & D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}')\\ & = & D'^*_{F(\Sigma)}(\alpha_\Sigma(\Phi)/\widetilde{\Omega}_{F(\Sigma)}(\mathbb{L}'))\\ & = & D'^*_{F(\Sigma)}(\beta_\Sigma(\Phi/\widetilde{\Omega}_\Sigma(\mathbb{L})).\end{array}$$

Thus, $\langle F,\beta\rangle : \mathbb{L}^* \vdash^\alpha \mathbb{L}'^*$ is an α-isomorphism, as claimed. ∎

In case $\mathbf{Sign}' = \mathbf{Sign}$ and $\langle I,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, with $I : \mathbf{Sign} \to \mathbf{Sign}$ the identity functor, then we obtain

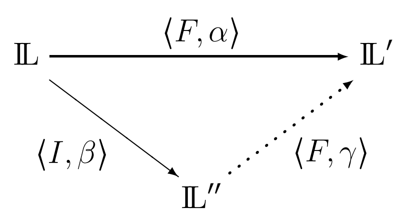
Corollary 1373 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle$ $N^\flat$*-algebraic systems and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *and* $\mathbb{L}' = \langle \mathbf{A}, D'\rangle$ $N^\flat$*-structures, based on* $\mathbf{A}$ *and* $\mathbf{A}'$*, respectively. If there exists a bilogical morphism* $\langle I,\alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$*, then*

$$\mathbb{L}^* \cong \mathbb{L}'^*.$$

Proof: Immediate by Proposition 1372. ∎

The next result is a "fill-in" lemma that provides sufficient conditions under which one can find a morphism that "fills-in" the third side of a commutative triangle, given arrows emanating from one of its vertices.

Proposition 1374 (Fill-In Lemma) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *and* $\mathbf{A}'' = \langle \mathbf{Sign}, \mathrm{SEN}'', N''\rangle$ $N^\flat$*-algebraic systems and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ *and* $\mathbb{L}'' = \langle \mathbf{A}'', D''\rangle$ $N^\flat$*-structures, based on* $\mathbf{A}$*,* $\mathbf{A}'$ *and* $\mathbf{A}''$*, respectively. Given a logical morphism* $\langle F,\alpha\rangle : \mathbb{L} \succ \mathbb{L}'$ *and a bilogical morphism* $\langle I,\beta\rangle : \mathbb{L} \vdash \mathbb{L}''$*, such that* $\ker(\langle I,\beta\rangle) \le \mathrm{Ker}(\langle F,\alpha\rangle)$*,*



there exists a unique logical morphism $\langle F,\gamma\rangle : \mathbb{L}'' \succ \mathbb{L}'$*, such that the triangle commutes. Moreover,* $\langle F,\gamma\rangle$ *is bilogical if and only if* $\langle F,\alpha\rangle$ *is bilogical.*

Proof: Define, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}''(\Sigma)$,

$$\gamma_\Sigma(\phi) = \alpha_\Sigma(\psi),$$

where $\psi \in \mathrm{SEN}(\Sigma)$, such that $\beta_\Sigma(\psi) = \phi$.

First, since, for all $\Sigma \in |\mathbf{Sign}|$, $\psi, \psi' \in \mathrm{SEN}(\Sigma)$, such that $\beta_\Sigma(\psi) = \beta_\Sigma(\psi')$, we have, by hypothesis, $\alpha_\Sigma(\psi) = \alpha_\Sigma(\psi')$, this definition is sound.

Second, $\gamma : \mathrm{SEN}'' \to \mathrm{SEN}' \circ F$ is a natural transformation: For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}''(\Sigma)$, such that $\phi = \beta_\Sigma(\psi)$, for some $\psi \in \mathrm{SEN}(\Sigma)$, we have

$$\begin{array}{ccc}
\mathrm{SEN}''(\Sigma) & \xrightarrow{\gamma_\Sigma} & \mathrm{SEN}'(F(\Sigma)) \\
{\scriptstyle \mathrm{SEN}''(f)} \downarrow & & \downarrow {\scriptstyle \mathrm{SEN}'(F(f))} \\
\mathrm{SEN}''(\Sigma') & \xrightarrow[\gamma_{\Sigma'}]{} & \mathrm{SEN}'(F(\Sigma'))
\end{array}$$

$$\begin{array}{rcl}
\mathrm{SEN}'(F(f))(\gamma_\Sigma(\phi)) & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi)) \\
& = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\psi)) \\
& = & \gamma_{\Sigma'}(\mathrm{SEN}''(f)(\phi)),
\end{array}$$

where the last equality follows from

$$\beta_{\Sigma'}(\mathrm{SEN}(f)(\psi)) = \mathrm{SEN}''(f)(\beta_\Sigma(\psi)) = \mathrm{SEN}''(f)(\phi)$$

and the definition of $\gamma_{\Sigma'}$.

Now it is clear that the triangle of the diagram commutes. Moreover, for all $T' \in \mathrm{ThFam}(\mathbb{L}')$, since $\langle F, \alpha \rangle$ is a logical morphism, $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathbb{L})$ and, hence, by commutativity, $\beta^{-1}(\gamma^{-1}(T')) \in \mathrm{ThFam}(\mathbb{L})$. Hence, since $\langle I, \beta \rangle$ is a bilogical morphism, $\gamma^{-1}(T') \in \mathrm{ThFam}(\mathbb{L}'')$. This proves that $\langle F, \gamma \rangle$ is also a logical morphism.

Finally, for the last statement, note that $\langle F, \gamma \rangle$ is surjective if and only if $\langle F, \alpha \rangle$ is surjective, and, furthermore, $\mathrm{ThFam}(\mathbb{L}'') = \gamma^{-1}(\mathrm{ThFam}(\mathbb{L}'))$ if and only if $\beta^{-1}(\mathrm{ThFam}(\mathbb{L}'')) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$ if and only if $\mathrm{ThFam}(\mathbb{L}) = \alpha^{-1}(\mathrm{ThFam}(\mathbb{L}'))$. We conclude, taking into account Part (vi) of Proposition 1360, that $\langle F, \gamma \rangle$ is bilogical if and only if $\langle F, \alpha \rangle$ is. ∎

19.3 Filter Families and π-Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ an $\mathbf{F}$-algebraic system. We have seen that the collection $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ of $\mathcal{I}$-filter families on $\mathcal{A}$ forms a complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) = \langle \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ under signature-wise inclusion. Therefore, the pair $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ constitutes an $\mathbf{F}$-structure. This $\mathbf{F}$-structure will also be denoted interchangeably by $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ or $\langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}} \rangle$, with reference to the closure (operator) family or the closed set family corresponding to $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Such pairs will play an important role in this chapter, since they will be used as models of $\mathcal{I}$ that provide a semantics for the logical system formalized by $\mathcal{I}$.

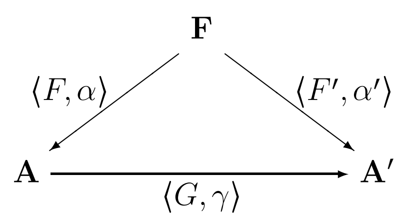
It is clear that the closure families of $\mathbf{F}$-structures of this form are structural and, hence, $\mathbf{F}$-structures of this form are actually π-institutions.

Proposition 1375 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system. Then* $C^{\mathcal{I},\mathcal{A}} : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ *is a structural closure operator on* SEN*.*

Proof: We use Proposition 1357. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $T \in \mathcal{C}^{\mathcal{I},\mathcal{A}}_{F(\Sigma')}$. Then, by Lemma 51, $\alpha^{-1}_{\Sigma'}(T) \in \mathcal{C}_{\Sigma'}$. Since C is structural, by Proposition 1357, $\mathrm{SEN}(f)^{-1}(\alpha^{-1}_{\Sigma'}(T)) \in \mathcal{C}_\Sigma$. By the naturality of $\alpha : \mathrm{SEN}^\flat \to \mathrm{SEN} \circ F$, we get $\alpha^{-1}_\Sigma(\mathrm{SEN}(F(f))^{-1}(T)) \in \mathcal{C}_\Sigma$, whence, again by Lemma 51, $\mathrm{SEN}(F(f))^{-1}(T) \in \mathcal{C}^{\mathcal{I},\mathcal{A}}_\Sigma$. Using the surjectivity of $\langle F, \alpha \rangle$ and Proposition 1357, we conclude that $C^{\mathcal{I},\mathcal{A}}$ is structural. ∎

Our next result characterizes bilogical morphisms between $\mathbf{F}$-structures of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

Proposition 1376 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $\mathbf{F}$*-algebraic systems, such that, there exists a surjective* $\langle G, \gamma \rangle : \mathbf{A} \to \mathbf{A}'$*, such that*



$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$*. Then the following statements are equivalent:*

(i) $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}} \rangle \vdash \langle \mathcal{A}', \mathcal{C}^{\mathcal{I},\mathcal{A}'} \rangle$ *is a bilogical morphism;*

(ii) For every $\Sigma \in |\mathbf{Sign}|$*,* $\gamma_\Sigma : \mathcal{C}^{\mathcal{I},\mathcal{A}}_\Sigma \to \mathcal{C}^{\mathcal{I},\mathcal{A}'}_{G(\Sigma)}$ *is an order isomorphism;*

(iii) For every $\Sigma \in |\mathbf{Sign}|$*, and all* $T \in \mathcal{C}^{\mathcal{I},\mathcal{A}}_\Sigma$*,* $\gamma_\Sigma(T) \in \mathcal{C}^{\mathcal{I},\mathcal{A}'}_{G(\Sigma)}$ *and, in addition, we have* $\mathrm{Ker}(\langle G, \gamma \rangle) \in \mathrm{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}} \rangle)$*.*

Proof:

(i)⇒(ii) This is a special case of Proposition 1361.

(ii)⇒(iii) The first assertion is obvious. For the second, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$, then, for every $T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}')$,

$$\gamma_\Sigma(\phi) \in T'_{G(\Sigma)} \quad \text{iff} \quad \gamma_\Sigma(\psi) \in T'_{G(\Sigma)}.$$

Hence, for every $T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}')$,

$$\phi \in \gamma_\Sigma^{-1}(T'_{G(\Sigma)}) \quad \text{iff} \quad \phi \in \gamma_\Sigma^{-1}(T'_{G(\Sigma)}).$$

Therefore, by hypothesis, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

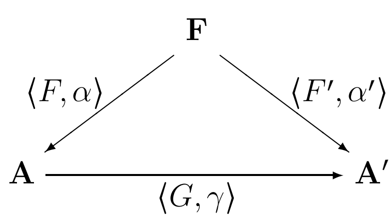
$$\phi \in T_\Sigma \quad \text{iff} \quad \psi \in T_\Sigma.$$

It now follows that $\mathrm{Ker}(\langle I, \gamma\rangle) \in \mathrm{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}}\rangle)$.

(iii)⇒(i) By hypothesis, we get $\gamma(\mathcal{C}_\Sigma^{\mathcal{I},\mathcal{A}}) \subseteq \mathcal{C}_{G(\Sigma)}^{\mathcal{I},\mathcal{A}'}$ and also that $\mathrm{Ker}(\langle I, \gamma\rangle) \in \mathrm{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}}\rangle)$. Therefore, by Part (v) of Proposition 1360, it suffices to show that $\mathcal{C}_{G(\Sigma)}^{\mathcal{I},\mathcal{A}'} \subseteq \gamma(\mathcal{C}_\Sigma^{\mathcal{I},\mathcal{A}})$. But this follows from the fact that, if $T' \in \mathcal{C}_{G(\Sigma)}^{\mathcal{I},\mathcal{A}'}$, then by Corollary 55, $\gamma_\Sigma^{-1}(T') \in \mathcal{C}_\Sigma^{\mathcal{I},\mathcal{A}}$ and, then, by surjectivity, $T' = \gamma_\Sigma(\gamma_\Sigma^{-1}(T'))$. ■

We also have the following related result that, roughly speaking, forces the closure family of a structure that is the bilogical morphism image of a structure whose closure family consists of all filter families to also consist of the entirely of filter families.

Proposition 1377 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$ *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ $\mathbf{F}$*-algebraic systems, such that, there exists a surjective* $\langle G, \gamma\rangle : \mathbf{A} \to \mathbf{A}'$*, such that*



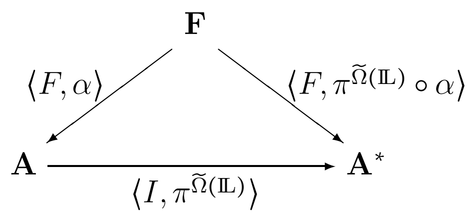
$\langle G, \gamma\rangle \circ \langle F, \alpha\rangle = \langle F', \alpha'\rangle$*. If* $\langle G, \gamma\rangle : \langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}}\rangle \vdash \langle \mathcal{A}', \mathcal{C}'\rangle$ *is a bilogical morphism, then* $\mathcal{C}' = \mathcal{C}^{\mathcal{I},\mathcal{A}'}$*.*

Proof: First, since $\langle G, \gamma\rangle$ is a bilogical morphism, for all $T' \in \mathcal{C}'$, we have $\gamma^{-1}(T') \in \mathcal{C}^{\mathcal{I},\mathcal{A}}$. Thus, by Corollary 55, $T' \in \mathcal{C}^{\mathcal{I},\mathcal{A}'}$. This proves that $\mathcal{C}' \subseteq \mathcal{C}^{\mathcal{I},\mathcal{A}'}$. Suppose, conversely, that $T' \in \mathcal{C}^{\mathcal{I},\mathcal{A}'}$. Then, again by Corollary 55, $\gamma^{-1}(T') \in \mathcal{C}^{\mathcal{I},\mathcal{A}}$. Therefore, since $\langle G, \gamma\rangle$ is a bilogical morphism, $T' = \gamma(\gamma^{-1}(T')) \in \mathcal{C}'$. We conclude that $\mathcal{C}' = \mathcal{C}^{\mathcal{I},\mathcal{A}'}$. ■

This result has the following immediate corollaries, one addressing reductions and the other isomorphisms.

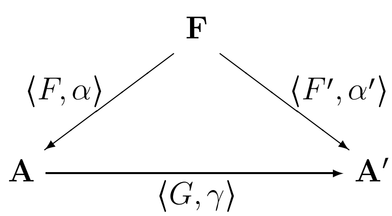
Corollary 1378 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system. Then* $(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$*.*

Proof: Let $\mathbb{L} = \langle \mathcal{A}, \mathcal{C}^{\mathcal{I},\mathcal{A}} \rangle$ and apply Proposition 1377 to the special configuration of morphisms depicted in the diagram:



■

Corollary 1379 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $\mathbf{F}$*-algebraic systems, such that, there exists an isomorphism* $\langle G, \gamma \rangle : \mathbf{A} \cong \mathbf{A}'$*, such that*

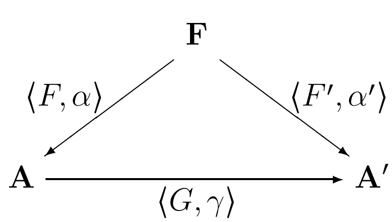


$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$*. If* $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{D} \rangle \vdash \langle \mathcal{A}', \mathcal{D}' \rangle$ *is a bilogical morphism, then* $\mathcal{D} = \mathcal{C}^{\mathcal{I},\mathcal{A}}$ *if and only if* $\mathcal{D}' = \mathcal{C}^{\mathcal{I},\mathcal{A}'}$*.*

Proof: We apply Proposition 1377 twice; once using $\langle G, \gamma \rangle : \mathcal{A} \to \mathcal{A}'$ and once using $\langle G, \gamma \rangle^{-1} : \mathcal{A}' \to \mathcal{A}$. ■

Corollary 1379 can be strengthened slightly but, to accomplish this, we need the following proposition, which is a sort of symmetric to Proposition 1377.

Proposition 1380 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems.*



If $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{D} \rangle \vdash^\alpha \langle \mathcal{A}', C^{\mathcal{I},\mathcal{A}'} \rangle$ *is an* α*-isomorphism, then* $\mathcal{D} = \mathcal{C}^{\mathcal{I},\mathcal{A}}$*.*

Proof: We show, first, that $\mathcal{D} \subseteq \mathcal{C}^{\mathcal{I},\mathcal{A}}$. Suppose $T \in \mathcal{D}$. Then, since $\langle G, \gamma\rangle$ is an α-isomorphism, there exists, by Proposition 1360, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$, such that $T = \gamma^{-1}(T')$. Now, by Corollary 55, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence, $\mathcal{D} \subseteq \mathcal{C}^{\mathcal{I},\mathcal{A}}$.

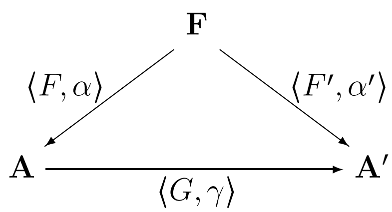
Suppose, conversely, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\langle G, \gamma\rangle$ is an α-isomorphism, there exists a unique $T' \in \mathrm{SenFam}(\mathcal{A}')$, such that $T = \gamma^{-1}(T')$. Thus, we have

$$\alpha'^{-1}(T') = \alpha^{-1}(\gamma^{-1}(T')) = \alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I}).$$

Hence, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$ and, since $\langle G, \gamma\rangle$ is a bilogical morphism, $T = \gamma^{-1}(T') \in \mathcal{D}$. We conclude that $\mathcal{C}^{\mathcal{I},\mathcal{A}} \subseteq \mathcal{D}$ and equality follows. ■

A generalization of Corollary 1379 relaxes the requirement that there exists an isomorphism between **F**-algebraic systems to the requirement that there exists an α-isomorphism.

Corollary 1381 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$ *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ **F***-algebraic systems, such that, there exists a surjective morphism* $\langle G, \gamma\rangle : \mathbf{A} \cong \mathbf{A}'$*, such that*



$\langle G, \gamma\rangle \circ \langle F, \alpha\rangle = \langle F', \alpha'\rangle$. *If* $\langle G, \gamma\rangle : \langle \mathcal{A}, \mathcal{D}\rangle \vdash^\alpha \langle \mathcal{A}', \mathcal{D}'\rangle$ *is an* α*-isomorphism, then* $\mathcal{D} = \mathcal{C}^{\mathcal{I},\mathcal{A}}$ *if and only if* $\mathcal{D}' = \mathcal{C}^{\mathcal{I},\mathcal{A}'}$.

Proof: We put together Proposition 1377 and Proposition 1380. ■

19.4 $\mathcal{I}$-Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, an **F**-algebraic system and $\mathbb{L} = \langle \mathcal{A}, D\rangle$ an **F**-structure. Define $C^{\mathbb{L}} = \{C^{\mathbb{L}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$C^{\mathbb{L}}_\Sigma : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$$

be defined, for all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in C^{\mathbb{L}}_\Sigma(\Phi) & \text{iff} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'),\\ & & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \subseteq D_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))).\end{array}$$

More generally, given a class L of **F**-structures, we set

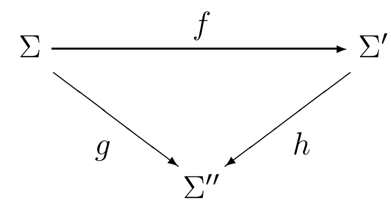
$$C^{\mathsf{L}} = \bigcap\{C^{\mathbb{L}} : \mathbb{L} \in \mathsf{L}\}.$$

We show that C^{L} is a closure system on **F** and, as a result, $\mathcal{I}^{\mathsf{L}} = \langle \mathbf{F}, C^{\mathsf{L}}\rangle$ qualifies as a π-institution.

Proposition 1382 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* L *a class of* $\mathbf{F}$*-structures. The collection* $C^{\mathsf{L}} : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$ *is a closure system on* $\mathbf{F}$*.*

Proof: Inflationarity, monotonicity and idempotency of C^{L} follow immediately from the corresponding properties of each of the operators of the $\mathbf{F}$-structures in L. We show structurality in more detail. Suppose $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathsf{L}}_\Sigma(\Phi)$. Then, for all $\langle \mathcal{A}, D \rangle \in \mathsf{L}$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma, \Sigma'')$,

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\phi)) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\Phi))).$$



Thus, for all $\langle \mathcal{A}, D \rangle \in \mathsf{L}$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $h \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$,

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(h)(\mathrm{SEN}^\flat(f)(\phi))) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(h)(\mathrm{SEN}^\flat(f)(\Phi)))).$$

This proves that $\mathrm{SEN}^\flat(f)(\phi) \in C^{\mathsf{L}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$, and, hence, that C^{L} is structural. ■

C^{L} is termed the **closure system on F generated by** L and we denote by $\mathcal{I}^{\mathsf{L}} = \langle \mathbf{F}, C^{\mathsf{L}} \rangle$ the π-institution corresponding to C^{L}.

Next, it is shown that $\mathbf{F}$-structures related by bilogical morphism generate identical closure systems.

Proposition 1383 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems,* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *two* $\mathbf{F}$*-structures and* $\langle G, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism, such that* $\langle F', \alpha' \rangle = \langle G, \gamma \rangle \circ \langle F, \alpha \rangle$*. Then* $C^{\mathbb{L}} = C^{\mathbb{L}'}$*.*

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

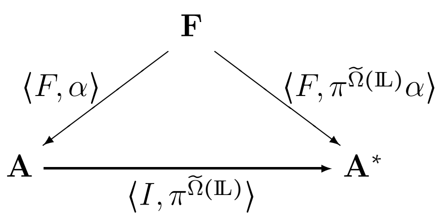
$$\begin{array}{lll}
\phi \in C^{\mathbb{L}}_\Sigma(\Phi) & \text{iff} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma') \\
& & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \subseteq D_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))) \\
& \text{iff} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma') \\
& & \gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))) \\
& & \qquad \subseteq D'_{G(F(\Sigma'))}(\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)))) \\
& \text{iff} & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma') \\
& & \alpha'_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \subseteq D'_{F'(\Sigma')}(\alpha'_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))) \\
& \text{iff} & \phi \in C^{\mathbb{L}'}_\Sigma(\Phi).
\end{array}$$

We conclude that $C^{\mathbb{L}} = C^{\mathbb{L}'}$. ■

As a special case of Proposition 1383, we get that both an $\mathbf{F}$-structure and its reduction generate the same closure system on the base algebraic system $\mathbf{F}$.

Corollary 1384 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *an* $\mathbf{F}$*-structure. Then* $C^{\mathbb{L}} = C^{\mathbb{L}^*}$*.*

Proof: This is obtained directly by Proposition 1383 once we recall that, since $\widetilde{\Omega}(\mathbb{L})$ is a congruence system of $\mathbb{L}$, $\langle I, \pi^{\widetilde{\Omega}(\mathbb{L})} \rangle : \mathbb{L} \to \mathbb{L}^*$ is a bilogical morphism.



And this gives the configuration of the diagram that matches the setup in the hypothesis of Proposition 1383. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, an $\mathbf{F}$-algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$-structure. We say that $\mathbb{L}$ is an $\mathcal{I}$-**structure** or a **model of** $\mathcal{I}$ if $C \leq C^{\mathbb{L}}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{implies} \quad \phi \in C^{\mathbb{L}}_\Sigma(\Phi).$$

Of course, $C \leq C^{\mathbb{L}}$ requires that, for all $T \in \mathrm{ThFam}(\mathbb{L})$, all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')},$$

i.e., that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, we obtain the following characterization:

Proposition 1385 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *an* $\mathbf{F}$*-structure.* $\mathbb{L}$ *is an* $\mathcal{I}$*-structure if and only if, for all* $T \in \mathrm{ThFam}(\mathbb{L})$*,* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, i.e., if and only if* $\mathrm{ThFam}(\mathbb{L}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Again, the defining condition of an $\mathcal{I}$-structure may be simplified due to the structurality of $\mathcal{I}$. More precisely, based on Lemma 50, we have:

Lemma 1386 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *an* $\mathbf{F}$*-structure. Then, the following conditions are equivalent:*

(a) $\mathbb{L}$ *is an* $\mathcal{I}$*-structure;*

(b) For all $T \in \mathrm{ThFam}(\mathbb{L})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$*, such that* $\phi \in C_\Sigma(\Phi)$*,*

$$\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)} \quad \textit{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)};$$

(c) For all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$*,* $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$*.*

Proof: Condition (a) clearly implies (b) and (b) and (c) are equivalent. So it remains to show that (b) implies (a). But, if Condition (*b*) holds, then, by Lemma 50, $\mathrm{ThFam}(\mathbb{L}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, whence, by Proposition 1385, $\mathbb{L}$ is an $\mathcal{I}$-structure. ■

We denote by $\mathrm{Str}(\mathcal{I})$ the class of all $\mathcal{I}$-structures and let

$$\mathrm{Str}^*(\mathcal{I}) = (\mathrm{Str}(\mathcal{I}))^*$$

be the class of all reduced $\mathcal{I}$-structures.

Since we know that $\mathbb{L} \in \mathrm{Str}(\mathcal{I})$ is and only if $\mathrm{ThFam}(\mathbb{L}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, it follows that, given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is the weakest $\mathcal{I}$-structure of $\mathcal{A}$, i.e., the one with the finest closure family.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **complete with respect to a given class** L of $\mathbf{F}$-structures if $C = C^{\mathsf{L}}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \phi \in C^{\mathsf{L}}_\Sigma(\Phi).$$

As consequences of Proposition 1383 and of its Corollary 1384, we have the following results about models of π-institutions and about classes of structures with respect to which a π-institution is complete.

Proposition 1387 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\langle \mathcal{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *are* $\mathbf{F}$*-structures and* $\langle G, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism, the* $\mathbb{L}$ *is an* $\mathcal{I}$*-structure if and only if* $\mathbb{L}'$ *is an* $\mathcal{I}$*-structure.*

(b) If $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *is an* $\mathbf{F}$*-structure, then* $\mathbb{L}$ *is an* $\mathcal{I}$*-structure if and only if* $\mathbb{L}^*$ *is an* $\mathcal{I}$*-structure.*

(c) If $\mathcal{I}$ *is complete with respect to a class* L *of* $\mathbf{F}$*-structures, then it is also complete with respect to* L^**.*

Proof: the first part is a consequence of Proposition 1383, whereas Parts (b) and (c) follow directly from Corollary 1384. ■

Proposition 1388 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* L *a class of* $\mathcal{I}$*-structures. If* L *includes* $\langle \mathcal{F}, C \rangle$ *or* $\langle \mathcal{F}, C \rangle^*$*, then* $\mathcal{I}$ *is complete with respect to both* L *and* L^**. In particular* $\mathcal{I}$ *is complete with respect to both* $\mathrm{Str}(\mathcal{I})$ *and* $\mathrm{Str}^*(\mathcal{I})$*.*

Proof: The key here is to notice that $C = C^{\langle \mathcal{F}, C \rangle} = C^{\langle \mathcal{F}, C \rangle^*}$. Then, the rest is easy because we have

$$C \le C^{\mathsf{L}} = C^{\mathsf{L}^*} \le C^{\langle \mathcal{F}, C \rangle} = C^{\langle \mathcal{F}, C \rangle^*} = C.$$

Therefore, we conclude $C = C^{\mathsf{L}} = C^{\mathsf{L}^*}$ and, hence, $\mathcal{I}$ is complete with respect to both L and L^*. ■

19.5 Full $\mathcal{I}$-Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$-structure. $\mathbb{L}$ is a **full $\mathcal{I}$-structure** or a **full model of $\mathcal{I}$** if

$$\mathbb{L}^* = \langle \mathcal{A}^*, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle,$$

i.e., if the closure family of the reduction of $\mathbb{L}$ consists of all $\mathcal{I}$-filter families on the $\mathbf{F}$-algebraic system $\mathcal{A}/\widetilde{\Omega}(\mathbb{L})$.

We denote the class of all full $\mathcal{I}$-structures by $\mathrm{FStr}(\mathcal{I})$ and the class of all reduced full $\mathcal{I}$-structures by $\mathrm{FStr}^*(\mathcal{I})$. We also write $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ for the collection of all full $\mathcal{I}$-structures on the $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$.

We show that full $\mathcal{I}$-structures are fully deserving of the name $\mathcal{I}$-structures.

Proposition 1389 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *a full* $\mathcal{I}$*-structure.*

(a) D *is structural;*

(b) $\mathbb{L}$ *is an* $\mathcal{I}$*-structure;*

(c) $\mathbb{L}$ *has theorems if and only if* $\mathcal{I}$ *has theorems.*

Proof:

(a) By Proposition 1375, D^* is structural. Therefore, by Proposition 1366, D is also structural.

(b) Suppose $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$. Then, by definition, $\mathrm{ThFam}(\mathbb{L}^*) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, by Proposition 1385, $\mathbb{L}^* \in \mathrm{Str}(\mathcal{I})$. Therefore, by Proposition 1387, $\mathbb{L} \in \mathrm{Str}(\mathcal{I})$.

(c) If $\mathcal{I}$ does not have theorems, then $\varnothing \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Therefore, by the definition of a full $\mathcal{I}$-structure, $\varnothing \in \mathrm{ThFam}(\mathbb{L}^*)$ and, hence $\varnothing \in \mathrm{ThFam}(\mathbb{L})$. Conversely, if $\varnothing \notin \mathrm{ThFam}(\mathcal{I})$, then $\varnothing \notin \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, hence, $\varnothing \notin \mathrm{ThFam}(\mathbb{L})$.

■

We now show that, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the pair $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is always a full $\mathcal{I}$-structure and, thus, the weakest such structure on $\mathcal{A}$.

Proposition 1390 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ *is the weakest full* $\mathcal{I}$*-structure on* $\mathcal{A}$.

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system. Then, by Corollary 1378,

$$(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*).$$

So $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a full $\mathcal{I}$-structure. Moreover, since, by Proposition 1389, every full $\mathcal{I}$-structure is an $\mathcal{I}$-structure, by Proposition 1385, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is the largest possible set of theory families of a full $\mathcal{I}$-structure. So $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is the weakest full $\mathcal{I}$-structure. ■

Specializing to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism, we get

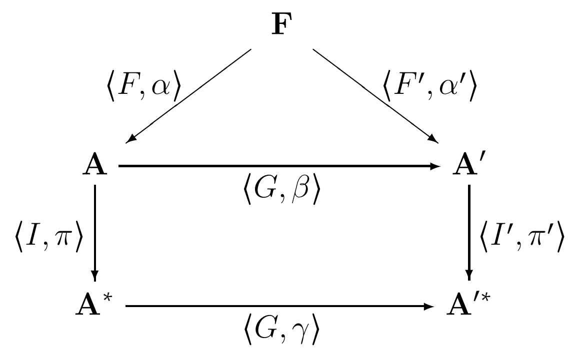
Corollary 1391 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. *Then* $\langle \mathcal{F}, C \rangle$ *is the weakest full* $\mathcal{I}$*-structure on* $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$.

Proof: By taking $\mathcal{A} = \mathcal{F}$ in Proposition 1390. ■

Next, we see that bilogical morphisms between **F**-structures preserve the property of being a full model in both directions.

Proposition 1392 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *two* $\mathbf{F}$*-structures. If there exists a bilogical morphism* $\langle G, \beta \rangle : \mathbb{L} \vdash \mathbb{L}'$, *then* $\mathbb{L}$ *is a full* $\mathcal{I}$*-structure if and only if* $\mathbb{L}'$ *is a full* $\mathcal{I}$*-structure.*

Proof: Suppose $\mathbb{L} = \langle \mathcal{A}, D\rangle$ and $\mathbb{L}' = \langle \mathcal{A}', D'\rangle$ are two $\mathbf{F}$-structures and let $\langle G, \beta\rangle : \mathbb{L} \vdash \mathbb{L}'$ be a bilogical morphism. Then, by Proposition 1372, there exists an α-isomorphism $\langle G, \gamma\rangle : \mathbb{L}^* \vdash^\alpha \mathbb{L}'^*$, such that the following diagram commutes.



where $\langle I, \pi\rangle : \mathbf{A} \to \mathbf{A}/\widetilde{\Omega}(\mathbb{L})$ and $\langle I', \pi'\rangle : \mathbf{A}' \to \mathbf{A}'/\widetilde{\Omega}(\mathbb{L}')$ denote the quotient morphisms. If $\mathbb{L}$ is a full $\mathcal{I}$-structure, then, by definition, $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, by Proposition 1377, $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}'^*)$. This shows that $\mathbb{L}'$ is a full $\mathcal{I}$-structure. If, conversely, $\mathbb{L}'$ is a full $\mathcal{I}$-structure, then, by definition $\mathcal{D}'^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}'^*)$. Thus, by Proposition 1380, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and, therefore, $\mathbb{L}$ is a full $\mathcal{I}$-structure, by definition. ■

Proposition 1392 allows the formulation of a characterizing property of full $\mathcal{I}$-structures in terms of bilogical morphisms and weakest full $\mathcal{I}$-structures.

Corollary 1393 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and $\mathbb{L} = \langle \mathcal{A}, D\rangle$ an $\mathbf{F}$-structure. $\mathbb{L}$ is a full $\mathcal{I}$-structure if and only if there exists a bilogical morphism from $\mathbb{L}$ onto an $\mathbf{F}$-structure of the form $\langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')\rangle$, for some $\mathbf{F}$-algebraic system $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$.*

Proof: The "only if" is clear, since, if $\mathbb{L} = \langle \mathcal{A}, D\rangle$ is a full $\mathcal{I}$-structure, then $\langle I, \pi\rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a bilogical morphism and, moreover, by the definition of fullness, $\mathbb{L}^* = \langle \mathcal{A}^*, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)\rangle$.

Assume, conversely, that $\langle H, \gamma\rangle : \mathbb{L} \vdash \langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')\rangle$ is a bilogical morphism. By Proposition 1390, $\langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')\rangle \in \mathrm{FStr}(\mathcal{I})$. Therefore, by Proposition 1392, $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$, as well. ■

We now formulate a result that can be used to show that a property of $\mathbf{F}$-structures for every full $\mathcal{I}$-structure of a π-institution $\mathcal{I}$ based on $\mathbf{F}$. It characterizes $\mathrm{FStr}(\mathcal{I})$ as the smallest class of $\mathbf{F}$-structures containing all $\mathbf{F}$-structures of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$, with $\mathcal{A}$ ranging over all $\mathbf{F}$-algebraic systems, and closed under bilogical morphisms. It follows that to prove that a property holds for all members of $\mathrm{FStr}(\mathcal{I})$ it suffices to show that it holds for all $\mathbf{F}$-structures of the specific form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ and that it is preserved under bilogical morphisms.

Corollary 1394 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. $\mathrm{FStr}(\mathcal{I})$ *is the smallest class containing* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and closed under both images and preimages under bilogical morphisms.*

Proof: By Proposition 1390, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the pair $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \in \mathrm{FStr}(\mathcal{I})$. Moreover, by Proposition 1392, $\mathrm{FStr}(\mathcal{I})$ is closed under both images and preimages under bilogical morphisms. On the other hand, let L be a class satisfying these properties and let $\langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. By Corollary 1393, there exists an $\mathbf{F}$-algebraic system $\mathcal{A}'$ and a bilogical morphism

$$\langle H, \gamma \rangle : \langle \mathcal{A}, D \rangle \vdash \langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle.$$

By hypothesis, $\langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle \in \mathsf{L}$ and, again by hypothesis, $\langle \mathcal{A}, D \rangle \in \mathsf{L}$. Thus, we conclude that $\mathrm{FStr}(\mathcal{I}) \subseteq \mathsf{L}$. This proves that $\mathrm{FStr}(\mathcal{I})$ is indeed the smallest class satisfying the given properties. ∎

An alternative characterization of full $\mathcal{I}$-structures uses both the Leibniz and the Tarski operators.

Theorem 1395 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *an* $\mathbf{F}$*-structure. Then* $\mathbb{L}$ *is a full* $\mathcal{I}$*-structure if and only if*

$$\mathcal{D} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}.$$

Proof: Let $\mathbb{L}$ be an $\mathbf{F}$-structure and set

$$\mathcal{T} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}.$$

Suppose, first, that $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. We must show $\mathcal{D} = \mathcal{T}$. To this end, let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Proposition 1385, $T \in \mathrm{FIFam}^{\mathcal{I}}(\mathcal{A})$ and, by the definition of the Tarski congruence system, $\widetilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)$. Thus, $\mathcal{D} \subseteq \mathcal{T}$. Conversely, if $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)$, then $\widetilde{\Omega}(\mathbb{L})$ is compatible with T. Setting $T' = T/\widetilde{\Omega}(\mathbb{L})$, we have, by Corollary 56, that $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}(\mathbb{L}))$ and $T = \pi^{-1}(T')$, where $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}(\mathbb{L})$ is the quotient morphism, which is also a bilogical morphism $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$. Since, by hypothesis $\mathbb{L}$ is full, we get that $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}(\mathbb{L}))$, whence, $T = \pi^{-1}(T') \in \pi^{-1}(\mathcal{D}^*) = \mathcal{D}$. We conclude that $\mathcal{T} \subseteq \mathcal{D}$.

Assume, conversely, that $\mathcal{D} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}$. Then, by Proposition 1360,

$$\langle I, \pi \rangle : \mathbb{L} \vdash \langle \mathcal{A}/\widetilde{\Omega}(\mathbb{L}), \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}(\mathbb{L})) \rangle$$

is a bilogical morphism. Therefore, $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}(\mathbb{L}))$, showing that $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$. ∎

19.6 $\mathcal{I}$-Algebraic Systems

Since $\langle\mathcal{A},\mathcal{D}\rangle$ is a full $\mathcal{I}$-structure if and only if $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$, we conclude that the reduced full $\mathcal{I}$-structures are exactly those structures of the form $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$, which are reduced.

Definition 1396 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*. An* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *if an* $\mathcal{I}$-**algebraic system** *if and only if the* $\mathbf{F}$*-structure* $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ *is reduced, i.e., if* $\mathcal{A}$ *is the underlying* $\mathbf{F}$*-algebraic system of a reduced full* $\mathcal{I}$*-structure.*

We denote by $\mathrm{AlgSys}(\mathcal{I})$ *the class of all* $\mathcal{I}$*-algebraic systems.*

Since $\mathcal{I}$-algebraic systems are determined based on reduced full $\mathcal{I}$-structures, the following characterization is useful in this context.

Proposition 1397 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle\mathcal{A},D\rangle$ *an* $\mathbf{F}$*-structure. Then the following are equivalent:*

(i) $\mathbb{L}$ *is a reduced full* $\mathcal{I}$*-structure;*

(ii) $\mathbb{L}$ *is reduced and* $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ *and* $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof:

(i)⇒(ii) Suppose that $\mathbb{L} = \langle\mathcal{A},D\rangle$ is a reduced full $\mathcal{I}$-structure. Since $\mathbb{L}$ is full, $\mathbb{L}^* = \langle\mathcal{A}^*,\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)\rangle$. Since $\mathbb{L}$ is reduced, $\mathbb{L}^* = \mathbb{L}$. Thus, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(ii)⇒(ii) Assume $\mathbb{L} = \langle\mathcal{A},D\rangle$ is reduced and $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\mathbb{L}$ is reduced, $\mathbb{L}^* = \mathbb{L} = \langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$. Therefore, $\mathbb{L}$ is also full and, consequently, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$.

(iii)⇒(i) Let $\mathbb{L} = \langle\mathcal{A},D\rangle$, with $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ and $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, there exists a closure family D' on $\mathcal{A}$, such that $\langle\mathcal{A},D'\rangle$ is a reduced full $\mathcal{I}$-structure. Since $\langle\mathcal{A},D'\rangle$ is full and reduced, we have $\mathcal{D}' = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since, by hypothesis, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that $\mathcal{D}' = \mathcal{D}$. Hence, $\mathbb{L} = \langle\mathcal{A},\mathcal{D}\rangle = \langle\mathcal{A},\mathcal{D}'\rangle$ is a reduced full $\mathcal{I}$-structure. ■

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$. Let, also, $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system. We denote by $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ the collection of all congruence systems θ on $\mathcal{A}$, such that the quotient algebraic system $\mathcal{A}^\theta$ is in $\mathrm{AlgSys}(\mathcal{I})$:

$$\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathcal{A}) : \mathcal{A}^\theta \in \mathrm{AlgSys}(\mathcal{I})\}.$$

A congruence system $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is called an $\mathcal{I}$-**congruence system on** $\mathcal{A}$.

It turns out that the Tarski congruence systems of full $\mathcal{I}$-structures are all $\mathcal{I}$-congruence systems.

Proposition 1398 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *an* $\mathbf{F}$*-structure. If* $\mathbb{L}$ *is full, then* $\mathcal{A}^* \in \mathrm{AlgSys}(\mathcal{I})$ *and, therefore,* $\widetilde{\Omega}(\mathbb{L}) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: Suppose that $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a full $\mathcal{I}$-structure. Then, by definition, $\mathbb{L}^* = \langle \mathcal{A}^*, \mathcal{D}^* \rangle = \langle \mathcal{A}^*, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$ is a reduced full $\mathcal{I}$-structure. Hence $\mathcal{A}^* \in \mathrm{AlgSys}(\mathcal{I})$ and, therefore, by definition, $\widetilde{\Omega}(\mathbb{L}) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. ■

Even though, according to the definition, $\mathcal{I}$-algebraic systems are determined as the $\mathbf{F}$-algebraic system reducts of reduced full $\mathcal{I}$-structures, they can also be characterized without reference to fullness.

Proposition 1399 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathrm{AlgSys}(\mathcal{I})$ *is the class of all underlying* $\mathbf{F}$*-algebraic systems of all reduced* $\mathcal{I}$*-structures:*

$$\mathrm{AlgSys}(\mathcal{I}) = \{\mathcal{A} : (\exists \langle \mathcal{A}, D \rangle \in \mathrm{Str}^{\mathcal{I}}(\mathcal{A}))(\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}})\}.$$

Proof: If $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, then, by Proposition 1397, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$-structure. Conversely, if $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a reduced $\mathcal{I}$-structure, then $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, therefore,

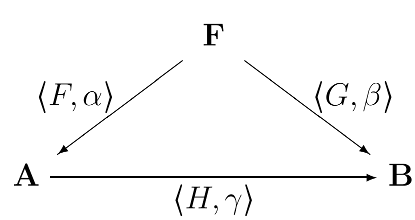
$$\widetilde{\Omega}(\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle) \leq \widetilde{\Omega}(\mathbb{L}) = \Delta^{\mathcal{A}}.$$

Thus, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$-structure and $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. ■

The class of all $\mathcal{I}$-algebraic systems is closed under isomorphisms.

Proposition 1400 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathrm{AlgSys}(\mathcal{I})$ *is closed under isomorphisms.*

Proof: Assume $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle \in \mathrm{AlgSys}(\mathcal{I})$ and let $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ be an isomorphism.



Then, we have that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \gamma^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B}))$, which shows that

$$\langle H,\gamma\rangle : \langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle \cong \langle\mathcal{B},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\rangle.$$

Now we can use Proposition 1363 to see that $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is reduced if and only if $\langle\mathcal{B},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\rangle$ is reduced and, therefore, by Proposition 1399, $\mathcal{A}\in\mathrm{AlgSys}(\mathcal{I})$ if and only if $\mathcal{B}\in\mathrm{AlgSys}(\mathcal{I})$. ■

Proposition 1397 gave characterizing conditions for reduced full $\mathcal{I}$-structures. An analog for full $\mathcal{I}$-structures is the following:

Proposition 1401 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathbb{L} = \langle\mathcal{A},D\rangle$ *an* $\mathbf{F}$*-structure. Then the following are equivalent:*

(i) $\mathbb{L}$ *is a full* $\mathcal{I}$*-structure;*

(ii) $\mathcal{A}^*\in\mathrm{AlgSys}(\mathcal{I})$ *and* $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$*;*

(iii) There exists a bilogical morphism $\langle H,\gamma\rangle : \mathbb{L}\vdash\langle\mathcal{A}',D'\rangle$*, such that* $\mathcal{A}'\in\mathrm{AlgSys}(\mathcal{I})$ *and* $\mathcal{D}' = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$*.*

Proof:

(i)⇒(ii) Suppose $\mathbb{L} = \langle\mathcal{A},D\rangle$ is a full $\mathcal{I}$-structure. Then, by definition, $\mathbb{L}^* = \langle\mathcal{A}^*,\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)\rangle$. Thus, $\mathcal{A}^*\in\mathrm{AlgSys}(\mathcal{I})$ and $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

(ii)⇒(iii) Obvious, since $\langle H,\gamma\rangle : \mathbb{L}\vdash\mathbb{L}^*$ is a bilogical morphism.

(iii)⇒(i) Assume that $\langle H,\gamma\rangle : \mathbb{L}\to\langle\mathcal{A}',\mathcal{D}'\rangle$ is a bilogical morphism, such that $\mathcal{A}'\in\mathrm{AlgSys}(\mathcal{I})$ and $\mathcal{D}' = \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A}')$. Then, by Proposition 1372, there exists an α-isomorphism $\mathbb{L}^*\vdash^\alpha\langle\mathcal{A}'^*,\mathcal{D}'^*\rangle$. Since $\mathcal{A}'\in\mathrm{AlgSys}(\mathcal{I})$ and $\mathcal{D}' = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$, it follows, by Proposition 1397, that $\langle\mathcal{A}',\mathcal{D}'\rangle$ is a reduced full $\mathcal{I}$-structure. So we have

$$\langle\mathcal{A}'^*,\mathcal{D}'^*\rangle = \langle\mathcal{A}',\mathcal{D}'\rangle = \langle\mathcal{A}',\mathrm{FiFam}(\mathcal{A}')\rangle.$$

Hence, by Proposition 1380, $\mathbb{L}^* = \langle\mathcal{A}^*,\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)\rangle$ and, therefore, $\mathbb{L}$ is a full $\mathcal{I}$-structure.

■

It turns out that, given a π-institution $\mathcal{I}$, the class of all full $\mathcal{I}$-structures, the class of all $\mathbf{F}$-structures of the form $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$, where $\mathcal{A}$ ranges over all $\mathbf{F}$-algebraic systems, as well as the class of all reduced full $\mathcal{I}$-structures are complete $\mathbf{F}$-structure semantics for $\mathcal{I}$.

Theorem 1402 (Completeness Theorem) *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is complete with respect to the following classes of* $\mathbf{F}$*-structures:*

(i) *The class of all full* $\mathcal{I}$*-structures;*

(ii) *The class of all* $\mathbf{F}$*-structures of the form* $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$*;*

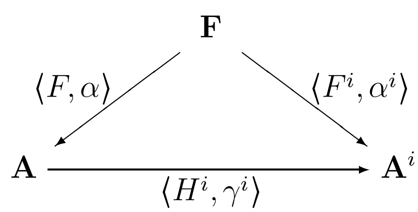
(iii) *The class of all reduced full* $\mathcal{I}$*-structures, i.e., structures of the form* $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$*, with* $\mathcal{A}\in\mathrm{AlgSys}(\mathcal{I})$*.*

Proof: Note that all three classes of $\mathbf{F}$-structures consist of $\mathcal{I}$-structures and include $\langle\mathcal{F},C\rangle^*$. Therefore, by Proposition 1388, $\mathcal{I}$ is complete with respect to each one of them. ∎

Let $\mathcal{I}=\langle\mathbf{F},C\rangle$ be a π-institution. To $\mathcal{I}$ we have associated (among others) two classes of $\mathbf{F}$-algebraic systems. One is the class $\mathrm{AlgSys}^*(\mathcal{I})$ of underlying $\mathbf{F}$-algebraic systems of reduced $\mathcal{I}$-matrix families. The other is the class $\mathrm{AlgSys}(\mathcal{I})$ of underlying $\mathbf{F}$-algebraic systems of reduced $\mathcal{I}$-structures (according to Proposition 1399). To explore an important relationship between these two classes, we introduce an operator on $\mathbf{F}$-algebraic systems, which is related to an operator on $\mathbf{F}$-matrix families, given the same name.

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and consider $\mathbf{F}$-algebraic systems $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ and $\mathcal{A}^i=\langle\mathbf{A}^i,\langle F^i,\alpha^i\rangle\rangle$, $i\in I$, and a system of surjective morphisms

$$\langle H^i,\gamma^i\rangle:\mathcal{A}\to\mathcal{A}^i,\quad i\in I.$$



We say $\{\langle H^i,\gamma^i\rangle:i\in I\}$ is a **subdirect intersection (system)** and call the $\langle H^i,\gamma^i\rangle$ **subdirect intersection morphisms** if

$$\bigcap_{i\in I}\mathrm{Ker}(\langle H^i,\gamma^i\rangle)=\Delta^{\mathcal{A}}.$$

If such a system exists, we say that $\mathcal{A}$ is a **subdirect intersection** of the $\mathbf{F}$-algebraic systems $\{\mathcal{A}^i:i\in I\}$. Given a class K of $\mathbf{F}$-algebraic systems and an $\mathbf{F}$-algebraic system $\mathcal{A}$, we write

$$\mathcal{A}\in\overset{\triangleleft}{\mathbb{\Pi}}(\mathsf{K})$$

to signify that $\mathcal{A}$ is a subdirect intersection of a collection $\{\mathcal{A}^i:i\in I\}$, with $\mathcal{A}^i\in\mathsf{K}$, for all $i\in I$.

We can show that the operator $\overset{\triangleleft}{\mathbb{\Pi}}$ is a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 1403 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*

$$\overset{\triangleleft}{\mathbb{I}\mathbb{P}} : \mathcal{P}(\mathrm{AlgSys}(\mathbf{F})) \to \mathcal{P}(\mathrm{AlgSys}(\mathbf{F}))$$

is a closure operator.

Proof: Suppose, first, that $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$ and $\mathcal{A} \in \mathsf{K}$. Since the identity morphism $\langle I, \iota \rangle : \mathcal{A} \to \mathcal{A}$ is a subdirect intersection, we get that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K})$. Thus, $\overset{\triangleleft}{\mathbb{I}\mathbb{P}}$ is inflationary.

Suppose, next, that $\mathsf{K} \subseteq \mathsf{K}' \subseteq \mathrm{AlgSys}(\mathbf{F})$ and $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K})$. Thus, $\mathcal{A}$ is a subdirect intersection of a collection $\{\mathcal{A}^i : i \in I\} \subseteq \mathsf{K}$. Then $\mathcal{A}$ is a subdirect intersection of $\{\mathcal{A}^i : i \in I\} \subseteq \mathsf{K}'$. Hence, $\overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K}) \subseteq \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K}')$ and, therefore, $\overset{\triangleleft}{\mathbb{I}\mathbb{P}}$ is also monotone.

Assume, finally, that $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$ and let $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K}))$. Thus, there exists a subdirect intersection system

$$\langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

where $\mathcal{A}^i \in \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K})$, for all $i \in I$. Consequently, for all $i \in I$, there exists a subdirect intersection system

$$\langle H^{ij}, \gamma^{ij} \rangle : \mathcal{A}^i \to \mathcal{A}^{ij}, \quad j \in J_i,$$

where $\mathcal{A}^{ij} \in \mathsf{K}$, for all $i \in I, j \in J_i$. We consider the collection

$$\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^{ij}, \quad i \in I, j \in J_i.$$

We have

$$\begin{array}{rcl}
\bigcap_{i\in I} \bigcap_{j\in J_i} \mathrm{Ker}(\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle) & = & \bigcap_{i\in I} \bigcap_{j\in J_i} (\gamma^i)^{-1}(\mathrm{Ker}(\langle H^{ij}, \gamma^{ij} \rangle)) \\
& = & \bigcap_{i\in I} (\gamma^i)^{-1}(\bigcap_{j\in J_i} (\mathrm{Ker}(\langle H^{ij}, \gamma^{ij} \rangle))) \\
& = & \bigcap_{i\in I} (\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\
& = & \bigcap_{i\in I} \mathrm{Ker}(\langle H^i, \gamma^i \rangle) \\
& = & \Delta^{\mathcal{A}}.
\end{array}$$

Thus, the system $\{\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^o \rangle : i \in I, j \in J_i\}$ is a subdirect intersection system, showing that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathsf{K})$. We conclude that $\overset{\triangleleft}{\mathbb{I}\mathbb{P}}$ is also idempotent. ∎

Using subdirect intersections, we can give the exact relationship between the classes $\mathrm{AlgSys}(\mathcal{I})$ and $\mathrm{AlgSys}^*(\mathcal{I})$. Namely, we show that the former is the class of all subdirect intersections of collections of algebraic systems in the latter class. In particular $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$.

Theorem 1404 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then*

$$\mathrm{AlgSys}(\mathcal{I}) = \overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathrm{AlgSys}^*(\mathcal{I})).$$

Proof: Assume, first, that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Then, we have

$$\bigcap\{\Omega^{\mathcal{A}}(T) : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} = \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}.$$

Now, consider the collection

$$\langle I, \pi^{\Omega^{\mathcal{A}}(T)}\rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T), \quad T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

By the preceding equation, this collection constitutes a subdirect intersection. Moreover, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle \in \mathrm{MatFam}^*(\mathcal{I})$ and, hence, $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I})$. Therefore, we get that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I}))$.

Suppose, conversely, that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I}))$. Thus, there exists a subdirect intersection

$$\langle H^i \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

with $\mathcal{A}^i \in \mathrm{AlgSys}^*(\mathcal{I})$, for all $i \in I$. Thus, for all $i \in I$, there exists $T^i \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i)$, such that $\Omega^{\mathcal{A}^i}(T^i) = \Delta^{\mathcal{A}^i}$. Now, we calculate:

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & = & \bigcap\{\Omega^{\mathcal{A}}(T) : T \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})\}\\ & \subseteq & \bigcap_{i\in I}\Omega^{\mathcal{A}}((\gamma^i)^{-1}(T^i))\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Omega^{\mathcal{A}^i}(T^i))\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Delta^{\mathcal{A}^i})\\ & = & \bigcap_{i\in I}\mathrm{Ker}(\langle H^i, \gamma^i\rangle)\\ & = & \Delta^{\mathcal{A}}.\end{array}$$

We conclude that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Thus, $\mathrm{AlgSys}(\mathcal{I}) \subseteq \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I}))$. ■

Corollary 1405 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then* $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$ *and, moreover,* $\mathrm{ALgSys}^*(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I})$ *if and only if* $\mathrm{AlgSys}^*(\mathcal{I})$ *is closed under subdirect intersections.*

Proof: We have

$$\begin{array}{rcll}\mathrm{AlgSys}^*(\mathcal{I}) & \subseteq & \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I})) & \text{(by Proposition 1403)}\\ & = & \mathrm{AlgSys}(\mathcal{I}). & \text{(by Theorem 1404)}\end{array}$$

If $\mathrm{AlgSys}^*(\mathcal{I})$ is closed under subdirect intersections,

$$\mathrm{AlgSys}(\mathcal{I}) = \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I})) \subseteq \mathrm{AlgSys}^*(\mathcal{I}).$$

Conversely, if $\mathrm{AlgSys}^*(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I})$, then $\overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathrm{AlgSys}^*(\mathcal{I})) = \mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. ■

Finally, we give a relation between the classes of algebraic systems associated in this way with π-institutions based on the same algebraic system that are related by $\leq$. Recall that, given $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and $\mathcal{I}' = \langle \mathbf{F}, C'\rangle$, we write $C \leq C'$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$, $C_\Sigma(\Phi) \subseteq C'_\Sigma(\Phi)$. If this is the case, we also write $\mathcal{I} \leq \mathcal{I}'$ and say that $\mathcal{I}'$ is stronger than $\mathcal{I}$ and that $\mathcal{I}$ is weaker than $\mathcal{I}'$. Recall, also, that, $\mathcal{I} \leq \mathcal{I}'$ if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proposition 1406 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$, $\mathcal{I}' = \langle \mathbf{F}, C'\rangle$ *be two π-institutions based on* $\mathbf{F}$. *If* $\mathcal{I} \leq \mathcal{I}'$, *then*

$$\mathrm{AlgSys}(\mathcal{I}') \subseteq \mathrm{AlgSys}(\mathcal{I}) \quad \textit{and} \quad \mathrm{AlgSys}^*(\mathcal{I}') \subseteq \mathrm{AlgSys}^*(\mathcal{I}).$$

Proof: If $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I}')$, then, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \Delta^{\mathcal{A}}$. But, since $\mathcal{I} \leq \mathcal{I}'$, we have $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. We now conclude that $\mathrm{AlgSys}^*(\mathcal{I}') \subseteq \mathrm{AlgSys}^*(\mathcal{I})$.

For the second inclusion, we get

$$\begin{array}{rcll}
\mathrm{AlgSys}(\mathcal{I}') & = & \overset{\triangleleft}{\mathrm{I}\mathrm{P}}(\mathrm{AlgSys}^*(\mathcal{I}')) & \text{(Theorem 1404)}\\
 & \subseteq & \overset{\triangleleft}{\mathrm{I}\mathrm{P}}(\mathrm{AlgSys}^*(\mathcal{I})) & \text{(Proposition 1403)}\\
 & = & \mathrm{AlgSys}(\mathcal{I}). & \text{(Theorem 1404)}
\end{array}$$

■

19.7 Lattice of Full $\mathcal{I}$-Structures

In this section we show that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{F}, \langle F, \alpha\rangle\rangle$, the poset $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq\rangle$ of full $\mathcal{I}$-structures on $\mathcal{A}$ and the poset $\langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq\rangle$ of $\mathcal{I}$-congruence systems on $\mathcal{A}$ are isomorphic through the Tarski operator

$$\langle \mathcal{A}, D\rangle \mapsto \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}).$$

We start by defining an operator which will turn out to be the inverse of the Tarski operator.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system. Given $\theta \in \mathrm{ConSys}(\mathcal{A})$, define

$$\widetilde{H}^{\mathcal{A}}(\theta) = \langle \mathcal{A}, \mathcal{D}^\theta\rangle,$$

by setting

$$\mathcal{D}^\theta = (\pi^\theta)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)),$$

where $\langle I, \pi^\theta\rangle : \mathcal{A} \to \mathcal{A}^\theta$ is the quotient morphism.

Note that, by definition of $\widetilde{H}^{\mathcal{A}}(\theta)$, the morphism

$$\langle I, \pi^\theta\rangle : \widetilde{H}^{\mathcal{A}}(\theta) \to \langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)\rangle$$

is a bilogical morphism.

We have the following properties concerning the operator $\widetilde{H}$.

Lemma 1407 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system.*

(a) For every $\theta \in \mathrm{ConSys}(\mathcal{A})$*,*

- *(i)* $\theta \in \mathrm{ConSys}(\widetilde{H}^{\mathcal{A}}(\theta))$*;*
- *(ii)* $\widetilde{H}^{\mathcal{A}}(\theta)/\theta = \langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$*;*
- *(iii)* $\widetilde{H}^{\mathcal{A}}(\theta) \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$*;*

(b) $\theta \mapsto \widetilde{H}^{\mathcal{A}}(\theta)$ *is order preserving, i.e., for all* $\theta, \theta' \in \mathrm{ConSys}(\mathcal{A})$*,* $\theta \le \theta'$ *implies* $\widetilde{H}^{\mathcal{A}}(\theta) \le \widetilde{H}^{\mathcal{A}}(\theta')$*.*

Proof:

(a) For Part (i) we must show that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\langle \phi, \psi \rangle \in \theta_\Sigma$ implies that $D^\theta_\Sigma(\phi) = D^\theta_\Sigma(\psi)$. Suppose, to this end, that $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$. Then, we have

$$C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\phi/\theta_\Sigma) = C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\psi/\theta_\Sigma),$$

i.e., $C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\pi^\theta_\Sigma(\phi)) = C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\pi^\theta_\Sigma(\psi))$. This gives that

$$(\pi^\theta_\Sigma)^{-1}(C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\pi^\theta_\Sigma(\phi))) = (\pi^\theta_\Sigma)^{-1}(C^{\mathcal{I},\mathcal{A}^\theta}_\Sigma(\pi^\theta_\Sigma(\psi))).$$

Since $\langle I, \pi^\theta \rangle : \widetilde{H}^{\mathcal{A}}(\theta) \to \langle \mathcal{A}^\theta, C^{\mathcal{I},\mathcal{A}^\theta} \rangle$ is a bilogical morphism, we get by Proposition 1360, $D^\theta_\Sigma(\phi) = D^\theta_\Sigma(\psi)$. We conclude that $\theta \in \mathrm{ConSys}(\widetilde{H}^{\mathcal{A}}(\theta))$.

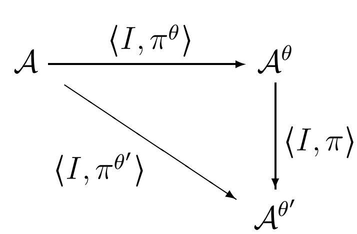
For Part (ii), we have

$$\pi^\theta(\mathcal{D}^\theta) = \pi^\theta((\pi^\theta)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta))) = \mathrm{FiFam}^{\mathcal{A}}(\mathcal{A}^\theta),$$

where the last equality follows from the fact that $\langle I, \pi^\theta \rangle$ is a bilogical morphism, by applying Proposition 1360.

Part (iii) follows from the fact that the morphism $\langle I, \pi^\theta \rangle : \widetilde{H}^{\mathcal{A}}(\theta) \to \langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$ is a bilogical morphism and Corollary 1393.

(b) Suppose $\theta, \theta' \in \mathrm{ConSys}(\mathcal{A})$, such that $\theta \le \theta'$. Then we have the following commutative diagram of $\mathbf{F}$-algebraic systems.



where, $\langle I, \pi \rangle : \mathcal{A}^\theta \to \mathcal{A}^{\theta'}$ is defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\pi_\Sigma(\phi/\theta_\Sigma) = \phi/\theta'_\Sigma.$$

Taking this diagram into account, we have

$$\begin{array}{rcll} \mathcal{D}^{\theta'} & = & (\pi^{\theta'})^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta'})) & (\text{Definition of } \mathcal{D}^{\theta'}) \\ & = & (\pi^{\theta})^{-1}(\pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta'}))) & (\pi \circ \pi^{\theta} = \pi^{\theta'}) \\ & \subseteq & (\pi^{\theta})^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta})) & (\text{Corollary 55}) \\ & = & \mathcal{D}^{\theta}. & (\text{Definition of } \mathcal{D}^{\theta}) \end{array}$$

Thus, we get $\widetilde{H}^{\mathcal{A}}(\theta) \leq \widetilde{H}^{\mathcal{A}}(\theta')$. ■

We are ready now for the main isomorphism theorem that was promised at the beginning of the section.

Theorem 1408 (Isomorphism Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system. Then*

$$\widetilde{\Omega}^{\mathcal{A}} : \langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \to \langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$$

is an order isomorphism, with inverse

$$\widetilde{H}^{\mathcal{A}} : \langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \to \langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle.$$

Proof: By Proposition 1398, if $\mathbb{L} \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, then $\widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. Moreover, by Lemma 1407, if $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, then $\widetilde{H}^{\mathcal{A}}(\theta) \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. So, both $\widetilde{\Omega}^{\mathcal{A}}$ and $\widetilde{H}^{\mathcal{A}}$ are well-defined, with domains and codomains as indicated.

We show, next, that they are mutually inverse mappings.

Suppose, first, that $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. Then, by Proposition 1398, $\mathcal{A}^* \in \mathrm{AlgSys}^{\mathcal{I}}(\mathcal{A})$ and $\widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. By fullness, $\mathcal{D} = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*))$, where $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is the quotient bilogical morphism. Then, by definition of $\widetilde{H}^{\mathcal{A}}$, we get that $\widetilde{H}^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{A}}(\mathbb{L})) = \mathbb{L}$.

Suppose, on the other hand, that $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. By definition, $\mathcal{A}^\theta \in \mathrm{AlgSys}(\mathcal{I})$. Thus, by definition,

$$\langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle \in \mathrm{FStr}(\mathcal{I}) \quad \text{and} \quad \widetilde{\Omega}^{\mathcal{A}^\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)) = \Delta^{\mathcal{A}^\theta}.$$

Now, we get

$$\begin{array}{rcll} \widetilde{\Omega}^{\mathcal{A}}(\widetilde{H}^{\mathcal{A}}(\theta)) & = & \widetilde{\Omega}^{\mathcal{A}}((\pi^\theta)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta))) & (\text{Definition of } \widetilde{H}^{\mathcal{A}}(\theta)) \\ & = & (\pi^\theta)^{-1}(\widetilde{\Omega}^{\mathcal{A}^\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta))) & (\text{Corollary 1364}) \\ & = & (\pi^\theta)^{-1}(\Delta^{\mathcal{A}^\theta}) & (\text{Hypothesis}) \\ & = & \theta. & (\text{Set Theory}) \end{array}$$

Since, by definition $\widetilde{\Omega}^{\mathcal{A}}$ is order preserving and, by Lemma 1407, $\widetilde{H}^{\mathcal{A}}$ is also order preserving, we conclude that $\widetilde{\Omega}^{\mathcal{A}}$ is an order isomorphism with inverse $\widetilde{H}^{\mathcal{A}}$. ■

We show next that the poset of $\mathcal{I}$-congruence systems on an $\mathbf{F}$-algebraic system $\mathcal{A}$ is a complete lattice with infimum given by signature-wise intersection. In conjunction with the Isomorphism Theorem, this will yield that the poset of full $\mathcal{I}$-structures on $\mathcal{A}$ is also a complete lattice.

Theorem 1409 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, the poset* $\langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ *is a complete lattice with infimum given by signature-wise intersection.*

Proof: First, note that $\nabla^{\mathcal{A}} \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, since $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\nabla^{\mathcal{A}})) = \Delta^{\mathcal{A}/\nabla^{\mathcal{A}}}$ and, hence, $\mathcal{A}/\nabla^{\mathcal{A}} \in \mathrm{AlgSys}(\mathcal{I})$. So $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ has a largest element. Assume, next, that, for all $i \in I$, $\theta^i \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. We must show that $\bigcap_{i\in I} \theta^i \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. To this end, set $\theta := \bigcap_{i\in I} \theta^i$ and consider the projection morphisms

$$\langle I, \pi^i \rangle : \mathcal{A}^\theta \to \mathcal{A}^{\theta^i}, \quad i \in I,$$

which are bilogical morphisms

$$\langle I, \pi^i \rangle : \langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle \vdash \langle \mathcal{A}^{\theta^i}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}) \rangle, \quad i \in I.$$

By hypothesis, $\langle \mathcal{A}^{\theta^i}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}) \rangle$ is reduced, i.e.,

$$\widetilde{\Omega}^{\mathcal{A}^{\theta^i}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i})) = \Delta^{\mathcal{A}^{\theta^i}}, \quad i \in I.$$

Now we have, for all $i \in I$,

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{A}^\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)) & \leq & \widetilde{\Omega}^{\mathcal{A}^\theta}((\pi^i)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}))) \\ & = & (\pi^i)^{-1}(\widetilde{\Omega}^{\mathcal{A}^{\theta^i}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}))) \\ & = & (\pi^i)^{-1}(\Delta^{\mathcal{A}^{\theta^i}}) \\ & = & \theta^i/\theta.\end{array}$$

Thus, we get

$$\widetilde{\Omega}^{\mathcal{A}^\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)) \leq \bigcap_{i\in I}(\theta^i/\theta) = (\bigcap_{i\in I}\theta^i)/\theta = \theta/\theta = \Delta^{\mathcal{A}^\theta}.$$

We conclude that $\langle \mathcal{A}^\theta, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$ is reduced and, hence, $\mathcal{A}^\theta \in \mathrm{AlgSys}(\mathcal{I})$, giving that $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$.

The conclusion of the theorem now follows. ∎

As a consequence of the Isomorphism Theorem 1408 and Theorem 1409, we get

Corollary 1410 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ *is a complete lattice and*

$$\widetilde{\Omega}^{\mathcal{A}} : \langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \to \langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$$

is a lattice isomorphism.

Proof: By Theorems 1408 and 1409. ∎

It follows from the preceding results that, given a collection $\{\mathbb{L}^i : i \in I\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, with $\mathbb{L}^i = \langle \mathcal{A}, D^i \rangle$, $i \in I$, its infimum in $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is the $\mathcal{I}$-structure

$$\langle \mathcal{A}, (\pi^\theta)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)\rangle,$$

where $\theta = \bigcap_{i \in I} \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i)$, and $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}^\theta$ is the quotient morphism. It is not necessarily the case, however, that this system be the signature-wise intersection of the $\mathbb{L}^i$'s. In other words, $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is not, in general, a sublattice of the complete lattice of all $\mathcal{I}$-structures on $\mathcal{A}$.

It turns out that bilogical morphisms with isomorphic functor components induce isomorphisms between principal ideals of the corresponding full structure lattices and, similarly isomorphisms between principal ideals of the corresponding lattices of congruence systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Let also $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system. Consider the complete lattice $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. Recall that the ordering $\leq$ reflects the ordering of the closure operators on $\mathcal{A}$, which is dual to the inclusion ordering of the corresponding closure set systems. So, when we refer to an ideal in $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ we mean in the form of closure (operator) families and this translates to a filter, when one views structures in the form of their theory families. Keeping this in mind, we introduce the notation $\mathrm{FStr}^{\mathcal{I}}(\mathbb{L})$ to refer to the principal ideal of all full $\mathcal{I}$-structures on $\mathcal{A}$ generated by $\mathbb{L}$. These are full $\mathcal{I}$-structures whose collection of theory families include $\mathcal{D}$.

$$\begin{array}{rcl}\mathrm{FStr}^{\mathcal{I}}(\langle \mathcal{A}, D \rangle) & = & \{\langle \mathcal{A}, D' \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) : D' \leq D\} \\ & = & \{\langle \mathcal{A}, \mathcal{D}' \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) : \mathcal{D} \leq \mathcal{D}'\}.\end{array}$$

Then we have the following.

Proposition 1411 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. *Let also* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems, over the same category of signatures,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$*-algebraic systems,* $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *full* $\mathcal{I}$*-structures and* $\langle I, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism. Then*

$$\langle \mathcal{A}, \mathcal{X} \rangle \mapsto \langle \mathcal{A}', \gamma(\mathcal{X}) \rangle$$

is an isomorphism from $\mathrm{FStr}^{\mathcal{I}}(\mathbb{L})$ *to* $\mathrm{FStr}^{\mathcal{I}}(\mathbb{L}')$.

Moreover, the principal ideals of $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *and of* $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}')$, *generated by* $\widetilde{\Omega}^{\mathcal{A}}(\mathbb{L})$ *and* $\widetilde{\Omega}^{\mathcal{A}'}(\mathbb{L}')$, *respectively, are isomorphic.*

Proof: By Corollary 1362, the displayed mapping is an isomorphism between $\mathbf{ClFam}(\mathbb{L})$ and $\mathbf{ClFam}(\mathbb{L}')$. Proposition 1392 gives the statement, since

$\langle I, \gamma \rangle$ induces bilogical morphisms between the corresponding elements in $\text{ClFam}(\mathbb{L})$ and $\text{ClFam}(\mathbb{L}')$. The second statement now follows by applying the Isomorphism Theorem 1408. ∎

Corollary 1412 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Let also* $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}, \text{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems, over the same category of signatures,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$*-algebraic systems and* $\langle I, \gamma \rangle : \mathcal{A} \to \mathcal{A}'$ *a surjective morphism, such that*

$$\langle I, \gamma \rangle : \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \vdash \langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$$

is a bilogical morphism. Then $\langle \mathcal{A}, \mathcal{X} \rangle \mapsto \langle \mathcal{A}', \gamma(\mathcal{X}) \rangle$ *is an isomorphism from* $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ *to* $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A}')$*. Moreover,* $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}')$*.*

Proof: This follows by Proposition 1411, since, by Proposition 1390, the $\mathcal{I}$-structures $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ and $\langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$ are the weakest full $\mathcal{I}$-structures on $\mathcal{A}$ and $\mathcal{A}'$, respectively. The last isomorphism follows by the second statement of Proposition 1411. ∎

We close the section by looking at some functors that relate the categories having as objects the structures that we have focused upon and with surjective homomorphism running between them.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We describe three categories related to $\mathcal{I}$.

- The category $\mathbf{FStr}(\mathcal{I})$:
  - The objects are full $\mathcal{I}$-structures $\mathbb{L} = \langle \mathcal{A}, D \rangle$;
  - Given objects $\mathbb{L} = \langle \mathcal{A}, D \rangle$ and $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$, a morphism in $\mathbf{FStr}(\mathcal{I})$

    $$\langle H, \gamma \rangle : \mathbb{L} \to \mathbb{L}'$$

    is a surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{A}'$, which is also a logical morphism $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$.

  It is not difficult to verify that these two clauses specify indeed a category, with composition being ordinary composition of morphisms.

- The category $\mathbf{FStr}^*(\mathcal{I})$:

  This is the full subcategory of $\mathbf{FStr}(\mathcal{I})$, with objects all full $\mathcal{I}$-structures.

- The category $\mathbf{AlgSys}(\mathcal{I})$:
  - The objects are $\mathcal{I}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$;

 – Given objects $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$, a morphism in $\mathbf{AlgSys}(\mathcal{I})$

$$\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{A}'$$

 is a surjective $\mathbf{F}$-algebraic system morphism.

It is not difficult in this case either to verify that these two clauses specify indeed a category, with composition being ordinary composition of morphisms.

The following picture gives an overview of the relationships that hold between these categories and will be established shortly. The categories $\mathbf{AlgSys}(\mathcal{I})$ and $\mathbf{FStr}^*(\mathcal{I})$ are isomorphic through an isomorphism

$$\Phi : \mathbf{AlgSys}(\mathcal{I}) \cong \mathbf{FStr}^*(\mathcal{I}),$$

which will be defined in the upcoming Theorem 1413. Moreover, the category $\mathbf{FStr}^*(\mathcal{I})$ is a reflective subcategory of the category $\mathbf{FStr}(\mathcal{I})$, with reflector the reduction functor $^* : \mathbf{FStr}(\mathcal{I}) \to \mathbf{FStr}^*(\mathcal{I})$ that will be visited in detail in the last Theorem 1414 of the section.

$$\mathbf{AlgSys}(\mathcal{I}) \underset{\Phi^{-1}}{\overset{\Phi}{\rightleftarrows}} \mathbf{FStr}^*(\mathcal{I}) \underset{*}{\overset{J}{\hookrightarrow\!\!\!\leftarrow}} \mathbf{FStr}(\mathcal{I})$$

Theorem 1413 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then the categories* $\mathbf{AlgSys}(\mathcal{I})$ *and* $\mathbf{FStr}^*(\mathcal{I})$ *are isomorphic.*

Proof: We define the functor

$$\Phi : \mathbf{AlgSys}(\mathcal{I}) \to \mathbf{FStr}^*(\mathcal{I})$$

by setting:

- For all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathrm{AlgSys}(\mathcal{I})$,

$$\Phi(\mathcal{A}) = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle;$$

- For all $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{A}'$ in $\mathbf{AlgSys}(\mathcal{I})$,

$$\Phi(\langle H, \gamma\rangle) = \langle H, \gamma\rangle : \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle \vdash \langle \mathcal{A}', \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')\rangle.$$

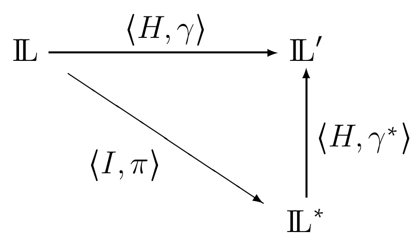
First, observe that, by Proposition 1397, if $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, then $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced full $\mathcal{I}$-structure. So Φ is correctly defined. Moreover, if $\langle \mathcal{A}, D\rangle \in \mathrm{FStr}^*(\mathcal{I})$, then, again by Proposition 1397, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Thus, Φ is a bijection on objects.

Finally, by Corollary 55, if $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{A}'$ is a surjective morphism, then, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$, $\gamma^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\Phi(\langle H,\gamma\rangle)$ is a well-defined logical morphism, by Proposition 1358. Since it is clear that Φ is bijective on morphisms as well, we get that $\Phi : \mathbf{AlgSys}(\mathcal{I}) \to \mathbf{FStr}^*(\mathcal{I})$ is indeed an isomorphism of categories. ■

Finally, for the reflection:

Theorem 1414 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then* $\mathbf{FStr}^*(\mathcal{I})$ *is a full reflective subcategory of* $\mathbf{FStr}(\mathcal{I})$ *with reflector the reduction functor* $^* : \mathbf{FStr}(\mathcal{I}) \to \mathbf{FStr}^*(\mathcal{I})$.

Proof: It is obvious that $\mathbf{FStr}^*(\mathcal{I})$ is a full subcategory of $\mathbf{FStr}(\mathcal{I})$. We must show that, given $\mathbb{L} = \langle \mathcal{A}, D\rangle \in \mathrm{FStr}(\mathcal{I})$, the pair $\langle \mathbb{L}^*, \langle I,\pi\rangle : \mathbb{L} \to \mathbb{L}^*\rangle$ is a reflector, i.e., that, given $\mathbb{L}' = \langle \mathcal{A}', D'\rangle \in \mathrm{FStr}^*(\mathcal{I})$ and $\langle H,\gamma\rangle : \mathbb{L} \to \mathbb{L}'$ in $\mathbf{FStr}(\mathcal{I})$, there exists a unique $\langle H,\gamma^*\rangle : \mathbb{L}^* \to \mathbb{L}'$ in $\mathbf{FStr}^*(\mathcal{I})$, such that the following diagram commutes.



Consider $\mathbb{L}^\gamma := \langle \mathcal{A}, \gamma^{-1}(\mathcal{D}')\rangle$. Clearly, since, by hypothesis and Proposition 1358, $\gamma^{-1}(\mathcal{D}') \subseteq \mathcal{D}$, we have that $\mathbb{L} \le \mathbb{L}^\gamma$. Now we have

$$\begin{array}{rcll}
\mathrm{Ker}(\langle I,\pi\rangle) & = & \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}) & \text{(Set Theory)}\\
& \le & \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}^\gamma) & (\mathbb{L} \le \mathbb{L}^\gamma)\\
& = & \gamma^{-1}(\widetilde{\Omega}^{\mathcal{A}'}(\mathbb{L}')) & \text{(Corollary 1364)}\\
& = & \gamma^{-1}(\Delta^{\mathcal{A}'}) & (\mathbb{L}' \in \mathrm{FStr}^*(\mathcal{I}))\\
& = & \mathrm{Ker}(\langle H,\gamma\rangle). & \text{(Set Theory)}
\end{array}$$

By the Fill-in Lemma (Proposition 1374), there exists a unique logical morphism $\langle H,\gamma^*\rangle : \mathbb{L}^* \to \mathbb{L}'$, such that the displayed diagram commutes, which, in addition, is surjective by the commutativity of the triangle. ■

19.8 Frege Relations Revisited

We revisit here in more detail the types of Frege relations and Frege operators one may consider in conjunction with π-institutions or π-structures, more generally.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $T \in \mathrm{SenFam}(\mathbf{A})$.

- The **local Frege relation family** $\lambda^{\mathbf{A}}(T) = \{\lambda^{\mathbf{A}}_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|}$ **of** T **on** $\mathbf{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\lambda^{\mathbf{A}}_\Sigma(T) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \phi \in T_\Sigma \text{ iff } \psi \in T_\Sigma\}.$$

- The **global Frege relation family** $\Lambda^{\mathbf{A}}(T) = \{\Lambda^{\mathbf{A}}_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|}$ **of** T **on** $\mathbf{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned}\Lambda^{\mathbf{A}}_\Sigma(T) &= \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma,\Sigma'),\\ &\qquad \mathrm{SEN}(f)(\phi) \in T_{\Sigma'} \text{ iff } \mathrm{SEN}(f)(\psi) \in T_{\Sigma'}\}.\end{aligned}$$

The operators $\lambda^{\mathbf{A}}, \Lambda^{\mathbf{A}} : \mathrm{SenFam}(\mathbf{A}) \to \mathrm{RelFam}(\mathbf{A})$ are called the **local** and **global Frege operators on A**, respectively.

Let now $\mathbf{A} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\mathbb{L} = \langle\mathbf{A}, D\rangle$ be a π-structure.

- The **local Frege relation family** $\widetilde{\lambda}^{\mathbf{A}}(\mathbb{L}) = \widetilde{\lambda}^{\mathbf{A}}(D) = \{\widetilde{\lambda}^{\mathbf{A}}_\Sigma(D)\}_{\Sigma\in|\mathbf{Sign}|}$ **of** $\mathbb{L}$, or **of** D **on A**, is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\widetilde{\lambda}^{\mathbf{A}}_\Sigma(D) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : D_\Sigma(\phi) = D_\Sigma(\psi)\}.$$

- The **global Frege relation family** $\widetilde{\Lambda}^{\mathbf{A}}(\mathbb{L}) = \widetilde{\Lambda}^{\mathbf{A}}(D) = \{\widetilde{\Lambda}^{\mathbf{A}}_\Sigma(D)\}_{\Sigma\in|\mathbf{Sign}|}$ **of** $\mathbb{L}$, or **of** D **on A**, is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned}\widetilde{\Lambda}^{\mathbf{A}}_\Sigma(D) &= \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma,\Sigma'),\\ &\qquad D_{\Sigma'}(\mathrm{SEN}(f)(\phi)) = D_{\Sigma'}(\mathrm{SEN}(f)(\psi))\}.\end{aligned}$$

Consider again an algebraic system $\mathbf{A} = \langle\mathbf{Sign}, \mathrm{SEN}, N\rangle$, a π-structure $\mathbb{L} = \langle\mathbf{A}, D\rangle$ and $X \in \mathrm{SenFam}(\mathbf{A})$. Recall the notation $D^X : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$ denoting the closure family on $\mathbf{A}$ that is defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$, by

$$D^X_\Sigma(\Phi) = D_\Sigma(X_\Sigma \cup \Phi).$$

- The **local Frege relation family**

$$\widetilde{\lambda}^{\mathbb{L}}(X) = \widetilde{\lambda}^{\mathbf{A},D}(X) = \{\widetilde{\lambda}^{\mathbf{A},D}_\Sigma(X)\}_{\Sigma\in|\mathbf{Sign}|}$$

of X **in** $\mathbb{L}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\widetilde{\lambda}^{\mathbf{A},D}_\Sigma(X) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : D^X_\Sigma(\phi) = D^X_\Sigma(\psi)\}.$$

- The **global Frege relation family**

$$\widetilde{\Lambda}^{\mathbb{L}}(X) = \widetilde{\Lambda}^{\mathbf{A},D}(X) = \{\widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X)\}_{\Sigma\in|\mathbf{Sign}|}$$

of X **in** $\mathbb{L}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned}\widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X) &= \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma,\Sigma'),\\ &\qquad D^X_{\Sigma'}(\mathrm{SEN}(f)(\phi)) = D^X_{\Sigma'}(\mathrm{SEN}(f)(\psi))\}.\end{aligned}$$

The operators $\widetilde{\lambda}^{\mathbf{A},D}, \widetilde{\Lambda}^{\mathbf{A},D} : \mathrm{SenFam}(\mathbf{A}) \to \mathrm{RelFam}(\mathbf{A})$ are called the **local** and **global Frege operators on** $\mathbb{L}$, respectively.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, $\mathbb{L} = \langle \mathbf{A}, D\rangle$ be a π-structure and $X \in \mathrm{SenFam}(\mathbf{A})$. Some obvious relationships hold between several of the notions defined above. We denote by $\mathrm{Thm}(\mathbb{L}) = \{\mathrm{Thm}_\Sigma(\mathbb{L})\}_{\Sigma\in|\mathbf{Sign}|}$, where $\mathrm{Thm}_\Sigma(\mathbb{L}) = D_\Sigma(\varnothing)$, an obvious generalization of the corresponding notion from π-institutions. Note, however, that, since D is not necessarily structural, in this case $\mathrm{Thm}(\mathbb{L})$ is a theory family, but not necessarily a theory system. Then, we have the following:

$$\begin{array}{rcl}\widetilde{\lambda}^{\mathbf{A}}(D) & = & \widetilde{\lambda}^{\mathbf{A},D}(\mathrm{Thm}(\mathbb{L}));\\ \widetilde{\Lambda}^{\mathbf{A}}(D) & = & \widetilde{\Lambda}^{\mathbf{A},D}(\mathrm{Thm}(\mathbb{L}));\\ & & \\ \widetilde{\lambda}^{\mathbf{A},D}(X) & = & \bigcap\{\lambda^{\mathbf{A}}(T) : X \le T \in \mathrm{ThFam}(\mathbb{L})\};\\ \widetilde{\Lambda}^{\mathbf{A},D}(X) & = & \bigcap\{\Lambda^{\mathbf{A}}(T) : X \le T \in \mathrm{ThFam}(\mathbb{L})\}.\end{array}$$

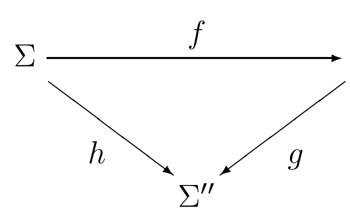
We show that all three local Frege operators give rise to equivalence families, whereas all three global operators give rise to equivalence systems on the underlying algebraic system $\mathbf{A}$.

Lemma 1415 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure and* $X \in \mathrm{SenFam}(\mathbf{A})$.

(a) $\lambda^{\mathbf{A}}(X)$, $\widetilde{\lambda}^{\mathbf{A}}(D)$ *and* $\widetilde{\lambda}^{\mathbf{A},D}(X)$ *are equivalence families on* $\mathbf{A}$*;*

(b) $\Lambda^{\mathbf{A}}(X)$, $\widetilde{\Lambda}^{\mathbf{A}}(D)$ *and* $\widetilde{\Lambda}^{\mathbf{A},D}(X)$ *are equivalence systems on* $\mathbf{A}$*.*

Proof: Because of the interdependencies between these concepts, pointed out before the lemma, it suffices to prove the statements only for $\lambda^{\mathbf{A}}(X)$ and $\Lambda^{\mathbf{A}}(X)$. That both $\lambda^{\mathbf{A}}(X)$ and $\Lambda^{\mathbf{A}}(X)$ are equivalence families is obvious because of the properties of the equivalence connective used in their definitions. So it suffices to show only that $\Lambda^{\mathbf{A}}(X)$ is a system, i.e., that it is invariant under signature morphisms. So suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi\rangle \in \Lambda^{\mathbf{A}}_\Sigma(X)$ and let $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$.



By the definition of $\Lambda^{\mathbf{A}}(X)$, we have that, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $h \in \mathbf{Sign}(\Sigma, \Sigma'')$,

$$D_{\Sigma''}(\mathrm{SEN}(h)(\phi)) = D_{\Sigma''}(\mathrm{SEN}(h)(\psi)).$$

A fortiori, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$, we have

$$D_{\Sigma''}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\phi))) = D_{\Sigma''}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\psi))).$$

By the definition of $\Lambda^{\mathbf{A}}(X)$, this proves that $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi)\rangle \in \Lambda^{\mathbf{A}}_{\Sigma'}(X)$. Thus $\Lambda^{\mathbf{A}}(X)$ is indeed an equivalence system on $\mathbf{A}$. ■

The next lemma shows that all four "tilde" Frege operators are monotone.

Lemma 1416 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure on* $\mathbf{A}$*.*

(a) $\widetilde{\lambda}^{\mathbf{A}}, \widetilde{\Lambda}^{\mathbf{A}} : \mathbf{ClFam}(\mathbf{A}) \to \mathbf{EqvFam}(\mathbf{A})$ *are monotone;*

(b) $\widetilde{\lambda}^{\mathbf{A},D}, \widetilde{\Lambda}^{\mathbf{A},D} : \mathbf{SenFam}(\mathbf{A}) \to \mathbf{EqvFam}(\mathbf{A})$ *are monotone.*

Proof: Suppose $D, D' \in \mathrm{ClFam}(\mathbf{A})$, such that $D \le D'$, and let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi\rangle \in \widetilde{\lambda}^{\mathbf{A}}_{\Sigma}(D)$. Then $D_\Sigma(\phi) = D_\Sigma(\psi)$, whence $D'_\Sigma(\phi) = D'_\Sigma(\psi)$. Thus, $\langle \phi, \psi\rangle \in \widetilde{\lambda}^{\mathbf{A}}_{\Sigma}(D')$. We conclude that $\widetilde{\lambda}^{\mathbf{A}}(D) \le \widetilde{\lambda}^{\mathbf{A}}(D')$. The proof for $\widetilde{\Lambda}^{\mathbf{A}} : \mathbf{ClFam}(\mathbf{A}) \to \mathbf{EqvFam}(\mathbf{A})$ is similar.

Suppose, next, that $X, X' \in \mathrm{SenFam}(\mathbf{A})$, such that $X \le X'$. Note that, in this situation, we have

$$\{T \in \mathrm{ThFam}(\mathbb{L}) : X' \le T\} \subseteq \{T \in \mathrm{ThFam}(\mathbb{L}) : X \le T\}.$$

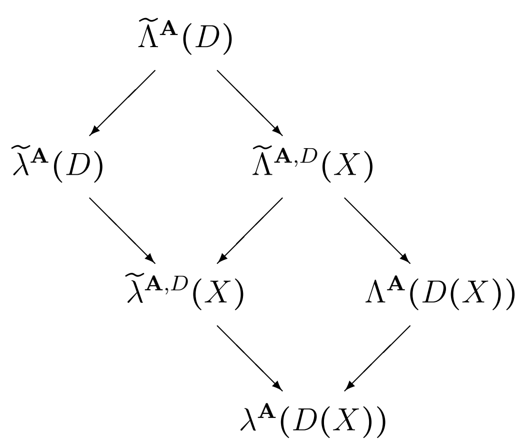
Therefore, we have

$$\begin{array}{rcl}\widetilde{\lambda}^{\mathbf{A},D}(X) & = & \bigcap\{\lambda^{\mathbf{A}}(T) : X \le T \in \mathrm{ThFam}(\mathbb{L})\}\\ & \le & \bigcap\{\lambda^{\mathbf{A}}(T) : X' \le T \in \mathrm{ThFam}(\mathbb{L})\}\\ & = & \widetilde{\lambda}^{\mathbf{A},D}(X').\end{array}$$

The proof for $\widetilde{\Lambda}^{\mathbf{A},D} : \mathbf{SenFam}(\mathbf{A}) \to \mathbf{EqvFam}(\mathbf{A})$ is similar. ■

The equivalence families produced by applying the six Frege operators form a hierarchy under inclusion that we now make explicit.

Proposition 1417 *Let* $\mathbf{A} = \langle \mathbf{A}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure and* $X \in \mathrm{SenFam}(\mathbf{A})$*. Then, we have the following inclusions between equivalence families on* $\mathbf{A}$*:*



Proof: First, note that the three southwest inclusions are obvious, since the conditions defining $\widetilde{\lambda}^{\mathbf{A}}$, $\widetilde{\lambda}^{\mathbf{A},D}$ and $\lambda^{\mathbf{A}}$ are special cases of the ones defining $\widetilde{\Lambda}^{\mathbf{A}}$, $\widetilde{\Lambda}^{\mathbf{A},D}$ and $\Lambda^{\mathbf{A}}$, respectively.

We show, next, the southeast inclusions between the λ's, since the ones between the Λ's may shown similarly. We have

$$\widetilde{\lambda}^{\mathbf{A}}(D) = \widetilde{\lambda}^{\mathbf{A},D}(\mathrm{Thm}(\mathbb{L})) \leq \widetilde{\lambda}^{\mathbf{A},D}(D(X)) = \widetilde{\lambda}^{\mathbf{A},D}(X).$$

Moreover,

$$\begin{array}{rcl}\widetilde{\lambda}^{\mathbf{A},D}(X) & = & \bigcap\{\lambda^{\mathbf{A}}(T) : X \leq T \in \mathrm{ThFam}(\mathbb{L})\}\\ & \leq & \lambda^{\mathbf{A}}(D(X)).\end{array}$$

Therefore, we have $\widetilde{\lambda}^{\mathbf{A}}(D) \leq \widetilde{\lambda}^{\mathbf{A},D}(X) \leq \lambda^{\mathbf{A}}(D(X))$. ■

In the case of structural π-structures, i.e., π-institutions, the hierarchy collapses to a smaller one, the top pair collapses and in the case of a sentence system, the middle pair does also. More precisely, we have

Proposition 1418 *Let* $\mathbf{A} = \langle\mathbf{A}, \mathrm{SEN}, N\rangle$ *be an algebraic system,* $\mathbb{L} = \langle\mathbf{A}, D\rangle$ *a* π*-structure and* $X \in \mathrm{SenSys}(\mathbf{A})$*. If* D *is structural, then*

$$\widetilde{\Lambda}^{\mathbf{A}}(D) = \widetilde{\lambda}^{\mathbf{A}}(D) \quad \textit{and} \quad \widetilde{\Lambda}^{\mathbf{A},D}(X) = \widetilde{\lambda}^{\mathbf{A},D}(X).$$

Proof: By the remarks preceding Lemma 1415, it suffices to show that the second equation holds. Since it is always the case that $\widetilde{\Lambda}^{\mathbf{A},D}(X) \leq \widetilde{\lambda}^{\mathbf{A},D}(X)$, we must prove the opposite inclusion. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi, \psi\rangle \in \widetilde{\lambda}^{\mathbf{A},D}_{\Sigma}(X)$. Then, we have, by definition, $D_\Sigma(X_\Sigma, \phi) = D_\Sigma(X_\Sigma, \psi)$. By the structurality of D, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

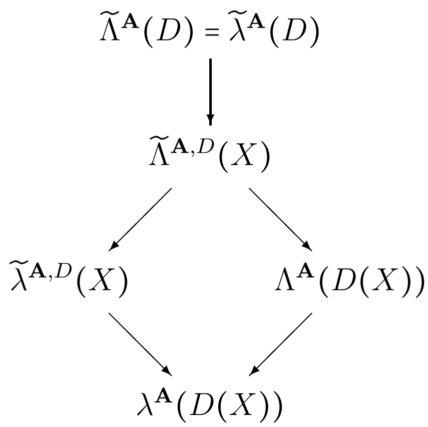
$$D_{\Sigma'}(\mathrm{SEN}(f)(X_\Sigma), \mathrm{SEN}(f)(\phi)) = D_{\Sigma'}(\mathrm{SEN}(f)(X_\Sigma), \mathrm{SEN}(f)(\psi)).$$

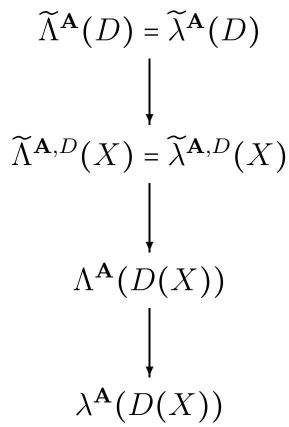
Therefore, is X is a sentence system, we get

$$D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\phi)) = D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\psi)).$$

We conclude that $\langle\phi, \psi\rangle \in \widetilde{\Lambda}^{\mathbf{A},D}_{\Sigma}(X)$. ■

Thus, if $\mathbb{L} = \langle\mathbf{A}, D\rangle$ is a π-institution, and $X \in \mathrm{SenFam}(\mathbf{A})$, we obtain the simplified hierarchy of Frege relation families shown on the left and, if, in addition, $X \in \mathrm{SenSys}(\mathbf{A})$, we get the linear hierarchy shown on the right.





We look next at how finitarity of a closure family relates to continuity of Frege operators.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system. Recall that:

- An $X \in \mathrm{SenFam}(\mathbf{A})$ is called **locally finite** if, for all $\Sigma \in |\mathbf{Sign}|$, X_Σ is finite. We write $Y \leq_{lf} X$ to suggest that Y is a locally finite sentence subfamily of X.

- A collection $\mathcal{X} \subseteq \mathrm{SenFam}(\mathbf{A})$ is said to be **locally directed** if, for every $\Sigma \in |\mathbf{Sign}|$ and finite $\mathcal{Y} \subseteq \mathcal{X}$, there exists $X \in \mathcal{X}$, such that $Y_\Sigma \leq X_\Sigma$, for all $Y \in \mathcal{Y}$.

Let $\mathbb{L} = \langle \mathbf{A}, D \rangle$ be a π-structure based on $\mathbf{A}$.

- $\mathbb{L}$ is **finitary** if, for all $X \in \mathrm{SenFam}(\mathbf{A})$,
$$D(X) = \bigcup \{D(Y) : Y \leq_{lf} X\}.$$

- The operator $\widetilde{\lambda}^{\mathbf{A},D} : \mathrm{SenFam}(\mathbf{A}) \to \mathrm{EqvFam}(\mathbf{A})$ is **locally continuous** if, for every locally directed $\{X^i : i \in I\} \subseteq \mathrm{SenFam}(\mathbf{A})$,
$$\widetilde{\lambda}^{\mathbf{A},D}(\bigcup_{i \in I} X^i) = \bigcup_{i \in I} \widetilde{\lambda}^{\mathbf{A},D}(X^i).$$

Proposition 1419 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system and* $\mathbb{L} = \langle \mathbf{A}, D \rangle$ *a* π*-structure based on* $\mathbf{A}$. $\mathbb{L}$ *is finitary if and only if*
$$\widetilde{\lambda}^{\mathbf{A},D} : \mathrm{SenFam}(\mathbf{A}) \to \mathrm{EqvFam}(\mathbf{A})$$
is locally continuous.

Proof: Suppose, first, that $\mathbb{L}$ is finitary and let $\{X^i : i \in I\} \subseteq \mathrm{SenFam}(\mathbf{A})$ be locally directed. Since, by Lemma 1416, $\widetilde{\lambda}^{\mathbf{A},D}$ is monotone, we have

$$\bigcup_{i\in I}\widetilde{\lambda}^{\mathbf{A},D}(X^i) \le \widetilde{\lambda}^{\mathbf{A},D}(\bigcup_{i\in I}X^i).$$

To show the reverse inclusion, let $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \widetilde{\lambda}^{\mathbf{A},D}_\Sigma(\bigcup_{i\in I}X^i)$. Then, by definition, $D_\Sigma(\bigcup_{i\in I}X^i_\Sigma,\phi) = D_\Sigma(\bigcup_{i\in I}X^i_\Sigma,\psi)$. Since $\mathbb{L}$ is finitary, there exists finite $\Phi \le_f \bigcup_{i\in I}X^i_\Sigma$, such that $D_\Sigma(\Phi,\phi) = D_\Sigma(\Phi,\psi)$. Hence, since $\{X^i : i \in I\}$ is locally directed, there exists $i \in I$, such that $\Phi \subseteq X^i_\Sigma$. Hence, $D_\Sigma(X^i_\Sigma,\phi) = D_\Sigma(X^i_\Sigma,\psi)$, i.e., $\langle\phi,\psi\rangle \in \widetilde{\lambda}^{\mathbf{A},D}_\Sigma(X^i)$. We conclude that $\widetilde{\lambda}^{\mathbf{A},D}(\bigcup_{i\in I}X^i) \le \bigcup_{i\in I}\widetilde{\lambda}^{\mathbf{A},D}(X^i)$.

Assume, conversely, that $\widetilde{\lambda}^{\mathbf{A},D}$ is locally continuous and consider $X \in \mathrm{SenFam}(\mathbf{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(X_\Sigma)$. Let $\mathcal{Z} = \{Z \in \mathrm{SenFam}(\mathbf{A}) : Z \le_{lf} X\}$. $\mathcal{Z}$ is a locally directed family, such that $\bigcup\mathcal{Z} = X$. For all $\psi \in X_\Sigma$, we have $D_\Sigma(X_\Sigma,\phi) = D_\Sigma(X_\Sigma,\psi) = D_\Sigma(X_\Sigma)$. So we get

$$\langle\phi,\psi\rangle \in \widetilde{\lambda}^{\mathbf{A},D}_\Sigma(X) = \widetilde{\lambda}^{\mathbf{A},D}_\Sigma(\bigcup\mathcal{Z}).$$

By the local directedness of $\mathcal{Z}$ and local continuity of $\widetilde{\lambda}^{\mathbf{A},D}$, we get $\langle\phi,\psi\rangle \in \bigcup_{Z\in\mathcal{Z}}\widetilde{\lambda}^{\mathbf{A},D}_\Sigma(Z)$. Therefore, we get, for some $Z \le_{lf} X$, $\phi \in D_\Sigma(Z_\Sigma,\psi) = D_\Sigma(Z_\Sigma)$. This shows that $\mathbb{L}$ is finitary. ∎

Among the key properties of Frege relations, which partly explains their usefulness in the algebraic study of logical systems, is that, loosely speaking, they are approximated from below by the Leibniz, the Tarski and the Suszko congruence systems.

Proposition 1420 *Let* $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$ *be an algebraic system and* $\mathbb{L} = \langle\mathbf{A},D\rangle$ *a* π*-structure based on* $\mathbf{A}$ *and* $T \in \mathrm{ThFam}(\mathbb{L})$.

(a) The Leibniz congruence system $\Omega^{\mathbf{A}}(T)$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\Lambda^{\mathbf{A}}(T)$ *and in* $\lambda^{\mathbf{A}}(T)$*;*

(b) The Tarski congruence system $\widetilde{\Omega}^{\mathbf{A}}(D)$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\Lambda}^{\mathbf{A}}(D)$ *and in* $\widetilde{\lambda}^{\mathbf{A}}(D)$*;*

(c) The Suszko congruence system $\widetilde{\Omega}^{\mathbf{A},D}(T)$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\Lambda}^{\mathbf{A},D}(T)$ *and in* $\widetilde{\lambda}^{\mathbf{A},D}(T)$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \Omega^{\mathbf{A}}_\Sigma(T)$. Since $\Omega^{\mathbf{A}}(T)$ is a congruence system, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma,\Sigma')$, $\langle\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi)\rangle \in \Omega^{\mathbf{A}}_{\Sigma'}(T)$. Thus, by the compatibility property of $\Omega^{\mathbf{A}}(T)$ with T, we get

$$\mathrm{SEN}(f)(\phi) \in T_{\Sigma'} \quad \text{iff} \quad \mathrm{SEN}(f)(\psi) \in T_{\Sigma'},$$

i.e., $\langle\phi,\psi\rangle \in \Lambda^{\mathbf{A}}_\Sigma(T)$. We conclude that $\Omega^{\mathbf{A}}(T) \le \Lambda^{\mathbf{A}}(T) \le \lambda^{\mathbf{A}}(T)$.

Suppose, next, that $\theta \in \mathrm{ConSys}(\mathbf{A})$, such that $\theta \leq \lambda^{\mathbf{A}}(T)$. If $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$ and $\phi \in T_\Sigma$, then $\langle \phi, \psi \rangle \in \lambda^{\mathbf{A}}(T)$ and $\phi \in T_\Sigma$, whence by the definition of $\lambda^{\mathbf{A}}(T)$, $\psi \in T_\Sigma$. Thus, θ is a congruence system on $\mathbf{A}$ compatible with T and, therefore, $\theta \leq \Omega^{\mathbf{A}}(T)$, by the maximality property of $\Omega^{\mathbf{A}}(T)$.

Parts (b) and (c) can be proved similarly. ∎

We show next that Frege relations are preserved under inverse surjective morphisms.

Lemma 1421 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be π-structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ a surjective morphism.*

(a) For every $X \in \mathrm{SenFam}(\mathbf{A}')$, $\Lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\Lambda^{\mathbf{A}'}(X))$ and, also, $\lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\lambda^{\mathbf{A}'}(X))$;

(b) If $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, then $\widetilde{\Lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\widetilde{\Lambda}^{\mathbf{A}'}(D'))$ and, also, $\widetilde{\lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\widetilde{\lambda}^{\mathbf{A}'}(D'))$.

Proof:

(a) Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$. We have $\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\Lambda^{\mathbf{A}'}(X))$ iff $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Lambda^{\mathbf{A}'}_{F(\Sigma)}(X)$ iff, by surjectivity, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) \in X_{F(\Sigma')} \quad \text{iff} \quad \mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi)) \in X_{F(\Sigma')},$$

iff, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \in X_{F(\Sigma')} \quad \text{iff} \quad \alpha_{\Sigma'}(\mathrm{SEN}'(f)(\psi)) \in X_{F(\Sigma')},$$

iff, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\phi) \in \alpha_{\Sigma'}^{-1}(X_{F(\Sigma')}) \quad \text{iff} \quad \mathrm{SEN}(f)(\psi) \in \alpha_{\Sigma'}^{-1}(X_{F(\Sigma')}),$$

iff, $\langle \phi, \psi \rangle \in \Lambda^{\mathbf{A}}_\Sigma(\alpha^{-1}(X))$.

The proof of $\lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\lambda^{\mathbf{A}'}(X))$ is similar.

(b) We have

$$\begin{array}{rcl}
\widetilde{\Lambda}(D) & = & \bigcap\{\Lambda^{\mathbf{A}}(T) : T \in \mathrm{ThFam}(\mathbb{L})\} \\
& = & \bigcap\{\Lambda(\alpha^{-1}(T')) : T' \in \mathrm{ThFam}(\mathbb{L}')\} \\
& = & \bigcap\{\alpha^{-1}(\Lambda^{\mathbf{A}'}(T')) : T' \in \mathrm{ThFam}(\mathbb{L}')\} \\
& = & \alpha^{-1}(\bigcap\{\Lambda^{\mathbf{A}'}(T') : T' \in \mathrm{ThFam}(\mathbb{L}')\}) \\
& = & \alpha^{-1}(\widetilde{\Lambda}^{\mathbf{A}'}(D')).
\end{array}$$

The proof of $\widetilde{\lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\widetilde{\lambda}^{\mathbf{A}'}(D'))$ is similar.

∎

19.9 Fullness and Metalogical Properties

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system.

An **F-rule** is a pair $\langle P, \rho \rangle$, with $P \cup \{\rho\} : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a finite set of natural transformations in $N^\flat$.

A **generalized** or **Gentzen F-rule**, or **F-grule** for short, is a pair

$$\langle \{\langle P^i, \rho^i \rangle : i \in I\}, \langle P, \rho \rangle \rangle,$$

where $\{\langle P^i, \rho^i \rangle : i \in I\} \cup \{\langle P, \rho \rangle\}$ is a finite set of **F**-rules. We sometimes write an **F**-grule in the "two-line" format

$$\frac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle} \quad \text{or} \quad \frac{P^i \vdash \rho^i : i \in I}{P \vdash \rho}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on **F**. $\mathcal{I}$ **satisfies** $\dfrac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\rho^i_\Sigma(\vec{\chi}) \in C_\Sigma(P^i_\Sigma(\vec{\chi})),\ i \in I, \quad \text{impies} \quad \rho_\Sigma(\vec{\chi}) \in C_\Sigma(P_\Sigma(\vec{\chi})).$$

Similarly, an **F**-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, **satisfies** $\dfrac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle}$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$,

$$\rho^i_\Sigma(\vec{\chi}) \in D_\Sigma(P^i_\Sigma(\vec{\chi})),\ i \in I, \quad \text{impies} \quad \rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi})).$$

Since an **F**-rule can be perceived as a a special case of an **F**-grule (with empty set of premises), this notion of satisfaction applies in particular to **F**-rules.

It turns out that satisfaction of **F**-rules is transferred from a π-institution to all its structure models.

Proposition 1422 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* **F**. *If* $\mathcal{I}$ *satisfies an* **F***-rule* $\langle P, \rho \rangle$*, then every* $\mathcal{I}$*-structure satisfies the same* **F***-rule.*

Proof: Suppose $\mathcal{I}$ satisfies $\langle P, \rho \rangle$ and let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be an $\mathcal{I}$-structure, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$. Then, for all $T \in \mathrm{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, we have $P_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}$ if and only if $\alpha_\Sigma(P_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}$ if and only if $P_\Sigma(\vec{\chi}) \subseteq \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. Thus, since, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get, by hypothesis, $\rho_\Sigma(\vec{\chi}) \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. This is equivalent to $\alpha_\Sigma(\rho_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$ and, in turn, to $\rho_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$. We conclude, by the surjectivity of $\langle F, \alpha \rangle$, that $\mathbb{L}$ satisfies $\langle P, \rho \rangle$ as well. ■

Moreover, it turns out that satisfaction of an **F**-grule, in general, is preserved by bilogical morphisms.

Proposition 1423 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ π*-structures based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism. Then* $\mathbb{L}$ *satisfies an* $\mathbf{F}$*-grule* $\langle \{\langle P^i, \rho^i \rangle : i \in I\}, \langle P, \rho \rangle \rangle$ *if and only if* $\mathbb{L}'$ *satisfies the same* $\mathbf{F}$*-grule.*

Proof: Suppose, first, that $\mathbb{L}$ satisfies the $\mathbf{F}$-grule and let $\Sigma \in |\mathbf{Sign}|$, $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that, for all $i \in I$,

$$\rho'^i_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'^i_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))).$$

This is equivalent to

$$\alpha_\Sigma(\rho^i_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(\alpha_\Sigma(P^i_{F(\Sigma)}(\vec{\chi}))).$$

Since $\langle F, \alpha \rangle$ is a bilogical morphism, we get $\rho^i_\Sigma(\vec{\chi}) \in D_\Sigma(P^i_\Sigma(\vec{\chi}))$. Since, by hypothesis, $\mathbb{L}$ satisfies the given $\mathbf{F}$-grule, we get that $\rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi}))$. Reversing the steps above, we conclude that

$$\rho'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))).$$

Since $\langle F, \alpha \rangle$ is surjective, this shows that $\mathbb{L}'$ satisfies the $\mathbf{F}$-grule as well.

Suppose, conversely, that $\mathbb{L}'$ satisfies the $\mathbf{F}$-grule $\langle \{\langle P^i, \rho^i \rangle : i \in I\}, \langle P, \rho \rangle \rangle$. Let $\Sigma \in |\mathbf{Sign}|$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that, for all $i \in I$,

$$\rho^i_\Sigma(\vec{\chi}) \in D_\Sigma(P^i_\Sigma(\vec{\chi})).$$

Since, $\langle F, \alpha \rangle$ is a bilogical morphism, we get

$$\alpha_\Sigma(\rho^i_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(\alpha_\Sigma(P^i_\Sigma(\vec{\chi}))),$$

which gives $\rho'^i_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'^i_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})))$. Since, by hypothesis, $\mathbb{L}'$ satisfies the given $\mathbf{F}$-grule, we now get

$$\rho'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))).$$

Reversing again the preceding steps, we finally obtain that

$$\rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi})).$$

Thus, $\mathbb{L}$ satisfies the same $\mathbf{F}$-grule as well. ■

19.9.1 The Congruence Property

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π-structure.

- $\mathbb{L}$ has the **Congruence Property** if $\widetilde{\Lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}$, i.e., by Proposition 1420, if and only if
$$\widetilde{\Lambda}^{\mathbf{A}}(D) = \widetilde{\Omega}^{\mathbf{A}}(D);$$
- $\mathbb{L}$ has the **strong Congruence Property** if $\widetilde{\lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}$, i.e., by Proposition 1420, if and only if
$$\widetilde{\lambda}^{\mathbf{A}}(D) = \widetilde{\Omega}^{\mathbf{A}}(D).$$

Of course, the strong Congruence Property implies the Congruence Property.

Proposition 1424 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π-structure. If $\mathcal{I}$ has the strong Congruence Property, then it has the Congruence Property.*

Proof: We know that $\widetilde{\Omega}^{\mathbf{A}}(D) \le \widetilde{\Lambda}^{\mathbf{A}}(T) \le \widetilde{\lambda}^{\mathbf{A}}(T)$. If $\mathbb{L}$ has the strong Congruence Property, $\widetilde{\Omega}^{\mathbf{A}}(D) = \widetilde{\lambda}^{\mathbf{A}}(T)$, whence, also, $\widetilde{\Omega}^{\mathbf{A}}(D) = \widetilde{\Lambda}^{\mathbf{A}}(T)$. Thus, $\mathbb{L}$ has the Congruence Property. ■

Corollary 1425 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a reduced π-structure based on $\mathbf{A}$.*

(a) $\mathbb{L}$ has the Congruence Property if and only if $\widetilde{\Lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$.

(b) $\mathbb{L}$ has the strong Congruence Property if and only if $\widetilde{\lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$.

Proof: $\mathbb{L}$ has the Congruence Property if and only if $\widetilde{\Lambda}^{\mathbf{A}}(D) = \widetilde{\Omega}^{\mathbf{A}}(D)$ if and only if, since $\mathbb{L}$ is reduced, $\widetilde{\Lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$. Part (b) is similar. ■

It turns out that the Congruence Property is preserved in both directions under bilogical morphisms.

Proposition 1426 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ π-structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism.*

(a) $\mathbb{L}$ has the Congruence Property if and only if $\mathbb{L}'$ has the Congruence Property;

(b) $\mathbb{L}$ has the strong Congruence Property if and only if $\mathbb{L}'$ has the strong Congruence Property.

Proof:

(a) We have

$$\begin{aligned}\widetilde{\Lambda}^{\mathbf{A}}(D) = \widetilde{\Omega}^{\mathbf{A}}(D) \quad &\text{iff} \quad \alpha^{-1}(\widetilde{\Lambda}^{\mathbf{A}'}(D')) = \alpha^{-1}(\widetilde{\Omega}^{\mathbf{A}'}(D'))\\ &\text{iff} \quad \widetilde{\Lambda}^{\mathbf{A}'}(D') = \widetilde{\Omega}^{\mathbf{A}'}(D'),\end{aligned}$$

the first equivalence by Corollary 1364 and Lemma 1421, and the second equivalence by the surjectivity of $\langle F, \alpha\rangle$. Therefore, $\mathbb{L}$ has the Congruence Property if and only if $\mathbb{L}'$ has the Congruence Property.

(b) Similarly,

$$\begin{aligned}\widetilde{\lambda}^{\mathbf{A}}(D) = \widetilde{\Omega}^{\mathbf{A}}(D) \quad &\text{iff} \quad \alpha^{-1}(\widetilde{\lambda}^{\mathbf{A}'}(D')) = \alpha^{-1}(\widetilde{\Omega}^{\mathbf{A}'}(D'))\\ &\text{iff} \quad \widetilde{\lambda}^{\mathbf{A}'}(D') = \widetilde{\Omega}^{\mathbf{A}'}(D'),\end{aligned}$$

the first equivalence by Corollary 1364 and Lemma 1421, and the second equivalence by the surjectivity of $\langle F, \alpha\rangle$. Therefore, $\mathbb{L}$ has the strong Congruence Property if and only if $\mathbb{L}'$ has the strong Congruence Property. ■

Using the Congruence Property, we are now able to introduce the first two classes of the Frege hierarchy of π-institutions, which will be looked more closely at in a subsequent chapter.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, \mathbb{N}^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **selfextensional** if it has the Congruence Property, i.e., if

$$\widetilde{\Lambda}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I}).$$

  Recall from Proposition 1418, that, since $\mathcal{I}$, is structural, this is equivalent to having the strong Congruence Property.

- $\mathcal{I}$ is **fully selfextensional** if every full $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D\rangle$ has the Congruence Property, i.e., if, for all $\mathbb{L} = \langle \mathcal{A}, D\rangle \in \mathrm{FStr}(\mathcal{I})$,

$$\widetilde{\Lambda}^{\mathcal{A}}(D) = \widetilde{\Omega}^{\mathcal{A}}(D).$$

  Recall, also, from Proposition 1389 and Proposition 1418, that, since every full $\mathcal{I}$-structure is structural, this amounts to every full $\mathcal{I}$-structure having the strong Congruence Property.

We give a characterization of selfextensional π-institutions next.

Proposition 1427 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is selfextensional if and only if, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$,*

$$\begin{aligned}&C_\Sigma(\phi_i) = C_\Sigma(\psi_i), \; i < k,\\ &\qquad \textit{imply} \quad C_\Sigma(\sigma^\flat_\Sigma(\phi_0, \dots, \phi_{k-1})) = C_\Sigma(\sigma^\flat_\Sigma(\psi_0, \dots, \psi_{k-1})).\end{aligned}$$

Proof: Suppose that $\mathcal{I}$ is selfextensional and let $\sigma^\flat \in N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$, such that $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$, $i < k$. Thus, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) = \widetilde{\Omega}_\Sigma(\mathcal{I})$, by selfextensionality. Since $\widetilde{\Omega}(\mathcal{I})$ is a congruence system,

$$\langle \sigma^\flat_\Sigma(\phi_0, \dots, \phi_{k-1}), \sigma^\flat_\Sigma(\psi_0, \dots, \psi_{k-1}) \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}) = \widetilde{\lambda}_\Sigma(\mathcal{I}).$$

We conclude that $C_\Sigma(\sigma^\flat_\Sigma(\phi_0, \dots, \phi_{k-1})) = C_\Sigma(\sigma^\flat_\Sigma(\psi_0, \dots, \psi_{k-1}))$.

Suppose, conversely, that the displayed condition holds. Then $\widetilde{\lambda}(\mathcal{I})$ is a congruence system on $\mathbf{F}$. Therefore, by Proposition 1420, we have that $\widetilde{\Omega}(\mathcal{I}) = \widetilde{\lambda}(\mathcal{I})$. We conclude that $\mathcal{I}$ is selfextensional. ∎

And also a characterization of fully selfextensional π-institutions.

Proposition 1428 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is fully selfextensional if and only if every $\mathbf{F}$-structure of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Congruence Property.*

Proof: Assume, first, that $\mathcal{I}$ is fully selfextensional. By definition, every full $\mathcal{I}$-structure has the Congruence Property. By Proposition 1390, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is full, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. Therefore, every $\mathbf{F}$-structure of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Congruence Property.

Assume, conversely, that every $\mathbf{F}$-structure of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Congruence Property. Let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be a full $\mathcal{I}$-structure. Then, by definition, the reduction morphism is a bilogical morphism

$$\langle I, \pi \rangle : \langle \mathcal{A}, D \rangle \vdash \langle \mathcal{A}^*, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle.$$

By hypothesis, $\langle \mathcal{A}^*, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$ has the Congruence Property. Thus, by Proposition 1426, $\mathbb{L}$ also has the Congruence Property. Therefore, every full $\mathcal{I}$-structure has the Congruence Property and we conclude that $\mathcal{I}$ is fully selfextensional. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Recall that the **Lindenbaum-Tarski algebraic system of** $\mathcal{I}$ is the algebraic system $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Recall, also, that, given a class of $\mathbf{F}$-algebraic systems, $Q(\mathsf{K})$ denotes the syntactic variety generated by K, i.e., those $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, such that $\bigcap \{\mathrm{Ker}(\mathcal{K}) : \mathcal{K} \in \mathsf{K}\} \leq \mathrm{Ker}(\mathcal{A})$. We denoted $\mathsf{Q}(\mathcal{I}) = Q(\mathcal{F}/\widetilde{\Omega}(\mathcal{I}))$, the syntactic variety generated by the Lindenbaum-Tarski $\mathbf{F}$-algebraic system of $\mathcal{I}$. Moreover, given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we write $\mathsf{K} \vDash_\Sigma \phi \approx \psi$ for $\langle \phi, \psi \rangle \in \bigcap_{\mathcal{K} \in \mathsf{K}} \mathrm{Ker}_\Sigma(\mathcal{K})$.

Using these conventions, we can formulate a proposition to the effect that, for a selfextensional π-institution $\mathcal{I}$, an equation is satisfied in $\mathsf{Q}(\mathcal{I})$ if and only if it is in the Frege equivalence family $\widetilde{\lambda}(\mathcal{I})$.

Proposition 1429 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is selfextensional, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\mathsf{Q}(\mathcal{I}) \vDash_\Sigma \phi \approx \psi \quad \textit{if and only if} \quad \langle \phi, \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}).$$

Proof: By the definition of $\mathsf{Q}(\mathcal{I})$, it is easy to see that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\mathsf{Q}(\mathcal{I}) \vDash_\Sigma \phi \approx \psi \quad \text{iff} \quad \langle \phi, \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}).$$

Since $\mathcal{I}$ is assumed selfextensional, this happens if and only if $\langle \phi, \psi \rangle \in \widetilde{\Lambda}_\Sigma(\mathcal{I})$, i.e., due to the structurality of C, if and only if $\langle \phi, \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$. ■

19.9.2 The Property of Conjunction

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system, such that, in N, there exists a binary natural transformation

$$\wedge : \mathrm{SEN}^2 \to \mathrm{SEN},$$

and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π-structure. We say that $\mathbb{L}$ has the **Conjunction Property with respect to** $\wedge$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\phi \wedge_\Sigma \psi) = D_\Sigma(\phi, \psi),$$

where $\phi \wedge_\Sigma \psi := \wedge_\Sigma(\phi, \psi)$. In this case, we also say $\wedge$ is a **conjunction** for $\mathbb{L}$ and that $\mathbb{L}$ is **conjunctive**.

Lemma 1430 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system, with* $\wedge : \mathrm{SEN}^2 \to \mathrm{SEN}$ *in* N*, and* $\mathbb{L} = \langle \mathbf{A}, D \rangle$ *a* π*-structure based on* $\mathbf{A}$*.* $\mathbb{L}$ *has the Conjunction Property with respect to* $\wedge$ *if and only if, for every* $T \in \mathrm{ThFam}(\mathbb{L})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \wedge_\Sigma \psi \in T_\Sigma \quad \textit{iff} \quad \phi \in T_\Sigma \textit{ and } \psi \in T_\Sigma.$$

Proof: Suppose that $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$ and let $T \in \mathrm{ThFam}(\mathbb{L})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$.

If $\phi \wedge_\Sigma \psi \in T_\Sigma$, then

$$\phi \in D_\Sigma(\phi, \psi) = D_\Sigma(\phi \wedge_\Sigma \psi) \subseteq D_\Sigma(T_\Sigma) = T_\Sigma.$$

Similarly, $\psi \in T_\Sigma$.

Conversely, if $\phi, \psi \in T_\Sigma$, then

$$\phi \wedge_\Sigma \psi \in D_\Sigma(\phi \wedge_\Sigma \psi) = D_\Sigma(\phi, \psi) \subseteq D_\Sigma(T_\Sigma) = T_\Sigma.$$

Thus, $\phi \wedge_\Sigma \psi \in T_\Sigma$ if and only if $\phi, \psi \in T_\Sigma$.

Suppose, conversely, that the displayed condition in the statement is satisfied. Then, for all $\Sigma \in |\mathbf{Sign}|$, and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rcl} D_\Sigma(\phi \wedge_\Sigma \psi) & = & \bigcap\{T_\Sigma : T \in \mathrm{ThFam}(\mathbb{L}) \text{ and } \phi \wedge_\Sigma \psi \in T_\Sigma\} \\ & = & \bigcap\{T_\Sigma : T \in \mathrm{Thfam}(\mathbb{L}) \text{ and } \phi, \psi \in T_\Sigma\} \\ & = & D_\Sigma(\phi, \psi). \end{array}$$

So $\wedge : \mathrm{SEN}^2 \to \mathrm{SEN}$ is a conjunction for $\mathbb{L}$. ■

In terms of **F**-rules one can characterize the Conjunction Property as follows.

Proposition 1431 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *based on* $\mathbf{F}$. $\mathcal{I}$ *has the Conjunction Property if and only if it satisfies*

$$p^{2,0}, p^{2,1} \vdash \wedge^\flat \circ \langle p^{2,0}, p^{2,1}\rangle, \quad \wedge^\flat \circ \langle p^{2,0}, p^{2,1}\rangle \vdash p^{2,0}, \quad \wedge^\flat \circ \langle p^{2,0}, p^{2,1}\rangle \vdash p^{2,1}.$$

Note that, in practice, we write these **F**-grules in the more familiar form

$$x, y \vdash x \wedge^\flat y, \quad x \wedge^\flat y \vdash x, \quad x \wedge^\flat y \vdash y,$$

where $x, y, z, \ldots$ stand for the corresponding projection natural transformations in $N^\flat$.

Proof: We have that $\mathcal{I}$ satisfies

$$x, y \vdash x \wedge^\flat y, \quad x \wedge^\flat y \vdash x, \quad x \wedge^\flat y \vdash y,$$

iff, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \wedge^\flat_\Sigma \psi \in C_\Sigma(\phi, \psi), \quad \phi \in C_\Sigma(\phi \wedge^\flat_\Sigma \psi), \quad \psi \in C_\Sigma(\phi \wedge^\flat_\Sigma \psi),$$

iff, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C_\Sigma(\phi \wedge^\flat_\Sigma \psi) = C_\Sigma(\phi, \psi)$$

iff $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^\flat$. ■

Having the Conjunction Property is preserved under bilogical morphisms in both directions.

Proposition 1432 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system with a binary* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$. *Suppose* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *are* $N^\flat$*-algebraic systems* $\mathbb{L} = \langle \mathbf{A}, D\rangle$, $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ π*-structures based on* $\mathbf{A}$, $\mathbf{A}'$*, respectively, and* $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism.* $\mathbb{L}$ *has the Conjunction Property with respect to* $\wedge$ *if and only if* $\mathbb{L}'$ *has the Conjunction Property with respect to* $\wedge'$.

Proof: This follows by Proposition 1431 and Proposition 1423. ∎

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\wedge : \mathrm{SEN}^2 \to \mathrm{SEN}$ a binary natural transformation in N. We denote by $N^\wedge$ the category of natural transformations on SEN generated by $\wedge$. Clearly, since $\wedge$ is in N, we have that $N^\wedge$ is a wide subcategory of N. Moreover, we denote

$$\mathbf{A}^\wedge = \langle \mathbf{Sign}, \mathrm{SEN}, N^\wedge\rangle$$

the algebraic system that results by taking $N^\wedge$ instead of N as its category of natural transformations. This corresponds to the well-known operation of reducing the type of an algebra.

Proposition 1433 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\wedge : \mathrm{SEN}^2 \to \mathrm{SEN}$ in N, and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ be a π-structure based on $\mathbf{A}$. If $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$, then $\widetilde{\Lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}^\wedge$. Moreover, for all $X \in \mathrm{SenFam}(\mathbf{A})$, $\widetilde{\Lambda}^{\mathbf{A},D}(X)$ is also a congruence system on $\mathbf{A}^\wedge$.*

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi, \phi'\rangle, \langle \psi, \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A}}_\Sigma(T) \quad \text{implies} \quad \langle \phi \wedge_\Sigma \psi, \phi' \wedge_\Sigma \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A}}_\Sigma(T).$$

To this end, suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \phi'\rangle$, $\langle \psi, \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A}}_\Sigma(T)$. Then, by definition, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\begin{array}{rcl} \mathrm{SEN}(f)(\phi) \in T_{\Sigma'} & \text{iff} & \mathrm{SEN}(f)(\phi') \in T_{\Sigma'}, \\ \mathrm{SEN}(f)(\psi) \in T_{\Sigma'} & \text{if} & \mathrm{SEN}(f)(\psi') \in T_{\Sigma'}. \end{array}$$

Thus, we have, by the Conjunction Property and Lemma 1430,

$$\begin{array}{rcl} \mathrm{SEN}(f)(\phi \wedge_\Sigma \psi) \in T_{\Sigma'} & \text{iff} & \mathrm{SEN}(f)(\phi) \wedge_{\Sigma'} \mathrm{SEN}(f)(\psi) \in T_{\Sigma'} \\ & \text{iff} & \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \in T_{\Sigma'} \\ & \text{iff} & \mathrm{SEN}(f)(\phi'), \mathrm{SEN}(f)(\psi') \in T_{\Sigma'} \\ & \text{iff} & \mathrm{SEN}(f)(\phi') \wedge_{\Sigma'} \mathrm{SEN}(f)(\psi') \in T_{\Sigma'} \\ & \text{iff} & \mathrm{SEN}(f)(\phi' \wedge_\Sigma \psi') \in T_{\Sigma'}. \end{array}$$

Thus, $\langle \phi \wedge_\Sigma \psi, \phi' \wedge_\Sigma \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A}}_\Sigma(T)$ and $\widetilde{\Lambda}^{\mathbf{A}}(T)$ is a congruence system on $\mathbf{A}^\wedge$.

The fact that $\widetilde{\Lambda}^{\mathbf{A}}(D)$ and $\widetilde{\Lambda}^{\mathbf{A},D}(X)$ are congruence systems on $\mathbf{A}^\wedge$ now follow from the relationships outlined before Lemma 1415. ∎

The Conjunction Property also satisfies a transfer property to the effect that a given π-institution has the Conjunction Property if and only if all its π-structure models have the Conjunction Property.

Proposition 1434 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has the Conjunction Property with respect to* $\wedge^\flat$ *if and only if, for every* $\mathcal{I}$*-structure* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*,* $\mathbb{L}$ *has the Conjunction Property with respect to* $\wedge$*.*

Proof: Suppose that $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^\flat$. Then, by Propositions 1431 and 1422, $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$.

The converse is trivial, since $\langle \mathcal{F}, C \rangle \in \mathrm{Str}(\mathcal{I})$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. ∎

Finally, we show that if a π-institution $\mathcal{I}$ has the Conjunction Property, then any finitary $\mathcal{I}$-structure with the Congruence Property is full.

Proposition 1435 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *a finitary* $\mathcal{I}$*-structure, which has no theorems if* $\mathcal{I}$ *has no theorems. If* $\mathcal{I}$ *has the Conjunction Property with respect to* $\wedge^\flat$ *and* $\mathbb{L}$ *has the strong Congruence Property, then* $\mathbb{L}$ *is a full* $\mathcal{I}$*-structure.*

Proof: Suppose $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a finitary $\mathcal{I}$-structure, without theorems, if $\mathcal{I}$ has no theorems, satisfying the strong Congruence Property. Our goal is to show that $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. We denote by $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ the bilogical quotient morphism.

Assume, first, that $T \in \mathcal{D}^*$. Then $\pi^{-1}(T) \in \mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{D})$, by Proposition 1385. Hence, by Corollary 55, $T \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}^*)$. We conclude that $\mathcal{D}^* \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Conversely, assume that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. If $T = \varnothing$, then $\mathcal{I}$ does not have theorems. Thus, by hypothesis, $\varnothing \in \mathcal{D}$ and, therefore, $\varnothing \in \mathcal{D}^*$. Suppose, next, that $T \neq \varnothing$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D^*_\Sigma(T_\Sigma)$. By hypothesis and Proposition 1365, there exist $\phi_0, \ldots, \phi_{n-1} \in T_\Sigma$, such that $\phi \in D^*_\Sigma(\phi_0, \ldots, \phi_{n-1})$. By the Conjunction Property and Proposition 1434, $\phi \in D^*_\Sigma(\phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1}))$. Therefore,

$$D^*_\Sigma(\phi \wedge_\Sigma (\phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1}))) = D^*_\Sigma(\phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1})).$$

By hypothesis, Proposition 1426 and Corollary 1425, we get that

$$\phi \wedge_\Sigma (\phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1})) = \phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1}).$$

Since $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^\flat$, $\phi_0, \ldots, \phi_{n-1} \in T_\Sigma$ imply that $\phi_0 \wedge_\Sigma (\cdots \wedge \phi_{n-1}) \in T_\Sigma$. Thus, by the displayed equation above, $\phi \wedge_\Sigma (\phi_0 \wedge_\Sigma (\cdots \wedge_\Sigma \phi_{n-1})) \in T_\Sigma$. By Proposition 1434, $\phi \in T_\Sigma$. So we have $D^*_\Sigma(T_\Sigma) = T_\Sigma$ and, hence, $T \in \mathcal{D}^*$. Thus, $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\mathbb{L}$ is a full $\mathcal{I}$-structure. ∎

19.9.3 The Deduction-Detachment Theorem

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\rightarrow: \mathrm{SEN}^2 \to \mathrm{SEN}$ a binary natural transformation in N, and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ a π-structure.

- $\mathbb{L}$ has the **Modus Ponens** or **Detachment with respect to** $\rightarrow$ if, for all $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}(\Sigma)$,
$$\phi \rightarrow_\Sigma \psi \in D_\Sigma(\Phi) \quad \text{implies} \quad \psi \in D_\Sigma(\Phi, \phi).$$
- $\mathbb{L}$ has the **Deduction Theorem with respect to** $\rightarrow$ if, for all $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}(\Sigma)$,
$$\psi \in D_\Sigma(\Phi, \phi) \quad \text{implies} \quad \phi \rightarrow_\Sigma \psi \in D_\Sigma(\Phi).$$
- $\mathbb{L}$ has the **Deduction Detachment Theorem with respect to** $\rightarrow$ if it has both the Modus Ponens and the Deduction Theorem with respect to $\rightarrow$.

Structures that have the Deduction Detachment Theorem always have theorems. The following proposition gives a few of those theorems that are inspired by classical propositional calculus.

Proposition 1436 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, with* $\rightarrow: \mathrm{SEN}^2 \to \mathrm{SEN}$ *a binary natural transformation in* N*, and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure that has the Deduction Detachment Theorem with respect to* $\rightarrow$*. Then, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$*,*

(a) $\phi \rightarrow_\Sigma \phi \in \mathrm{Thm}_\Sigma(\mathbb{L})$*;*

(b) $\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \phi) \in \mathrm{Thm}_\Sigma(\mathbb{L})$*;*

(c) $(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi)) \rightarrow_\Sigma ((\phi \rightarrow_\Sigma \psi) \rightarrow_\Sigma (\phi \rightarrow_\Sigma \chi)) \in \mathrm{Thm}_\Sigma(\mathbb{L})$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$.

(a) Since $\phi \in D_\Sigma(\phi)$, we get by the Deduction Theorem, $\phi \rightarrow_\Sigma \phi \in D_\Sigma(\varnothing)$. So $\phi \rightarrow_\Sigma \phi \in \mathrm{Thm}_\Sigma(\mathbb{L})$.

(b) Since $\phi \in D_\Sigma(\phi, \psi)$, we get, by the Deduction Theorem, $\psi \rightarrow_\Sigma \phi \in D_\Sigma(\phi)$. By yet another application of the Deduction Theorem, we conclude that $\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \phi) \in D_\Sigma(\varnothing)$. Therefore, $\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \phi) \in \mathrm{Thm}_\Sigma(\mathbb{L})$.

(c) Since $\phi \rightarrow_\Sigma \psi \in D_\Sigma(\phi \rightarrow_\Sigma \psi)$ and $\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi) \in D_\Sigma(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi))$, we get, by Modus Ponens, $\psi \in D_\Sigma(\phi \rightarrow_\Sigma \psi, \phi)$ and $\psi \rightarrow_\Sigma \chi \in$

$D_\Sigma(\phi \to_\Sigma (\psi \to_\Sigma \chi), \phi)$. Moreover, since $\psi \to_\Sigma \chi \in D_\Sigma(\psi \to_\Sigma \chi)$, we get, by Modus Ponens, $\chi \in D_\Sigma(\psi \to_\Sigma \chi, \psi)$. Thus, we obtain

$$\chi \in D_\Sigma(\psi \to_\Sigma \chi, \psi) \subseteq D_\Sigma(\phi \to_\Sigma (\psi \to_\Sigma \chi), \phi \to_\Sigma \psi, \phi).$$

By the Deduction Theorem, $\phi \to_\Sigma \chi \in D_\Sigma(\phi \to_\Sigma (\psi \to_\Sigma \chi), \phi \to_\Sigma \psi)$. By another application of the Deduction Theorem, $(\phi \to_\Sigma \psi) \to_\Sigma (\phi \to_\Sigma \chi) \in D_\Sigma(\phi \to_\Sigma (\psi \to_\Sigma \chi))$. A final application of the Deduction Theorem yields

$$(\phi \to_\Sigma (\psi \to_\Sigma \chi)) \to_\Sigma ((\phi \to_\Sigma \psi) \to_\Sigma (\phi \to_\Sigma \chi)) \in D_\Sigma(\varnothing).$$

Therefore, $(\phi \to_\Sigma (\psi \to_\Sigma \chi)) \to_\Sigma ((\phi \to_\Sigma \psi) \to_\Sigma (\phi \to_\Sigma \chi)) \in \mathrm{Thm}_\Sigma(\mathbb{L})$. ■

Corollary 1437 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ a binary natural transformation in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, which has the Deduction Detachment Theorem with respect to $\to^\flat$. Then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, and every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T \neq \varnothing$. Consequently, for every $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathcal{I})$, $\mathrm{Thm}(\mathbb{L}) \neq \varnothing$.*

Proof: Clear by Proposition 1436. ■

We now give a characterization of the Podus Ponens property.

Proposition 1438 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system, with $\to : \mathrm{SEN}^2 \to \mathrm{SEN}$ in N, and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ a π-structure. $\mathbb{L}$ has the Modus Ponens with respect to $\to$ if and only if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,*

$$\psi \in D_\Sigma(\phi, \phi \to_\Sigma \psi)$$

if and only if, for all $T \in \mathrm{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{and} \quad \phi \to_\Sigma \psi \in T_\Sigma \quad \text{imply} \quad \psi \in T_\Sigma.$$

Proof: Suppose, first, that $\mathbb{L}$ has the Modus Ponens with respect to $\to$ and let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$. Then $\phi \to_\Sigma \psi \in D_\Sigma(\phi \to_\Sigma \psi)$, whence, by the Modus Ponens, $\psi \in D_\Sigma(\phi \to_\Sigma \psi, \phi)$. Conversely, suppose, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\psi \in D_\Sigma(\phi, \phi \to_\Sigma \psi)$ and let $\Phi \subseteq \mathrm{SEN}(\Sigma)$, such that $\phi \to_\Sigma \psi \in D_\Sigma(\Phi)$. Then, we have

$$\psi \in D_\Sigma(\phi, \phi \to_\Sigma \psi) \subseteq D_\Sigma(\Phi, \phi).$$

So $\mathbb{L}$ has the Modus Ponens with respect to $\to$.

The second equivalence is straightforward. ■

The Modus Ponens in a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ may also be characterized in terms of $\mathbf{F}$-rules.

Proposition 1439 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\rightarrow^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has the Modus Ponens with respect to* $\rightarrow^\flat$ *if and only if it satisfies the* $\mathbf{F}$*-rule*

$$x, x \rightarrow^\flat y \vdash y.$$

Proof: $\mathcal{I}$ satisfies $x, x \rightarrow^\flat y \vdash y$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\psi \in C_\Sigma(\phi, \phi \rightarrow^\flat_\Sigma \psi)$$

if and only if, by Proposition 1438, $\mathcal{I}$ has the Modus Ponens with respect to $\rightarrow^\flat$. ■

Since the Modus Ponens in a π-institution is expressible in terms of $\mathbf{F}$-rules, we may use Propositions 1422 and 1423 to draw the conclusions that the Modus Ponens transfers to all models and, moreover, that it is preserved by all bilogical morphisms.

Corollary 1440 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\rightarrow^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *has the Modus Ponens with respect to* $\rightarrow^\flat$*, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and every* $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathcal{I})$*,* $\mathbb{L}$ *has the Modus Ponens with respect to* $\rightarrow$*.*

Proof: This follows by combing Proposition 1439 with Proposition 1422. ■

Corollary 1441 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\rightarrow^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ *be* $N^\flat$*-structures based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism.* $\mathbb{L}$ *has the Modus Ponens with respect to* $\rightarrow$ *if and only if* $\mathbb{L}'$ *has the Modus Ponens with respect to* $\rightarrow'$*.*

Proof: The conclusion follows by combining Proposition 1439 with Proposition 1423. ■

It turns out that the Deduction Theorem also transfers under bilogical morphisms.

Proposition 1442 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat$ *be an algebraic system, with* $\rightarrow^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ *be* $N^\flat$*-structures based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism.* $\mathbb{L}$ *has the Deduction Theorem with respect to* $\rightarrow$ *if and only if* $\mathbb{L}'$ *has the Deduction Theorem with respect to* $\rightarrow'$*.*

Proof: Suppose, first, that $\mathbb{L}$ has the Deduction Theorem with respect to $\to$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}(\Sigma)$, such that

$$\alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)).$$

Then, since $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, $\psi \in D_\Sigma(\Phi, \phi)$. Thus, since $\mathbb{L}$ has the Deduction Theorem, $\phi \to_\Sigma \psi \in D_\Sigma(\Phi)$. Again, by the fact that $\langle F, \alpha\rangle$ is a bilogical morphism, we obtain $\alpha_\Sigma(\phi \to_\Sigma \psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ or, equivalently, $\alpha_\Sigma(\phi) \to'_{F(\Sigma)} \alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Since $\langle F, \alpha\rangle$ is surjective, we conclude that $\mathbb{L}'$ also has the Deduction Theorem with respect to $\to'$.

Suppose, conversely, that $\mathbb{L}'$ has the Deduction Theorem with respect to $\to'$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}(\Sigma)$, such that $\psi \in D_\Sigma(\Phi, \phi)$. Since $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we get that

$$\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)).$$

Since $\mathbb{L}'$ has the Deduction Theorem with respect to $\to'$, $\alpha_\Sigma(\phi) \to'_{F(\Sigma)} \alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ or, equivalently, $\alpha_\Sigma(\phi \to_\Sigma \psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Again by the fact that $\langle F, \alpha\rangle$ is a bilogical morphism, we get $\phi \to_\Sigma \psi \in D_\Sigma(\Phi)$. Therefore, $\mathbb{L}$ also has the Deduction Theorem with respect to $\to$. ■

In an analog of Theorem 1433, we prove that, in case a π-structure has the Deduction Detachment Theorem, with respect to a binary natural transformation, then, Frege relation systems defined on the π-structure are congruence systems if one restricts to the category of natural transformations generated by the binary natural transformation.

Proposition 1443 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, with* $\to: \mathrm{SEN}^2 \to \mathrm{SEN}$ *in* N*, and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *be a* π*-structure based on* $\mathbf{A}$*. If* $\mathbb{L}$ *has the Deduction Detachment Property with respect to* $\to$*, then* $\widetilde{\Lambda}^{\mathbf{A}}(D)$ *is a congruence system on* $\mathbf{A}^\to$*. Moreover, for all* $X \in \mathrm{SenFam}(\mathbf{A})$*,* $\widetilde{\Lambda}^{\mathbf{A},D}(X)$ *is also a congruence system on* $\mathbf{A}^\to$*.*

Proof: It suffices to show that, for all $X \in \mathrm{SenFam}(\mathbf{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi, \phi'\rangle, \langle \psi, \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X) \quad \text{implies} \quad \langle \phi \to_\Sigma \psi, \phi' \to_\Sigma \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X).$$

So, suppose $X \in \mathrm{SenFam}(\mathbf{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \phi'\rangle, \langle \psi, \psi'\rangle \in \widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X)$. Thus, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\begin{array}{rcl} D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\phi)) & = & D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\phi')),\\ D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\psi)) & = & D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\psi')).\end{array}$$

Now, using the Modus Ponens with respect to $\to$ and the displayed equations, we get

$$\begin{array}{c}\mathrm{SEN}(f)(\psi) \in D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\phi) \to_{\Sigma'} \mathrm{SEN}(f)(\psi), \mathrm{SEN}(f)(\phi)),\\ \mathrm{SEN}(f)(\phi) \in D_{\Sigma'}(X_{\Sigma'}, \mathrm{SEN}(f)(\phi')).\end{array}$$

Therefore,

$$\begin{array}{rcl}\mathrm{SEN}(f)(\psi') & \in & D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\psi))\\ & \subseteq & D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi)\to_{\Sigma'}\mathrm{SEN}(f)(\psi),\mathrm{SEN}(f)(\phi))\\ & \subseteq & D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi)\to_{\Sigma'}\mathrm{SEN}(f)(\psi),\mathrm{SEN}(f)(\phi')).\end{array}$$

By the Deduction Theorem, we now get

$$\mathrm{SEN}(f)(\phi')\to_{\Sigma'}\mathrm{SEN}(f)(\psi')\in D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi)\to_{\Sigma'}\mathrm{SEN}(f)(\psi)).$$

This is equivalent to $\mathrm{SEN}(f)(\phi'\to_\Sigma\psi')\in D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi\to_\Sigma\psi))$. Thus, by symmetry, we get that, for all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$, $D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi\to_\Sigma\psi))=D_{\Sigma'}(X_{\Sigma'},\mathrm{SEN}(f)(\phi'\to_\Sigma\psi'))$ and, we conclude that $\langle\phi\to_\Sigma\psi,\phi'\to_\Sigma\psi'\rangle\in\widetilde{\Lambda}^{\mathbf{A},D}_\Sigma(X)$. ■

Our next goal is to show that, if a finitary π-institution $\mathcal{I}$ has the Deduction Detachment Theorem, then every full $\mathcal{I}$-structure also has the Deduction Detachment Theorem.

Theorem 1444 *Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, with $\to^\flat$: $(\mathrm{SEN}^\flat)^2\to\mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I}=\langle\mathbf{F},C\rangle$ a finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\to^\flat$, then every full $\mathcal{I}$-structure $\mathbb{L}=\langle\mathcal{A},D\rangle$ has the Deduction Detachment Theorem with respect to $\to$.*

Proof: Suppose $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\to^\flat$. By Corollary 1393, Corollary 1441 and Proposition 1442, it is enough to show that every $\mathcal{I}$-structure of the form $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ has the Deduction Detachment Theorem with respect to $\to$. By Corollary 1440, every $\mathcal{I}$-structure has the Modus Ponens with respect to $\to$. So it suffices to show that $\langle\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ has the Deduction Theorem with respect to $\to$, i.e., that, for all $\Sigma'\in|\mathbf{Sign}|$ and all $\Phi'\cup\{\phi',\psi'\}\subseteq\mathrm{SEN}(\Sigma')$,

$$\psi'\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi')\quad\text{implies}\quad\phi'\to_{\Sigma'}\psi'\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi').$$

We do this, using Proposition 114, by applying induction on $n<\omega$ to show that, for all $n<\omega$,

$$\psi'\in\Xi^n_{\Sigma'}(\Phi',\phi')\quad\text{implies}\quad\phi'\to_{\Sigma'}\psi'\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi').$$

For $n=0$, we get $\psi'\in\Xi^0_{\Sigma'}(\Phi',\phi')=\Phi'\cup\{\phi'\}$.

- If $\psi'=\phi'$, then $\phi'\to_{\Sigma'}\psi'=\phi'\to_{\Sigma'}\phi'\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\varnothing)\subseteq C^{\mathcal{A},\mathcal{I}}_{\Sigma'}(\Phi')$, because of Proposition 1436.
- If $\psi'\in\Phi'$, then $\psi'\to_{\Sigma'}(\phi'\to_{\Sigma'}\psi')\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\varnothing)\subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')$, again by Proposition 1436. Since $\psi'\in\Phi'\subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')$, we get by the Modus Ponens, $\phi'\to_{\Sigma'}\psi'\in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')$.

Assume, next that, if, for some $i < n$, $\psi' \in \Xi^i_\Sigma(\Phi', \phi')$, then $\phi' \to_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')$. Consider $\psi' \in \Xi^n_{\Sigma'}(\Phi', \phi')$. By definition, there exists $\Sigma \in |\mathbf{Sign}^\flat|$, such that $F(\Sigma) = \Sigma'$, and $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that

$$\psi \in C_\Sigma(\Phi, \phi), \quad \alpha_\Sigma(\Phi) \subseteq \Xi^{n-1}_{\Sigma'}(\Phi', \phi'), \quad \alpha_\Sigma(\phi) = \phi', \quad \alpha_\Sigma(\psi) = \psi'.$$

Now, we have, on the one hand, by the Induction Hypothesis, $\phi' \to_{\Sigma'} \alpha_\Sigma(\chi) \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')$, for all $\chi \in \Phi$. On the other hand, since $\psi \in C_\Sigma(\Phi, \phi)$, we get, using Modus Ponens,

$$\psi \in C_\Sigma(\Phi, \phi) \subseteq C_\Sigma(\{\phi \to^\flat_\Sigma \chi : \chi \in \Phi\}, \phi)$$

and, therefore, by the Deduction Theorem, $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\{\phi \to^\flat_\Sigma \chi : \chi \in \Phi\})$. Therefore, we obtain

$$\phi' \to_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\{\phi' \to_{\Sigma'} \alpha_\Sigma(\chi) : \chi \in \Phi\}).$$

Finally, we obtain

$$\begin{array}{rcl} \phi' \to_{\Sigma'} \psi' & \in & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\{\phi' \to_{\Sigma'} \alpha_\Sigma(\chi) : \chi \in \Phi\}) \\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi')) \\ & = & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi'). \end{array}$$

We conclude that $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ has the Deduction Detachment Theorem and therefore, every full $\mathcal{I}$-structure does also. ∎

Finally, we show that if a π-institution has the Deduction Detachment Theorem, then every finitary $\mathcal{I}$-structure, with the Deduction Theorem and the Congruence Property is a full $\mathcal{I}$-structure.

Proposition 1445 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution that has the Deduction Detachment Theorem with respect to $\to^\flat$. If $\mathbb{L} = \langle \mathcal{A}, D\rangle$ is a finitary $\mathcal{I}$-structure with the Deduction Theorem and the strong Congruence Property, then $\mathbb{L}$ is a full $\mathcal{I}$-structure.*

Proof: Suppose $\mathbb{L} = \langle \mathcal{A}, D\rangle$ is a finitary $\mathcal{I}$-structure with the Deduction Theorem and the Congruence Property. Then, by Proposition 1385, $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and our goal is to show that $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Suppose, first, that $T' \in \mathcal{D}^*$. Consider the bilgical quotient morphism $\langle I, \pi\rangle : \mathbb{L} \vdash \mathbb{L}^*$. Then we have $T = \pi^{-1}(T') \in \mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, by Corollary 55, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. We conclude that $\mathcal{D}^* \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Suppose, conversely, that $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Since $\mathcal{I}$ has the Deduction Detachment Theorem, by Corollary 1437, $T' \neq \varnothing$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi^* \in D^*_\Sigma(T'_\Sigma)$. By the finitarity of $\mathbb{L}$ and Proposition 1365, there exist $\phi_0, \ldots, \phi_{n-1} \in \mathrm{SEN}(\Sigma)$, such that $\phi^*_0, \ldots, \phi^*_{n-1} \in T'_\Sigma$ and

$\phi^* \in D^*_\Sigma(\phi^*_0,\dots,\phi^*_{n-1})$. Since $\mathbb{L}$ has the Deduction Theorem, by Proposition 1442, so does $\mathbb{L}^*$, whence

$$\phi^*_0 \to^*_\Sigma (\cdots(\phi^*_{n-1} \to^*_\Sigma \phi^*)\cdots) \in D^*_\Sigma(\varnothing) = D^*_\Sigma(\phi^* \to^*_\Sigma \phi^*),$$

the last equality, by Proposition 1436. Now we get

$$D^*_\Sigma(\phi^*_0 \to^*_\Sigma (\cdots(\phi^*_{n-1} \to^*_\Sigma \phi^*)\cdots)) = D^*_\Sigma(\phi^* \to^*_\Sigma \phi^*).$$

Since $\mathbb{L}$ has the strong Congruence Property, by Proposition 1426, so does $\mathbb{L}^*$. Hence, by Corollary 1425,

$$\phi^*_0 \to^*_\Sigma (\cdots(\phi^*_{n-1} \to^*_\Sigma \phi^*)\cdots) = \phi^* \to^*_\Sigma \phi^* \in T'_\Sigma.$$

Since $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\phi^*_0,\dots,\phi^*_{n-1} \in T'_\Sigma$, we get by the Modus Ponens, $\phi^* \in T'_\Sigma$. We conclude that $D^*_\Sigma(T'_\Sigma) \subseteq T'_\Sigma$ and, therefore, $T' \in \mathcal{D}^*$. So $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Hence, $\mathbb{L} = \langle \mathcal{A}, D\rangle$ is a full $\mathcal{I}$-structure. ■

19.9.4 The Property of Disjunction

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\vee : \mathrm{SEN}^2 \to \mathrm{SEN}$ a binary natural transformation in N, and $\mathbb{L} = \langle \mathcal{A}, D\rangle$ a π-structure.

$\mathbb{L}$ has the **Disjunction Property with respect to** $\vee$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi,\psi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\Phi, \phi \vee_\Sigma \psi) = D_\Sigma(\Phi,\phi) \cap D_\Sigma(\Phi,\psi).$$

In the next proposition, we discuss some of the $\mathbf{F}$(g)rules that a π-institution having the Disjunction Property satisfies.

Proposition 1446 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\vee^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Disjunction Property with respect to $\vee^\flat$, then $\mathcal{I}$ satisfies the following $\mathbf{F}$-grules:*

(a) $x \vdash x \vee^\flat y$ *and* $y \vdash x \vee^\flat y$*;*

(b) $\dfrac{X, x \vdash z, \quad X, y \vdash z}{X, x \vee^\flat y \vdash z}$*, where X consists of any set of projections;*

(c) $x \vee^\flat y \vdash y \vee^\flat x$*;*

(d) $x \vdash x \vee^\flat x$ *and* $x \vee^\flat x \vdash x$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi,\psi,\chi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$.

(a) By the Disjunction Property, $\phi \vee^\flat_\Sigma \psi \in C_\Sigma(\phi) \cap C_\Sigma(\psi)$.

(b) Suppose $\chi \in C_\Sigma(\Phi,\phi)$ and $\chi \in C_\Sigma(\Phi,\psi)$. Then, by the Disjunction Property,
$$\chi \in C_\Sigma(\Phi,\phi) \cap C_\Sigma(\Phi,\psi) = C_\Sigma(\Phi,\phi \vee^\flat_\Sigma \psi).$$

(c) We have, using the Disjunction Property,
$$\begin{array}{rcl}\psi \vee^\flat_\Sigma \phi & \in & C_\Sigma(\psi \vee^\flat_\Sigma \phi) = C_\Sigma(\psi) \cap C_\Sigma(\phi)\\ & = & C_\Sigma(\phi) \cap C_\Sigma(\psi) = C_\Sigma(\phi \vee^\flat_\Sigma \psi).\end{array}$$

(d) We have
$$\phi \vee^\flat_\Sigma \phi \in C_\Sigma(\phi \vee^\flat_\Sigma \phi) = C_\Sigma(\phi) \cap C_\Sigma(\phi) = C_\Sigma(\phi)$$
and, also,
$$\phi \in C_\Sigma(\phi) = C_\Sigma(\phi) \cap C_\Sigma(\phi) = C_\Sigma(\phi \vee^\flat_\Sigma \phi).$$
■

It is not difficult to see that the Disjunction Property is also preserved under bilogical morphisms.

Proposition 1447 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\vee^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems,* $\mathbb{L} = \langle \mathbf{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ *be* $N^\flat$*-structures based on* $\mathbf{A}$*,* $\mathbf{A}'$*, respectively, and* $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism.* $\mathbb{L}$ *has the Disjunction Property with respect to* $\vee$ *if and only if* $\mathbb{L}'$ *has the Disjunction Property with respect to* $\vee'$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi,\psi\} \subseteq \mathrm{SEN}(\Sigma)$. Then, since $\langle F,\alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we have, using Proposition 1360,
$$\begin{array}{rcl}D_\Sigma(\Phi,\phi \vee_\Sigma \psi) & = & \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee'_{F(\Sigma)} \alpha_\Sigma(\psi));\\ D_\Sigma(\Phi,\phi) \cap D_\Sigma(\Phi,\psi) & = & \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi))\\ & & \quad \cap\, \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi))\\ & = & \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi))\\ & & \quad \cap\, D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi))).\end{array}$$
Now, using the surjectivity of $\langle F,\alpha \rangle$, we get that
$$D_\Sigma(\Phi,\phi \vee_\Sigma \psi) = D_\Sigma(\Phi,\phi) \cap D_\Sigma(\Phi,\psi)$$
if and only if
$$\begin{array}{l}D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee'_{F(\Sigma)} \alpha_\Sigma(\psi))\\ \quad = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi))\end{array}$$
Once more, taking into account the surjectivity of $\langle F,\alpha \rangle$, we conclude that $\mathbb{L}$ has the Disjunction Property with respect to $\vee$ if and only if $\mathbb{L}'$ has the Disjunction Property with respect to $\vee'$. ■

Using induction, we can extend the defining equation of the Disjunction Property so that we can accommodate a finite number of conjunctions instead of only a single conjunction.

Proposition 1448 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, with* $\vee : \mathrm{SEN}^2 \to \mathrm{SEN}$ *in* N*, and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure. If* $\mathbb{L}$ *has the Disjunction Property with respect to* $\vee$*, then, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\Phi \cup \{\phi_0, \dots, \phi_{n-1}\} \subseteq \mathrm{SEN}(\Sigma)$*,*

$$D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) = D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi).$$

Proof: First, note that, for all $\Sigma \in |\mathbf{Sign}|$, all $\Phi \cup \{\phi_0, \dots, \phi_{n-1}, \psi\} \subseteq \mathrm{SEN}(\Sigma)$ and all $i < n$,

$$\begin{array}{rcl}\phi_i \vee_\Sigma \psi & \in & D_\Sigma(\Phi, \phi_i) \cap D_\Sigma(\Phi, \psi)\\ & \subseteq & D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi).\end{array}$$

Thus, we get

$$D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) \subseteq D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi).$$

For the reverse inclusion, we use induction on n.

For $n = 1$, by the Disjunction Property, we get $D_\Sigma(\Phi, \phi_0) \cap D_\Sigma(\Phi, \psi) = D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi)$.

Assume that the inclusion holds for n.

Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi_0, \dots, \phi_n, \psi\} \subseteq \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{l}D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi)\\ = D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi) \cap D_\Sigma(\Phi, \psi)\\ \subseteq D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi)\\ \subseteq D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \psi)\\ \subseteq D_\Sigma(\Phi, \phi_0, \vee_\Sigma \psi, \phi_1 \vee_\Sigma \psi, \dots, \phi_n \vee_\Sigma \psi).\end{array}$$

Hence the inclusion - and, therefore, the equation - holds for all $n < \omega$. ∎

Another property of structures having disjunction is that, if a specific entailment with a finite number of premises holds and the hypotheses are disjuncted with the same sentence, then the disjunction of the conclusion with the same sentence follows from the disjuncted hypotheses.

Lemma 1449 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, with* $\vee : \mathrm{SEN}^2 \to \mathrm{SEN}$ *in* N*, and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure. If* $\mathbb{L}$ *has the Disjunction Property with respect to* $\vee$*, then, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi_0, \phi_{n-1}, \phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \in D_\Sigma(\phi_0, \dots, \phi_{n-1}) \quad \textit{implies} \quad \phi \vee_\Sigma \psi \in D_\Sigma(\phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi).$$

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\phi_0, \phi_{n-1}, \phi, \psi \in \mathrm{SEN}(\Sigma)$. By Proposition 1448,

$$D_\Sigma(\phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) = D_\Sigma(\phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\psi).$$

But, by hypothesis, $\phi \in D_\Sigma(\phi_0,\dots,\phi_{n-1})$. So we get

$$\begin{array}{rcl}\phi \vee_\Sigma \psi & \in & D_\Sigma(\phi) \cap D_\Sigma(\psi)\\ & \subseteq & D_\Sigma(\phi_0,\dots,\phi_{n-1}) \cap D_\Sigma(\psi)\\ & = & D_\Sigma(\phi_0 \vee_\Sigma \psi,\dots,\phi_{n-1} \vee_\Sigma \psi).\end{array}$$

■

Our final goal is to show that, if a finitary π-institution has the Disjunction Property, then every full $\mathcal{I}$-structure also has the Disjunction Property. To accomplish this, we prove, first, a lemma to the effect that, if an entailment holds in a model then the disjunct of the conclusion with an arbitrary sentence is entailed by the same premises except for one, which is replaced by the disjunct of the original with the same sentence.

Lemma 1450 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\vee^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a finitary* π*-institution based on* $\mathbf{F}$*, which has the Disjunction Property with respect to* $\vee^\flat$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$*, all* $\Sigma' \in |\mathbf{Sign}|$ *and all* $\Phi' \cup \{\phi',\psi',\chi'\} \subseteq \mathrm{SEN}(\Sigma')$*,*

$$\chi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi') \quad \textit{implies} \quad \chi' \vee_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi' \vee_{\Sigma'} \psi').$$

Proof: Let $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi',\psi',\chi'\} \subseteq \mathrm{SEN}(\Sigma')$. By Proposition 114, $C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi') = \Xi_{\Sigma'}(\Phi',\phi') = \bigcup_{n<\omega} \Xi^n_{\Sigma'}(\Phi',\phi')$. We show by induction on $n < \omega$ that, for all $n < \omega$

$$\chi' \in \Xi^n_{\Sigma'}(\Phi',\phi') \quad \text{implies} \quad \chi' \vee_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi' \vee_{\Sigma'} \psi').$$

If $n = 0$, the hypothesis is $\chi' \in \Xi^0_{\Sigma'}(\Phi',\phi') = \Phi' \cup \{\phi'\}$.

- If $\chi' = \phi'$, then the conclusion follows trivially.
- Suppose that $\chi' \in \Phi'$. Then, we have $\chi' \vee_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\chi') \subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi') \subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi' \vee_{\Sigma'} \psi')$, where the first inclusion follows by Propositions 1446 and 1422.

Assume that the displayed implication holds for all $i < n$. Let $\chi' \in \Xi^n_{\Sigma'}(\Phi',\phi')$. By definition, there exists $\Sigma \in |\mathbf{Sign}^\flat|$, such that $F(\Sigma) = \Sigma'$, and $\phi_0,\dots,\phi_{k-1},\chi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\chi \in C_\Sigma(\phi_0,\dots,\phi_{k-1}), \quad \alpha_\Sigma(\chi) = \chi', \quad \alpha_\Sigma(\phi_i) \in \Xi^{n-1}_{\Sigma'}(\Phi',\phi'),\ i < k.$$

By the induction hypothesis, $\alpha_\Sigma(\phi_i) \vee_{\Sigma'} \psi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi' \vee_{\Sigma'} \psi')$, for all $i < k$. Note that, by the surjectivity of $\langle F,\alpha\rangle$, there exists $\psi \in \mathrm{SEN}(\Sigma)$, such that $\alpha_\Sigma(\psi) = \psi'$. Since $\chi \in C_\Sigma(\phi_0,\dots,\phi_{k-1})$, we get, by Lemma 1449, $\chi \vee^\flat_\Sigma \psi \in C_\Sigma(\phi_0 \vee^\flat_\Sigma \psi,\dots,\phi_{k-1} \vee^\flat_\Sigma \psi)$. Therefore, applying $\langle F,\alpha\rangle$,

$$\begin{array}{rcl}\chi' \vee_{\Sigma'} \psi' & \in & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\alpha_\Sigma(\phi_0) \vee_{\Sigma'} \psi',\dots,\alpha_\Sigma(\phi_{k-1}) \vee_{\Sigma'} \psi')\\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\Phi',\phi' \vee_{\Sigma'} \psi').\end{array}$$

Thus, the displayed formula holds for all $n < \omega$, yielding the conclusion. ∎

Finally, we show that all full models of a given finitary π-institution with the Disjunction Property also have the Disjunction Property.

Theorem 1451 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\vee^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Disjunction Property with respect to $\vee^\flat$, then every full $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ has the Disjunction Property with respect to $\vee$.*

Proof: By Corollary 1393 and Proposition 1447, it suffices to show that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}&C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ &\qquad = C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)).\end{aligned}$$

By Propositions Propositions 1446 and 1422, we have

$$\begin{aligned}&C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ &\qquad C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)).\end{aligned}$$

Conversely, suppose that, for some $\chi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha_\Sigma(\chi) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)).$$

Then, by Lemma 1450,

$$\begin{aligned}\alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi) &\in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)), \\ \alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi) &\in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)).\end{aligned}$$

Now we get

$$\begin{array}{rcl}\alpha_\Sigma(\chi) & \in & C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)) \\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)) \\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)).\end{array}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathbb{L}$ has the Disjunction Property with respect to $\vee$. ∎

19.9.5 Reductio ad Absurdum

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\neg : \mathrm{SEN} \to \mathrm{SEN}$ a unary natural transformation in N, and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ a π-structure based on $\mathbf{A}$.

$\mathbb{L}$ has the **Intuitionistic Reductio ad Absurdum with respect to** $\neg$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\neg_\Sigma \phi \in D_\Sigma(\Phi) \quad \text{if and only if} \quad D_\Sigma(\Phi, \phi) = \mathrm{SEN}(\Sigma).$$

$\mathbb{L}$ has the **Reductio ad Absurdum with respect to** $\neg$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{if and only if} \quad D_\Sigma(\Phi, \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma).$$

The two properties of the Reductio ad Absurdum are related.

Proposition 1452 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\neg : \mathrm{SEN} \to \mathrm{SEN}$ in N, and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ a π-structure based on $\mathbf{A}$. $\mathbb{L}$ has the Reductio as Absurdum with respect to $\neg$ if and only if it has the Intuitionistic Reductio ad Absurdum with respect to $\neg$ and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$.*

Proof: Suppose, first, that $\mathbb{L}$ has the Reduction ad Absurdum with respect to $\neg$ and let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$.

Since $\neg_\Sigma \phi \in D_\Sigma(\neg_\Sigma \phi)$, we get $D_\Sigma(\neg_\Sigma \phi, \neg_\Sigma \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma)$. Therefore, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$.

Suppose, next, that $\neg_\Sigma \phi \in D_\Sigma(\Phi)$. Note that, since $\phi \in D_\Sigma(\phi)$, we also have $D_\Sigma(\phi, \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma)$. So, finally, $\mathrm{SEN}(\Sigma) = D_\Sigma(\phi, \neg_\Sigma \phi) \subseteq D_\Sigma(\Phi, \phi)$ and equality follows.

On the other hand, if $D_\Sigma(\Phi, \phi) = \mathrm{SEN}(\Sigma)$, then $D_\Sigma(\Phi, \neg_\Sigma \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma)$, whence $\neg_\Sigma \phi \in D_\Sigma(\phi)$.

Suppose, conversely, that $\mathbb{L}$ has the Intuitionistic Reductio ad Absurdum and that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$, and let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$.

Suppose, first, $\phi \in D_\Sigma(\Phi)$. Since $\neg_\Sigma \phi \in D_\Sigma(\neg_\Sigma \phi)$, we get $D_\Sigma(\phi, \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma)$. Therefore, $\mathrm{SEN}(\Sigma) = D_\Sigma(\phi, \neg_\Sigma \phi) \subseteq D_\Sigma(\Phi, \neg_\Sigma \phi)$.

On the other hand, if $D_\Sigma(\Phi, \neg_\Sigma \phi) = \mathrm{SEN}(\Sigma)$, then $\neg_\Sigma \neg_\Sigma \phi \in D_\Sigma(\Phi)$, whence $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi) \subseteq D_\Sigma(\phi)$. ■

We also show for future reference that the Intuitionistic Reductio ad Absurdum is preserved under bilogical morphisms.

Proposition 1453 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\neg^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be $N^\flat$-algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D\rangle$, $\mathbb{L}' = \langle \mathbf{A}', D'\rangle$ be $N^\flat$-structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha\rangle : \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. $\mathbb{L}$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg$ if and only if $\mathbb{L}'$ has the Intuitionistic Reduction ad Absurdum with respect to $\neg'$.*

Proof: Suppose $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$. Then, we have

$$\begin{array}{rll} \neg_\Sigma\phi \in D_\Sigma(\Phi) & \text{iff} & \alpha_\Sigma(\neg_\Sigma\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \\ & \text{iff} & \neg'_{F(\Sigma)}(\alpha_\Sigma(\phi)) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)). \end{array}$$

Moreover, using the surjectivity of $\langle F, \alpha\rangle$,

$$D_\Sigma(\Phi,\phi) = \mathrm{SEN}(\Sigma) \quad \text{iff} \quad D'_{F(\Sigma)}(\alpha_\Sigma(\Phi),\alpha_\Sigma(\phi)) = \mathrm{SEN}'(F(\Sigma)).$$

Thus, the equivalence

$$\neg_\Sigma\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad D_\Sigma(\Phi,\phi) = \mathrm{SEN}(\Sigma)$$

holds if and only if the equivalence

$$\neg'_{F(\Sigma)}\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \quad \text{iff} \quad D'_{F(\Sigma)}(\alpha_\Sigma(\Phi),\alpha_\Sigma(\phi)) = \mathrm{SEN}'(F(\Sigma))$$

holds. In other words, $\mathbb{L}$ has the Intuitionistic Reduction ad Absurdum with respect to $\neg$ if and only if $\mathbb{L}'$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg'$. ■

The Intuitionistic Reductio ad Absurdum is also closely related with are called inconsistent elements or inconsistencies.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, with $\bot : \mathrm{SEN} \to \mathrm{SEN}$ a unary natural transformation in N, and $\mathbb{L} = \langle \mathbf{A}, D\rangle$ a π-structure based on $\mathbf{A}$. $\bot$ is an **inconsistency** in $\mathbb{L}$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\bot_\Sigma\phi) = \mathrm{SEN}(\Sigma).$$

Having an inconsistency is clearly expressible by an $\mathbf{F}$-rule and, therefore, if a π-institution has an inconsistency then all its models do also.

Lemma 1454 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\bot^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\bot^\flat$ is an inconsistency in $\mathcal{I}$ if and only if $\mathcal{I}$ satisfies the $\mathbf{F}$-rule $\bot^\flat x \vdash y$.*

Proof: We have that $\mathcal{I}$ satisfies $\bot^\flat x \vdash y$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\psi \in C_\Sigma(\bot^\flat_\Sigma\phi)$, if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $C_\Sigma(\bot^\flat_\Sigma\phi) = \mathrm{SEN}(\Sigma)$, if and only if $\bot^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ is an inconsistency in $\mathcal{I}$. ■

Corollary 1455 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\bot^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\bot^\flat$ is an inconsistency in $\mathbb{L}$, then, $\bot$ is an inconsistency in every $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D\rangle$, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$.*

Proof: By Lemma 1454 and Proposition 1422. ■

The following proposition exhibits the relation between the Intuitionistic Reductio ad Absurdum and inconsistencies.

Proposition 1456 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, with* $\to : \mathrm{SEN}^2 \to \mathrm{SEN}$, *and* $\mathbb{L} = \langle \mathbf{A}, D\rangle$ *a* π*-structure that has the Deduction Detachment Theorem with respect to* $\to$. $\mathbb{L}$ *has the Intuitionistic Reductio ad Absurdum with respect to some* $\neg : \mathrm{SEN} \to \mathrm{SEN}$ *in* N *if and only if it has an inconsistency* $\bot : \mathrm{SEN} \to \mathrm{SEN}$ *in* N. *Moreover, in that case, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$,

$$D_\Sigma(\neg_\Sigma \phi) = D_\Sigma(\phi \to_\Sigma \bot_\Sigma \phi).$$

Proof: Suppose that $\mathbb{L}$ has the Deduction Detachment Theorem with respect to $\to$.

Assume, first, that $\mathbb{L}$ also has the Intuitionistic Reductio ad Absurdum with respect to $\neg$. Let $\bot : \mathrm{SEN} \to \mathrm{SEN}$ be defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\bot_\Sigma \phi = \neg_\Sigma(\phi \to_\Sigma \phi).$$

First, note, that, since $\bot = \neg \circ \to \circ \langle p^{1,0}, p^{1,0}\rangle$ and both $\to$ and $\neg$ are in N, we get that $\bot$ is also in N. Moreover, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ll} & \neg_\Sigma(\phi \to_\Sigma \phi) \in D_\Sigma(\neg_\Sigma(\phi \to_\Sigma \phi)) \\ \text{iff} & D_\Sigma(\phi \to_\Sigma \phi, \neg_\Sigma(\phi \to_\Sigma \phi)) = \mathrm{SEN}(\Sigma) \\ & \text{(by the Intuitionistic Reductio ad Absurdum)} \\ \text{iff} & D_\Sigma(\neg_\Sigma(\phi \to_\Sigma \phi)) = \mathrm{SEN}(\Sigma). \\ & \text{(by Proposition 1436)} \end{array}$$

Thus, $\bot$ is an inconsistency in $\mathbb{L}$.

Assume, conversely, that $\bot : \mathrm{SEN} \to \mathrm{SEN}$ is an inconsistency in $\mathbb{L}$. Define $\neg : \mathrm{SEN} \to \mathrm{SEN}$, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\neg_\Sigma \phi = \phi \to_\Sigma \bot_\Sigma \phi.$$

Since $\neg = \to \circ \langle p^{1,0}, \bot\rangle$ and, both $\to$ and $\bot$ are in N, it follows that $\neg$ is also in N. Moreover, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$, we have

$$\begin{array}{lll} \neg_\Sigma \phi \in D_\Sigma(\Phi) & \text{iff} & \phi \to_\Sigma \bot_\Sigma \phi \in D_\Sigma(\Phi) \\ & \text{iff} & \bot_\Sigma \phi \in D_\Sigma(\Phi, \phi) \\ & \text{iff} & D_\Sigma(\Phi, \phi) = \mathrm{SEN}(\Sigma). \end{array}$$

Thus, $\mathbb{L}$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg$.

Finally, it remains to prove the last equality. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. On the one hand, we have, by the Modus Ponens, $\bot_\Sigma \phi \in D_\Sigma(\phi, \phi \to_\Sigma$

$\bot_\Sigma\phi$), whence, since $\bot$ is an inconsistency, $D_\Sigma(\phi, \phi \to_\Sigma \bot_\Sigma\phi) = \mathrm{SEN}(\Sigma)$ and, hence, by the Intuitionistic Reductio ad Absurdum, $\neg_\Sigma\phi \in D_\Sigma(\phi \to_\Sigma \bot_\Sigma\phi)$. On the other hand, since $\neg_\Sigma\phi \in D_\Sigma(\neg_\Sigma\phi)$, by the Intuitionistic Reductio ad Absurdum, $D_\Sigma(\phi, \neg_\Sigma\phi) = \mathrm{SEN}(\Sigma)$ and, hence, $\neg_\Sigma\phi \in D_\Sigma(\phi, \neg_\Sigma\phi)$. Therefore, by the Deduction Theorem, $\phi \to_\Sigma \bot_\Sigma\phi \in D_\Sigma(\neg_\Sigma\phi)$. These two parts allow us to conclude that $D_\Sigma(\neg_\Sigma\phi) = D_\Sigma(\phi \to_\Sigma \bot_\Sigma\phi)$. ■

Since both the Deduction Detachment Theorem and inconsistencies are inherited by the full models of a finitary π-institution, we obtain the following concerning transference of the Intuitionistic Reductio ad Absurdum by full models.

Corollary 1457 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ and $\neg^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\to^\flat$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg^\flat$, then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, every full $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ also has the Deduction Detachment Theorem with respect to $\to$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg$.*

Proof: Assume the hypothesis and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. By Theorem 1444, $\mathbb{L}$ has the Deduction Detachment Theorem with respect to $\to$. By Proposition 1456, $\bot^\flat = \neg^\flat \circ \to^\flat \circ \langle p^{1,0}, p^{1,0} \rangle$ is an inconsistency in $\mathcal{I}$. Therefore, by Corollary 1455, $\bot$ is an inconsistency in $\mathbb{L}$. Finally, we use again Proposition 1456 to conclude that $\mathbb{L}$ has both the Deduction Detachment Theorem with respect to $\to$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg$. ■

19.9.6 Modality Introduction

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system, with $\# : \mathrm{SEN} \to \mathrm{SEN}$ a unary natural transformation in N, and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π-structure based on $\mathbf{A}$. $\mathbb{L}$ has **Modality Introduction with respect to** $\#$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \#_\Sigma\phi \in D_\Sigma(\#_\Sigma\Phi),$$

where $\#_\Sigma\Phi = \{\#_\Sigma\chi : \chi \in \Phi\}$.

It turns out that Modality Introduction is also preserved under bilogical morphisms.

Proposition 1458 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\#^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be $N^\flat$-algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be $N^\flat$-structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. $\mathbb{L}$ has the Modality Introduction with respect to $\#$ if and only if $\mathbb{L}'$ has the Modality Introduction with respect to $\#'$.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$. Then, since $\langle F, \alpha\rangle$ is a bilogical morphism, we have

$$\begin{array}{rcl}\phi \in D_\Sigma(\Phi) & \text{iff} & \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi));\\ \#_\Sigma\phi \in D_\Sigma(\#_\Sigma\Phi) & \text{iff} & \#'_{F(\Sigma)}\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\#'_{F(\Sigma)}\alpha_\Sigma(\Phi)).\end{array}$$

Therefore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \#_\Sigma\phi \in D_\Sigma(\#_\Sigma\Phi)$$

is equivalent to

$$\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \quad \text{implies} \quad \#'_{F(\Sigma)}\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\#'_{F(\Sigma)}\alpha_\Sigma(\Phi)).$$

Taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that $\mathbb{L}$ has Modality Introduction with respect to $\#$ if and only if $\mathbb{L}'$ has Modality Introduction with respect to $\#'$. ∎

We conclude this section by showing that modality introduction is inherited by all full $\mathcal{I}$-structures if $\mathcal{I}$ is a finitary π-institution possessing the property.

Proposition 1459 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\#^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has Modality Introduction with respect to $\#^\flat$, then every full $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D\rangle$ has the Modality Introduction with respect to $\#$.*

Proof: By Corollary 1393 and Proposition 1458, it suffices to show that every $\mathcal{I}$-structure of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ has the Modality Introduction with respect to $\#$. Let $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi'\} \subseteq \mathrm{SEN}(\Sigma')$. By Proposition 114, it suffices to show that

$$\phi' \in \Xi_{\Sigma'}(\Phi') \quad \text{implies} \quad \#_{\Sigma'}\phi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\#_{\Sigma'}\Phi').$$

We do this by applying induction on $n < \omega$ to show that, for all $n < \omega$,

$$\phi' \in \Xi^n_{\Sigma'}(\Phi') \quad \text{implies} \quad \#_{\Sigma'}\phi' \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\#_{\Sigma'}\Phi').$$

If $n = 0$, then the hypothesis is $\phi' \in \Xi^0_{\Sigma'}(\Phi') = \Phi'$ and the conclusion is trivial. Assume that the displayed formula holds, for all $i < n$ and assume $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi'\} \subseteq \mathrm{SEN}(\Sigma')$, such that $\phi' \in \Xi^n_{\Sigma'}(\Phi')$. Then, by definition, there exists $\Sigma \in |\mathbf{Sign}^\flat|$, such that $F(\Sigma) = \Sigma'$, and $\phi_0, \ldots, \phi_{k-1}, \phi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\phi \in C_\Sigma(\phi_0, \ldots, \phi_{k-1}), \quad \alpha_\Sigma(\phi) = \phi', \quad \alpha_\Sigma(\phi_i) \in \Xi^{n-1}_{\Sigma'}(\Phi'),\ i < k.$$

By the induction hypothesis, for all $i < k$, $\#_{\Sigma'}\alpha_\Sigma(\phi_i) \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\#_{\Sigma'}\Phi')$. Moreover, since $\mathcal{I}$ has Modality Introduction with respect to $\#^\flat$, we get $\#^\flat_\Sigma\phi \in C_\Sigma(\#^\flat_\Sigma\phi_0,\dots,\#^\flat_\Sigma\phi_{k-1})$. Therefore, applying $\langle F,\alpha\rangle$,

$$\begin{array}{lcl}\#_{F(\Sigma)}\phi' & \in & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\#_{F(\Sigma)}\alpha_\Sigma(\phi_0),\dots,\#_{F(\Sigma)}\alpha_\Sigma(\phi_{k-1}))\\ & \subseteq & C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(\#_\Sigma\Phi').\end{array}$$

This proves the induction step and shows that $\mathbb{L}$ has the Modality Introduction with respect to $\#$. ■

19.10 $\mathcal{I}$-Structures and Protoalgebraicity

We now work with an arbitrary π-institution $\mathcal{I}$ and look at its $\mathcal{I}$-structures and their properties. We start with a characterization of protoalgebraicity involving $\mathcal{I}$-structures.

Proposition 1460 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Then the following conditions are equivalent.*

(i) $\mathcal{I}$ is protoalgebraic;

(ii) For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and every $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D\rangle$, $\widetilde{\Omega}^{\mathcal{A}}(D) = \Omega^{\mathcal{A}}(\mathrm{Thm}(\mathbb{L}))$;

(iii) For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and every $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T\rangle$, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})) = \Omega^{\mathcal{A}}(T)$;

(iv) For every $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}(\mathcal{I}^T) = \Omega(T)$.

Proof:

(i)⇒(ii) Assume $\mathcal{I}$ is protoalgebraic and let $\mathbb{L} = \langle \mathcal{A}, D\rangle$ be an $\mathcal{I}$-structure. Then, by Proposition 1385, $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, by Theorem 179, $\Omega^{\mathcal{A}}$ is monotone on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence, we get

$$\widetilde{\Omega}^{\mathcal{A}}(D) = \bigcap\{\Omega^{\mathcal{A}}(T) : T \in \mathcal{D}\} = \Omega^{\mathcal{A}}(\bigcap\mathcal{D}) = \Omega^{\mathcal{A}}(\mathrm{Thm}(\mathbb{L})).$$

(ii)⇒(iii) Follows by applying (ii) to $\mathbb{L} = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$.

(iii)⇒(iv) Follows by applying (iii) to $\mathcal{A} = \langle \mathcal{F}, T\rangle$, where, as usual, $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$, $\langle I,\iota\rangle : \mathbf{F} \to \mathbf{F}$ the identity morphism.

(iv)⇒(i) Suppose that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}(\mathcal{I}^T) = \Omega(T)$ and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \le T'$. Then $T' \in \mathrm{ThFam}(\mathcal{I}^T)$, whence $\widetilde{\Omega}(\mathcal{I}^T) \le \Omega(T')$. But, by hypothesis, $\widetilde{\Omega}(\mathcal{I}^T) = \Omega(T)$. Thus, we get $\Omega(T) \le \Omega(T')$. We conclude that Ω is monotone on theory families and, therefore, $\mathcal{I}$ is protoalgebraic.

■

Recall that to a π-institution $\mathcal{I}$, we have associated two different classes of algebraic systems. On the one hand, the class $\mathrm{AlgSys}^*(\mathcal{I})$ consists of the $\mathbf{F}$-algebraic system reducts of the reduced $\mathcal{I}$-matrix families. On the other, the class $\mathrm{AlgSys}(\mathcal{I})$ consists of the $\mathbf{F}$-algebraic system reducts of the reduced full $\mathcal{I}$-structures, or, equivalently, as was shown in Proposition 1399, by the $\mathbf{F}$-algebraic system reducts of the reduced $\mathcal{I}$-structures. Under the hypothesis of protoalgebraicity, it turns out that the two classes $\mathrm{AlgSys}(\mathcal{I})$ and $\mathrm{AlgSys}^*(\mathcal{I})$ coincide.

Proposition 1461 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is protoalgebraic, then* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$.

Proof: By Theorem 1404, we know that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. Assume, conversely, that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathrm{AlgSys}(\mathcal{I})$. Then, there exists, by Proposition 1399, $\mathcal{D} \in \mathrm{ClFam}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}}$. Thus, by Proposition 1460, $\widetilde{\Omega}^{\mathcal{A}}(\bigcap \mathcal{D}) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}}$, whence, since $\bigcap \mathcal{D} \in \mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. ■

Protoalgebraicity is strong enough to allow full $\mathcal{I}$-structures on an algebraic system to be determined by their theorem systems.

Lemma 1462 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. If* $\mathcal{I}$ *is protoalgebraic and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathcal{A}, D' \rangle$ *are full* $\mathcal{I}$ *structures based on* $\mathcal{A}$*, such that* $\mathrm{Thm}(\mathbb{L}) = \mathrm{Thm}(\mathbb{L}')$*, then* $\mathbb{L} = \mathbb{L}'$.

Proof: Since $\mathcal{I}$ is protoalgebraic, we have, by Proposition 1460,

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Omega^{\mathcal{A}}(\mathrm{Thm}(\mathbb{L})) = \Omega^{\mathcal{A}}(\mathrm{Thm}(\mathbb{L}')) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}').$$

By the Isomorphism Theorem 1408, $\widetilde{\Omega}^{\mathcal{A}} : \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism, in particular one-to-one. So we get that $\mathbb{L} = \mathbb{L}'$. ■

For protoalgebraic π-institutions, it follows that all full $\mathcal{I}$-models have the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{A}}(\langle \mathcal{A}, T \rangle) \rangle$, i.e., their closure systems are principal filters in the lattice of $\mathcal{I}$-filter families of the underlying algebraic system.

Theorem 1463 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $\mathcal{I}$*-structures in* $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ *have the form* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) \rangle$*, for some* $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^{\mathcal{I}}(\mathcal{A})$.

Proof: Assume, first, that $\mathcal{I}$ is protoalgebraic and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. Let $T = \mathrm{Thm}(\mathbb{L})$ and set $\mathfrak{A} = \langle \mathcal{A}, T \rangle$. Clearly, $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$. By protoalgebracity and Proposition 1460, $\widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}) = \Omega^{\mathcal{A}}(T)$. Therefore, if $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$ denotes the quotient morphism, $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a bilogical morphism. Since $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$, $\mathcal{D}^* = \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}^*)$. But then, if $T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathfrak{A})$, $T \leq T'$, whence $\Omega^{\mathcal{A}}(T)$ is compatible with T' and, hence, by Corollary 56, $T'/\Omega^{\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) = \mathcal{D}^*$. Therefore, $T' = \pi^{-1}(T'/\Omega^{\mathcal{A}}(T)) \in \mathcal{D}$. So $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathcal{D}$.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\mathcal{I}$-structures in $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ have the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) \rangle$, for some $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^{\mathcal{I}}(\mathcal{A})$. Let $T, T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Since, by Theorem 1404, $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$, $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. Therefore, by the Isomorphism Theorem 1408, there exists $\mathbb{L} = \langle \mathcal{A}, \mathcal{D} \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Omega^{\mathcal{A}}(T)$. Let $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$ be the quotient morphism. Then $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a bilogical morphism and, since $\mathbb{L}$ is full, $\mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, $T = \pi^{-1}(T/\Omega^{\mathcal{A}}(T)) \in \mathcal{D}$. By hypothesis, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$, for some $\mathfrak{A} = \langle \mathcal{A}, T'' \rangle \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, $T'' \leq T'$, whence $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \mathcal{D}$. We now get $\Omega^{\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \leq \Omega^{\mathcal{A}}(T')$. So $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{A}$. Since $\mathcal{A}$ was arbitrary, we conclude that $\mathcal{I}$ is protoalgebraic. ∎

We proved that, for a protoalgebraic π-institution $\mathcal{I}$, all full $\mathcal{I}$-structures have the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We seek now to characterize those $\mathcal{I}$-filter families T for which the pair $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is a full $\mathcal{I}$-model, i.e., those $\mathcal{I}$-filter families T that give rise, through the principal filters they determine in $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ to full $\mathcal{I}$-structures.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. We define

$$\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})\}.$$

Using the Isomorphism Theorem 1408, it is not difficult to see that, under protoalgebraicity, there exists an order isomorphism between the poset determined by $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$ and the lattice of all $\mathcal{I}$-congruence systems on $\mathcal{A}$.

Proposition 1464 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is protoalgebraic, then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Consider the mapping $T \mapsto \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^T) \rangle$. This is a mapping from $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$ into $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, by the definition of $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$. Clearly, it is one-to-one and both order preserving and order reflecting. If $\mathcal{I}$ is protoalgebraic, by Theorem 1463, it is also surjective. Hence, it is an order isomorphism. By the Isomorphism Theorem 1408, $\widetilde{\Omega}^{\mathcal{A}} : \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is also an order isomorphism. Thus, $T \mapsto \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$ is an order isomorphism from $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$ onto $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. By Protoalgebraicity and Proposition 1460, we have $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) = \Omega^{\mathcal{A}}(T)$ and. moreover, by Proposition 1461, $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) = \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Hence, we conclude that $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order-isomorphism. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. Define

$$\sim^{\mathcal{I},\mathcal{A}} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^2$$

by setting, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \sim^{\mathcal{I},\mathcal{A}} T' \quad \text{iff} \quad \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T'),$$

i.e., $\sim^{\mathcal{I},\mathcal{A}}$ is the kernel of the Leibniz operator on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

It is clear from the definition that $\sim^{\mathcal{I},\mathcal{A}}$ is an equivalence relation on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. In case $\mathcal{I}$ is protoalgebraic, we have another important property.

Lemma 1465 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, SEN^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. If $\mathcal{I}$ is protoalgebraic, then each equivalence class of $\sim^{\mathcal{I},\mathcal{A}}$ has a minimum element.*

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and consider the equivalence class $[T]$ of T under $\sim^{\mathcal{I},\mathcal{A}}$. Then we have $\bigcap[T] \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, moreover,

$$\begin{array}{rcl}\Omega^{\mathcal{A}}(\bigcap[T]) & = & \bigcap\{\Omega^{\mathcal{A}}(T'); T' \in [T]\} \\ & = & \bigcap\{\Omega^{\mathcal{A}}(T) : T' \in [T]\} \\ & = & \Omega^{\mathcal{A}}(T).\end{array}$$

So $\bigcap[T] \in [T]$ and, therefore, $\bigcap[T]$ is the minimum element of $[T]$. ∎

The next proposition provides the promised characterization of those $\mathcal{I}$-filter families that determine full $\mathcal{I}$-structures through their principal filters in $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, in the case of a protoalgebraic $\mathcal{I}$.

Proposition 1466 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π-institution based on $\mathbf{F}$. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, the following conditions are equivalent:*

(i) $T \in \mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$, *i.e.,* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$;

(ii) $T = \min[T]$, *where* $[T]$ *is the equivalence class of* T *under* $\sim^{\mathcal{I},\mathcal{A}}$;

(iii) $T/\Omega^{\mathcal{A}}(T) = \min \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$.

Proof:

(ii)⇒(iii) Assume that $T = \min [T]$ and let $Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. Our goal is to show that $T/\Omega^{\mathcal{A}}(T) \le Y$. Consider the quotient morphism $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$ and let $X = \pi^{-1}(Y) \cap T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then

$$X = \pi^{-1}(Y) \cap \pi^{-1}(\pi(T)) = \pi^{-1}(Y \cap \pi(T)).$$

It follows that $\Omega^{\mathcal{A}}(T)$ is compatible with X and, hence, $\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(X)$. But, by definition, $X \le T$ and, thus, by protoalgebraicity, $\Omega^{\mathcal{A}}(X) \le \Omega^{\mathcal{A}}(T)$. We conclude that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(X)$ and, hence, $T \sim^{\mathcal{I},\mathcal{A}} X$. By hypothesis, we now get $T \le \pi^{-1}(Y)$, i.e., $T/\Omega^{\mathcal{A}}(T) \le X$. Since $Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$ was arbitrary, we conclude that $T/\Omega^{\mathcal{A}}(T) = \min \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$.

(iii)⇒(i) Suppose that $T/\Omega^{\mathcal{A}}(T) = \min \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. By protoalgebraicity (see the Correspondence Theorem 1336),

$$\pi : \mathbf{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T\rangle) \cong \mathbf{FiFam}^{\mathcal{I}}(\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle).$$

By hypothesis,

$$\mathrm{FiFam}^{\mathcal{I}}(\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T)).$$

Since, by Proposition 1460, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T\rangle)) = \Omega^{\mathcal{A}}(T)$, we obtain

$$\mathrm{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T\rangle)^* = \mathrm{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T\rangle^*).$$

This proves that $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T\rangle)\rangle$ is a full $\mathcal{I}$-structure. We conclude that $T \in \mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$.

(i)⇒(ii) Suppose $T \in \mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A})$. Since $\mathcal{I}$ is protoalgebraic, by Lemma 1465, there exists $T' = \min [T]$. By the proofs of the two preceding implications (ii)⇒(iii)⇒(i), $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'}\rangle$ is a full $\mathcal{I}$-structure. But, by hypothesis, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T}\rangle$ is also a full $\mathcal{I}$-structure. Now observe that, by Proposition 1460,

$$\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'}) = \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T}).$$

By the Isomorphism Theorem 1408, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T}$ and, therefore, $T' = T$. So we conclude that $T = \min [T]$.

■

Since, for a protoalgebraic π-institution $\mathcal{I}$, the filter families determining full $\mathcal{I}$-structures are the ones that are minimal in their equivalence classes under $\sim^{\mathcal{I},\mathcal{A}}$, we can easily conclude that the class of those filter families consists of all filter families just in case all equivalence classes are singletons.

Proposition 1467 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$. *Then* $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *(i.e., for all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ *is a full* $\mathcal{I}$*-structure) if and only if* $\Omega^{\mathcal{A}}$ *is injective on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof: By Proposition 1466, $\mathrm{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ if and only if, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T = \min[T]$, if and only if, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ implies $T = T'$, if and only if $\Omega^{\mathcal{A}}$ is injective on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Recall that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is called **weakly family algebraizable**, or **WF algebraizable** for short, if the Leibniz operator Ω is monotone and injective on the theory families of $\mathcal{I}$. Equivalently, by Theorem 295, $\mathcal{I}$ is WF algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator on $\mathcal{A}$ is monotone and injective on $\mathcal{I}$-filter families.

The following theorem provides additional characterizations in terms of $\mathcal{I}$-structures and $\mathcal{I}$-congruence systems.

Theorem 1468 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then the following conditions are equivalent.*

(i) $\mathcal{I}$ *is protoalgebraic and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T) = \min \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$;

(ii) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ *is monotone and injective on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$;

(iii) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $T \mapsto \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ *is a bijection between* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and* $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ *and, hence, an order isomorphism from* $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ *to* $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$;

(iv) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is an order isomorphism;*

(v) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism.*

Proof:

(i)⇔(ii) By Propositions 1466 and 1467.

(i)⇒(iii) It is clear that $T \to \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is injective. By Proposition 1466, it is into $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ and, by Theorem 1463, it is onto $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. Hence it is a bijection, as claimed.

(iii)⇒(iv) Since, by hypothesis, every full $\mathcal{I}$-structure is of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$, by Theorem 1463, $\mathcal{I}$ is protoalgebraic. The composition of the given isomorphism

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$$

with the isomorphism established in the Isomorphism Theorem 1408,

$$\widetilde{\Omega}^{\mathcal{A}} : \mathbf{FStr}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$$

gives an isomorphism

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}),$$

which by protoalgebraicity and Proposition 1460 is identical to the Leibniz operator.

(iv)⇒(v) By Corollary 1405, $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. Thus, $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. By the hypothesis, every $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is of the form $\Omega^{\mathcal{A}}(T)$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) \subseteq \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$.

(v)⇒(ii) is trivial.

■

In the context of weakly family algebraizable π-institutions, we look, also at the local continuity of the Leibniz and the Tarski operators.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system.

- $\Omega^{\mathcal{A}}$ is **continuous** if, for every directed collection $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcup_{i \in I} T^i \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have
$$\Omega^{\mathcal{A}}(\bigcup_{i \in I} T^i) = \bigcup_{i \in I} \Omega^{\mathcal{A}}(T^i).$$
- $\widetilde{\Omega}^{\mathcal{A}}$ is **continuous** if, for every directed family $\{\mathbb{L}^i : i \in I\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$,
$$\widetilde{\Omega}^{\mathcal{A}}(\sup\{\mathbb{L}^i : i \in I\}) = \bigcup_{i \in I} \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i).$$

Proposition 1469 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is weakly family algebraizable, then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is continuous if and only if $\widetilde{\Omega}^{\mathcal{A}}$ is continuous.*

Proof: Let $\Phi : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ be the bijection of Theorem 1468. Then, by Proposition 1460,

$$\Omega^{\mathcal{A}} = \widetilde{\Omega}^{\mathcal{A}} \circ \Phi \quad \text{and} \quad \widetilde{\Omega}^{\mathcal{A}} = \Omega^{\mathcal{A}} \circ \Phi^{-1}.$$

Suppose, first, that $\Omega^{\mathcal{A}}$ is continuous and let $\{\mathbb{L}^i : i \in I\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ be directed. If $T^i = \Phi^{-1}(\mathbb{L}^i)$, $i \in I$, then $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is also directed. Directedness implies local directedness and, therefore, by Proposition 112, $\bigcup_{i\in I} T^i \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Now we get

$$\Phi(\bigcup_{i\in I} T^i) = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\bigcup_{i\in I} T^i}\rangle = \langle \mathcal{A}, \bigcap_{i\in I} \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^i}\rangle,$$

whence $\Phi(\bigcup_{i\in I} T^i) = \sup_{i\in I} \mathbb{L}^i$. Therefore, we get

$$\widetilde{\Omega}^{\mathcal{A}}(\sup_{i\in I} \mathbb{L}^i) = (\Omega^{\mathcal{A}} \circ \Phi^{-1})(\Phi(\bigcup_{i\in I} T^i)) = \Omega^{\mathcal{A}}(\bigcup_{i\in I} T^i) = \bigcup_{i\in I} \Omega^{\mathcal{A}}(T^i) = \bigcup_{i\in I} \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i).$$

So $\widetilde{\Omega}^{\mathcal{A}}$ is also continuous.

Assume, conversely, $\widetilde{\Omega}^{\mathcal{A}}$ is continuous. Let $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ be directed. Then $\{\Phi(T^i) : i \in I\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ is also directed and we have

$$\Omega^{\mathcal{A}}(\bigcup_{i\in I} T^i) = \widetilde{\Omega}^{\mathcal{A}}(\Phi(\bigcup_{i\in I} T^i)) = \widetilde{\Omega}^{\mathcal{A}}(\sup_{i\in I} \mathbb{L}^i) = \bigcup_{i\in I} \widetilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i) = \bigcup_{i\in I} \Omega^{\mathcal{A}}(T^i).$$

Therefore $\Omega^{\mathcal{A}}$ is also continuous. ■

19.11 $\mathcal{I}$-Structures and Fregeanity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is called **Fregean** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, the π-structure $\mathcal{I}^T$ has the Congruence Property, i.e., for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\Lambda}^{\mathcal{I}}(T) = \widetilde{\Omega}^{\mathcal{I}}(T).$$

Clearly, $\mathcal{I}$ is Fregean if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, if, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}^\flat(f)(\phi)) = C_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}^\flat(f)(\psi)),$$

then, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'}, \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi})) = C_{\Sigma'}(T_{\Sigma'}, \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})).$$

$\mathcal{I}$ is called **strongly Fregean** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, the π-structure $\mathcal{I}^T$ has the strong Congruence Property, i.e., for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\lambda}^{\mathcal{I}}(T) = \widetilde{\Omega}^{\mathcal{I}}(T).$$

In this case, we get that $\mathcal{I}$ is strongly Fregean if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C_\Sigma(T_\Sigma, \phi) = C_\Sigma(T_\Sigma, \psi)$$

implies, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'},\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})) = C_{\Sigma'}(T_{\Sigma'},\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})).$$

A consequence of strong Fregeanity is that every reduced matrix family model has either an empty filter family or a filter family all of whose components are singletons.

Proposition 1470 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly Fregean, then, for every reduced $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T\rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, we have, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 0$, or, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$.*

We abbreviate the first disjunct of the conclusion, as usual, by $T = \varnothing$ and the second by writing $|T| = 1$.

Proof: Assume that $T \neq \varnothing$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi,\psi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. Hence,

$$C_\Sigma(\alpha^{-1}_\Sigma(T_{F(\Sigma)}),\phi) = C_\Sigma(\alpha^{-1}_\Sigma(T_{F(\Sigma)}),\psi),$$

i.e., $\langle \phi,\psi\rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(\alpha^{-1}(T))$. By strong Fregeanity, $\langle\phi,\psi\rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(\alpha^{-1}(T))$. Thus, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\begin{array}{l} C_{\Sigma'}(\alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})) \\ \qquad = C_{\Sigma'}(\alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})).\end{array}$$

Now we get

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in \alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}) \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \in \alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}).$$

Equivalently,

$$\begin{array}{l} \sigma_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)),\alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \qquad \text{iff} \quad \sigma_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\psi)),\alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')}.\end{array}$$

Taking into account the surjectivity of $\langle F,\alpha\rangle$, we get that $\langle \alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T) = \Delta^{\mathcal{A}}_{F(\Sigma)}$, the last equation holding since $\mathfrak{A}$ is reduced. Hence, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$ and, therefore, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$. ∎

Of course, in the case of Fregeanity and protoalgebraicity, the role of the Tarski operator may be substituted by the Leibniz operator.

Proposition 1471 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ *is protoalgebraic and Fregean if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \widetilde{\Lambda}^{\mathcal{I}}(T)$;

(b) $\mathcal{I}$ *is protoalgebraic and strongly Fregean if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \widetilde{\lambda}^{\mathcal{I}}(T)$.

Proof: We only prove Part (a), since Part (b) can be proven by following a similar reasoning.

If $\mathcal{I}$ is protoalgebraic, then, by Proposition 1460, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \widetilde{\Omega}^{\mathcal{I}}(T)$. If $\mathcal{I}$ is Fregean, then ,by definition, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}}(T) = \widetilde{\Lambda}^{\mathcal{I}}(T)$. Therefore, if $\mathcal{I}$ is protoalgebraic and Fregean, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \widetilde{\Lambda}^{\mathcal{I}}(T)$.

Assume, conversely, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we have $\Omega(T) = \widetilde{\Lambda}^{\mathcal{I}}(T)$. Then, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$, we have

$$\Omega(T) = \widetilde{\Lambda}^{\mathcal{I}}(T) \overset{\text{Lemma 1416}}{\leq} \widetilde{\Lambda}^{\mathcal{I}}(T') = \Omega(T').$$

Thus, Ω is monotone on $\mathrm{ThFam}(\mathcal{I})$ and $\mathcal{I}$ is protoalgebraic. Moreover, since, by Proposition 1460, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}}(T) = \Omega(T)$, we get $\widetilde{\Omega}^{\mathcal{I}}(T) = \widetilde{\Lambda}^{\mathcal{I}}(T)$ and, therefore, $\mathcal{I}$ is also Fregean. ■

Recall that a π-institution $\mathcal{I}$ is self extensional if

$$\widetilde{\Omega}(\mathcal{I}) = \widetilde{\Lambda}(\mathcal{I}) \ (= \widetilde{\lambda}(\mathcal{I})).$$

It turns out that Fregeanity (and, therefore, strong Fregeanity) implies self extensionality.

Corollary 1472 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is Fregean, then it is self extensional.*

Proof: We have

$$\begin{aligned} \widetilde{\Omega}(\mathcal{I}) &= \widetilde{\Omega}^{\mathcal{I}}(\mathrm{Thm}(\mathcal{I})) \quad \text{(by definition)} \\ &= \widetilde{\Lambda}^{\mathcal{I}}(\mathrm{Thm}(\mathcal{I})) \quad \text{(by Fregeanity)} \\ &= \widetilde{\Lambda}(\mathcal{I}). \quad \text{(by definition)} \end{aligned}$$

So $\mathcal{I}$ is self extensional. ■

If a π-institution $\mathcal{I}$ is strongly Fregean and has theorems, then the mapping $T \mapsto \mathcal{I}^T$ establishes an order embedding from the lattice of the theory families of $\mathcal{I}$ into the lattice of full $\mathcal{I}$-structures on the algebraic system $\mathcal{F}$.

Proposition 1473 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is strongly Fregean with theorems, then* $T \mapsto \mathcal{I}^T$ *is an order embedding of* $\mathbf{ThFam}(\mathcal{I})$ *into* $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$.

Proof: We start by showing that the proposed mapping is indeed well-defined into $\mathrm{FStr}^{\mathcal{I}}(\mathcal{F})$, i.e., that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\mathcal{I}^T = \langle \mathcal{F}, \mathrm{ThFam}(\mathcal{I})^T \rangle$ is a full $\mathcal{I}$-structure. To this end, let $T \in \mathrm{ThFam}(\mathcal{I})$ and set $\theta = \widetilde{\Omega}^{\mathcal{I}}(T) = \widetilde{\lambda}^{\mathcal{I}}(T)$. To verify that $\mathcal{I}^T$ is a full $\mathcal{I}$-structure, it suffices to show that $\mathrm{ThFam}(\mathcal{I}^T)/\theta = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$.

If $T' \in \mathrm{ThFam}(\mathcal{I}^T)$, then, by definition of θ, θ is compatible with T'. Therefore, by Corollary 56, $T'/\theta \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$. Thus, $\mathrm{ThFam}(\mathcal{I}^T)/\theta \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$.

If, on the other hand, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$, then, setting $\langle I, \pi \rangle : \mathcal{F} \to \mathcal{F}/\theta$ the quotient morphism, we have, by Corollary 55, $\pi^{-1}(T') \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{F})$, i.e., $\pi^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$. We also have, taking into account that $\mathcal{I}$ has theorems, that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi \in T_\Sigma$ and $\psi \in T_\Sigma \cap \pi_\Sigma^{-1}(T'_\Sigma)$,

$$\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(T) = \theta_\Sigma.$$

So $\pi_\Sigma(\phi) = \pi_\Sigma(\psi)$, whence $\phi \in \pi_\Sigma^{-1}(\pi_\Sigma(\psi)) \in \pi_\Sigma^{-1}(T'_\Sigma)$. Since $\phi \in T_\Sigma$ was arbitrary, $T \le \pi^{-1}(T')$ and, hence, $\pi^{-1}(T') \in \mathrm{ThFam}(\mathcal{I}^T)$. This shows that $T' \in \mathrm{ThFam}(\mathcal{I}^T)/\theta$ and allows us to conclude that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta) \subseteq \mathrm{ThFam}(\mathcal{I}^T)/\theta$.

As for the rest, everything follows, since $T \mapsto \mathcal{I}^T$ is clearly one-to-one and both order preserving and order reflecting. ∎

If one adds protoalgebraicity into the mix, then the order embedding of Proposition 1473 becomes an order isomorphism.

Proposition 1474 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a strongly Fregean protoalgebraic* π*-institution with theorems, based on* $\mathbf{F}$*. Then* $T \mapsto \mathcal{I}^T$ *is an isomorphism between* $\mathbf{ThFam}(\mathcal{I})$ *and* $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$*.*

Proof: By Proposition 1473, it suffices to show that the mapping $T \mapsto \mathcal{I}^T$ is also onto $\mathrm{FStr}^{\mathcal{I}}(\mathcal{F})$. The latter follows from Theorem 1463. ∎

Strong Fregeanity, protoalgebraicity and the existence of theorems have very strong consequences for a π-institution. They ensure that the π-institution is weakly family algebraizable, that the Leibniz operator is continuous (in case of finitarity) and that all reduced matrix families have singleton filter families.

Proposition 1475 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a strongly Fregean protoalgebraic* π*-institution with theorems.*

(a) $\mathcal{I}$ *is family injective and hence weakly family algebraizable;*

(b) If $\mathcal{I}$ *is finitary, then* Ω *is locally continuous;*

(c) For every $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})$*,* $|T| = 1$*.*

Proof: By Proposition 1460, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \widetilde{\Omega}^{\mathcal{I}}(T)$. Thus, composing the mapping $T \mapsto \mathcal{I}^T$ of Proposition 1474, with the isomorphism of Theorem 1408, we obtain an isomorphism $\Omega : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ConSys}^{\mathcal{I}}(\mathcal{F})$. By Proposition 1471, $\Omega = \widetilde{\lambda}^{\mathcal{I}}$ and, hence, by Proposition 1419, Ω is locally continuous. Finally, if $\mathfrak{A} = \langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, then, since $\mathcal{I}$ has theorems, $T \neq \varnothing$ and, therefore, by Proposition 1470, $|T| = 1$. ■

We saw in Corollary 1472 that Fregeanity implies self extensionality. On the other hand, even though we cannot prove that strong Fregeanity, coupled with protoalgebraicity, are strong enough to guarantee full self extensionality, we can show that they imply a weaker property, namely a version of full self extensionality applying only to full $\mathcal{I}$-structures with isomorphic functor components. We start with a technical lemma.

Lemma 1476 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a strongly Fregean protoalgebraic π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system, with $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ an isomorphism. Then, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\Omega^{\mathcal{A}}(T) = \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T).$$

Proof: Note that, by protoalgebraicity, $\Omega^{\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. Therefore, by compatibility, $\Omega^{\mathcal{A}}(T) \leq \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. It therefore suffices to show the reverse inclusion. To this end and taking into account the surjectivity of $\langle F, \alpha\rangle$, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \widetilde{\lambda}^{\mathcal{A}}_{F(\Sigma)}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. Then, by definition, for all $T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have

$$\alpha_\Sigma(\phi) \in T''_{F(\Sigma)} \quad \text{iff} \quad \alpha_\Sigma(\psi) \in T''_{F(\Sigma)}.$$

However, since $\mathcal{I}$ is protoalgebraic, we get, by the Correspondence Theorem 1336, that, for all $\alpha^{-1}(T) \leq T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\phi \in T'_\Sigma \quad \text{iff} \quad \psi \in T'_\Sigma.$$

Hence, by definition,

$$\begin{array}{rcll}\langle \phi, \psi\rangle & \in & \widetilde{\lambda}^{\mathcal{I}}_\Sigma(\alpha^{-1}(T)) & \\ & = & \Omega_\Sigma(\alpha^{-1}(T)) & \text{(strong Fregeanity)} \\ & = & \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T)). & \text{(Proposition 24)}\end{array}$$

Hence $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T)$. Taking into account the surjectivity of $\langle F, \alpha\rangle$, we now conclude that $\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \leq \Omega^{\mathcal{A}}(T)$. ■

Proposition 1477 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly Fregean and protoalgebraic, then, every full $\mathcal{I}$-structure, with an isomorphic functor component, has the Congruence Property.*

Proof: We deal first with the case $\mathrm{Thm}(\mathcal{I}) = \varnothing$. Then, since $\mathcal{I}$ is protoalgebraic, the only option is

$$\mathrm{ThFam}(\mathcal{I}) = \{T : T_\Sigma = \varnothing \text{ or } \mathrm{SEN}^\flat(\Sigma), \text{ for all } \Sigma \in |\mathbf{Sign}^\flat|\}.$$

In this case, given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, the only full $\mathcal{I}$-structures on $\mathcal{A}$ are of the form $\langle \mathcal{A}, \mathcal{D}\rangle$, with

$$\mathcal{D} = \{T : T_\Sigma = \varnothing \text{ or } \mathrm{SEN}(\Sigma), \text{ for all } \Sigma \in |\mathbf{Sign}|\}.$$

All those have the Congruence Property.

Assume, next, that $\mathcal{I}$ has theorems. By Lemma 1476, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ an isomorphism, and every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\Omega^{\mathcal{A}}(T) = \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T).$$

Thus, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T\rangle$ has the strong Congruence Property. Since, by Theorem 1463, every full $\mathcal{I}$-structure, with an isomorphic functor component has this form, we conclude that every full $\mathcal{I}$-structure, with an isomorphic functor component, has the Congruence Property. ∎

For finitary fully self extensional π-institutions, we obtain the following characterizations of weak family algebraizability.

Proposition 1478 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a finitary, fully self extensional π-institution based on $\mathbf{F}$. Then the following conditions are equivalent.*

(i) $\mathcal{I}$ is strongly Fregean, protoalgebraic and has theorems;

(ii) $\mathcal{I}$ is weakly family algebraizable and Ω is locally continuous;

(iii) $\mathcal{I}$ is weakly family algebraizable.

Proof: (i)⇒(ii) follows from Proposition 1475. (ii)⇒(iii) is trivial. For (iii)⇒(i) note, first, that, by hypothesis $\mathcal{I}$ is family monotone and family injective. Thus, $\mathcal{I}$ is protoalgebraic. By Proposition 1468, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\mathcal{I}^T \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{F})$. Hence, by full self extensionality, $\mathcal{I}^T$ has the strong Congruence Property and, hence, $\mathcal{I}$ is strongly Fregean. Finally, since $\Omega(\varnothing) = \Omega(\mathrm{SEN}^\flat) = \nabla^{\mathcal{F}}$, we get, by injectivity, $\varnothing \notin \mathrm{ThFam}(\mathcal{I})$ and $\mathcal{I}$ has theorems. ∎

Chapter 20

Full Adequacy

20.1 Gentzen π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\Sigma \in |\mathbf{Sign}^\flat|$. A Σ-**sequent** is a pair

$$\langle \Phi, \phi \rangle,$$

where $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$ (with Φ possibly empty). Sometimes we write

$$\Phi \rhd_\Sigma \phi \quad \text{or} \quad \Phi \vdash_\Sigma \phi$$

to denote the Σ-sequent $\langle \Phi, \phi \rangle$. The set Φ is called **set of antecedents of** $\langle \Phi, \phi \rangle$ and ϕ is called the **consequent of** $\langle \Phi, \phi \rangle$.

The collection of Σ-sequents is denoted by $\mathrm{Seq}_\Sigma(\mathbf{F})$ and the set of all Σ-sequents with nonempty set of antecedents is denoted by $\mathrm{Seq}^0_\Sigma(\mathbf{F})$. We then set

$$\mathrm{Seq}(\mathbf{F}) = \{\mathrm{Seq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|} \quad \text{and} \quad \mathrm{Seq}^0(\mathbf{F}) = \{\mathrm{Seq}^0_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}.$$

We sometimes use boldface Greek letters such as $\boldsymbol{\gamma}, \boldsymbol{\delta}, \ldots$ to denote Σ-sequents and boldface capital Greek letters such as $\boldsymbol{\Gamma}, \boldsymbol{\Delta}, \ldots$ for sets of Σ-sequents. Moreover, we write $\Gamma \vdash_\Sigma \Phi$ to stand for the set $\{\Gamma \vdash_\Sigma \phi : \phi \in \Phi\}$ of Σ-sequents.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A **Gentzen π-institution based on F of type 1** (**of type 0**, respectively) is a pair

$$\mathfrak{G} = \langle \mathbf{F}, G \rangle,$$

where $G : \mathcal{P}(\mathrm{Seq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}(\mathbf{F}))$ ($G : \mathcal{P}(\mathrm{Seq}^0(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}^0(\mathbf{F}))$, respectively) is a closure system on $\mathrm{Seq}(\mathbf{F})$ ($\mathrm{Seq}^0(\mathbf{F})$, respectively) that, in addition, satisfies the following **structural rules**, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$:

$$\begin{array}{rl} \text{(Axiom)} & \phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing); \\ \text{(Weakening)} & \Phi, \Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi); \\ \text{(Cut)} & \Phi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \Psi,\ \Phi, \Psi \vdash_\Sigma \phi). \end{array}$$

If $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$ we call $\Phi \vdash_\Sigma \phi$ a Σ-**theorem** or a **derivable Σ-sequent** of $\mathfrak{G}$.

Each Gentzen π-institution based on an algberaic system $\mathbf{F}$ defines in a natural way a π-institution based on $\mathbf{F}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. The **π-institution $\mathcal{I}^{\mathfrak{G}} = \langle F, C^{\mathfrak{G}} \rangle$ defined** or **determined by $\mathfrak{G}$** is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C^{\mathfrak{G}}_\Sigma(\Phi) \quad \text{iff} \quad \Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing).$$

Proposition 1479 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$. $C^{\mathfrak{G}} : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$ *is a closure system on* $\mathrm{SEN}^\flat$ *and, hence,* $\mathcal{I}^{\mathfrak{G}} = \langle \mathbf{F}, C^{\mathfrak{G}} \rangle$ *is a* π*-institution.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$.

If $\phi \in \Phi$, then, by (Axiom) $\phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$ and by (Weakening) $\Phi \vdash_\Sigma \phi \in G_\Sigma(\phi \vdash_\Sigma \phi)$, whence $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Therefore $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$.

If $\Phi \subseteq \Psi$ and $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$, then $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$ and, by (Weakening), $\Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi)$, whence $\Psi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$, giving $\phi \in C^{\mathfrak{G}}_\Sigma(\Psi)$.

If $\phi \in C^{\mathfrak{G}}_\Sigma(C^{\mathfrak{G}}_\Sigma(\Phi))$, then $C^{\mathfrak{G}}_\Sigma(\Phi) \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$ and, by (Weakening),

$$\Phi, C^{\mathfrak{G}}_\Sigma(\Phi) \vdash_\Sigma \phi \in G_\Sigma(C^{\mathfrak{G}}_\Sigma(\Phi) \vdash_\Sigma \phi) \subseteq G_\Sigma(\varnothing).$$

Moreover, by definition $\Phi \vdash_\Sigma C^{\mathfrak{G}}_\Sigma(\Phi) \subseteq G_\Sigma(\varnothing)$, whence, by (Cut),

$$\Phi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma C^{\mathfrak{G}}_\Sigma(\Phi),\ \Phi, C^{\mathfrak{G}}_\Sigma(\Phi) \vdash_\Sigma \phi) \subseteq G_\Sigma(\varnothing).$$

Therefore, $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$.

Finally, suppose $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$, $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then, by definition, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$ and, by structurality,

$$\mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in G_{\Sigma'}(\varnothing).$$

This shows that $\mathrm{SEN}^\flat(f)(\phi) \in C^{\mathfrak{G}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$ and, therefore, $C^{\mathfrak{G}}$ is a closure system on $\mathrm{SEN}^\flat$, as was to be shown. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution, also based on $\mathbf{F}$. We say that $\mathfrak{G}$ is **adequate for** $\mathcal{I}$ if $C = C^{\mathfrak{G}}$ and, moreover,

- $\mathfrak{G}$ is of type 1 if $\mathcal{I}$ has theorems and
- $\mathfrak{G}$ is of type 0 if $\mathcal{I}$ does not have theorems.

The following proposition clarifies the distinction imposed on the type, since it reveals the fact that, if $\mathcal{I}$ has no theorems, then it is sufficient to assume that a Gentzen π-institution adequate for $\mathcal{I}$ has type 0.

Proposition 1480 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$.

(a) If $\mathfrak{G}$ *is of type 0, then* $\mathcal{I}^{\mathfrak{G}}$ *does not have theorems.*

(b) If $\mathfrak{G}$ *is of type 1, then its restriction* $\mathfrak{G}^0 = \langle \mathbf{F}, G^0 \rangle$ *to* $\mathrm{Seq}^0(\mathbf{F})$ *is a Gentzen* π*-institution of type 0.*

(c) If $\mathfrak{G}$ *is of type 1 and* $\mathcal{I}^{\mathfrak{G}}$ *has no theorems, then* $\mathcal{I}^{\mathfrak{G}} = \mathcal{I}^{\mathfrak{G}^0}$.

Proof:

(a) Suppose $\mathcal{I}^{\mathfrak{G}}$ has theorems. Thus, for all $\Sigma \in |\mathbf{Sign}^\flat|$, there exists $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathfrak{G}}_\Sigma(\varnothing)$. Thus, by definition, $\varnothing \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Therefore, $\mathfrak{G}$ cannot be of type 0 (since it admits a sequent with an empty set of antecedents).

(b) Suppose $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ is of type 1. Consider $\mathfrak{G}^0 = \langle \mathbf{F}, G^0\rangle$. We must show that $G^0 : \mathcal{P}(\mathrm{Seq}^0(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}^0(\mathbf{F}))$ is a closure system on $\mathrm{Seq}^0(\mathbf{F})$ that satisfies the structural rules.

- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in \mathbf{\Gamma}$. Then $\boldsymbol{\gamma} \in G_\Sigma(\mathbf{\Gamma})$ and, hence, $\boldsymbol{\gamma} \in G^0_\Sigma(\mathbf{\Gamma})$.
- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \mathbf{\Delta} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in G^0_\Sigma(\mathbf{\Gamma})$ and $\mathbf{\Gamma} \subseteq \mathbf{\Delta}$. Then, by definition, $\boldsymbol{\gamma} \in G_\Sigma(\mathbf{\Gamma})$ and $\mathbf{\Gamma} \subseteq \mathbf{\Delta}$, whence $\boldsymbol{\gamma} \in G_\Sigma(\mathbf{\Delta})$. So $\boldsymbol{\gamma} \in G^0_\Sigma(\mathbf{\Delta})$.
- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in G^0_\Sigma(G^0_\Sigma(\mathbf{\Gamma}))$. Then $\boldsymbol{\gamma} \in G_\Sigma(G_\Sigma(\mathbf{\Gamma})) = G_\Sigma(\mathbf{\Gamma})$. As $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, it follows that $\boldsymbol{\gamma} \in G^0_\Sigma(\mathbf{\Gamma})$.
- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in G^0_\Sigma(\mathbf{\Gamma})$, $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then $\boldsymbol{\gamma} \in G_\Sigma(\mathbf{\Gamma})$, whence $\mathrm{SEN}^\flat(f)(\boldsymbol{\gamma}) \in G_{\Sigma'}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$. Observing that, if $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}^0_\Sigma(\mathbf{F})$, then $\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}) \cup \{\mathrm{SEN}^\flat(f)(\boldsymbol{\gamma})\} \subseteq \mathrm{Seq}^0_{\Sigma'}(\mathbf{F})$, we conclude that
$$\mathrm{SEN}^\flat(f)(\boldsymbol{\gamma}) \in G^0_{\Sigma'}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma})).$$

Next, for the structural rules:

(Axiom) For $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \vdash_\Sigma \phi \in \mathrm{Seq}^0_\Sigma(\mathbf{F})$, whence, since, by (Axiom), $\phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$, $\phi \vdash_\Sigma \phi \in G^0_\Sigma(\varnothing)$.

(Weakening) Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\Phi \neq \varnothing$. Then, since $\Phi \cup \Psi \neq \varnothing$ and since, by (Weakening), $\Phi, \Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi)$, we conclude that $\Phi, \Psi \vdash_\Sigma \phi \in G^0_\Sigma(\Phi \vdash_\Sigma \phi)$.

(Cut) Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, with $\Phi \neq \varnothing$. Then $\Phi \cup \Psi \neq \varnothing$ and, since, by (Cut), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \Psi,\ \Phi, \Psi \vdash_\Sigma \phi)$, we get $\Phi \vdash_\Sigma \phi \in G^0_\Sigma(\Phi \vdash_\Sigma \Psi,\ \Phi, \Psi \vdash_\Sigma \phi)$.

(c) Suppose $\mathfrak{G}$ is of type 1 and $\mathcal{I}^{\mathfrak{G}}$ has no theorems. Clearly, $G^0 \leq G$ so that $C^{\mathfrak{G}^0} \leq C^{\mathfrak{G}}$. On the other hand, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$. Since $\mathcal{I}^{\mathfrak{G}}$ has no theorems, $\Gamma \neq \varnothing$. Moreover, by definition, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Thus, $\Phi \vdash_\Sigma \phi \in G^0_\Sigma(\varnothing)$. We conclude that $\phi \in C^{\mathfrak{G}^0}_\Sigma(\Phi)$. So $C^{\mathfrak{G}} \leq C^{\mathfrak{G}^0}$ and equality follows.

■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\Sigma \in |\mathbf{Sign}^\flat|$.

- A **Gentzen Σ-axiom** is a Σ-sequent $\gamma \in \mathrm{Seq}_\Sigma(\mathbf{F})$;
- A **Gentzen Σ-rule** is a pair $\langle \mathbf{\Gamma}, \gamma \rangle$, where $\mathbf{\Gamma} \cup \{\gamma\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$.

A **Gentzen axiom system** is a collection $\mathrm{Ax} = \{\mathrm{Ax}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where Ax_Σ is a set of Gentzen Σ-axioms, which is $\mathbf{Sign}^\flat$-invariant.

A **Gentzen rule system** is a collection $\mathrm{Ir} = \{\mathrm{Ir}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where Ir_Σ is a set of Gentzen Σ-rules, which is also $\mathbf{Sign}^\flat$-invariant. Set

$$R = \mathrm{Ax} \cup \mathrm{Ir}.$$

The **Gentzen closure system** $G^R \subseteq \mathcal{P}(\mathrm{Seq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}(\mathbf{F}))$ **generated by** R is the least closure system on $\mathrm{Seq}(\mathbf{F})$, satisfying the structural rules, that contains R, i.e., such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

- $\gamma \in G^R_\Sigma(\varnothing)$, for all $\gamma \in \mathrm{Ax}_\Sigma$, and
- $\gamma \in G^R_\Sigma(\mathbf{\Gamma})$, for all $\langle \mathbf{\Gamma}, \gamma \rangle \in \mathrm{Ir}_\Sigma$.

We denote by $\mathfrak{G}^R = \langle \mathbf{F}, G^R \rangle$ the corresponding Gentzen π-institution, called the **Gentzen π-institution generated by** R.

A Finitary Parenthesis

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $R = \mathrm{Ax} \cup \mathrm{Ir}$ a set of finitary Gentzen axioms and rules of inference (i.e., such that the set of antecedents of all sequents involved is finite and the set of hypotheses of each rule of inference is also finite), and $\mathbf{\Gamma} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$ a set of Σ-sequents. We define a family

$$\Xi^R_\Sigma(\mathbf{\Gamma}) = \bigcup \{\Xi^{R,n}_\Sigma(\mathbf{\Gamma}) : n < \omega\},$$

where $\Xi^{R,n}_\Sigma(\mathbf{\Gamma})$ is defined by induction on $n < \omega$ as follows:

- $\Xi^{R,0}_\Sigma(\mathbf{\Gamma}) = \{\phi \vdash_\Sigma \phi : \phi \in \mathrm{SEN}^\flat(\Sigma)\} \cup \mathrm{Ax}_\Sigma \cup \mathbf{\Gamma}$;
- For all $n \geq 0$, $\Phi \cup \Psi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rcl}\Xi^{R,n+1}_\Sigma(\mathbf{\Gamma}) & = & \{\Phi, \Psi \vdash_\Sigma \phi : \Phi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})\} \\ & & \cup \{\Phi \vdash_\Sigma \phi : \Phi \vdash_\Sigma \Psi,\ \Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})\} \\ & & \cup \{\Phi \vdash_\Sigma \phi : \langle \mathbf{\Delta}, \Phi \vdash_\Sigma \phi \rangle \in \mathrm{Ir}_\Sigma, \mathbf{\Delta} \subseteq \Xi^{R,n}_\Sigma(\mathbf{\Gamma})\}.\end{array}$$

We define $\Xi^R : \mathcal{P}(\mathrm{Seq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}(\mathbf{F}))$, by letting $\Xi^R \coloneqq \{\Xi^R_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where $\Xi^R_\Sigma : \mathcal{P}(\mathrm{Seq}_\Sigma(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}_\Sigma(\mathbf{F}))$ as defined above.

We show, next, that this is closure system on $\mathrm{Seq}(\mathbf{F})$, which satisfies the structural rules, includes Ax and is closed under Ir.

Lemma 1481 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $R = \mathrm{Ax} \cup \mathrm{Ir}$ *a collection of finitary axioms and rules of inference.* $\Xi^R : \mathcal{P}(\mathrm{Seq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}(\mathbf{F}))$ *is a closure system on* $\mathrm{Seq}(\mathbf{F})$*, satisfying the structural rules and including* R*.*

Proof: We show, first, that Ξ^R is a closure system on $\mathrm{Seq}(\mathbf{F})$.

- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in \mathbf{\Gamma}$. Then $\boldsymbol{\gamma} \in \Xi^{R,0}_\Sigma(\mathbf{\Gamma})$ and, hence, $\boldsymbol{\gamma} \in \Xi^R_\Sigma(\mathbf{\Gamma})$.
- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \mathbf{\Delta} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in \Xi^R_\Sigma(\mathbf{\Gamma})$ and $\mathbf{\Gamma} \subseteq \mathbf{\Delta}$. Then, for some $n < \omega$, $\boldsymbol{\gamma} \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})$ and $\mathbf{\Gamma} \subseteq \mathbf{\Delta}$. We show by induction on n, that then $\boldsymbol{\gamma} \in \Xi^{R,n}_\Sigma(\mathbf{\Delta})$.
  - If $n = 0$, then the conclusion follows directly from the inclusion $\mathbf{\Gamma} \subseteq \mathbf{\Delta}$.
  - Now suppose that $n > 0$ and that the conclusion holds for $n - 1$.
    * If $\boldsymbol{\gamma} = \Phi, \Psi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, then, by the induction hypothesis, $\Phi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Delta})$, whence, it follows that $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Delta})$.
    * If $\boldsymbol{\gamma} = \Phi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, we get, by the induction hypothesis, $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Delta})$, whence $\Phi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Delta})$.
    * If $\boldsymbol{\gamma} = \Phi \vdash_\Sigma \phi$, with $\langle \mathbf{\Upsilon}, \Phi \vdash_\Sigma \phi \rangle \in \mathrm{Ir}_\Sigma$ and $\mathbf{\Upsilon} \subseteq \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, then, by the induction hypothesis, $\mathbf{\Upsilon} \subseteq \Xi^{R,n-1}_\Sigma(\mathbf{\Delta})$, whence, again, $\Phi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Delta})$.
- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \{\boldsymbol{\gamma}\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in \Xi^R_\Sigma(\Xi^R_\Sigma(\mathbf{\Gamma}))$. Then, for some $n < \omega$, $\boldsymbol{\gamma} \in \Xi^{R,n}_\Sigma(\Xi^R_\Sigma(\mathbf{\Gamma}))$. We show by induction on n, that then $\boldsymbol{\gamma} \in \Xi^R_\Sigma(\mathbf{\Gamma})$.
  - If $n = 0$, then $\boldsymbol{\gamma}$ is of the form $\phi \vdash_\Sigma \phi$ or is in Ax_Σ or in $\Xi^R_\Sigma(\mathbf{\Gamma})$. In the first two cases, it is in $\Xi^{R,0}_\Sigma(\mathbf{\Gamma}) \subseteq \Xi^R_\Sigma(\mathbf{\Gamma})$ and in the last in $\Xi^R_\Sigma(\mathbf{\Gamma})$.
  - Suppose $n > 0$ and the conclusion holds for $n - 1$.
    * If $\boldsymbol{\gamma} = \Phi, \Psi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\Xi^R_\Sigma(\mathbf{\Gamma}))$, then, by the induction hypothesis, $\Phi \vdash_\Sigma \phi \in \Xi^R_\Sigma(\mathbf{\Gamma})$, i.e., $\Phi \vdash_\Sigma \phi \in \Xi^{R,m}_\Sigma(\mathbf{\Gamma})$, for some $m < \omega$. Thus $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,m+1}_\Sigma(\mathbf{\Gamma}) \subseteq \Xi^R_\Sigma(\mathbf{\Gamma})$.
    * If $\boldsymbol{\gamma} = \Phi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\Xi^R_\Sigma(\mathbf{\Gamma}))$, we get, by the induction hypothesis, $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^R_\Sigma(\mathbf{\Gamma})$. Since Ψ is finite, there exists $m > 0$, such that $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,m}_\Sigma(\mathbf{\Gamma})$. Thus, $\Phi \vdash_\Sigma \phi \in \Xi^{R,m+1}_\Sigma(\mathbf{\Gamma}) \subseteq \Xi^R_\Sigma(\mathbf{\Gamma})$.

- * If $\gamma = \Phi \vdash_\Sigma \phi$, with $\langle \mathbf{\Delta}, \Phi \vdash_\Sigma \phi \rangle \in \mathrm{Ir}_\Sigma$ and $\mathbf{\Delta} \subseteq \Xi_\Sigma^{R,n-1}(\Xi_\Sigma^R(\mathbf{\Gamma}))$, then, by the induction hypothesis, $\mathbf{\Delta} \subseteq \Xi_\Sigma^R(\mathbf{\Gamma})$, whence, again, since $\mathbf{\Delta}$ is finite, there exists $m > 0$, such that $\mathbf{\Delta} \subseteq \Xi_\Sigma^{R,m}(\mathbf{\Gamma})$. Therefore, $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,m+1}(\mathbf{\Gamma}) \subseteq \Xi_\Sigma^R(\mathbf{\Gamma})$.

- Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Gamma} \cup \{\gamma\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\gamma \in \Xi_\Sigma^R(\mathbf{\Gamma})$, and let $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then, for some $n < \omega$, $\gamma \in \Xi_\Sigma^{R,n}(\mathbf{\Gamma})$. We show by induction on n, that then $\mathrm{SEN}^\flat(f)(\gamma) \in \Xi_{\Sigma'}^{R,n}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$.

  - If $n = 0$, then γ is of the form $\phi \vdash_\Sigma \phi$ or in Ax_Σ or in $\mathbf{\Gamma}$. In the first case, $\mathrm{SEN}^\flat(f)(\gamma) = \mathrm{SEN}^\flat(f)(\phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,0}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$, by definition. In the second case, the conclusion holds by the postulated invariance of Ax under $\mathbf{Sign}^\flat$. In the last case, it holds because, by definition, $\mathrm{SEN}^\flat(f)(\gamma) \in \Xi_{\Sigma'}^{R,0}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$.
  - Suppose $n > 0$ and the conclusion holds for $n - 1$.
    * If $\gamma = \Phi, \Psi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n-1}(\mathbf{\Gamma})$, then, by the induction hypothesis,

      $$\mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,n-1}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma})),$$

      whence, by definition. $\mathrm{SEN}^\flat(f)(\Phi \cup \Psi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$.
    * If $\gamma = \Phi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n-1}(\mathbf{\Gamma})$, we get, by the induction hypothesis, $\mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\Psi)$, $\mathrm{SEN}^\flat(f)(\Phi \cup \Psi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,n-1}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$. So, again by definition,

      $$\mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma})).$$

    * If $\gamma = \Phi \vdash_\Sigma \phi$, with $\langle \mathbf{\Delta}, \Phi \vdash_\Sigma \phi \rangle \in \mathrm{Ir}_\Sigma$ and $\mathbf{\Delta} \subseteq \Xi_\Sigma^{R,n-1}(\mathbf{\Gamma})$, then, by the induction hypothesis,

      $$\mathrm{SEN}^\flat(f)(\mathbf{\Delta}) \subseteq \Xi_{\Sigma'}^{R,n}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma})),$$

      whence, since Ir is invariant under $\mathbf{Sign}^\flat$, we get, by definition, $\mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\mathrm{SEN}^\flat(f)(\mathbf{\Gamma}))$.

We have concluded the proof that Ξ^R is a closure system on $\mathrm{Seq}(\mathbf{F})$.

Next, we show that it satisfies the structural rules.

- For (Axiom), if $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, then, by definition, $\phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,0}(\varnothing) \subseteq \Xi_\Sigma^R(\varnothing)$.

- For (Weakening), if $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, such that $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^R(\mathbf{\Gamma})$, then, there exists $n < \omega$, such that $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n}(\mathbf{\Gamma})$. Therefore, by definition, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n+1}(\mathbf{\Gamma}) \subseteq \Xi_\Sigma^R(\mathbf{\Gamma})$.

- For (Cut), if $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, such that $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^R_\Sigma(\mathbf{\Gamma})$, then, since $\Psi \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, there exists $n < \omega$, such that $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})$. Thus, by definition, $\Phi \vdash_\Sigma \phi \in \Xi^{R,n+1}_\Sigma(\mathbf{\Gamma}) \subseteq \Xi^R_\Sigma(\mathbf{\Gamma})$.

So Ξ^R does satisfy all three structural rules.

Finally, it does include all rules in R:

- For $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\gamma} \in \mathrm{Ax}_\Sigma$, we have $\boldsymbol{\gamma} \in \mathrm{Ax}_\Sigma \subseteq \Xi^{R,0}_\Sigma(\varnothing) \subseteq \Xi^R_\Sigma(\varnothing)$.
- For $\Sigma \in |\mathbf{Sign}^\flat|$, $\langle \mathbf{\Gamma}, \boldsymbol{\gamma}\rangle \in \mathrm{Ir}_\Sigma$, such that $\mathbf{\Gamma} \subseteq \Xi^R_\Sigma(\mathbf{\Delta})$, since $\mathbf{\Gamma}$ is finite, there exists $n < \omega$, such that $\mathbf{\Gamma} \subseteq \Xi^{R,n}_\Sigma(\mathbf{\Delta})$. Thus, by definition, $\boldsymbol{\gamma} \in \Xi^{R,n+1}_\Sigma(\mathbf{\Delta}) \subseteq \Xi^R_\Sigma(\mathbf{\Delta})$.

This concludes the proof of the statement. ■

We show that, given a system R of finitary Gentzen axioms and rules of inference, the closure $G^R_\Sigma(\mathbf{\Gamma})$ of a set $\mathbf{\Gamma}$ of Σ-sequents in the least Gentzen π-institution generated by R is exactly $\Xi^R_\Sigma(\mathbf{\Gamma})$.

Proposition 1482 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $R = \mathrm{Ax} \cup \mathrm{Ir}$ *a set of finitary Gentzen axioms and rules of inference. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\mathbf{\Gamma} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$,

$$G^R_\Sigma(\mathbf{\Gamma}) = \Xi^R_\Sigma(\mathbf{\Gamma}).$$

Proof: Suppose, first, that $\boldsymbol{\gamma} \in \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\gamma} \in \Xi^R_\Sigma(\mathbf{\Gamma})$. Then, $\boldsymbol{\gamma} \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})$, for some $n < \omega$. We show by induction on $n < \omega$ that, if $\boldsymbol{\gamma} \in \Xi^{R,n}_\Sigma(\mathbf{\Gamma})$, then $\boldsymbol{\gamma} \in G^R_\Sigma(\mathbf{\Gamma})$.

- The conclusion is obvious for $n = 0$, since, by definition, $G^R_\Sigma(\mathbf{\Gamma})$ satisfies the structural rules, contains Ax_Σ and, clearly, includes $\mathbf{\Gamma}$;
- A similar clause applies for the induction step:
  - If $\boldsymbol{\gamma} = \Phi, \Psi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, then, by the induction hypothesis, $\Phi \vdash_\Sigma \phi \in G^R_\Sigma(\mathbf{\Gamma})$ and, since G^R satisfies the structural rules, $\Phi, \Psi \vdash_\Sigma \phi \in G^R_\Sigma(\mathbf{\Gamma})$ also.
  - If $\boldsymbol{\gamma} = \Phi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \Psi \subseteq \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$ and $\Psi \vdash_\Sigma \phi \in \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, then, again by the induction hypothesis, $\Phi \vdash_\Sigma \Psi \subseteq G^R_\Sigma(\mathbf{\Gamma})$ and $\Psi \vdash_\Sigma \phi \in G^R_\Sigma(\mathbf{\Gamma})$, whence, since G^R satisfies the structural rules, $\Phi \vdash_\Sigma \phi \in G^R_\Sigma(\mathbf{\Gamma})$.
  - If $\boldsymbol{\gamma} = \Phi \vdash_\Sigma \phi$, with $\langle \mathbf{\Delta}, \boldsymbol{\gamma}\rangle \in \mathrm{Ir}_\Sigma$ and $\mathbf{\Delta} \subseteq \Xi^{R,n-1}_\Sigma(\mathbf{\Gamma})$, then, by the induction hypothesis, $\mathbf{\Delta} \subseteq G^R_\Sigma(\mathbf{\Gamma})$ and, since G^R is closed under the rules of inference, we get that $\Phi \vdash_\Sigma \phi \in G^R_\Sigma(\mathbf{\Gamma})$.

We conclude that $\Xi^{R,n}_\Sigma(\mathbf{\Gamma}) \subseteq G^R_\Sigma(\mathbf{\Gamma})$, for all $n < \omega$, and, therefore, $\Xi^R_\Sigma(\mathbf{\Gamma}) \subseteq G^R_\Sigma(\mathbf{\Gamma})$.

Conversely, since, by Lemma 1481, $\Xi^R : \mathcal{P}(\mathrm{Seq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Seq}(\mathbf{F}))$ is a closure system on $\mathrm{Seq}(\mathbf{F})$, which satisfies the structural rules, contains Ax and is closed under Ir, we conclude by the minimality of G^R, that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\mathbf{\Gamma} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, $G^R_\Sigma(\mathbf{\Gamma}) \subseteq \Xi^R_\Sigma(\mathbf{\Gamma})$. From this, the conclusion follows. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Define a Gentzen π-institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$, as follows:

1. If $\mathcal{I}$ has theorems, $\mathfrak{G}^{\mathcal{I}}$ is of type 1 and if $\mathcal{I}$ does not have theorems, then $\mathfrak{G}^{\mathcal{I}}$ is of type 0;
2. Set $\mathrm{Ax}^{\mathcal{I}} = \{\mathrm{Ax}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Ax}^{\mathcal{I}}_\Sigma = \{\Phi \vdash_\Sigma \phi : \phi \in C_\Sigma(\Phi)\}.$$
Let $R^{\mathcal{I}} := \mathrm{Ax}^{\mathcal{I}}$. Then set $\mathfrak{G}^{\mathcal{I}} := \mathfrak{G}^{R^{\mathcal{I}}}$.

Of course, $\mathfrak{G}^{\mathcal{I}}$ is a Gentzen π-institution. Moreover, it turns out that, if $\mathcal{I}$ is finitary, then $\mathfrak{G}^{\mathcal{I}}$ is adequate for the π-institution $\mathcal{I}$.

Lemma 1483 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. Then $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$ is a Gentzen π-institution adequate for $\mathcal{I}$.*

Proof: Note that, by hypothesis and Proposition 1482, $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, \Xi^{R^{\mathcal{I}}} \rangle$.

Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$. We must show that
$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \Phi \vdash_\Sigma \phi \in \Xi^{R^{\mathcal{I}}}_\Sigma(\varnothing).$$

First, if $\phi \in C_\Sigma(\Phi)$, then, by definition $\Phi \vdash_\Sigma \phi \in \mathrm{Ax}^{\mathcal{I}}_\Sigma$. Therefore, since $\mathrm{Ax}^{\mathcal{I}}_\Sigma \subseteq \Xi^{R^{\mathcal{I}}}_\Sigma(\varnothing)$, we get $\Phi \vdash_\Sigma \phi \in \Xi^{R^{\mathcal{I}}}_\Sigma(\varnothing)$.

Conversely, we must show that, if $\Phi \vdash_\Sigma \phi \in \Xi^{R^{\mathcal{I}}}_\Sigma(\varnothing)$, then $\phi \in C_\Sigma(\Phi)$. We do this by showing, using induction on $n < \omega$, that
$$\Phi \vdash_\Sigma \phi \in \Xi^{R^{\mathcal{I}},n}_\Sigma(\varnothing) \quad \text{implies} \quad \phi \in C_\Sigma(\Phi).$$

- If $\Phi \vdash_\Sigma \phi \in \Xi^{R^{\mathcal{I}},0}_\Sigma(\varnothing)$, then it is either of the form $\phi \vdash_\Sigma \phi$ or in $\mathrm{Ax}^{\mathcal{I}}_\Sigma$. In the first case, the conclusion follows by the inflationarity of C and, in the second, by the definition of $\mathrm{Ax}^{\mathcal{I}}$.
- Suppose $n > 0$ and that the conclusion holds for $n - 1$. Then, since $\mathrm{Ir}^{\mathcal{I}} = \varnothing$, there are only two cases to consider.

- If $\Phi \vdash_\Sigma \phi$ is of the form $\Phi_1, \Phi_2 \vdash_\Sigma \phi \in \Xi_\Sigma^{R^{\mathcal{I}},n}(\varnothing)$, with $\Phi_1 \vdash_\Sigma \phi \in \Xi_\Sigma^{R^{\mathcal{I}},n-1}(\varnothing)$, then, by the induction hypothesis, $\phi \in C_\Sigma(\Phi_1)$ and, hence, by the monotonicity of C, $\phi \in C_\Sigma(\Phi_1, \Phi_2)$.
- If $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R^{\mathcal{I}},n}(\varnothing)$, with $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R^{\mathcal{I}},n-1}(\varnothing)$, then, by the induction hypothesis, $\Psi \subseteq C_\Sigma(\Phi)$ and $\phi \in C_\Sigma(\Phi, \Psi)$, whence

$$\begin{array}{rcll} \phi & \in & C_\Sigma(\Phi, \Psi) & \text{(hypothesis)} \\ & \subseteq & C_\Sigma(\Phi, C_\Sigma(\Phi)) & \text{(monotonicity)} \\ & \subseteq & C_\Sigma(C_\Sigma(\Phi)) & \text{(monotonicity)} \\ & = & C_\Sigma(\Phi). & \text{(idempotency)} \end{array}$$

This finishes the induction and concludes the proof. ■

End of the Finitary Parenthesis

20.2 $\mathfrak{G}$-Structures and $\mathfrak{G}$-Algebraic Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$-structure. $\mathbb{L}$ is a **$\mathfrak{G}$-structure** or a **model of $\mathfrak{G}$** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$,

$$\begin{array}{c} \Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\}) \text{ and } \alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \\ \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi)). \end{array}$$

In relation to $\mathfrak{G}$-structures, we use the following notation:

- $D \in \mathrm{ClFam}^{\mathfrak{G}}(\mathcal{A})$ if $\langle \mathcal{A}, D \rangle$ is a $\mathfrak{G}$-structure;
- $\mathrm{Str}(\mathfrak{G})$ is the collection of all $\mathfrak{G}$-structures;
- $\mathrm{Str}^{\mathfrak{G}}(\mathcal{A})$ is the collection of all $\mathfrak{G}$-structures on the $\mathbf{F}$-algebraic system $\mathcal{A}$.

Let, again, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$ and $\mathbf{\Gamma} = \{\mathbf{\Gamma}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|} \in \mathrm{ThFam}(\mathfrak{G})$. Define $D^{\mathbf{\Gamma}} : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$D_\Sigma^{\mathbf{\Gamma}}(\Phi) = \{\phi \in \mathrm{SEN}^\flat(\Sigma) : \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma\}.$$

We show that $D^{\mathbf{\Gamma}}$, thus defined, is a closure family on $\mathrm{SEN}^\flat$ and, therefore, $\langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is an $\mathbf{F}$-structure. In fact, $\langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is a $\mathfrak{G}$-structure.

Lemma 1484 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution based on* $\mathbf{F}$ *and* $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$*. Then* $\mathbb{L}^{\mathbf{\Gamma}} = \langle \mathcal{F}, C^{\mathbf{\Gamma}} \rangle$ *is a $\mathfrak{G}$-structure.*

Proof: We show, first, that $D^{\mathbf{\Gamma}}$ is a closure family on $\mathcal{F}$.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \Phi$. Then, by (Axiom) $\phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. By (Weakening), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\phi \vdash_\Sigma \phi)$. Therefore, by (Cut), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Therefore, $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma$ and, hence, $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi)$.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi)$ and $\Phi \subseteq \Psi$. By definition, $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma$. Hence, by (Weakening) $\Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi) \subseteq G_\Sigma(\mathbf{\Gamma}_\Sigma) = \mathbf{\Gamma}_\Sigma$. We conclude that $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Psi)$.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi))$. Then, by definition, $D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi)) \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma$ and $D^{\mathbf{\Gamma}}_\Sigma(\Phi) \vdash_\Sigma D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi)) \subseteq \mathbf{\Gamma}_\Sigma$. Now we get

$$\begin{array}{rcl} D^{\mathbf{\Gamma}}_\Sigma(\Phi) \vdash_\Sigma \phi & \in & G_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi), D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi)) \vdash_\Sigma \phi, \\ & & \qquad D^{\mathbf{\Gamma}}_\Sigma(\Phi) \vdash_\Sigma D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi))) \\ & \subseteq & G_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi)) \vdash_\Sigma \phi, \\ & & \qquad D^{\mathbf{\Gamma}}_\Sigma(\Phi) \vdash_\Sigma D^{\mathbf{\Gamma}}_\Sigma(D^{\mathbf{\Gamma}}_\Sigma(\Phi))) \\ & \subseteq & G_\Sigma(\mathbf{\Gamma}_\Sigma) \\ & = & \mathbf{\Gamma}_\Sigma. \end{array}$$

  Therefore, by definition, $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi)$.

We conclude that $\mathbb{L}^{\mathbf{\Gamma}} = \langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is an $\mathbf{F}$-structure. We show, next, that $\mathbb{L}^{\mathbf{\Gamma}}$ is a $\mathfrak{G}$-structure. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that

- $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ and
- $\phi_i \in D^{\mathbf{\Gamma}}_\Sigma(\Phi_i)$, for all $i \in I$.

Then, by definition, $\Phi_i \vdash_\Sigma \phi_i \in \mathbf{\Gamma}_\Sigma$, for all $i \in I$. Since $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$, we get $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma$. Thus, by definition, $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi)$. So $\mathbb{L}^{\mathbf{\Gamma}} = \langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is a $\mathfrak{G}$-structure. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$, and $\mathbb{L} = \langle \mathcal{F}, D \rangle$ a $\mathfrak{G}$-structure. We define $\mathbf{\Gamma}^{\mathbb{L}} = \{\mathbf{\Gamma}^{\mathbb{L}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathbf{\Gamma}^{\mathbb{L}}_\Sigma = \{\Phi \vdash_\Sigma \phi \in \mathrm{Seq}_\Sigma(\mathbf{F}) : \phi \in D_\Sigma(\Phi)\}.$$

We show that $\mathbf{\Gamma}^{\mathbb{L}}$, thus defined, is a theory family of the Gentzen π-institution $\mathfrak{G}$.

Lemma 1485 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution based on* $\mathbf{F}$*, and* $\mathbb{L} = \langle \mathcal{F}, D \rangle$ *a $\mathfrak{G}$-structure. Then* $\mathbf{\Gamma}^{\mathbb{L}} \in \mathrm{ThFam}(\mathfrak{G})$.

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that

- $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ and
- $\Phi_i \vdash_\Sigma \phi_i \in \mathbf{\Gamma}^{\mathbb{L}}_\Sigma$, for all $i \in I$.

Then, by definition, $\phi_i \in D_\Sigma(\Phi_i)$, for all $i \in I$. Thus, since $\mathbb{L}$ is a $\mathfrak{G}$-structure, $\phi \in D_\Sigma(\Phi)$. Therefore, $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}^{\mathbb{L}}_\Sigma$. We conclude $\mathbf{\Gamma}^{\mathbb{L}} \in \mathrm{ThFam}(\mathfrak{G})$. ■

We show next that the two preceding constructions, of a $\mathfrak{G}$-structure $\mathbb{L}^{\mathbf{\Gamma}}$ out of a given theory family $\mathbf{\Gamma}$ of $\mathfrak{G}$ and of a theory family $\mathbf{\Gamma}^{\mathbb{L}}$ out of a given $\mathfrak{G}$-structure $\mathbb{L} = \langle \mathcal{F}, D\rangle$ are inverses of one another.

Proposition 1486 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution based on $\mathbf{F}$ and $\mathbb{L} = \langle \mathcal{F}, D\rangle$ an $\mathbf{F}$-structure.*

(a) $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$ if and only if $\mathbf{\Gamma}^{\mathbb{L}} \in \mathrm{ThFam}(\mathfrak{G})$ and $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}}$;

(b) $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$ if and only if $\mathbb{L}^{\mathbf{\Gamma}} \in \mathrm{Str}(\mathfrak{G})$ and $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^{\mathbf{\Gamma}}}$;

(c) $\mathcal{I}^{\mathfrak{G}} = \langle \mathbf{F}, C^{\mathfrak{G}}\rangle$ is the smallest $\mathfrak{G}$-structure on $\mathcal{F}$ and $C^{\mathfrak{G}} = D^{\mathrm{Thm}(\mathfrak{G})}$.

Proof:

(a) Suppose, first, that $\mathbb{L} = \langle \mathcal{F}, D\rangle \in \mathrm{Str}(\mathfrak{G})$. Then, by Lemma 1485, $\mathbf{\Gamma}^{\mathbb{L}} \in \mathrm{ThFam}(\mathfrak{G})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{rll} \phi \in D^{\mathbf{\Gamma}^{\mathbb{L}}}_\Sigma(\Phi) & \text{iff} & \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}^{\mathbb{L}}_\Sigma \\ & \text{iff} & \phi \in D_\Sigma(\Phi). \end{array}$$

So $D = D^{\mathbf{\Gamma}^{\mathbb{L}}}$.

Assume, conversely, that $\mathbf{\Gamma}^{\mathbb{L}} \in \mathrm{ThFam}(\mathfrak{G})$ and $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}}$. By Lemma 1484, $\mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}} \in \mathrm{Str}(\mathfrak{G})$. Thus, $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}} \in \mathrm{Str}(\mathfrak{G})$.

(b) Suppose, first, that $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$. Then, by Lemma 1484, $\mathbb{L}^{\mathbf{\Gamma}} \in \mathrm{Str}(\mathfrak{G})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rll} \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}^{\mathbb{L}^{\mathbf{\Gamma}}}_\Sigma & \text{iff} & \phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi) \\ & \text{iff} & \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma. \end{array}$$

So $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^{\mathbf{\Gamma}}}$.

Suppose, conversely, that $\mathbb{L}^{\mathbf{\Gamma}} \in \mathrm{Str}(\mathfrak{G})$ and $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^{\mathbf{\Gamma}}}$. Then, by Lemma 1485, $\mathbf{\Gamma}^{\mathbb{L}^{\mathbf{\Gamma}}} \in \mathrm{ThFam}(\mathfrak{G})$ and, hence, $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$.

(c) By Parts (a) and (b),

$$\mathbb{L} \longmapsto \mathbf{\Gamma}^{\mathbb{L}}$$
$$\mathbb{L}^{\mathbf{\Gamma}} \longleftarrow\!\!\dashv \mathbf{\Gamma}$$

are mutually inverse mappings between $\mathrm{ThFam}(\mathfrak{G})$ and $\mathrm{Str}^{\mathfrak{G}}(\mathcal{F})$ and both are clearly order-preserving. Thus $\mathbb{L}^{\mathrm{Thm}(\mathfrak{G})} = \mathcal{I}^{\mathfrak{G}}$ is the least $\mathfrak{G}$-structure on $\mathcal{F}$.

■

The next result shows that a Gentzen π-institution is complete with respect to class of all $\mathfrak{G}$-structures.

Proposition 1487 (Completeness Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$*,* $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ *if and only if, for every* $\mathfrak{G}$*-structure* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*, with* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \textit{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$.

Suppose, first, that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G})$, such that $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, for all $i \in I$. Then, by the definition of a $\mathfrak{G}$-structure, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$.

Assume, conversely, that the displayed condition in the statement holds. Let $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$, such that $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \subseteq \mathbf{\Gamma}_\Sigma$. Then, by definition, $\phi_i \in D^{\mathbf{\Gamma}}_\Sigma(\Phi_i)$, for all $\in I$. Since, by Lemma 1484, $\mathbb{L}^{\mathbf{\Gamma}}$ is a $\mathfrak{G}$-structure, we get, by hypothesis, $\phi \in D^{\mathbf{\Gamma}}_\Sigma(\Phi)$. Therefore, $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma$. We conclude that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$. ■

Next, we show that the property of being a model of a Gentzen π-institution is preserved under bilogical morphisms.

Proposition 1488 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems,* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *two* $\mathbf{F}$*-structures and* $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism.* $\mathbb{L}$ *is a* $\mathfrak{G}$*-structure if and only if* $\mathbb{L}'$ *is a* $\mathfrak{G}$*-structure.*

Proof: For the proof, it suffices to notice that, since $\langle H, \gamma \rangle$ is a bilogical morphism, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rl} \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi)) & \text{iff} \quad \gamma_{F(\Sigma)}(\alpha_\Sigma(\phi)) \in D'_{H(F(\Sigma))}(\gamma_{F(\Sigma)}(\alpha_\Sigma(\Phi))) \\ & \text{iff} \quad \alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi)). \end{array}$$

The rest of the argument is straightforward: If $\mathbb{L}$ is a $\mathfrak{G}$-structure, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash \phi_i : i \in I\})$ and $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, for all $i \in I$, we get $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, for all $i \in I$, whence, by hypothesis, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$, which gives $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi))$. We conclude that $\mathbb{L}'$ is also a $\mathfrak{G}$-structure. If, conversely, $\mathbb{L}'$ is a $\mathfrak{G}$-structure, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$, such that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash \phi_i : i \in I\})$ and $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, for all $i \in I$, we get $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, for all $i \in I$, whence, by hypothesis, $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi))$, which gives $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. We conclude that $\mathbb{L}$ is also a $\mathfrak{G}$-structure. ■

In particular, we obtain

Corollary 1489 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. An $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a $\mathfrak{G}$-structure if and only if its reduction $\mathbb{L}^*$ is a $\mathfrak{G}$-structure.*

Proof: This follows directly from Proposition 1488, since the quotient morphism $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a bilogical morphism. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. $\mathcal{A}$ is a **$\mathfrak{G}$-algebraic system** if it is the underlying algebraic system of a reduced $\mathfrak{G}$-structure. We denote the class of all $\mathfrak{G}$-algebraic systems by $\mathrm{AlgSys}(\mathfrak{G})$, i.e., we have

$$\mathrm{AlgSys}(\mathfrak{G}) = \{\mathcal{A} : (\exists D \in \mathrm{ClFam}^{\mathfrak{G}}(\mathcal{A}))(\widetilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}})\}.$$

We show that, if a Gentzen π-institution $\mathfrak{G}$ happens to be adequate for a π-institution $\mathcal{I}$, then every $\mathfrak{G}$-algebraic system is also an $\mathcal{I}$-algebraic system.

Lemma 1490 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$ that is adequate for $\mathcal{I}$. Then:*

(a) Every $\mathfrak{G}$-structure is an $\mathcal{I}$-structure;

(b) $\mathrm{AlgSys}(\mathfrak{G}) \subseteq \mathrm{AlgSys}(\mathcal{I})$.

Proof:

(a) Let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G})$. Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. By the adequacy of $\mathfrak{G}$ for $\mathcal{I}$, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Since $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Thus, by Lemma 50, $\mathbb{L}$ is an $\mathcal{I}$-structure.

(b) Assume that $\mathfrak{G}$ is adequate for $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathrm{AlgSys}(\mathfrak{G})$. Then, there exists a $\mathfrak{G}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, such that $\widetilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$. To conclude that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, it suffices, by Proposition 1399, to show that $\mathbb{L} \in \mathrm{Str}^{\mathcal{I}}(\mathcal{A})$. But this was done in Part (a).

■

20.3 Fully Adequate Gentzen π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$, such that $\mathfrak{G}$ is adequate for $\mathcal{I}$. Then, with $\mathcal{I}$ may be associated two classes of $\mathbf{F}$-algebraic systems and two classes of $\mathcal{I}$-structures:

- $\mathcal{I}$-algebraic systems and full $\mathcal{I}$-structures;
- $\mathfrak{G}$-algebraic systems and $\mathfrak{G}$-structures.

We devise certain conditions that, when possible to enforce, would guarantee that a Gentzen π-institution $\mathfrak{G}$ adequate for $\mathcal{I}$ can be picked in such a way as to have $\mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathcal{I})$ and $\mathrm{Str}(\mathfrak{G}) = \mathrm{FStr}(\mathcal{I})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. $\mathfrak{G}$ is said to be **fully adequate for** $\mathcal{I}$ if one of the following two conditions holds:

- $\mathcal{I}$ has theorems, $\mathfrak{G}$ is of type 1 and, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$;
- $\mathcal{I}$ does not have theorems, $\mathfrak{G}$ is of type 0 and, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$ and $\mathbb{L}$ does not have theorems.

We show that, if $\mathfrak{G}$ is fully adequate for $\mathcal{I}$, then it is also adequate for $\mathcal{I}$.

Proposition 1491 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. If $\mathfrak{G}$ is fully adequate for $\mathcal{I}$, then $\mathfrak{G}$ is adequate for $\mathcal{I}$.*

Proof: Assume that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$.

If $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$, then, by definition, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing)$. Since, by Corollary 1391, $\langle \mathcal{F}, C \rangle \in \mathrm{FStr}(\mathcal{I})$, we get, by hypothesis, $\langle \mathcal{F}, C \rangle \in \mathrm{Str}(\mathfrak{G})$. Therefore, $\phi \in C_\Sigma(\Phi)$.

Assume, conversely, that $\phi \in C_\Sigma(\Phi)$. Since, by Proposition 1486, $\langle \mathcal{F}, C^{\mathfrak{G}} \rangle \in \mathrm{Str}(\mathfrak{G})$, which, additionally, does not have theorems, if $\mathcal{I}$ has no theorems, we get, by hypothesis, $\langle \mathcal{F}, C^{\mathfrak{G}} \rangle \in \mathrm{FStr}(\mathcal{I})$. But, by Corollary 1391, $\langle \mathcal{F}, C \rangle$ is the weakest full $\mathcal{I}$-structure on $\mathcal{F}$. Therefore, since $\phi \in C_\Sigma(\Phi)$, we get that $\phi \in C^{\mathfrak{G}}_\Sigma(\Phi)$. ■

We provide next a characterization of full adequacy, which also showcases its features and hints at why it is a useful notion in trying to connect π-institutions with Gentzen π-institutions.

Proposition 1492 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is fully adequate for* $\mathcal{I}$ *if and only if*

1. $\mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathcal{I})$;
2. *For all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ *is the only reduced* $\mathfrak{G}$*-structure on* $\mathcal{A}$ *(without theorems if* $\mathcal{I}$ *does not have any);*
3. $\mathcal{I}$ *has theorems and* $\mathfrak{G}$ *is of type 1 or* $\mathcal{I}$ *does not have theorems and* $\mathfrak{G}$ *is of type 0.*

Proof: Assume $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. Note that Condition 3 holds by definition. By Proposition 1491, $\mathcal{I}$ is adequate for $\mathcal{I}$. By Lemma 1490, $\mathrm{AlgSys}(\mathfrak{G}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. If, on the other hand, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, then $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced full $\mathcal{I}$-structure. Thus, by hypothesis, it is a reduced $\mathfrak{G}$-structure. It follows that $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$. This shows that Condition 1 also holds. It remains now to prove Condition 2. To this end, suppose $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Then $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced full $\mathcal{I}$-structure. By hypothesis, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced $\mathfrak{G}$-structure. By the Isomorphism Theorem 1408, it is the only full $\mathcal{I}$-structure on $\mathcal{A}$ that is reduced. Hence, by hypothesis, it is the only reduced $\mathfrak{G}$-structure on $\mathcal{A}$. This proves Condition 2 and concludes the "only if".

Assume, conversely, that Conditions 1-3 hold. Then, for all $\mathbf{F}$-structures $\mathbb{L} = \langle \mathcal{A}, D\rangle$,

$$\begin{array}{lll} \mathbb{L} \in \mathrm{FStr}(\mathcal{I}) & \text{iff} & \mathcal{A}^* \in \mathrm{AlgSys}(\mathcal{I}) \text{ and } \mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \\ & \text{iff} & \mathcal{A}^* \in \mathrm{AlgSys}(\mathfrak{G}) \text{ and } \langle \mathcal{A}^*, \mathcal{D}^*\rangle \in \mathrm{Str}(\mathfrak{G}) \\ & & \text{(w/o theorems if } \mathcal{I} \text{ does not have any)} \\ & \text{iff} & \langle \mathcal{A}, \mathcal{D}\rangle \in \mathrm{Str}(\mathfrak{G}) \\ & & \text{(w/o theorems if } \mathcal{I} \text{ does not have any).} \end{array}$$

This, combined with Condition 3, gives that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. ■

If a π-institution $\mathcal{I}$ has a fully adequate Gentzen π-institution, then that Gentzen π-institution is unique.

Proposition 1493 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *two Gentzen* π*-institutions based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are fully adequate for* $\mathcal{I}$*, then* $\mathfrak{G} = \mathfrak{G}'$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \mathrm{Seq}_\Sigma(\mathbf{F})$. Then, we get $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ if and only if, by Proposition 1487, for every $\langle \mathcal{A}, D\rangle \in \mathrm{Str}(\mathfrak{G})$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by full adequacy, for all $\langle \mathcal{A}, D\rangle \in \mathrm{FStr}(\mathcal{I})$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by full adequacy, for every $\langle \mathcal{A}, D\rangle \in \mathrm{Str}(\mathfrak{G}')$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by Proposition 1487, $\Phi \vdash_\Sigma \phi \in G'_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$. Therefore, $G = G'$ and, hence, $\mathfrak{G} = \mathfrak{G}'$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system. Recall the notation for the family of $\mathbf{F}$-equations $\mathrm{Eq}(\mathbf{F}) = \{\mathrm{Eq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where $\mathrm{Eq}_\Sigma(\mathbf{F}) = \mathrm{SEN}^\flat(\Sigma)^2$. Let K be a class of $\mathbf{F}$-algebraic systems and recall the relative equational consequence of K

$$C^{\mathsf{K}} = \{C^{\mathsf{K}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|} : \mathcal{P}(\mathrm{Eq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Eq}(\mathbf{F}))$$

given, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, by

$$\phi \approx \psi \in C^{\mathsf{K}}_\Sigma(E) \quad \text{iff} \quad \begin{array}{l}\text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathsf{K},\\ E \subseteq \mathrm{Ker}_\Sigma(\mathcal{A}) \text{ implies } \langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\mathcal{A}).\end{array}$$

We show that the structure $\mathcal{Q}^{\mathsf{K}} = \langle \mathbf{F}^2, C^{\mathsf{K}}\rangle$ is a π-structure.

Lemma 1494 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and let K be a class of $\mathbf{F}$-algebraic systems. Then $\mathcal{Q}^{\mathsf{K}} = \langle \mathbf{F}^2, C^{\mathsf{K}}\rangle$ is a π-structure.*

Proof: By Lemma **??**. ■

Recall from Proposition 115, that $\mathcal{Q}^{\mathsf{K}}$ satisfies the properties of reflexivity, symmetry, transitivity, congruence and invariance. So we have

Corollary 1495 *et $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and let K be a class of $\mathbf{F}$-algebraic systems. Then $\mathcal{Q}^{\mathsf{K}} = \langle \mathbf{F}^2, C^{\mathsf{K}}\rangle$ is an equational π-structure.*

Proof: By Lemma 1494 and Proposition 115. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution based on $\mathbf{F}$ and K a class of $\mathbf{F}$-algebraic systems. According to the framework developed in Chapter 12, we say that $\mathfrak{G}$ is **equivalent to** $\mathcal{Q}^{\mathsf{K}}$ if there exists a conjugate pair of translations $(t,s):\mathfrak{G}\rightleftarrows\mathcal{Q}^{\mathsf{K}}$, where

$$t:\quad \mathfrak{G}\longrightarrow\mathcal{Q}^{\mathsf{K}}$$
$$\mathfrak{G}\longleftarrow\mathcal{Q}^{\mathsf{K}}\quad :s$$

We will focus specifically on the case in which the translation $sq:\mathrm{Eq}(\mathbf{F})\to\mathrm{SenFam}(\mathfrak{G})$ is natural and given by the natural transformation $\kappa:\mathrm{Eq}(\mathbf{F})\to\mathcal{P}(\mathrm{Seq}(\mathbf{F}))$, determined, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi,\psi\in\mathrm{SEN}^\flat(\Sigma)$, by

$$\kappa_\Sigma(\phi,\psi)=\{\phi\vdash_\Sigma\psi,\psi\vdash_\Sigma\phi\}.$$

Recall that, in this case, since κ does not have any parameters, we have that, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi,\psi\in\mathrm{SEN}^\flat(\Sigma)$,

$$sq_\Sigma[\phi\approx\psi]=\{sq_{\Sigma,\Sigma'}[\phi\approx\psi]\}_{\Sigma'\in|\mathbf{Sign}^\flat|},$$

where

$$sq_{\Sigma,\Sigma'}[\phi\approx\psi]=\{\mathrm{SEN}^\flat(f)(\phi\vdash_\Sigma\psi),\mathrm{SEN}^\flat(\psi\vdash_\Sigma\phi):f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')\}.$$

Finally, we say that the Gentzen π-institution $\mathfrak{G}$ **has** or **satisfies Congruence** if, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi_i,\psi_i\in\mathrm{SEN}^\flat(\Sigma)$, $i<k$,

$$\sigma^\flat_\Sigma(\vec{\phi})\vdash_\Sigma\sigma^\flat_\Sigma(\vec{\psi})\in G_\Sigma(\bigcup_{i<k}sq_\Sigma[\phi_i\approx\psi_i]).$$

We show that the equivalence of a Gentzen π-institution $\mathfrak{G}$ with an equational π-institution $\mathcal{Q}^{\mathsf{K}}$ implies that $\mathfrak{G}$ satisfies Congruence and, moreover, that it has interesting consequences for any π-institution for which $\mathfrak{G}$ happens to be adequate. More precisely, such a π-institution must be self extensional and the variety generated by its Lindenbaum-Tarski $\mathbf{F}$-algebraic system must coincide with the variety generated by the class K.

Proposition 1496 *Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathfrak{G}=\langle\mathbf{F},G\rangle$ a Gentzen π-institution based on $\mathbf{F}$ and K a class of $\mathbf{F}$-algebraic systems. If $\mathfrak{G}$ is equivalent to $\mathcal{Q}^{\mathsf{K}}$ via a conjugate pair $(t,sq):\mathfrak{G}\rightleftarrows\mathcal{Q}^{\mathsf{K}}$, then $\mathfrak{G}$ satisfies Congruence. If, in addition, $\mathfrak{G}$ is adequate for a π-institution $\mathcal{I}=\langle\mathbf{F},C\rangle$, then $\mathcal{I}$ is self extensional and $Q(\mathsf{K})=\mathsf{K}^{\mathcal{I}}$.*

Proof: Suppose $\mathfrak{G}$ is equivalent to $\mathcal{Q}^{\mathsf{K}}$ via a conjugate pair $(t,sq):\mathfrak{G}\rightleftarrows\mathcal{Q}^{\mathsf{K}}$ and let $\sigma^\flat:(\mathrm{SEN}^\flat)^k\to\mathrm{SEN}^\flat$ in $N^\flat$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\phi_i,\psi_i\in\mathrm{SEN}^\flat(\Sigma)$, $i<k$. By Proposition 115,

$$\sigma^\flat_\Sigma(\vec{\phi})\approx\sigma^\flat_\Sigma(\vec{\psi})\in C^{\mathsf{K}}_\Sigma(\{\phi_i\approx\psi_i:i<k\}).$$

Thus, by the hypothesis,

$$\sigma^\flat_\Sigma(\vec{\phi})\vdash_\Sigma\sigma^\flat_\Sigma(\vec{\psi})\in G_\Sigma(\bigcup_{i<k}sq_\Sigma[\phi_i\approx\psi_i]).$$

Thus, $\mathfrak{G}$ satisfies Congruence.

Suppose, next, that $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a π-institution, for which $\mathfrak{G}$ is adequate, and let $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$, such that $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$. By structurality, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) = C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))$. Then, by adequacy,

$$\mathrm{SEN}^\flat(f)(\phi_i \vdash_\Sigma \psi_i), \mathrm{SEN}^\flat(f)(\psi_i \vdash_\Sigma \phi_i) \in G_{\Sigma'}(\varnothing).$$

Since $\mathfrak{G}$ has Congruence, we get

$$\begin{array}{rcl}\sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}), \sigma^\flat_\Sigma(\vec{\psi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\phi}) & \in & G_\Sigma(\bigcup_{i<k} sq_\Sigma[\phi_i \approx \psi_i]) \\ & \subseteq & G_\Sigma(G_\Sigma(\varnothing)) \\ & = & G_\Sigma(\varnothing)\end{array}.$$

Again using adequacy, $C_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(\sigma^\flat_\Sigma(\vec{\psi}))$. Therefore, $\widetilde{\lambda}(\mathcal{I})$ is a congruence system on $\mathbf{F}$ and, by Proposition 1427, $\mathcal{I}$ is self extensional.

For the last claim, recall that

$$\begin{array}{rcl} Q(\mathsf{K}) & = & \{\mathcal{A} : \mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})\}; \\ \mathsf{K}^\mathcal{I} = Q(\mathcal{F}/\widetilde{\Omega}(\mathcal{I})) & = & \{\mathcal{A} : \widetilde{\Omega}(\mathcal{I}) \leq \mathrm{Ker}(\mathcal{A})\}. \end{array}$$

Moreover, note that $\mathrm{Ker}(\mathsf{K}) = \mathrm{Thm}(\mathcal{Q}^\mathsf{K})$. Therefore, to see that the claim holds, it suffices to show that $\mathrm{Thm}(\mathcal{Q}^\mathsf{K}) = \widetilde{\Omega}(\mathcal{I})$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll} \phi \approx \psi \in D^\mathsf{K}_\Sigma(\varnothing) & \text{iff} & sq_\Sigma[\phi \approx \psi] \leq G(\varnothing) \quad \text{(by hypothesis)} \\ & \text{iff} & C_\Sigma(\phi) = C_\Sigma(\psi) \quad \text{(by adequacy)} \\ & \text{iff} & \langle \phi, \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) \quad \text{(by definition)} \\ & \text{iff} & \langle \phi, \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}). \quad \text{(by self extensionality)} \end{array}$$

Thus, we have $Q(\mathsf{K}) = \mathsf{K}^\mathcal{I}$, as claimed. ■

In closing the section, we show that, given a π-institution $\mathcal{I}$ that has an adequate finitary Gentzen π-institution $\mathfrak{G}$, satisfying Congruence, the equational consequence based on the variety $\mathsf{K}^\mathcal{I}$ is translated into the consequence of the Gentzen π-institution via sq.

Proposition 1497 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a finitary Gentzen π-institution, having Congruence, that is adequate for $\mathcal{I}$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $E \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,*

$$\phi \approx \psi \in D^{\mathsf{K}^\mathcal{I}}_\Sigma(E) \quad \textit{implies} \quad sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E]).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi \in D^{\mathsf{K}^\mathcal{I}}_\Sigma(E)$. By Theorem 119, we have $D^{\mathsf{K}^\mathcal{I}} = \Xi^{\mathrm{Ker}(\mathsf{K}^\mathcal{I})} = \Xi^{\widetilde{\Omega}(\mathcal{I})}$. So, we get $\phi \approx \psi \in \Xi^{\widetilde{\Omega}(\mathcal{I})}_\Sigma(E)$. We show by induction on $n < \omega$, that, for all $n < \omega$,

$$\phi \approx \psi \in \Xi^{\widetilde{\Omega}(\mathcal{I}),n}_\Sigma(E) \quad \text{implies} \quad sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E]).$$

- For $n = 0$, we must have $\phi = \psi$ or $\langle\phi,\psi\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$ or $\phi \approx \psi \in E$.

  In the first case the conclusion follows by (Axiom).

  In the second case, we have that $C_\Sigma(\phi) = C_\Sigma(\psi)$, whence, by adequacy, $sq_\Sigma[\phi \approx \psi] \leq G(\varnothing) \leq G(sq_\Sigma[E])$.

  In the last case, the conclusion follows by the inflationarity of G.

- Suppose, now, that the implication holds for $n > 0$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi_\Sigma^{\widetilde{\Omega}(\mathcal{I}),n+1}(E)$.

  If $\psi \approx \phi \in \Xi_\Sigma^{\widetilde{\Omega}(\mathcal{I}),n}(E)$, then, by the induction hypothesis, $sq_\Sigma[\psi \approx \phi] \leq G(sq_\Sigma[E])$. Since $sq_\Sigma[\phi \approx \psi] = sq_\Sigma[\psi \approx \phi]$, we conclude that $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$.

  If $\phi \approx \chi, \chi \approx \psi \in \Xi_\Sigma^{\widetilde{\Omega}(\mathcal{I}),n}(E)$, then, by the induction hypothesis,

  $$sq_\Sigma[\phi \approx \chi], sq_\Sigma[\chi \approx \psi] \leq G(sq_\Sigma[E]).$$

  Using (Cut) and monotonicity, we get

  $$\begin{array}{rcl} sq_\Sigma[\phi \approx \psi] & \leq & G(sq_\Sigma[\phi \approx \chi], sq_\Sigma[\chi \approx \psi]) \\ & \leq & G(sq_\Sigma[E]). \end{array}$$

  If $\phi \approx \psi$ is of the form $\sigma_\Sigma^\flat(\vec{\phi}) \approx \sigma_\Sigma^\flat(\vec{\psi})$, with $\phi_i \approx \psi_i \in \Xi_\Sigma^{\widetilde{\Omega}(\mathcal{I}),n}(E)$, $i < k$, then, by the induction hypothesis, $sq_\Sigma[\phi_i \approx \psi_i] \leq G(sq_\Sigma[E])$ $i < k$. Then, since $\mathfrak{G}$ has Congruence, we conclude

  $$\begin{array}{rcl} sq_\Sigma[\sigma_\Sigma^\flat(\vec{\phi}) \approx \sigma_\Sigma^\flat(\vec{\psi})] & \leq & G(\bigcup_{i<k} sq_\Sigma[\phi_i \approx \psi_i]) \\ & \leq & G(sq_\Sigma[E]). \end{array}$$

  Last, assume that $\phi \approx \psi$ has the form $\mathrm{SEN}^\flat(f)(\phi' \approx \psi')$, for some $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma',\Sigma)$, such that $\phi' \approx \psi' \in \Xi_{\Sigma'}^{\widetilde{\Omega}(\mathcal{I}),n}(E)$. Then, by the induction hypothesis, $sq_{\Sigma'}[\phi' \approx \psi'] \leq G(sq_\Sigma[E])$. But, note that $sq_\Sigma[\phi \approx \psi] = sq_\Sigma[\mathrm{SEN}^\flat(f)(\phi' \approx \psi')] \leq sq_{\Sigma'}[\phi' \approx \psi']$. Thus, we get $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$.

We conclude that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, $\phi \approx \psi \in D_\Sigma^{\mathsf{K}^\mathcal{I}}(E)$ implies that $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$. ■

20.4 Smoothness and Finitary Adaptations

In this section we define smooth Gentzen π-institutions and we also adapt some of the preceding results to the case of finitary π-institutions. This work is meant to pave the way for upcoming results on self extensionality and conjunction, presented in the next section, and on self extensionality and the deduction detachment theorem, which follow in the section after that.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. We say that $\mathfrak{G}$ is **smooth** if G operates on finite sequents and it is systemic, i.e., by Proposition 149, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\mathrm{SEN}^\flat(f)(\Phi \vdash_\Sigma \phi) \in G_{\Sigma'}(\Phi \vdash_\Sigma \phi).$$

In the case of smooth Gentzen systems, the equivalence of the Gentzen system with an algebraic π-structure may be simplified as follows.

Proposition 1498 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a smooth Gentzen π-institution and K a class of $\mathbf{F}$-algebraic systems. Then $\mathfrak{G}$ is equivalent to $\mathcal{Q}^{\mathsf{K}}$ via the conjugate pair $(t, sq) : \mathfrak{G} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$ if and only if its is equivalent to $\mathcal{Q}^{\mathsf{K}}$ via the conjugate pair $(t, \kappa) : \mathfrak{G} \rightleftarrows \mathcal{Q}^{\mathsf{K}}$.*

Proof: By Lemma 889, it is enough to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$G(sq_\Sigma[\phi \approx \psi]) = G(\kappa_\Sigma(\phi \approx \psi)).$$

This is, however, a consequence of smoothness. ■

Moreover, for a smooth Gentzen π-institution $\mathfrak{G}$, satisfying Congruence is equivalent to an apparently simpler condition.

Proposition 1499 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a smooth Gentzen π-institution. $\mathfrak{G}$ satisfies Congruence if and only if, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$,*

$$\sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \in G_\Sigma(\{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i < k\}).$$

Proof: Assume, first, that $\mathfrak{G}$ satisfies Congruence. Then, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$,

$$\begin{array}{rcl}\sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) & \in & G_\Sigma(\bigcup_{i<k} sq_\Sigma[\phi_i \approx \psi_i]) \\ & & \text{(by Congruence)} \\ & \subseteq & G_\Sigma(\{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i < k\}). \\ & & \text{(by Smoothness)}\end{array}$$

Assume, conversely, that the given condition holds. Then, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$,

$$\begin{array}{rcl}\sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) & \in & G_\Sigma(\{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i < k\}) \\ & & \text{(Hypothesis)} \\ & \subseteq & G_\Sigma(\bigcup_{i<k} sq_\Sigma[\phi_i \approx \psi_i]). \\ & & \text{(by Monotonicity)}\end{array}$$

We conclude that $\mathfrak{G}$ has Congruence. ∎

If a π-institution $\mathcal{I}$ is finitary, any $\mathcal{I}$-structure must also be finitary. Therefore, for any Gentzen π-institution $\mathfrak{G}$, no infinitary $\mathfrak{G}$-structure can be a full $\mathcal{I}$-structure. It is this observation that leads to the following modification of the definition of full adequacy for finitary π-institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. $\mathfrak{G}$ is said to be **fully adequate for** $\mathcal{I}$ if one of the following two conditions holds:

- $\mathcal{I}$ has theorems, $\mathfrak{G}$ is of type 1 and, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$ if and only if $\mathbb{L}$ is finitary and $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$;
- $\mathcal{I}$ does not have theorems, $\mathfrak{G}$ is of type 0 and, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \mathrm{Str}(\mathfrak{G})$ and $\mathbb{L}$ is finitary without theorems.

For the sequel we need a finitary adaptation of Proposition 1492. This is a characterization of full adequacy of a Gentzen system for a finitary π-institution $\mathcal{I}$.

Proposition 1500 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary π-institution based on* $\mathbf{F}$ *and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is fully adequate for* $\mathcal{I}$ *if and only if*

1. $\mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathcal{I})$*;*
2. *For all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ *is the only finitary and reduced* $\mathfrak{G}$*-structure on* $\mathcal{A}$ *(without theorems if* $\mathcal{I}$ *does not have any);*
3. $\mathcal{I}$ *has theorems and* $\mathfrak{G}$ *is of type 1 or* $\mathcal{I}$ *does not have theorems and* $\mathfrak{G}$ *is of type 0.*

Proof: Assume $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. Then, by Proposition 1492, Conditions 1-3 hold, where in Condition 2 $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is finitary by Proposition 114. Thus, the "only if" holds.

Assume, conversely, that Conditions 1-3 hold. Then, for all $\mathbf{F}$-structures $\mathbb{L} = \langle \mathcal{A}, D \rangle$,

$$\begin{array}{lll} \mathbb{L} \in \mathrm{FStr}(\mathcal{I}) & \text{iff} & \mathcal{A}^* \in \mathrm{AlgSys}(\mathcal{I}), \mathcal{D}^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \\ & \text{iff} & \mathcal{A}^* \in \mathrm{AlgSys}(\mathfrak{G}) \text{ and } \langle \mathcal{A}^*, \mathcal{D}^* \rangle \in \mathrm{Str}(\mathfrak{G}) \\ & & \text{finitary (w/o theorems if } \mathcal{I} \text{ does not have any)} \\ & \text{iff} & \langle \mathcal{A}, \mathcal{D} \rangle \in \mathrm{Str}(\mathfrak{G}) \text{ finitary} \\ & & \text{(w/o theorems if } \mathcal{I} \text{ does not have any).} \end{array}$$

This, combined with Condition 3, gives that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. ∎

20.5 IsoFull Adequacy and the DD Theorem

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and, for all $n < \omega$, $\Delta^n : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a collection of natural transformations in $N^\flat$, with $n+1$ distinguished arguments. Set

$$\Delta = \{\Delta^n : n < \omega\}.$$

Given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on $\mathbf{F}$, and $T \in \mathrm{ThFam}(\mathcal{I})$, Δ is a **Parameterized Graded Deduction Detachment** (**PGDD**) **system for** $\mathcal{I}$ **over** T if, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_0, \dots, \phi_{n-1}, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1}) \quad \text{iff} \quad \Delta^n_\Sigma[\phi_0, \dots, \phi_{n-1}, \psi] \le T.$$

The left-to-right implication is the **Graded Deduction Property over** T and the right-to-left implication is the **Graded Detachment Property over** T.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\Delta = \{\Delta^n : n < \omega\}$ in $N^\flat$. Define a family $r^{\Delta^n} = \{r^{\Delta^n}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of Gentzen $\mathbf{F}$-rules by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$r^{\Delta^n}_\Sigma = \{\langle \{\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi\}, \vdash_\Sigma \Delta^n_\Sigma(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \rangle : \vec{\phi}, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)\}.$$

Existence of a PGDD system Δ over a theory family T guarantees that the $\mathcal{I}$-structure $\langle \mathcal{F}, C^T \rangle$ satisfies all Gentzen $\mathbf{F}$-rules in r^{Δ^n}, $n < \omega$.

Lemma 1501 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Delta = \{\Delta^n : n < \omega\}$ a PGDD system for $\mathcal{I}$ over T. Then, for all $n < \omega$,*

$$\langle \mathcal{F}, \mathrm{ThFam}(\mathcal{I})^T \rangle \vDash r^{\Delta^n}.$$

Proof: Suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi}, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\psi \in C^T_\Sigma(\phi_0, \dots, \phi_{n-1})$. Equivalently, we get $\psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1})$. By hypothesis, since Δ is a PGDD system for $\mathcal{I}$ over T, we get $\Delta^n_\Sigma[\phi_0, \dots, \phi_{n-1}, \psi] \le T$. In particular, we get, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\Delta^n_\Sigma(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \subseteq T_\Sigma$. Equivalently, $\vdash_\Sigma \Delta^n_\Sigma(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \in C^T_\Sigma(\varnothing)$. Thus, $\langle \mathcal{F}, \mathrm{ThFam}(\mathcal{I})^T \rangle \vDash r^{\Delta^n}$. ∎

We show, next, that all Gentzen $\mathbf{F}$-rules are preserved by bilogical morphisms between $\mathbf{F}$-structures.

Lemma 1502 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$-algebraic systems, $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ two $\mathbf{F}$-structures and $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, every $\mathbf{F}$-sequent $\Psi \vdash_\Sigma \psi$ and every Gentzen $\mathbf{F}$-rule $r := \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$,*

(a) $\mathbb{L} \vDash_\Sigma \Psi \vdash_\Sigma \psi$ *if and only if* $\mathbb{L}' \vDash_\Sigma \Psi \vdash_\Sigma \psi$;

(b) $\mathbb{L} \vDash_\Sigma r$ *if and only if* $\mathbb{L}' \vDash_\Sigma r$.

Proof:

(a) We have

$$\begin{array}{lll}\mathbb{L} \vDash_\Sigma \Psi \vdash_\Sigma \psi & \text{iff} & \alpha_\Sigma(\psi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Psi)) \\ & \text{iff} & \gamma_{F(\Sigma)}(\alpha_\Sigma(\psi)) \in D'_{H(F(\Sigma))}(\gamma_{H(F(\Sigma))}(\alpha_\Sigma(\Psi))) \\ & \text{iff} & \alpha'_\Sigma(\psi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Psi)) \\ & \text{iff} & \mathbb{L}' \vDash_\Sigma \Psi \vdash_\Sigma \psi.\end{array}$$

(b) This part follows easily from Part (a).

($\Rightarrow$) If $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, $i \in I$, then $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$, $i \in I$, whence $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. So $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi))$.

($\Leftarrow$) If $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, $i \in I$, then $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, $i \in I$, whence $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, $i \in I$, and, therefore, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$.

■

Some of the elements of the discussion that follows will be revisited in Chapter 21 on $\mathcal{I}$-operators in a more general context. We give a preview of a few results here, as needed, restricting the discussion mostly to protoalgebraic π-institutions. This restriction will be lifted in Chapter 21, where the concepts will be revisited in full generality.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and an $\mathcal{I}$-filter family $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we let

$$[T] = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)\},$$

the **equi-Leibniz class of** T. If $[T]$ has a smallest member, it is denoted by T^*. T is called a **Leibniz filter** if $T = T^*$, i.e., if it is the smallest filter in its equi-Leibniz class. We denote by $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ the collection of all Leibniz $\mathcal{I}$-filter families of $\mathcal{A}$.

We show that Leibniz filter families are preserved under inverse surjective morphisms with isomorphic functor components. For a more general result, see Corollary 1575 in Chapter 21.

Lemma 1503 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism. Then*

$$\gamma^{-1}(\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B})) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Let $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B})$ and $T = \gamma^{-1}(T')$. Then $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$. Consider $X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $X \in [T]$, i.e., such that $\Omega^{\mathcal{A}}(X) = \Omega^{\mathcal{A}}(T)$. Then, since $\Omega^{\mathcal{A}}(T) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$, $\mathrm{Ker}(\langle H, \gamma\rangle)$ is compatible with X. Hence $\gamma(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Furthermore,

$$\gamma^{-1}(\Omega^{\mathcal{B}}(\gamma(X))) = \Omega^{\mathcal{A}}(\gamma^{-1}(\gamma(X))) = \Omega^{\mathcal{A}}(X) = \Omega^{\mathcal{A}}(T) = \gamma^{-1}(\Omega^{\mathcal{B}}(T')).$$

So $\Omega^{\mathcal{B}}(\gamma(X)) = \Omega^{\mathcal{B}}(T')$. Thus, since $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B})$, $T' \le \gamma(X)$. Now we get, taking again into account the compatibility of $\mathrm{Ker}(\langle H, \gamma\rangle)$ with X, $T = \gamma^{-1}(T') \le \gamma^{-1}(\gamma(X)) = X$. This proves that $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

As a corollary, we obtain

Corollary 1504 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle$ $\mathbf{F}$-algebraic systems and $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism. Then, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that T'^* exists,*

$$\gamma^{-1}(T'^*) = \gamma^{-1}(T')^*.$$

Proof: Suppose $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that T'^* exists. Then $\gamma^{-1}(T'^*) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, by Lemma 1503. Hence, we have

$$\Omega^{\mathcal{A}}(\gamma^{-1}(T'^*)) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'^*)) = \gamma^{-1}(\Omega^{\mathcal{B}}(T')) = \Omega^{\mathcal{A}}(\gamma^{-1}(T')).$$

Thus, since $\gamma^{-1}(T'^*)$ is Leibniz, we get $\gamma^{-1}(T'^*) = \gamma^{-1}(T')^*$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. An $\mathcal{I}$-structure $\mathbb{L} = \langle \mathcal{A}, D\rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, is called **isofull** if it is full and F is an isomorphism.

We show, next, that, if $\Delta = \{\Delta^n : n < \omega\}$ is a PGDD system for $\mathcal{I}$ over every $\mathcal{I}$-theory family, then every isofull $\mathcal{I}$-structure satisfies the Gentzen $\mathbf{F}$-rules r^{Δ^n}.

Lemma 1505 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a protoalgebraic π-institution based on $\mathbf{F}$ and $\Delta = \{\Delta^n : n < \omega\}$ a PGDD system for $\mathcal{I}$ over every Leibniz $\mathcal{I}$-theory family. Then every isofull $\mathcal{I}$-structure satisfies r^{Δ^n}, for all $n < \omega$.*

Proof: By Lemma 1502, it suffices to show that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with F an isomorphism, and every $n < \omega$,

$$\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle \vDash r^{\Delta^n}.$$

Let $T = C^{\mathcal{I},\mathcal{A}}(\varnothing)$ be the smallest $\mathcal{I}$-filter family on $\mathcal{A}$. By the Correspondence Theorem for protoalgebraic π-institutions, we have $\alpha^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) =$

$\mathrm{ThFam}(\mathcal{I})^{\alpha^{-1}(T)}$. Since T is least among all $\mathcal{I}$-filter families of $\mathcal{A}$, we have $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Therefore, by Lemma 1503, $\alpha^{-1}(T) \in \mathrm{ThFam}^*(\mathcal{I})$. Thus, by the hypothesis and Lemma 1501, we get that $\langle\mathcal{F}, \mathrm{ThFam}(\mathcal{I})^{\alpha^{-1}(T)}\rangle \vDash r^{\Delta^n}$. However, $\langle F,\alpha\rangle : \langle\mathcal{F}, \mathrm{ThFam}(\mathcal{I})^{\alpha^{-1}(T)}\rangle \vdash \langle\mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a bilogical morphism, whence, by Lemma 1502, we get $\langle\mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle \vDash r^{\Delta^n}$. ∎

In the next lemma, it is shown that, in case the π-institution $\mathcal{I}$ is syntactically protoalgebraic, the witnessing transformations may be used to generate Leibniz filter families.

Lemma 1506 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a syntactically protoalgebraic* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then*

$$T^* = C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T)\}).$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We set

$$\widetilde{T} = C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T)\}).$$

Our goal is to show that $T^* = \widetilde{T}$. First, let $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T' \in [T]$, i.e., $\Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Then, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rll}\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T) & \text{iff} & \langle\phi,\psi\rangle\Omega^{\mathcal{A}}_\Sigma(T')\\ & \text{iff} & \overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] \leq T'.\end{array}$$

We conclude that $\widetilde{T} \leq T^*$ and, by protoalgebraicity, $\Omega^{\mathcal{A}}(\widetilde{T}) \leq \Omega^{\mathcal{A}}(T^*)$. On the other hand, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$, $\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] \leq \widetilde{T}$. Thus, $\Omega^{\mathcal{A}}(T^*) = \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(\widetilde{T})$. Therefore, $\Omega^{\mathcal{A}}(\widetilde{T}) = \Omega^{\mathcal{A}}(T^*)$ and, since we showed that $\widetilde{T} \leq T^*$, we get by the minimality property of T^* in $[T]$, $T^* = \widetilde{T}$. ∎

Corollary 1507 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a syntactically protoalgebraic* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then* $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ *if and only if, there exists* $X \leq \mathrm{SEN}^2$*, such that*

$$T = C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in X_\Sigma\}).$$

Proof: For the left-to-right implication, assume $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Take $X = \Omega^{\mathcal{A}}(T)$. Then we have, using the hypothesis and Lemma 1506, $T = T^* = C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in X_\Sigma\})$.

Suppose, conversely, that $T = C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in X_\Sigma\})$, for some $X \leq \mathrm{SEN}$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$, $\langle\phi,\psi\rangle \in X_\Sigma$ implies $\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] \leq T$. Thus, $\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$. Therefore, by Lemma 1506, $T \leq C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_\Sigma[\phi,\psi] : \Sigma \in |\mathbf{Sign}|, \langle\phi,\psi\rangle \in X_\Sigma\}) = T^*$. Since, it is always the case that $T^* \leq T$, we get that $T = T^*$ and $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ∎

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. A collection $\Delta = \{\Delta^n : n < \omega\}$, where $\Delta^n : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}$ in $N^\flat$, with $n+1$ distinguished arguments, is called **Leibniz generating over** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi},\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\Delta^n_\Sigma[\vec{\phi},\psi]) \in \mathrm{ThFam}^*(\mathcal{I}),$$

for all $n < \omega$.

We show that, for a syntactically protoalgebraic π-institution $\mathcal{I}$, the property of being Leibniz generating over $\mathcal{I}$, transfers, in certain sense, to the filter families over arbitrary $\mathbf{F}$-algebraic systems.

Lemma 1508 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a syntactically protoalgebraic π-institution based on $\mathbf{F}$, with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\Delta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a Leibniz generating collection in $N^\flat$, with $n+1$ distinguished arguments. Then for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$, $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi},\psi \in \mathrm{SEN}(\Sigma)$,*

$$C^{\mathcal{I},\mathcal{A}}(\Delta^{\mathcal{A}}_\Sigma[\vec{\phi},\psi]) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: By hypothesis, Δ is Leibniz generating. Hence, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi},\psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\Delta_\Sigma[\vec{\phi},\psi]) \in \mathrm{ThFam}^*(\mathcal{I})$. Thus, by Corollary 1507, there exists $X \leq (\mathrm{SEN}^\flat)^2$, such that

$$C(\Delta_\Sigma[\vec{\phi},\psi]) = C(\bigcup\{\overset{\leftrightarrow\flat}{I}_{\Sigma'}[\phi',\psi'] : \Sigma' \in |\mathbf{Sign}^\flat|, \langle\phi',\psi'\rangle \in X_{\Sigma'}\}).$$

Now we get

$$\begin{aligned}
&C^{\mathcal{I},\mathcal{A}}(\Delta^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\vec{\phi}),\alpha_\Sigma(\psi)])\\
&= C^{\mathcal{I},\mathcal{A}}(\alpha(\Delta_\Sigma[\phi,\psi]))\\
&= C^{\mathcal{I},\mathcal{A}}(\alpha(C(\bigcup\{\overset{\leftrightarrow\flat}{I}_{\Sigma'}[\phi',\psi'] : \Sigma' \in |\mathbf{Sign}^\flat|, \langle\phi',\psi'\rangle \in X_{\Sigma'}\})))\\
&= C^{\mathcal{I},\mathcal{A}}(\alpha(\bigcup\{\overset{\leftrightarrow\flat}{I}_{\Sigma'}[\phi',\psi'] : \Sigma' \in |\mathbf{Sign}^\flat|, \langle\phi',\psi'\rangle \in X_{\Sigma'}\}))\\
&= C^{\mathcal{I},\mathcal{A}}(\bigcup\{\overset{\leftrightarrow\mathcal{A}}{I}_{F(\Sigma')}[\alpha_{\Sigma'}(\phi'),\alpha_{\Sigma'}(\psi')] : \Sigma' \in |\mathbf{Sign}^\flat|,\\
&\qquad\qquad \langle\alpha_{\Sigma'}(\phi'),\alpha_{\Sigma'}(\psi')\rangle \in \alpha_{\Sigma'}(X_{\Sigma'})\}).
\end{aligned}$$

Thus, taking into account the surjectivity of $\langle F,\alpha\rangle$, we obtain, using again Corollary 1507, that for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi},\psi \in \mathrm{SEN}(\Sigma)$, $C^{\mathcal{I},\mathcal{A}}(\Delta^{\mathcal{A}}_\Sigma[\vec{\phi},\psi]) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. A PGDD system $\Delta = \{\Delta^n : n < \omega\}$ for $\mathcal{I}$ is called **Leibniz generating** if Δ^n is Leibniz generating, for every $n < \omega$.

It is not difficult to see that Leibniz generating PGDD systems have a graded Modus Ponens property, in the sense detailed in the following

Lemma 1509 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\Delta = \{\Delta^n : n < \omega\}$ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family, then, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \psi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$\psi \in C_\Sigma(\Delta^n_\Sigma[\vec{\phi}, \psi], \vec{\phi}).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and set $T = C(\Delta^n_\Sigma[\vec{\phi}, \psi])$. By hypothesis, $T \in \mathrm{ThFam}^*(\mathcal{I})$. Since Δ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family, we get

$$\psi \in C_\Sigma(T_\Sigma, \vec{\phi}) \quad \text{iff} \quad \Delta^n_\Sigma[\vec{\phi}, \psi] \leq C(T) = T.$$

Thus, since the right hand side of the equivalence holds, we obtain $\psi \in C_\Sigma(T_\Sigma, \vec{\phi}) = C_\Sigma(C_\Sigma(\Delta^n_\Sigma[\vec{\phi}, \psi]), \vec{\phi}) = C_\Sigma(\Delta^n_\Sigma[\vec{\phi}, \psi], \vec{\phi})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\Delta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with a single distinguished argument. We say that Δ **isodefines Leibniz filter families over** $\mathcal{I}$ if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and all $\Sigma \in |\mathbf{Sign}|$,

$$T^*_\Sigma = \{\phi \in \mathrm{SEN}(\Sigma) : \Delta^{\mathcal{A}}_\Sigma[\phi] \leq T\}.$$

We show, next, that, in a syntactically protoalgebraic π-institution $\mathcal{I}$, which has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over every Leibniz theory family, the 0-th component Δ^0 does isodefine Leibniz filter families over $\mathcal{I}$.

A couple of lemmas are needed first.

Lemma 1510 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π-institution based on $\mathbf{F}$. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T \leq T'$ implies $T^* \leq T'^*$.*

Proof: Suppose $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. By protoalgebraicity of $\mathcal{I}$, we get

$$\Omega^{\mathcal{A}}(T \cap T'^*) = \Omega^{\mathcal{A}}(T) \cap \Omega^{\mathcal{A}}(T'^*) = \Omega^{\mathcal{A}}(T) \cap \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T).$$

Thus $T^* \leq T \cap T'^* \leq T'^*$. ■

Lemma 1511 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I}) \quad \textit{iff} \quad T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: We have, using Theorem 1395 and protoalgebraicity, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$ if and only if

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\}.$$

Since, under protoalgebraicity, it always holds that

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\},$$

it suffices to show that

$$\begin{array}{lll} T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) & \text{iff} & \text{for all } T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}), \\ & & \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \text{ implies } T \leq T'. \end{array}$$

The right to left implication is trivial, since the condition on the right implies that T is smallest among all filter families sharing the same Leibniz congruence system with T. For the converse, suppose T is a Leibniz filter family of $\mathcal{A}$ and that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then, using protoalgebraicity, we get $\Omega(T \cap T') = \Omega^{\mathcal{A}}(T) \cap \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Thus, we conclude that $T = T^* \leq T \cap T' \leq T'$. ∎

Theorem 1512 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a syntactically protoalgebraic* π*-institution based on* $\mathbf{F}$*, with* $\Delta = \{\Delta^n : n < \omega\}$ *a Leibniz generating PGDD system for* $\mathcal{I}$ *over every Leibniz theory family. Then* Δ^0 *isodefines Leibniz filter families over* $\mathcal{I}$*.*

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, with F an isomorphism, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$.

Suppose, first, that $\Delta^0_\Sigma[\phi] \leq T$. Let $T' = C^{\mathcal{I},\mathcal{A}}(\Delta^0_\Sigma[\phi])$. By hypothesis and Lemma 1508, $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Since $T' \leq T$, by Lemma 1510, $T' \leq T^*$. Hence, $\Delta^0_\Sigma[\phi] \leq T^*$. Therefore, by Lemma 1509, $\phi \in T^*_\Sigma$.

Suppose, conversely, that $\phi \in T^*_\Sigma$. Then, by definition, the $\mathcal{I}$-structure $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} \rangle$ satisfies $\vdash_\Sigma \phi$. By Lemma 1511, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} \rangle \in \mathrm{FStr}(\mathcal{I})$. Thus, by Lemma 1505, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{A}}(\mathcal{A})^{T^*} \rangle$ satisfies r^{Δ^0}. Hence, for all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$, $\Delta^0_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T^*_{\Sigma'} \subseteq T_{\Sigma'}$. We conclude that $\Delta^0_\Sigma[\phi] \leq T$. ∎

We are ready now to prove one half of the main result of this section. We would like to show that, for a syntactically protoalgebraic finitary π-institution, the existence of a Leibniz generating PGDD system over all

Leibniz theory families implies the existenc of an isofully adequate Gentzen π-institution.

We define that institution, first, preceding the statement of the theorem that involves it in its proof.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\Delta = \{\Delta^n : n < \omega\}$ in $N^\flat$, where Δ^n has $n+1$ distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Define:

- $\mathrm{Ax}^{\mathcal{I}} = \{\mathrm{Ax}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Ax}^{\mathcal{I}}_\Sigma = \{\Phi \vdash_\Sigma \phi : \phi \in C_\Sigma(\Phi)\};$$
- $\mathrm{Ir}^{\mathcal{I}} = \{\mathrm{Ir}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Ir}^{\mathcal{I}}_\Sigma = \{r^{\Delta^n}_\Sigma : n < \omega\}.$$

Set $R^{\mathcal{I}} = \mathrm{Ax}^{\mathcal{I}} \cup \mathrm{Ir}^{\mathcal{I}}$ and let
$$\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$$
be the Gentzen π-institution generated by $R^{\mathcal{I}}$ (recall that $G^{\mathcal{I}}$ is required to be a structural closed system on $\mathrm{Seq}(\mathbf{F})$ and, therefore, it is assumed to satisfy, by default, (Axiom), (Weakening) and (Cut)).

Theorem 1513 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, then it has an isofully adequate Gentzen π-institution, namely the Gentzen π-institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$.*

Proof: We must show that, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, we have
$$\mathbb{L} \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}}) \quad \text{iff} \quad \mathbb{L} \in \mathrm{FStr}(\mathcal{I}).$$
Suppose, first, that $\mathbb{L} \in \mathrm{FStr}(\mathcal{I})$. Then $\mathbb{L}$ is, in particular, an $\mathcal{I}$-structure. Therefore, it satisfies $\mathrm{Ax}^{\mathcal{I}}$. Moreover, by Lemma 1505, $\mathbb{L}$ satisfies r^{Δ^n}, for all $n < \omega$. Hence, it also satisfies $\mathrm{Ir}^{\mathcal{I}}$. We conclude that $\mathbb{L} \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$.

Suppose, conversely, that $\mathbb{L} \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$. Clearly, $\mathbb{L} \in \mathrm{Str}(\mathcal{I})$, since it satisfies $\mathrm{Ax}^{\mathcal{I}}$. So it suffices to show that it is also full. Assume, to the contrary, that $\mathbb{L}$ is not full and let $T = D(\varnothing)$. Since $\mathcal{I}$ is protoalgebraic and $\mathbb{L}$ is not full, we have, using Lemma 1511, $\mathcal{D} \subsetneq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$. Consider $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} - \mathcal{D}$. Then we get $D(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$ and $T^* \leq T' \lneq D(T')$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(T') - T'_\Sigma$. Then, there exists $\Phi \subseteq_f T'_\Sigma$, such that $\phi \in D_\Sigma(\Phi)$. Since $\mathbb{L}$ satisfies $\mathrm{Ir}^{\mathcal{I}}$, we get $\Delta^n_\Sigma[\Phi, \phi] \leq T$. But Δ is also Leibniz generating, whence, by Lemma 1508,

$D(\Delta^n_\Sigma[\Phi,\phi]) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Therefore, by Lemma 1510, $\Delta^n_\Sigma[\Phi,\phi] \le T^*$. Now we get $\phi \in D_\Sigma(T'_\Sigma,\Phi) \subseteq D_\Sigma(T'_\Sigma) = T'_\Sigma$, which contradicts our assumption. Therefore, $\mathbb{L}$ is also full, as was to be shown. ■

Suppose, now, that $\mathcal{I}$ is a syntactically protoalgebraic, finitary π-institution with an isofully adequate Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G\rangle$. Then, for all $\langle \mathcal{F}, D\rangle \in \mathrm{Str}(\mathfrak{G})$, we must have$\langle \mathcal{F}, D\rangle \in \mathrm{FStr}(\mathcal{I})$ and, therefore, taking into account Lemma 1511, we get that $\mathcal{D} = \mathrm{ThFam}(\mathcal{I})^T$, where $T \in \mathrm{ThFam}^*(\mathcal{I})$. We denote by

$$h^{\mathfrak{G}} : \mathrm{Str}^{\mathfrak{G}}(\mathcal{F}) \to \mathrm{ThFam}^*(\mathcal{I})$$

the bijection that is established by this association, which is, in addiction an order isomorphism.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution based on $\mathbf{F}$. Given a theory family $\mathbf{\Gamma} \in \mathrm{ThFam}(\mathfrak{G})$, recall the $\mathbf{F}$-structure $\mathbb{L}^{\mathbf{\Gamma}} = \langle \mathcal{F}, D^{\mathbf{\Gamma}}\rangle$, which was shown in Lemma 1484 to be a $\mathfrak{G}$-structure. For notational purposes, given $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi_0,\dots,\phi_{n-1},\psi \in \mathrm{SEN}^\flat(\Sigma)$, let us write

$$\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi] \coloneqq \mathbb{L}^{G(\phi_0,\dots,\phi_{n-1}\vdash_\Sigma\psi)},$$

where, as usual, $G(\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi)$ denotes the least theory family of $\mathfrak{G}$ including the $\mathbf{F}$-sequent $\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi$.

We call the Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ **transformational** if, for all all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_0,\dots,\phi_{n-1},\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi]) = C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi]),$$

for some $\Delta^n : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with $n+1$ distinguished arguments.

We can show that the isofully adequate Gentzen π-institution $\mathfrak{G}^{\mathcal{I}}$ associated with a syntactically protoalgebraic finitary π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ that has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, as in Theorem 1513, is, in fact, a transformational Gentzen π-institution.

Theorem 1514 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a syntactically protoalgebraic finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, then the isofully adequate Gentzen π-institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}}\rangle$ for $\mathcal{I}$ is transformational.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi_0,\dots,\phi_{n-1},\psi \in \mathrm{SEN}^\flat(\Sigma)$ and denote

$$T \coloneqq C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi]).$$

By hypothesis, we have $T \in \mathrm{ThFam}^*(\mathcal{I})$. Since T is a Leibniz $\mathcal{I}$-theory family and Δ is a PGDD system over all Leibniz theory families, T is closed under all axioms and rules of $\mathfrak{G}^{\mathcal{I}}$. Moreover, if $\phi_0,\dots,\phi_{n-1} \in T_\Sigma$, then, since $\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi] \le T$, we get, by Lemma 1509, $\psi \in T_\Sigma$. Hence, T is a theory family of the $\mathbf{F}$-structure $\mathfrak{G}^{\mathcal{I}}[\phi_0,\dots,\phi_{n-1},\psi]$. Since, by definition, $h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi])$ is its least theory family, we get that $h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi]) \le C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi])$.

On the other hand, by definition,

$$\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi \in G^{\mathcal{I}}_\Sigma(\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi),$$

whence, writing $\mathfrak{G}^{\mathcal{I}}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi] \coloneqq \langle \mathcal{F}, D\rangle$, we get $\psi \in D_\Sigma(\phi_0,\dots,\phi_{n-1})$. Recalling that every full model is structural, we get, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$\mathrm{SEN}^\flat(f)(\psi) \in D_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_0),\dots,\mathrm{SEN}^\flat(f)(\phi_{n-1})).$$

Thus, since $\mathfrak{G}^{\mathcal{I}}$ satisfies r^{Δ^n}, we get, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\Delta_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_0),\dots,\mathrm{SEN}^\flat(f)(\phi_{n-1}),\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \subseteq D_\Sigma(\varnothing),$$

i.e., that $\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi] \le h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi])$. We now conclude that

$$C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi]) \le h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi]).$$

Therefore, for all all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_0,\dots,\phi_{n-1},\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1} \vdash_\Sigma \psi]) = C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi]),$$

showing that $\mathfrak{G}^{\mathcal{I}}$ is transformational. ∎

Finally, we show that, for a syntactically protoalgebraic, finitary π-institution $\mathcal{I}$, the existence of an isofully adequate, transformational Gentzen π-institution $\mathfrak{G}$ for $\mathcal{I}$ implies that $\mathcal{I}$ has a Leibniz generating PGDD system over every Leibniz theory family.

Theorem 1515 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a syntactically protoalgebraic, finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has an isofully adequate transformational Gentzen π-institution, then $\mathcal{I}$ has a Leibniz generating PGDD system over every Leibniz theory family.*

Proof: Suppose that $\mathcal{I}$ has an isofully adequate transformational Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G\rangle$. Thus, by definition, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi_0,\dots,\phi_{n-1},\psi \in \mathrm{SEN}^\flat(\Sigma)$, there exists a collection $\Delta^n : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with $n+1$ distinguished arguments, such that

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0,\dots,\phi_{n-1},\psi]) = C(\Delta^n_\Sigma[\phi_0,\dots,\phi_{n-1},\psi]).$$

By the fact that $h^{\mathfrak{G}}$ maps, by hypothesis and Lemma 1511, into $\mathrm{ThFam}^*(\mathcal{I})$, ensures that $\Delta = \{\Delta^n : n < \omega\}$ is Leibniz generating. So it suffices to show that Δ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family. To this end, assume that $T \in \mathrm{ThFam}^*(\mathcal{I})$, $n < \omega$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi_0, \ldots, \phi_{n-1}, \psi \in \mathrm{SEN}^\flat(\Sigma)$. We must show that

$$\psi \in C_\Sigma(T_\Sigma, \phi_0, \ldots, \phi_{n-1}) \quad \text{iff} \quad \Delta^n_\Sigma[\phi_0, \ldots, \phi_{n-1}, \psi] \leq T.$$

We have

$$\begin{array}{lll}\psi \in C_\Sigma(T_\Sigma, \phi_0, \ldots, \phi_{n-1}) & \text{iff} & \psi \in C^T_\Sigma(\phi_0, \ldots, \phi_{n-1}) \\ & \text{iff} & \mathfrak{G}[\phi_0, \ldots, \phi_{n-1} \vdash_\Sigma \psi] \leq \mathcal{C}^T \\ & \text{iff} & h^{\mathfrak{G}}(\mathfrak{G}(\phi_0, \ldots, \phi_{n-1} \vdash_\Sigma \psi]) \leq T \\ & \text{iff} & C(\Delta^n_\Sigma[\phi_0, \ldots, \phi_{n-1}, \psi]) \leq T \\ & \text{iff} & \Delta^n_\Sigma[\phi_0, \ldots, \phi_{n-1}, \psi] \leq T.\end{array}$$

We conclude that Δ is indeed Leibniz generating PGDD system for $\mathcal{I}$ over every Leibniz theory family. ■

In conclusion, we have

Theorem 1516 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. A syntactically protoalgebraic, finitary* π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *based on* $\mathbf{F}$ *has an isofully adequate transformational Gentzen* π*-institution if and only if it has a Leibniz generating PGDD system over every Leibniz theory family.*

Proof: The "if" was proven in Theorems 1513 and 1514. The "only if" is by Theorem 1515. ■

Chapter 21

Operators on π-Institutions

21.1 $\mathcal{I}$-Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system.

An **$\mathcal{I}$-operator on $\mathcal{A}$** is a map

$$O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{I}) \to \mathrm{EqvFam}(\mathcal{A}),$$

where $\mathrm{EqvFam}(\mathcal{A})$ is the collection of equivalence families on $\mathcal{A}$.

Given an $\mathcal{I}$-operator $O^{\mathcal{A}}$ on $\mathcal{A}$, we define three derived operators (functions) as follows:

- The **lifting of** $O^{\mathcal{A}}$, $\widetilde{O}^{\mathcal{A}} : \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \to \mathrm{EqvFam}(\mathcal{A})$, is given, for all $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, by
$$\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \bigcap \{O^{\mathcal{A}}(T) : T \in \mathcal{T}\};$$
- The **relativization of** $O^{\mathcal{A}}$ **to** $\mathcal{I}$, $\widetilde{O}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$, is given, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, by
$$\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) = \bigcap \{O^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} = \widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T);$$
- $O^{\mathcal{A}^{-1}} : \mathrm{EqvFam}(\mathcal{A}) \to \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$ is given, for all $\theta \in \mathrm{EqvFam}(\mathcal{A})$, by
$$O^{\mathcal{A}^{-1}}(\theta) = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \theta \leq O^{\mathcal{A}}(T)\}.$$

Note that the lifting of the Leibniz operator $\Omega^{\mathcal{A}}$ on $\mathcal{A}$ is the Tarski operator $\widetilde{\Omega}^{\mathcal{A}}$ on $\mathcal{A}$, whereas the relativization of the Leibniz operator on $\mathcal{A}$ is the Suszko operator $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ on $\mathcal{A}$.

Immediately from the definitions, we obtain the following:

Lemma 1517 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ an $\mathcal{I}$-operator on $\mathcal{A}$.*

(a) $\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) \leq O^{\mathcal{A}}(T)$, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$;

(b) $\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \leq O^{\mathcal{A}}(T)$, for all $T \in \mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof: Obvious from the definitions. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, let there be given an $\mathcal{I}$-operator $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$. We write

$$O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$$

and refer to this family as a **family of $\mathcal{I}$-operators**.

Since $\mathcal{I}$-operators are meant to abstract the operators of abstract algebraic logic, those properties that were studied in preceding chapters concerning the Leibniz operator play also a significant role when it comes to $\mathcal{I}$-operators.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and

$$O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$-operator on $\mathcal{A}$.

- $O^{\mathcal{A}}$ is **order-preserving** or **monotone** if, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,
$$T \leq T' \quad \text{implies} \quad O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T');$$
- $O^{\mathcal{A}}$ is **order-reflecting** or **reflective** if, for all $T, T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$,
$$O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{implies} \quad T \leq T';$$
- $O^{\mathcal{A}}$ is **completely order reflecting** or **c-reflective** if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,
$$\bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

Some important characterizations are related to these properties.

Lemma 1518 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ an $\mathcal{I}$-operator on $\mathcal{A}$.*

$$O^{\mathcal{A}} \textit{ is monotone if and only if } O^{\mathcal{A}} = \widetilde{O}^{\mathcal{I},\mathcal{A}}.$$

Proof: Suppose, first, that $O^{\mathcal{A}}$ is monotone. Then, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{array}{rcl} O^{\mathcal{A}}(T) & = & \bigcap\{O^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & = & \widetilde{O}^{\mathcal{I},\mathcal{A}}(T). \end{array}$$

If, conversely, $O^{\mathcal{A}} = \widetilde{O}^{\mathcal{I},\mathcal{A}}$, then, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$, we get

$$\begin{array}{rcl} O^{\mathcal{A}}(T) & = & \widetilde{O}^{\mathcal{I},\mathcal{A}}(T) \\ & = & \bigcap\{O^{\mathcal{A}}(T'') : T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & \leq & \bigcap\{O^{\mathcal{A}}(T'') : T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & = & \widetilde{O}^{\mathcal{I},\mathcal{A}}(T') \\ & = & O^{\mathcal{A}}(T'). \end{array}$$

Therefore, $O^{\mathcal{A}}$ is monotone. ■

Lemma 1519 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*.* $O^{\mathcal{A}}$ *is c-reflective if and only if, for all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) \le O^{\mathcal{A}}(T') \quad \textit{implies} \quad T \le T'.$$

Proof: Assume, first, that $O^{\mathcal{A}}$ is c-reflective and let $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) \le O^{\mathcal{A}}(T')$. Then, by definition, $\bigcap\{O^{\mathcal{A}}(T'') : T \le T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \le O^{\mathcal{A}}(T')$. By c-reflectivity, $\bigcap\{T'' : T \le T'' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})\} \le T'$, i.e., $T \le T'$.

Suppose, conversely, that the displayed condition holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \le O^{\mathcal{A}}(T')$. Then we get

$$\widetilde{O}^{\mathcal{I},\mathcal{A}}(\bigcap \mathcal{T}) \le \bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \le O^{\mathcal{A}}(T').$$

Hence, by the hypothesis, $\bigcap \mathcal{T} \le T'$ and $O^{\mathcal{A}}$ is c-reflective. ∎

We now show that the operators $\widetilde{O}^{\mathcal{A}}$ and $O^{\mathcal{A}^{-1}}$, associated with a given $\mathcal{I}$-operator $O^{\mathcal{A}}$, establish a Galois connection between the class $\mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$ of bundles of $\mathcal{I}$-filters on $\mathcal{A}$ and the class $\mathrm{EqvFam}(\mathcal{A})$ of equivalence families on $\mathcal{A}$. This will yield several important consequences.

Proposition 1520 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*. The maps*

$$\begin{array}{rcl} \widetilde{O}^{\mathcal{A}} : \ \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & \longrightarrow & \mathrm{EqvFam}(\mathcal{A}) \\ \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & \longleftarrow & \mathrm{EqvFam}(\mathcal{A}) \quad : O^{\mathcal{A}^{-1}} \end{array}$$

establish a Galois connection, where $\mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$ *is ordered under the subclass relation and* $\mathrm{EqvFam}(\mathcal{A})$ *under signature-wise inclusion.*

Proof: We must show that, for all $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\theta \in \mathrm{EqvFam}(\mathcal{A})$,

$$\mathcal{T} \subseteq O^{\mathcal{A}^{-1}}(\theta) \quad \text{iff} \quad \widetilde{O}^{\mathcal{A}}(\mathcal{T}) \ge \theta.$$

In fact, we have

$$\begin{array}{rll} \mathcal{T} \subseteq O^{\mathcal{A}^{-1}}(\theta) & \text{iff} & \theta \le O^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \theta \le \bigcap\{O^{\mathcal{A}}(T) : T \in \mathcal{T}\} \\ & \text{iff} & \theta \le \widetilde{O}^{\mathcal{A}}(\mathcal{T}). \end{array}$$

Thus $(\widetilde{O}^{\mathcal{A}}, O^{\mathcal{A}^{-1}}) : \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \rightleftarrows \mathrm{EqvFam}(\mathcal{A})$ is, in fact, a Galois connection. ∎

Corollary 1521 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*.*

(a) The operators

$$\widetilde{O}^{\mathcal{A}} : \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \to \mathrm{EqvFam}(\mathcal{A})$$
$$O^{\mathcal{A}^{-1}} : \mathrm{EqvFam}(\mathcal{A}) \to \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$$

are order reversing;

(b) The operators

$$O^{\mathcal{A}^{-1}} \circ \widetilde{O}^{\mathcal{A}} : \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \to \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$$
$$\widetilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}} : \mathrm{EqvFam}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$$

are closure operators;

(c) The collection of fixed-points of $O^{\mathcal{A}^{-1}} \circ \widetilde{O}^{\mathcal{A}}$ *is the range of* $O^{\mathcal{A}^{-1}}$ *and the collection of fixed-points of* $\widetilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}}$ *is the range of* $\widetilde{O}^{\mathcal{A}}$*;*

(d) $\widetilde{O}^{\mathcal{A}}$ *and* $O^{\mathcal{A}^{-1}}$ *restrict to mutually inverse order isomorphisms between the collections of fixed-points of* $O^{\mathcal{A}^{-1}} \circ \widetilde{O}^{\mathcal{A}}$ *and of fixed-points of* $\widetilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}}$*.*

Proof: Known facts about Galois connections. ■

We capture the elements described in Part (c) of Corollary 1521, by making the following definitions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and

$$O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$-operator on $\mathcal{A}$.

- A family $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is called $O^{\mathcal{A}}$-**full** if $\mathcal{T} = O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T}))$ if and only if $\mathcal{T} \in \mathrm{Ran}(O^{\mathcal{A}^{-1}})$;
- An equivalence family $\theta \in \mathrm{EqvFam}(\mathcal{A})$ is $O^{\mathcal{A}}$-**full** if $\theta = \widetilde{O}^{\mathcal{A}}(O^{\mathcal{A}^{-1}}(\theta))$ if and only if $\theta \in \mathrm{Ran}(\widetilde{O}^{\mathcal{A}})$.

The following statements provide a justification of the terminology used.

Proposition 1522 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*.*

(a) *A collection* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *is* $O^{\mathcal{A}}$*-full if and only if it is the largest* $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\widetilde{O}^{\mathcal{A}}(\mathcal{D}) = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$*;*

(b) *An equivalence family* $\theta \in \mathrm{EqvFam}(\mathcal{A})$ *is* $O^{\mathcal{A}}$*-full if and only if it is the largest* $\eta \in \mathrm{EqvFam}(\mathcal{A})$*, such that* $O^{\mathcal{A}^{-1}}(\eta) = O^{\mathcal{A}^{-1}}(\theta)$*.*

Proof: We do Part (a). Part (b) can be proved analogously. Suppose, first, that $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$-full and let $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{A}}(\mathcal{D}) = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$. Then, we have

$$\mathcal{D} \subseteq O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{D})) = O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T})) = \mathcal{T}.$$

Suppose, conversely, that $\mathcal{T}$ is the largest among $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{A}}(\mathcal{D}) = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$ and let $T \in O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T}))$. Then, by definition, $\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \le O^{\mathcal{A}}(T)$. Hence, $\widetilde{O}^{\mathcal{A}}(\mathcal{T} \cup \{T\}) = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$. By the maximality of $\mathcal{T}$, we conclude that $T \in \mathcal{T}$. This shows that $O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T})) \subseteq \mathcal{T}$. Since the opposite inclusion always holds, we conclude that $\mathcal{T}$ is a fixed point of $O^{\mathcal{A}^{-1}} \circ \widetilde{O}^{\mathcal{A}}$ and, hence, it is $O^{\mathcal{A}}$-full. ■

We have the following consequences:

Corollary 1523 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*.*

(a) $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *is* $O^{\mathcal{A}}$*-full;*

(b) $\nabla^{\mathcal{A}}$ *is* $O^{\mathcal{A}}$*-full;*

(c) *If* $O^{\mathcal{A}}$ *is monotone and* $\mathcal{T}$ *is* $O^{\mathcal{A}}$*-full, then* $\mathcal{T}$ *is an upset in the poset* $\mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$*.*

Proof: All three statements are direct consequences of Proposition 1522. ■

21.2 Congruential $\mathcal{I}$-Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. An $\mathcal{I}$-operator $O^{\mathcal{A}}$: $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ is called **congruential** if, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $O^{\mathcal{A}}(T) \in \mathrm{ConSys}(\mathcal{A})$. Thus a congruential $\mathcal{I}$-operator is an operator $O^{\mathcal{A}}$: $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$.

Proposition 1524 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system,* $\theta \in \mathrm{ConSys}(\mathcal{A})$ *and* $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\theta$ *the quotient natural transformation.*

(a) $\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$ *and* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) = \pi(\Omega^{\mathcal{A}^{-1}}(\theta))$*;*

(b) The mappings

$$\begin{array}{l}\pi : \mathrm{SenFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{SenFam}(\mathcal{A}/\theta)\\ \pi^{-1} : \mathrm{SenFam}(\mathcal{A}/\theta) \to \mathrm{SenFam}(\mathcal{A})\end{array}$$

restrict to mutually inverse order isomorphisms between $\Omega^{\mathcal{A}^{-1}}(\theta)$ *and* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$*.*

Proof:

(a) Suppose $T \in \Omega^{\mathcal{A}^{-1}}(\theta)$. Then $\theta \le \Omega^{\mathcal{A}}(T)$. Hence θ is compatible with T, which implies, by Corollary 57, $\pi(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$. Suppose, conversely, that $T \in \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$. Then $\pi(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$ and, hence, by Corollary 57, $\pi^{-1}(\pi(T)) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, T is compatible with θ, showing that $\theta \le \Omega^{\mathcal{A}}(T)$. This gives $T \in \Omega^{\mathcal{A}^{-1}}(\theta)$.

The second equality of Part (a) is obtained from the first, using the surjectivity of $\langle I, \pi\rangle$.

(b) By Part (a), the mappings

$$\begin{array}{l}\pi \restriction_{\Omega^{\mathcal{A}^{-1}}(\theta)}: \Omega^{\mathcal{A}^{-1}}(\theta) \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\\ \pi^{-1} \restriction_{\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})}: \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \Omega^{\mathcal{A}^{-1}}(\theta)\end{array}$$

are well-defined. Moreover, they are clearly inverses of one another and order preserving. Thus, they establish an order isomorphism between $\Omega^{\mathcal{A}^{-1}}(\theta)$ and $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$.

■

21.3 O-Classes and O-Filter Families

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and

$$O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$-operator on $\mathcal{A}$. For all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, the O-**class of** T, denoted $[\![T]\!]^O$, is the collection

$$[\![T]\!]^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : O^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')\}.$$

It turns out that this class forms a closure family on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proposition 1525 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*. For all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $[\![T]\!]^O$ *is a closure family on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: First, observe that $\Omega^{\mathcal{A}}(\mathrm{SEN}) = \nabla^{\mathcal{A}}$, whence $\mathrm{SEN} \in [\![T]\!]^O$. Next, let $\{T^i : i \in I\} \subseteq [\![T]\!]^O$. Then, we have

$$O^{\mathcal{A}}(T) \leq \bigcap_{i\in I} \Omega^{\mathcal{A}}(T^i) \leq \Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i).$$

So $\bigcap_{i\in I} T^i \in [\![T]\!]^O$ and $[\![T]\!]^O$ is a closure family on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Something even stronger is true in case $O^{\mathcal{A}}$ happens to be a congruential $\mathcal{I}$-operator. In that case, the pair $\langle \mathcal{A}, [\![T]\!]^O\rangle$ turns out to be a full $\mathcal{I}$-structure.

Proposition 1526 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *a congruential* $\mathcal{I}$*-operator on* $\mathcal{A}$*. For all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\langle \mathcal{A}, [\![T]\!]^O\rangle$ *is a full* $\mathcal{I}$*-structure.*

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then $[\![T]\!]^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T))$. By hypothesis, $O^{\mathcal{A}}(T) \in \mathrm{ConSys}(\mathcal{A})$. Thus, by Proposition 1524,

$$[\![T]\!]^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))),$$

where $\langle I, \pi\rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$ is the quotient natural transformation. Thus, by definition, $\langle \mathcal{A}, [\![T]\!]^O\rangle$ is a full $\mathcal{I}$-structure. ■

As a corollary, we obtain the fact that $[\![T]\!]^O$ is a closure system on $\mathcal{A}$ and, therefore, $\langle \mathcal{A}, [\![T]\!]^O\rangle$ is a π-institution and not merely a π-structure.

Corollary 1527 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *a congruential* $\mathcal{I}$*-operator on* $\mathcal{A}$*. For all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $[\![T]\!]^O$ *is a closure system on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: By Propositions 1526 and 1389. ■

Corollary 1527 justifies the following definition.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and

$$O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$$

a congruential $\mathcal{I}$-operator on $\mathcal{A}$. For all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, the least element of the O-class of T is denoted by T^O:

$$T^O = \bigcap [\![T]\!]^O.$$

A $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is called an O-**filter family** if $T = T^O$. Note that, by Corollary 1527, an O-filter family must be an $\mathcal{I}$-filter system.

The collection of all O-filter systems of $\mathcal{A}$ is denoted by $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$.

Proposition 1528 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *an* $\mathcal{I}$*-operator on* $\mathcal{A}$*.* $O^{\mathcal{A}}$ *is reflective (and, hence, injective) on* $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$*.*

Proof: Let $T, T' \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$, such that $O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T')$. Then, $[\![T']\!]^O \subseteq [\![T]\!]^O$. Therefore,

$$\begin{array}{rcl} T & = & T^O \quad (T \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})) \\ & = & \bigcap [\![T]\!]^O \quad \text{(definition)} \\ & \leq & \bigcap [\![T']\!]^O \quad ([\![T']\!]^O \subseteq [\![T]\!]^O) \\ & = & T'^O \quad \text{(definition)} \\ & = & T'. \quad (T' \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})) \end{array}$$

We conclude that $O^{\mathcal{A}}$ is reflective. ■

Proposition 1529 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *a monotone* $\mathcal{I}$*-operator on* $\mathcal{A}$*. Then the mapping* $T \mapsto T^O$ *is monotone, i.e., for all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T \leq T' \quad \textit{implies} \quad T^O \leq T'^O.$$

Proof: We have, for all $T, T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{array}{rll} T \leq T' & \text{implies} & O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{(hypothesis)} \\ & \text{implies} & [\![T']\!]^O \subseteq [\![T]\!]^O \quad (\text{definitions of } [\![T]\!]^O, [\![T']\!]^O) \\ & \text{implies} & T^O \leq T'^O. \quad (\text{definitions of } T^O, T'^O) \end{array}$$

So $T \mapsto T^O$ is a monotone mapping. ■

Proposition 1530 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system,* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *a congruential* $\mathcal{I}$*-operator on* $\mathcal{A}$ *and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $T \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$ *if and only if* $T/O^{\mathcal{A}}(T)$ *is the least* $\mathcal{I}$*-filter family of* $\mathcal{A}/O^{\mathcal{A}}(T)$*.*

Proof: By hypothesis, $O^{\mathcal{A}}(T) \in \mathrm{ConSys}(\mathcal{A})$. Consider the quotient natural transformation

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/O^{\mathcal{A}}(T).$$

Since $\Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = [\![T]\!]^O$, we get, by Proposition 1524, that

$$\pi : [\![T]\!]^O \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/O^{\mathcal{A}}(T))$$

is an order isomorphism. Thus, $T^O/O^{\mathcal{A}}(T)$ is the least $\mathcal{I}$-filter family on $\mathcal{A}/O^{\mathcal{A}}(T)$. ■

21.4 Compatibility $\mathcal{I}$-Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ an $\mathcal{I}$-operator on $\mathcal{A}$. $O^{\mathcal{A}}$ is called a **compatibility $\mathcal{I}$-operator** if, for all $T \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$,

$$O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T).$$

Clearly, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ is the largest compatibility $\mathcal{I}$-operator on $\mathcal{A}$. If one assumes monotonicity, then this role is played by the Suszko operator instead:

Lemma 1531 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the Suszko operator $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ is the largest monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$.*

Proof: Suppose that $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ is a monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$. Then, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{array}{rcl} O^{\mathcal{A}}(T) & = & \widetilde{O}^{\mathcal{I},\mathcal{A}}(T) \quad \text{(by Lemma 1518)} \\ & = & \bigcap\{O^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \quad \text{(by Definition)} \\ & \leq & \bigcap\{\Omega^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \quad \text{(by Compatibility)} \\ & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T). \quad \text{(by Definition)} \end{array}$$

So $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is the largest monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$. ■

For compatibility $\mathcal{I}$-operators, we have the following properties pertaining to O-classes and O-filter systems.

Lemma 1532 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ a compatibility $\mathcal{I}$-operator on $\mathcal{A}$. Then, for every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T \in [\![T]\!]^O \quad \textit{and} \quad T^O \leq T.$$

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $O^{\mathcal{A}}$ is a compatibility $\mathcal{I}$-operator, $O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$. Thus, by definition of $[\![T]\!]^O$, we get $T \in [\![T]\!]^O$. Moreover, since $T \in [\![T]\!]^O$, we now get $T^O = \bigcap [\![T]\!]^O \leq T$. ■

For monotone compatibility $\mathcal{I}$-operators, we have the following properties.

Lemma 1533 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ a monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$. Then, for every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$:*

(a) $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq [\![T]\!]^O$*;*

(b) $[\![T]\!]^O = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *iff* $T = T^O$ *iff* $T \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$.

Proof:

(a) Suppose $T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then

$$\begin{array}{rcll} O^{\mathcal{A}}(T) & \leq & O^{\mathcal{A}}(T') & \text{(by Monotonicity)} \\ & \leq & \Omega^{\mathcal{A}}(T'). & \text{(by Compatibility)} \end{array}$$

So, by definition of $[\![T]\!]^O$, $T' \in [\![T]\!]^O$.

(b) The second equivalence if simply the definition of $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$. So it suffices to prove the first equivalence. Assume, first, that $[\![T]\!]^O = \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, we have $T^O = \bigcap [\![T]\!]^O = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = T$.

Assume, conversely, that $T = T^O$. Then, if $T' \in [\![T]\!]^O$, we get $T = T^O = \bigcap [\![T]\!]^O \leq T'$. Thus, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Since, by Part (a), the converse always holds, we get $[\![T]\!]^O = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$.

■

In the case of compatibility $\mathcal{I}$-operators, there are also close relationships between their classes and their filter families and those associated to the Leibniz operator. More precisely, we get:

Lemma 1534 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ *a compatibility* $\mathcal{I}$*-operator on* $\mathcal{A}$*. Then, for every* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*:*

(a) $[\![T]\!]^\Omega \subseteq [\![T]\!]^O$*;*

(b) $T^O \leq T^\Omega$*;*

(c) $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$*.*

Proof:

(a) Let $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{array}{rlll} T' \in [\![T]\!]^\Omega & \text{implies} & \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') & \text{(by Definition of } [\![T]\!]^\Omega) \\ & \text{implies} & O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') & \text{(by Compatibility)} \\ & \text{implies} & T' \in [\![T]\!]^O. & \text{(by Definition of } [\![T]\!]^O) \end{array}$$

Thus, $[\![T]\!]^\Omega \subseteq [\![T]\!]^O$.

(b) Using Part (a), we get $T^O = \bigcap [\![T]\!]^O \leq \bigcap [\![T]\!]^\Omega = T^\Omega$.

(c) Assume $T' \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, by definition, $T'^{O} = T'$. Thus, by Part (b), $T' \le T'^{\Omega}$. Since, by Lemma 1532, $T'^{\Omega} \le T'$, we get $T'^{\Omega} = T'$ and, therefore, $T' \in \mathrm{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$. We conclude that $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$.

■

For monotone compatibility $\mathcal{I}$-operators, we have similar relationships between their classes and their filter families and those associated to the Suszko operator.

Lemma 1535 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ a monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$. Then, for every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$:*

(a) $[\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} \le [\![T]\!]^{O}$;

(b) $T^{O} \le T^{\widetilde{\Omega}^{\mathcal{I}}}$;

(c) $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I},\widetilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$.

Proof:

(a) Let $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{array}{lll} T' \in [\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} & \text{implies} & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T') \quad (\text{by Definition of } [\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}}) \\ & \text{implies} & O^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T') \quad (\text{by Lemma 1531}) \\ & \text{implies} & T' \in [\![T]\!]^{O}. \quad (\text{by Definition of } [\![T]\!]^{O}) \end{array}$$

Thus, $[\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} \subseteq [\![T]\!]^{O}$.

(b) Using Part (a), we get $T^{O} = \bigcap [\![T]\!]^{O} \le \bigcap [\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} = T^{\widetilde{\Omega}^{\mathcal{I}}}$.

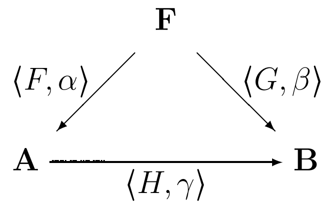
(c) Assume $T' \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, by definition, $T'^{O} = T'$. Thus, by Part (b), $T' \le T'^{\widetilde{\Omega}^{\mathcal{I}}}$. Since, by Lemma 1532, $T'^{\widetilde{\Omega}^{\mathcal{I}}} \le T'$, we get $T'^{\widetilde{\Omega}^{\mathcal{I}}} = T'$ and, therefore, $T' \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$. We conclude that $\mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I},\widetilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$.

■

21.5 Commuting $\mathcal{I}$-Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$-algebraic systems and $\langle H, \gamma \rangle$:

$\mathcal{A} \to \mathcal{B}$ a surjective morphism.



Let, also $O^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ and $O^{\mathcal{B}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B}) \to \mathrm{EqvFam}(\mathcal{B})$ be $\mathcal{I}$-operators on $\mathcal{A}$ and on $\mathcal{B}$, respectively. We say that the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is **commuting** if, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')).$$

More generally, let $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ be a family of $\mathcal{I}$-operators. We say that O is a **commuting family** if, for every pair $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ of $\mathbf{F}$-algebraic systems, and every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$, the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is commuting.

A slightly more relaxed version, which will be of use to us later, is that of semi-commutation. We say that a family of $\mathcal{I}$-operators $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ is a **semi-commuting family** if, for every pair $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ of $\mathbf{F}$-algebraic systems, and every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$, with H an isomorphism, the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is commuting.

It turns out that semi-commutation is too restrictive when applied to compatibility $\mathcal{I}$-operators, since there is only one semi-commuting family of compatibility $\mathcal{I}$-operators, namely, the Leibniz operator.

Theorem 1536 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-commuting family of compatibility* $\mathcal{I}$*-operators. Then* $O = \Omega$*.*

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T).$$

We get, using Compatibility,

$$O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) \le \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}.$$

So, we get $O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}$. Since, by hypothesis, O is a semi-commuting family, we now get

$$\begin{array}{rcl} O^{\mathcal{A}}(T) & = & O^{\mathcal{A}}(\pi^{-1}(T/\Omega^{\mathcal{A}}(T))) \\ & = & \pi^{-1}(O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T))) \\ & = & \pi^{-1}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}) \\ & = & \Omega^{\mathcal{A}}(T). \end{array}$$

We conclude that $O = \Omega$. ■

In particular, we have

Corollary 1537 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The Suszko operator* $\widetilde{\Omega}^{\mathcal{I}}$ *is semi-commuting if and only if* $\widetilde{\Omega}^{\mathcal{I}} = \Omega$*.*

Proof: If $\widetilde{\Omega}^{\mathcal{I}} = \Omega$, then, by Proposition 24, $\widetilde{\Omega}^{\mathcal{I}}$ is commuting and, hence,semi-commuting. If conversely, $\widetilde{\Omega}^{\mathcal{I}}$ is semi-commuting, then, by Theorem 1536, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$. ∎

21.6 Coherent $\mathcal{I}$-Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a family of $\mathcal{I}$-operators. Moreover, let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

- The morphism $\langle H, \gamma \rangle$ is said to be O-**compatible with** T if
$$\mathrm{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T);$$
- The morphism $\langle H, \gamma \rangle$ is said to be O-**compatible with** $\mathcal{T}$ if
$$\mathrm{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T},$$
i.e., if and only if
$$\mathrm{Ket}(\langle H, \gamma \rangle) \leq \widetilde{O}^{\mathcal{A}}(\mathcal{T}).$$

For the Leibniz operator, we have

Corollary 1538 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}, \mathcal{B}$ $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism.* $\langle H, \gamma \rangle$ *is* Ω*-compatible with* T *if and only if* $\mathrm{Ker}(\langle H, \gamma \rangle)$ *is compatible with* T*.*

Proof: We have $\langle H, \gamma \rangle$ is Ω-compatible with T if and only if, by definition, $\mathrm{Ker}(\langle H, \gamma \rangle) \leq \Omega^{\mathcal{A}}(T)$ if and only if, by the compatibility of $\Omega^{\mathcal{A}}(T)$ with T, $\mathrm{Ker}(\langle H, \gamma \rangle)$ is compatible with T. ∎

Moreover, for a family O of compatibility $\mathcal{I}$-operators, we get

Corollary 1539 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a family of compatibility* $\mathcal{I}$*-operators,* $\mathcal{A}, \mathcal{B}$ $\mathbf{F}$*-algebraic systems,* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. If* $\langle H, \gamma \rangle$ *is* O*-compatible with* T*, then:*

(a) $\langle H, \gamma \rangle$ *is* Ω*-compatible with* T*;*

(b) *If H is an isomorphism, $T = \gamma^{-1}(\gamma(T))$;*

(c) *If H is an isomorphism, $O^{\mathcal{A}}(T) = \gamma^{-1}(\gamma(O^{\mathcal{A}}(T))$.*

Proof:

(a) We have

$$\begin{array}{rcll}\mathrm{Ker}(\langle H,\gamma\rangle) & \leq & O^{\mathcal{A}}(T) & \text{(hypothesis)}\\ & \leq & \Omega^{\mathcal{A}}(T). & \text{(by Compatibility)}\end{array}$$

Thus, $\langle H,\gamma\rangle$ is Ω-compatible with T.

(b) Suppose H is an isomorphism. By Part (a) and Corollary 1539, we get $\mathrm{Ker}(\langle H,\gamma\rangle)$ is compatible with T. Therefore, $\gamma^{-1}(\gamma(T)) \leq T$. Since the reverse inclusion is always satisfied, we get $T = \gamma^{-1}(\gamma(T))$.

(c) Again the inclusion $O^{\mathcal{A}}(T) \leq \gamma^{-1}(\gamma(O^{\mathcal{A}}(T)))$ is always satisfied. So it suffices to show the reverse inclusion. So assume $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \gamma_\Sigma^{-1}(\gamma_\Sigma(O_\Sigma^{\mathcal{A}}(T)))$. Thus, by definition, $\langle\gamma_\Sigma(\phi),\gamma_\Sigma(\psi)\rangle \in \gamma_\Sigma(O_\Sigma^{\mathcal{A}}(T))$. Therefore, there exist $\phi',\psi' \in \mathrm{SEN}(\Sigma)$, with $\langle\phi',\psi'\rangle \in O_\Sigma^{\mathcal{A}}(T)$, such that $\langle\gamma_\Sigma(\phi),\gamma_\Sigma(\psi)\rangle = \langle\gamma_\Sigma(\phi'),\gamma_\Sigma(\psi')\rangle$. This shows that

$$\langle\phi,\phi'\rangle,\langle\psi,\psi'\rangle \in \mathrm{Ker}_\Sigma(\langle H,\gamma\rangle) \leq O_\Sigma^{\mathcal{A}}(T).$$

Since $\langle\phi',\psi'\rangle \in O_\Sigma^{\mathcal{A}}(T)$ and $O^{\mathcal{A}}(T)$ is an equivalence family, we get, using symmetry and transitivity, that $\langle\phi,\psi\rangle \in O_\Sigma^{\mathcal{A}}(T)$. We conclude that $\gamma^{-1}(\gamma(O^{\mathcal{A}}(T))) \leq O^{\mathcal{A}}(T)$.

■

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a family of $\mathcal{I}$-operators.

- O is called **coherent** if, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$, $\mathcal{B}$, every surjective morphism $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ and all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\langle H,\gamma\rangle\ O\text{-compatible with } \gamma^{-1}(T') \text{ implies } O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')).$$

- O is called **semi-coherent** if, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$, $\mathcal{B}$, every surjective morphism $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$, with H an isomorphism, and all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\langle H,\gamma\rangle\ O\text{-compatible with } \gamma^{-1}(T') \text{ implies } O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')).$$

Clearly, if O is coherent, then it is also semi-coherent.

We define the **identity** $\mathcal{I}$-operator

$$I = \{I^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\},$$

by letting, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $I^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$, be given, for all $T \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A})$, by

$$I^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}.$$

Lemma 1540 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The identity* I *is a coherent family of compatibility* $\mathcal{I}$*-operators.*

Proof: It is clear that $I^{\mathcal{A}}$ is a compatibility $\mathcal{I}$-operator, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. So it suffices to prove coherence. To this end, let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\mathrm{Ker}(\langle H, \gamma \rangle) \leq I^{\mathcal{A}}(\gamma^{-1}(T')) = \Delta^{\mathcal{A}}$. Thus, we have $\mathrm{Ker}(\langle H, \gamma \rangle) = \Delta^{\mathcal{A}}$. Now we get

$$\gamma^{-1}(I^{\mathcal{B}}(T')) = \gamma^{-1}(\Delta^{\mathcal{B}}) = \mathrm{Ker}(\langle H, \gamma \rangle) = \Delta^{\mathcal{A}} = I^{\mathcal{A}}(\gamma^{-1}(T)).$$

Thus, I is a coherent family of compatibility $\mathcal{I}$-operators. ∎

Another example of a coherent $\mathcal{I}$-operator is the Leibniz operator.

Lemma 1541 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The Leibniz operator* Ω *is a coherent family of compatibility operators.*

Proof: By definition Ω is a family of compatibility $\mathcal{I}$-operators. For coherence, assume that $\mathcal{A}$, $\mathcal{B}$ are $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Since, by Proposition 24, $\Omega^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$, we get that the coherence implication is trivially satisfied and, hence Ω is a coherent family of compatibility $\mathcal{I}$-operators. ∎

For semi-coherence of compatibility $\mathcal{I}$-operators, we get the following characterization.

Lemma 1542 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a family of compatibility* $\mathcal{I}$*-operators.* O *is semi-coherent if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$*,* $\mathcal{B}$*, all surjective morphisms* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$*, with* H *an isomorphism, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, if* $\langle H, \gamma \rangle$ *is* O*-compatible with* T*, then* $\gamma(O^{\mathcal{A}}(T)) = O^{\mathcal{B}}(\gamma(T))$*.*

Proof: Suppose, first, that O is semi-coherent and let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that

$$\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(T).$$

Then, by Corollary 1539, $\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(\gamma^{-1}(\gamma(T)))$. Applying semi-coherence gives

$$\begin{array}{rcl}\gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) & = & O^{\mathcal{A}}(\gamma^{-1}(\gamma(T))) \quad \text{(by semi-coherence)}\\ & = & O^{\mathcal{A}}(T). \quad \text{(by Corollary 1539)}\end{array}$$

By the surjectivity of $\langle H,\gamma\rangle$, $O^{\mathcal{B}}(\gamma(T)) = \gamma(O^{\mathcal{A}}(T))$.

Assume, conversely, that the condition in the statement holds. Let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that

$$\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(\gamma^{-1}(T')).$$

Then, we get

$$\begin{array}{rcl}O^{\mathcal{A}}(\gamma^{-1}(T')) & = & \gamma^{-1}(\gamma(O^{\mathcal{A}}(\gamma^{-1}(T')))) \quad \text{(by Corollary 1539)}\\ & = & \gamma^{-1}(O^{\mathcal{B}}(\gamma(\gamma^{-1}(T'))) \quad \text{(by hypothesis)}\\ & = & \gamma^{-1}(O^{\mathcal{B}}(T')). \quad \text{(by surjectivity of } \langle H,\gamma\rangle)\end{array}$$

So O is a semi-coherent family of compatibility $\mathcal{I}$-operators. ∎

We also have the following alternative characterization for semi-coherence of compatibility $\mathcal{I}$-operators.

Lemma 1543 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a family of compatibility $\mathcal{I}$-operators. O is semi-coherent if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$, $\mathcal{B}$ and all surjective morphisms $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$, with H an isomorphism,*

$$O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle)) = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}.$$

Proof: Suppose O is semi-coherent and let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

- If $T \in O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle))$, then, by definition, $\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(T)$. Thus, by Lemma 1542, $\gamma(O^{\mathcal{A}}(T)) = O^{\mathcal{B}}(\gamma(T))$. Hence,

$$\gamma^{-1}(\gamma(O^{\mathcal{A}}(T))) = \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))).$$

  Thus, by Corollary 1539, $O^{\mathcal{A}}(T) = \gamma^{-1}(O^{\mathcal{B}}(\gamma(T)))$.

- If $\gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)$, then we get $\mathrm{Ker}(\langle H,\gamma\rangle) = \gamma^{-1}(\Delta^{\mathcal{B}}) \le \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)$. Thus, $T \in O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle))$.

We conclude that $O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle)) = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}$.

Assume, conversely, that the condition of the statement holds. Let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(\gamma^{-1}(T'))$. Then $\gamma^{-1}(T') \in O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle))$, whence, by hypothesis,

$$\gamma^{-1}(O^{\mathcal{B}}(\gamma(\gamma^{-1}(T')))) = O^{\mathcal{A}}(\gamma^{-1}(T')).$$

By surjectivity of $\langle H,\gamma\rangle$, $\gamma^{-1}(O^{\mathcal{B}}(T')) = O^{\mathcal{A}}(\gamma^{-1}(T'))$ and, hence, O is a semi-coherent family of compatibility $\mathcal{I}$-operators. ■

Next we show that semi-coherence of compatibility $\mathcal{I}$-operators is preserved under relativization.

Proposition 1544 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$-operators. Then*

$$\widetilde{O}^{\mathcal{I}} = \{\widetilde{O}^{\mathcal{I},\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$$

is also a semi-coherent family of compatibility $\mathcal{I}$-operators.

Proof: It is easy to see that $\widetilde{O}^{\mathcal{I}}$ is also a compatibility operator. We have, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{array}{rcll} \widetilde{O}^{\mathcal{I},\mathcal{A}}(T) & = & \bigcap\{O^{\mathcal{A}}(T') : T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} & \text{(definition)}\\ & \le & \bigcap\{\Omega^{\mathcal{A}}(T') : T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} & \text{(compatibility)}\\ & \le & \Omega^{\mathcal{A}}(T). \quad \text{(set theory)} & \end{array}$$

Thus, $\widetilde{O}^{\mathcal{I}}$ is indeed a compatibility $\mathcal{I}$-operator.

For semi-coherence, assume $\mathcal{A}$, $\mathcal{B}$ are $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{O}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T'))$. We must show that

$$\widetilde{O}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\widetilde{O}^{\mathcal{I},\mathcal{B}}(T')).$$

Claim: We have

$$\{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(T') \le T\} = \{\gamma^{-1}(T'') : T' \le T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\}.$$

- Suppose $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\gamma^{-1}(T') \le T$. Then, by Corollary 1539, $T = \gamma^{-1}(\gamma(T))$, where, by Corollary 56, $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Moreover, by hypothesis and the surjectivity of $\langle H,\gamma\rangle$, $T' = \gamma(\gamma^{-1}(T')) \le \gamma(T)$. This proves the left-to-right inclusion.

- Let $T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Then, by Corollary 55, we obtain $\gamma^{-1}(T'') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by hypothesis, $\gamma^{-1}(T') \leq \gamma^{-1}(T'')$. This shows that the right-to-left inclusion also holds.

This proves the Claim. Now, based on the Claim, we reason as follows:

$$\begin{array}{rcl}\gamma^{-1}(\widetilde{O}^{\mathcal{I},\mathcal{B}}(T')) & = & \gamma^{-1}(\bigcap\{O^{\mathcal{B}}(T'') : T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\}) \\ & = & \bigcap\{\gamma^{-1}(O^{\mathcal{B}}(T'')) : T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\} \\ & = & \bigcap\{O^{\mathcal{A}}(\gamma^{-1}(T'')) : T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})\} \\ & & \text{(by Semi-Coherence of } O) \\ & = & \bigcap\{O^{\mathcal{A}}(T) : \gamma^{-1}(T') \leq T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & & \text{(by the Claim)} \\ & = & \widetilde{O}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T')).\end{array}$$

Thus, $\widetilde{O}^{\mathcal{I}}$ is indeed semi-coherent. ■

Proposition 1545 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a coherent family of compatibility* $\mathcal{I}$*-operators. Let, also,* $\mathcal{A}$*,* $\mathcal{B}$ *be* $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism. For all* $\mathcal{T}' \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B}')$*, such that* $\langle H, \gamma \rangle$ *is* O*-compatible with* $\gamma^{-1}(\mathcal{T}')$*,*

$$\widetilde{O}^{\mathcal{A}}(\gamma^{-1}(\mathcal{T}')) = \gamma^{-1}(\widetilde{O}^{\mathcal{B}}(\mathcal{T}')).$$

Proof: We have

$$\begin{array}{rcl}\gamma^{-1}(\widetilde{O}^{\mathcal{B}}(\mathcal{T}')) & = & \gamma^{-1}(\bigcap\{O^{\mathcal{B}}(T') : T' \in \mathcal{T}'\}) \\ & = & \bigcap\{\gamma^{-1}(O^{\mathcal{B}}(T')) : T' \in \mathcal{T}'\} \\ & = & \bigcap\{O^{\mathcal{A}}(\gamma^{-1}(T')) : T' \in \mathcal{T}'\} \\ & & \text{(hypothesis and coherence)} \\ & = & \bigcap\{O^{\mathcal{A}}(T) : T \in \gamma^{-1}(\mathcal{T}')\} \\ & = & \widetilde{O}^{\mathcal{A}}(\gamma^{-1}(\mathcal{T}')).\end{array}$$

■

Proposition 1546 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators. Let, also,* $\mathcal{A}$*,* $\mathcal{B}$ *be* $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism. For all* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\langle H, \gamma \rangle$ *is* O*-compatible with* $\mathcal{T}$*,* $\gamma(\widetilde{O}^{\mathcal{A}}(\mathcal{T})) = \widetilde{O}^{\mathcal{B}}(\gamma(\mathcal{T}))$*.*

Proof: By the hypothesis and Corollary 1539, we get that $\mathcal{T} = \gamma^{-1}(\gamma(\mathcal{T}))$. So exploiting Proposition 1545, we get

$$\begin{array}{rcl}\gamma(\widetilde{O}^{\mathcal{A}}(\mathcal{T})) & = & \gamma(\widetilde{O}^{\mathcal{A}}(\gamma^{-1}(\gamma(\mathcal{T})))) \\ & = & \gamma(\gamma^{-1}(\widetilde{O}^{\mathcal{B}}(\gamma(\mathcal{T})))) \\ & = & \widetilde{O}^{\mathcal{B}}(\gamma(\mathcal{T})).\end{array}$$

■

21.7 Semi-Coherence and Full Objects

We start by providing a characterization of the inverse operator associated with a semi-coherent family of compatibility $\mathcal{I}$-operators.

Proposition 1547 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^\mathcal{A} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\theta \in \mathrm{ConSys}(\mathcal{A})$*,*

$$\begin{array}{rcl} O^{\mathcal{A}^{-1}}(\theta) & = & \{T \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^\mathcal{A}(T)\} \\ & = & \pi^{-1}(\{T' \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^\mathcal{A}(\pi^{-1}(T'))\}), \end{array}$$

where $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\theta$ *denotes the quotient morphism.*

Proof: We have by hypothesis and Lemma 1543,

$$O^{\mathcal{A}^{-1}}(\theta) = \{T \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^\mathcal{A}(T)\}.$$

For the second equality, if $T \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A})$, such that $\pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^\mathcal{A}(T)$, then $T = \pi^{-1}(T/\theta)$ and, also,

$$\pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^\mathcal{A}(T) = O^\mathcal{A}(\pi^{-1}(T/\theta)).$$

This proves the left-to-right inclusion, since, by Corollary 57, we have $T/\theta \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}/\theta)$.

Assume, conversely, that $T' \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}/\theta)$, such that $\pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^\mathcal{A}(\pi^{-1}(T'))$. Then, by Corollary, 57, $\pi^{-1}(T') \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A})$ and, moreover,

$$\pi^{-1}(O^{\mathcal{A}/\theta}(\pi^{-1}(T')/\theta)) = \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^\mathcal{A}(\pi^{-1}(T')).$$

This proves the right-to-left-inclusion. ■

We now give a characterization of O-full $\mathcal{I}$-classes for semi-coherent families of congruential compatibility $\mathcal{I}$-operators.

Corollary 1548 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^\mathcal{A} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathcal{T} \subseteq \mathrm{FiFam}^\mathcal{I}(\mathcal{A})$*.* $\mathcal{T}$ *is* $O^\mathcal{A}$*-full if and only if, for some surjective* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$*, with* H *an isomorphism, which may be taken to be the quotient morphism* $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{O}(\mathcal{T})$*,*

$$\mathcal{T} = \{T \in \mathrm{FiFam}^\mathcal{I}(\mathcal{A}) : \gamma^{-1}(O^\mathcal{B}(\gamma(T))) = O^\mathcal{A}(T)\}.$$

Proof: Suppose $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$-full. By definition, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T}))$. Let $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})$ be the quotient morphism. Then we have $\mathcal{T} = O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle I,\pi\rangle))$ whence, by Proposition 1547,

$$\mathcal{T} = \{T \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(T)}(\pi(T))) = O^{\mathcal{A}}(T)\}.$$

Assume, conversely, that $\mathcal{T} = \{T \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}$, for some surjective $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$, with H an isomorphism. By Proposition 1547, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\mathrm{Ker}(\langle H,\gamma\rangle))$, whence $\mathcal{T} \in \mathrm{Ran}(O^{\mathcal{A}^{-1}})$, showing that $\mathcal{T}$ is $O^{\mathcal{A}}$-full. ∎

Corollary 1549 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $\mathcal{T}$ *is* $O^{\mathcal{A}}$*-full if and only if, for some* $\theta \in \mathrm{ConSys}(\mathcal{I})$*, which can be taken to be* $\widetilde{O}^{\mathcal{A}}(\mathcal{T})$*, and with* $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\theta$ *the corresponding quotient morphism,*

$$\mathcal{T} = \pi^{-1}(\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

Proof: Assume, first, that $\mathcal{T}$ is $O^{\mathcal{A}}$-full. Then, by definition, we have $\mathcal{T} = O^{\mathcal{A}^{-1}}(\widetilde{O}^{\mathcal{A}}(\mathcal{T}))$. Take $\theta = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$. Then $\mathcal{T} = O^{\mathcal{A}^{-1}}(\theta)$, whence, by Proposition 1547,

$$\mathcal{T} = \pi^{-1}(\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

Assume, conversely, that $\mathcal{T}$ is given by the displayed expression above, for some $\theta \in \mathrm{ConSys}(\mathcal{A})$ and $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\theta$ the quotient morphism. Then, by Proposition 1547, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\theta) \in \mathrm{Ran}(O^{\mathcal{A}^{-1}})$ and, therefore, $\mathcal{T}$ is $O^{\mathcal{A}}$-full, by definition. ∎

Turning, next, to the full congruence systems, we obtain the following characterization.

Proposition 1550 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*.* θ *is* $O^{\mathcal{A}}$*-full if and only if*

$$\widetilde{O}^{\mathcal{A}/\theta}(\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}) = \Delta^{\mathcal{A}/\theta},$$

where $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\theta$ *is the quotient morphism.*

Proof: Let $\mathcal{T}' = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}$. Then $\langle I,\pi\rangle$ is compatible with $\pi^{-1}(\mathcal{T}')$, since, for all $T' \in \mathcal{T}'$,

$$\mathrm{Ker}(\langle I,\pi\rangle) = \pi^{-1}(\Delta^{\mathcal{A}/\theta}) \leq \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T')).$$

Thus, by Propositions 1547 and 1545, θ is $O^{\mathcal{A}}$-full if and only if

$$\theta = \widetilde{O}^{\mathcal{A}}(O^{\mathcal{A}^{-1}}(\theta)) = \widetilde{O}^{\mathcal{A}}(\pi^{-1}(\mathcal{T}')) = \pi^{-1}(\widetilde{O}^{\mathcal{A}/\theta}(\mathcal{T}')).$$

Now, if θ is $O^{\mathcal{A}}$-full, then we get, using the surjectivity of the quotient morphism,

$$\begin{array}{rcl}\widetilde{O}^{\mathcal{A}/\theta}(\mathcal{T}') & = & \pi(\pi^{-1}(\widetilde{O}^{\mathcal{A}/\theta}(\mathcal{T}'))) \\ & = & \pi(\theta) = \Delta^{\mathcal{A}/\theta}.\end{array}$$

If, conversely, $\widetilde{O}^{\mathcal{A}/\theta}(\mathcal{T}') = \Delta^{\mathcal{A}/\theta}$, then $\theta = \pi^{-1}(\Delta^{\mathcal{A}/\theta}) = \pi^{-1}(\widetilde{O}^{\mathcal{A}/\theta}(\mathcal{T}'))$. Hence, by the equivalence detailed above, θ is $O^{\mathcal{A}}$-full. ■

Since Ω is a semi-coherent family of compatibility $\mathcal{I}$-operators, we now get

Corollary 1551 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*. Then*

$$\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)),$$

where $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\theta$ *is the quotient morphism.*

Proof: By Proposition 1547,

$$\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta') : \pi^{-1}(\Omega^{A/\theta}(T')) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

But, by Proposition 24, Ω is commuting and, hence,

$$\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta') : \pi^{-1}(\Omega^{A/\theta}(T')) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))\} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta).$$

Therefore, $\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$. ■

21.8 The General Correspondence Theorem

Theorem 1552 (General Correspondence Theorem) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators. Then, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$*, all surjective morphisms* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$*, with* H *an isomorphism, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, if* $\langle H, \gamma \rangle$ *is* O*-compatible with* T*, then* γ *induces an order isomorphism from* $[\![T]\!]^{O^{\mathcal{A}}}$ *onto* $[\![\gamma(T)]\!]^{O^{\mathcal{B}}}$*, with inverse* γ^{-1}*.*

Proof: Assume that $\langle H, \gamma \rangle$ is O-compatible with T. By Corollary 1539, $\langle H, \gamma \rangle$ is Ω-compatible with T. By the same Corollary and by Corollary 56, $T = \gamma^{-1}(\gamma(T))$ and $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$.

Suppose, next, that $T' \in [\![T]\!]^{O^{\mathcal{A}}}$. Then, $\mathrm{Ker}(\langle H,\gamma\rangle) \le O^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. Again, based on Corollaries 1539 and 56, we get $\gamma^{-1}(\gamma(T')) = T'$ and $\gamma(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Moreover, we get

$$\begin{array}{rcll} O^{\mathcal{B}}(\gamma(T)) & = & \gamma(O^{\mathcal{A}}(T)) & \text{(by Lemma 1542)} \\ & \le & \gamma(\Omega^{\mathcal{A}}(T')) & \\ & = & \Omega^{\mathcal{B}}(\gamma(T')). & \text{(by Lemma 1542)} \end{array}$$

Thus, $\gamma(T') \in [\![\gamma(T)]\!]^{O^{\mathcal{B}}}$.

Suppose, next, that $T'' \in [\![\gamma(T)]\!]^{O^{\mathcal{B}}}$. Then, we get $O^{\mathcal{B}}(\gamma(T)) \le \Omega^{\mathcal{B}}(T')$. By Corollary 55, $\gamma^{-1}(T'') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and by surjectivity, $\gamma(\gamma^{-1}(T'')) = T''$. Since $\langle H,\gamma\rangle$ is O-compatible with $T = \gamma^{-1}(\gamma(T))$, we get, using semi-coherence,

$$\begin{array}{rcl} O^{\mathcal{A}}(T) & = & O^{\mathcal{A}}(\gamma^{-1}(\gamma(T)) \\ & = & \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) \\ & \le & \gamma^{-1}(\Omega^{\mathcal{B}}(T')) \\ & = & \Omega^{\mathcal{A}}(\gamma^{-1}(T')). \end{array}$$

Hence, $\gamma^{-1}(T'') \in [\![T]\!]^{O^{\mathcal{A}}}$. We conclude that γ is a bijection from $[\![T]\!]^{O^{\mathcal{A}}}$ onto $[\![\gamma(T)]\!]^{O^{\mathcal{B}}}$, with inverse γ^{-1}. But, clearly, both γ and γ^{-1} are order preserving functions, whence they establish an order isomorphism between these two ordered sets. ■

The General Correspondence Theorem has the following consequence concerning O-filter systems on different $\mathbf{F}$-algebraic systems.

Corollary 1553 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators. Then, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$, *all surjective morphisms* $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$, *with* H *an isomorphism, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, *if* $\langle H,\gamma\rangle$ *is* O*-compatible with* T*, then*

$$T \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) \quad \textit{iff} \quad \gamma(T) \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{B}).$$

Proof: We have the following chain of equivalences:

$$\begin{array}{rll} T \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{A}) & \text{iff} & T = T^O \\ & \text{iff} & T = \bigcap [\![T]\!]^{O^{\mathcal{A}}} \\ & \text{iff} & \gamma(T) = \bigcap [\![\gamma(T)]\!]^{O^{\mathcal{B}}} \quad \text{(by Theorem 1552)} \\ & \text{iff} & \gamma(T) = \gamma(T)^O \\ & \text{iff} & \gamma(T) \in \mathrm{FiFam}^{\mathcal{I},O}(\mathcal{B}). \end{array}$$

Thus, the claim is established. ■

For semi-coherent congruential compatibility $\mathcal{I}$-operators, we obtain a relation between the O-filter systems on an algebraic system and those on the quotient algebraic system.

Corollary 1554 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T^O / O^{\mathcal{A}}(T) = (T / O^{\mathcal{A}}(T))^O$$

and it is the least $\mathcal{I}$*-filter family on* $\mathcal{A}/O^{\mathcal{A}}(T)$*.*

Proof: Consider the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/O^{\mathcal{A}}(T)$. $\langle I, \pi \rangle$ is surjective, with I an isomorphism, and it is O-compatible with T. By Theorem 1552, $\pi : [\![T]\!]^{O^{\mathcal{A}}} \to [\![T/O^{\mathcal{A}}(T)]\!]^{O^{\mathcal{A}/O^{\mathcal{A}}(T)}}$ is an order isomorphism with inverse π^{-1}. Since T^O is the least $\mathcal{I}$-filter family of $[\![T]\!]^{O^{\mathcal{A}}}$, it follows that $T^O/O^{\mathcal{A}}(T)$ must be the least $\mathcal{I}$-filter family of $[\![T/O^{\mathcal{A}}(T)]\!]^{O^{\mathcal{A}/O^{\mathcal{A}}(T)}}$, which is, by definition, $(T/O^{\mathcal{A}}(T))^O$. Finally, since $O^{\mathcal{A}/O^{\mathcal{A}}(T)}(T/O^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/O^{\mathcal{A}}(T)}$, it follows that $[\![T/O^{\mathcal{A}}(T)]\!]^{O^{\mathcal{A}/O^{\mathcal{A}}(T)}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/O^{\mathcal{A}}(T))$. Thus, $(T/O^{\mathcal{A}}(T))^O$ is the least $\mathcal{I}$-filter family on $\mathcal{A}/O^{\mathcal{A}}(T)$. ■

Finally, applying the General Correspondence Theorem to the relativization of an operator, we obtain the following:

Theorem 1555 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of compatibility* $\mathcal{I}$*-operators. Then, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$*, all surjective morphisms* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$*, with* H *an isomorphism, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, if* $\langle H, \gamma \rangle$ *is* $\widetilde{O}^{\mathcal{I}}$*-compatible with* T*, then* γ *induces an order isomorphism from* $[\![T]\!]^{\widetilde{O}^{\mathcal{I},\mathcal{A}}}$ *onto* $[\![\gamma(T)]\!]^{\widetilde{O}^{\mathcal{I},\mathcal{B}}}$*, with inverse* γ^{-1}*.*

Proof: It is clear that if O is a compatibility $\mathcal{I}$-operator, the same holds for $\widetilde{O}^{\mathcal{I}}$. Moreover, by Proposition 1544, if O is a semi-coherent family, then $\widetilde{O}^{\mathcal{I}}$ is also semi-coherent. Therefore, under the given hypotheses, we can apply Theorem 1552 with $\widetilde{O}^{\mathcal{I}}$ in place of O and the result immediately follows. ■

21.9 Algebraic Systems of $\mathcal{I}$-Operators

With a given family of congruential operators, there are associated several classes of algebraic systems, which it is the purpose of this section to study closely, in analogy to the various classes ensued from applications of the Leibniz operator, and to explore their interrelationships.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a family of congruential $\mathcal{I}$-operators. We define the following classes of $\mathbf{F}$-algebraic systems associated with O (assuming closure under isomorphisms):

- $\mathrm{AlgSys}^O(\mathcal{I}) = \{\mathcal{A}/O^{\mathcal{A}}(T) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$;
- $\mathrm{AlgSys}_O(\mathcal{I}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(O^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}$;
- $\mathrm{AlgSys}^{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) = \{\mathcal{A}/\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$;
- $\mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}$;
- $\mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I}) = \{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), \mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$;
- $\mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\exists \mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}})\}$.

Names corresponding to these classes go as follows:

- $\mathrm{AlgSys}^O(\mathcal{I})$ is the class of O-**reduced F-algebraic systems**;
- $\mathrm{AlgSys}_O(\mathcal{I})$ is the class of O-**reductions of F-algebraic systems**;
- $\mathrm{AlgSys}^{\widetilde{O}^{\mathcal{I}}}(\mathcal{I})$ is the class of $\widetilde{O}^{\mathcal{I}}$-**reduced F-algebraic systems**;
- $\mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I})$ is the class of $\widetilde{O}^{\mathcal{I}}$-**reductions of F-algebraic systems**;
- $\mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I})$ is the class of $\widetilde{O}$-**reduced F-algebraic systems**;
- $\mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I})$ is the class of $\widetilde{O}$-**reductions of F-algebraic systems**.

We provide some alternative characterizations for the classes associated with the lifting $\widetilde{O}$ of the operator O.

Lemma 1556 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ a family of congruential $\mathcal{I}$-operators.*

(a) $\mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I}) = \{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), \mathcal{T}\ O^{\mathcal{A}}\text{-full}\}$*;*

(b) $\mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}) = \{\mathcal{A} : \widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}\}$*;*

(c) $\mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}) = \{\mathcal{A} : (\exists \mathcal{T}\ O^{\mathcal{A}}\text{-full})(\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}})\}$.

Proof: Note that, for all three equalities claimed, the right-to-left inclusions are trivial, given the definitions of the corresponding classes on the left. Therefore, in working out the various parts, it suffices to show the left-to-right inclusions.

(a) Suppose that $\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I})$, for some $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{A}}(\mathcal{A})$. Since $\widetilde{O}^{\mathcal{A}}(\mathcal{T})$ is by definition, an O-full congruence system on $\mathcal{A}$, there exists, by Corollary 1521, an O-full $\mathcal{T}' \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{A}}(\mathcal{T}') = \widetilde{O}^{\mathcal{A}}(\mathcal{T})$. Thus, we get $\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}') \in \{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T\ O^{\mathcal{A}}\text{-full}\}$.

(b) Assume $\mathcal{A} \in \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I})$. Then, by definition, there exists a collection $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. Therefore,

$$\widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{A}}(\mathcal{A})) \leq \widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}.$$

Thus, $\widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$. We get that $\mathcal{A} \in \{\mathcal{A} : \widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}\}$.

(c) This follows directly from Part (b) and Corollary 1523. ∎

We now show that the three pairs of classes of reduced - classes of reductions, associated with the same operator, consist of identical classes of **F**-algebraic systems. This is due to the fact that the reduction of an **F**-algebraic system results in a reduced **F**-algebraic system, taken with respect to the same operator.

Lemma 1557 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. For all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\theta \in \mathrm{ConSys}(\mathcal{A})$*,*

$$\theta \leq O^{\mathcal{A}}(T) \quad \textit{implies} \quad O^{\mathcal{A}/\theta}(T/\theta) = O^{\mathcal{A}}(T)/\theta.$$

In particular, $O^{\mathcal{A}/O^{\mathcal{A}}(T)}(T/O^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/O^{\mathcal{A}}(T)}$*.*

Proof: Let $\mathcal{A}$ be an **F**-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\theta \in \mathrm{ConSys}(\mathcal{A})$, such that $\theta \leq O^{\mathcal{A}}(T)$. Consider the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\theta$. It is surjective and, by hypothesis, O-compatible with T. By the assumption of semi-coherence and Lemma 1542, we get

$$O^{\mathcal{A}/\theta}(T/\theta) = O^{\mathcal{A}/\theta}(\pi(T)) = \pi(O^{\mathcal{A}}(T)) = O^{\mathcal{A}}(T)/\theta.$$

The last assertion in the statement is the specialization of what was just proven for $\theta = O^{\mathcal{A}}(T)$. ∎

Proposition 1558 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators. Then*

$$\mathrm{AlgSys}^{O}(\mathcal{I}) = \mathrm{AlgSys}_{O}(\mathcal{I}).$$

Proof: Suppose $\mathcal{A} \in \mathrm{AlgSys}_{O}(\mathcal{I})$. Then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $O^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. But then $\mathcal{A} \cong \mathcal{A}/\Delta^{\mathcal{A}} = \mathcal{A}/O^{\mathcal{A}}(T) \in \mathrm{AlgSys}^{O}(\mathcal{I})$.

On the other hand, if $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ so that $\mathcal{A}/O^{\mathcal{A}}(T) \in \mathrm{AlgSys}^{O}(\mathcal{I})$, then, for $T/O^{\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/O^{\mathcal{A}}(T))$, we get, by Lemma 1557,

$$O^{\mathcal{A}/O^{\mathcal{A}}(T)}(T/O^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/O^{\mathcal{A}}(T)},$$

whence, by definition $\mathcal{A}/O^{\mathcal{A}}(T) \in \mathrm{AlgSys}_{O}(\mathcal{I})$. ∎

Corollary 1559 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators. Then*

$$\mathrm{AlgSys}^{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) = \mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}).$$

Proof: By Proposition 1544 together with Proposition 1558. ∎

Lemma 1560 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. For all* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$

$$\widetilde{O}^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}(\mathcal{T}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})) = \Delta^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}.$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})$. It is surjective and O-compatible with $\mathcal{T}$. By the assumption of semi-coherence and Proposition 1546, we get

$$\begin{array}{rcl}\widetilde{O}^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}(\mathcal{T}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})) & = & \widetilde{O}^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}(\pi(\mathcal{T})) \\ & = & \pi(\widetilde{O}^{\mathcal{A}}(\mathcal{T})) \\ & = & \widetilde{O}^{\mathcal{A}}(\mathcal{T})/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \\ & = & \Delta^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}.\end{array}$$

This concludes the proof of the statement. ∎

Proposition 1561 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators. Then*

$$\mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I}) = \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}).$$

Proof: Suppose $\mathcal{A} \in \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I})$. Then, there exists $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{O}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. But then $\mathcal{A} \cong \mathcal{A}/\Delta^{\mathcal{A}} = \mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I})$.

On the other hand, if $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ so that $\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I})$, then, for $\mathcal{T}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}))$, we get, by Lemma 1560,

$$\widetilde{O}^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})}(\mathcal{T}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})) = \Delta^{\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T})},$$

whence, by definition $\mathcal{A}/\widetilde{O}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I})$. ∎

Proposition 1562 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $O = \{O^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ *a semi-coherent family of congruential compatibility* $\mathcal{I}$*-operators. Then*

$$\mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I}) = \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}) = \mathrm{AlgSys}^{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) = \mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}).$$

Proof: For every **F**-algebraic system and every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. This equality gives that

$$\mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) \subseteq \mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I}) \quad \text{and} \quad \mathrm{AlgSys}^{\widetilde{O}^{\mathcal{I}}}(\mathcal{I}) \subseteq \mathrm{AlgSys}^{\widetilde{O}}(\mathcal{I}).$$

Assume, conversely, in the first case, that $\mathrm{AlgSys}_{\widetilde{O}}(\mathcal{I})$. By Lemma 1556, $\widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$. Let $T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we get

$$\widetilde{O}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{O}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) = \widetilde{O}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}.$$

This shows that $\mathcal{A} \in \mathrm{AlgSys}_{\widetilde{O}^{\mathcal{I}}}(\mathcal{I})$. Due to Corollary 1559 and Proposition 1561 the equality just proven suffices to guarantee the conclusion. ∎

21.10 Leibniz Operator as an $\mathcal{I}$-Operator

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on **F**. We consider in this section the Leibniz operator

$$\Omega = \{\Omega^{\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\},$$

which is a coherent, congruential, compatibility $\mathcal{I}$-operator. We saw that its lifting is the Tarski operator $\widetilde{\Omega}$ and its relativization is the Suszko operator $\widetilde{\Omega}^{\mathcal{I}}$. Using the definition, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\theta \in \mathrm{ConSys}(\mathcal{A})$, we have

$$\begin{aligned} \Omega^{\mathcal{A}^{-1}}(\theta) &= \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \theta \le \Omega^{\mathcal{A}}(T)\} \\ &= \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \theta \text{ is compatible with } T\}. \end{aligned}$$

We have the following characterizations of Ω-full objects:

Proposition 1563 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on **F**, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an **F**-algebraic system and $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. $\mathcal{T}$ is Ω-full if and only if $\langle \mathcal{A}, \mathcal{T} \rangle$ is a full $\mathcal{I}$-structure.*

Proof: We have

$$\begin{aligned} \mathcal{T} \text{ is } \Omega\text{-full} \quad &\text{iff} \quad \mathcal{T} = \Omega^{\mathcal{A}^{-1}}(\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})) \\ &\qquad \text{(by definition of } \Omega\text{-full)} \\ &\text{iff} \quad \mathcal{T} = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')\} \\ &\qquad \text{(by definition of } \Omega^{\mathcal{A}^{-1}}) \\ &\text{iff} \quad \langle \mathcal{A}, \mathcal{T} \rangle \text{ is a full } \mathcal{I}\text{-structure.} \\ &\qquad \text{(by Theorem 1395)} \end{aligned}$$

∎

Recall that $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ denotes the collection of all $\mathrm{AlgSys}(\mathcal{I})$-congruence systems on an **F**-algebraic system $\mathcal{A}$, i.e., those congruence systems θ on $\mathcal{A}$, such that $\mathcal{A}/\theta \in \mathrm{ConSys}(\mathcal{I})$. For Ω-full congruence systems, we get

Proposition 1564 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*.* θ *is* Ω*-full if and only if* $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: We have

$$\begin{array}{lll} \theta \text{ is } \Omega\text{-full} & \text{iff} & \widetilde{\Omega}^{\mathcal{A}/\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}/\theta} \\ & & \text{(by Proposition 1550)} \\ & \text{iff} & \mathcal{A}/\theta \in \mathrm{AlgSys}(\mathcal{I}) \\ & & \text{(by Proposition 1399)} \\ & \text{iff} & \theta \in \mathrm{ConSys}(\mathcal{A}). \\ & & \text{(by definition).} \end{array}$$

■

As a corollary of these two characterizations, we can derive from our work on Galois connections (more precisely Corollary 1521) the Isomorphism Theorem 1408 between full $\mathcal{I}$-structures and $\mathcal{I}$-congruence systems.

Corollary 1565 (Isomorphism Theorem 1408) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. The operators* $\widetilde{\Omega}^{\mathcal{A}}$ *and* $\Omega^{\mathcal{A}^{-1}}$ *establish a Galois connection between* $\mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$ *and* $\mathrm{EqvFam}(\mathcal{A})$*, which restricts to mutually inverse isomorphisms between* $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ *and* $\langle \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$*.*

Proof: By Corollary 1521 and Propositions 1563 and 1564, noting that the order on $\langle \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is the converse from that inherited by $\langle \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})), \subseteq \rangle$. ■

By applying Proposition 1522 to the Leibniz operator, we get a characterization of full $\mathcal{I}$-structures.

Proposition 1566 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $\langle \mathcal{A}, \mathcal{T} \rangle$ *is a full* $\mathcal{I}$*-structure if and only if* $\mathcal{T}$ *is the largest collection* $\mathcal{D} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$*.*

Proof: By instantiating Proposition 1522 to the Leibniz operator. ■

Moreover, directly from Lemma 1518, we get:

Proposition 1567 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if* $\widetilde{\Omega}^{\mathcal{I}} = \Omega$*.*

Proof: By instantiating Lemma 1518 to the Leibniz operator. ■

We turn now to Ω-classes and Ω-filter families. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

The Ω-**class of** T or **Leibniz class of** T is

$$[\![T]\!]^* := \Omega^{\mathcal{A}^{-1}}(\Omega^{\mathcal{A}}(T)) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\}.$$

The **Leibniz filter family of** T is the $\mathcal{I}$-filter family

$$T^* = \bigcap [\![T]\!]^*.$$

We say that T is a **Leibniz filter family** if $T^* = T$. The collection of all Leibniz filter families of $\mathcal{A}$ is denoted by $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$.

We further denote by $[T]$ the **equi-Leibniz class of** T, i.e., the collection of all $\mathcal{I}$-filter families of $\mathcal{A}$ that share the same Leibniz congruence system with T:

$$[T] = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)\} \subseteq [\![T]\!]^*.$$

Some basic properties involving these concepts follow.

Lemma 1568 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

(a) $T^* \leq \bigcap [T] \leq T$*;*

(b) If $T^* = T$*, then* $T = \bigcap [T]$*;*

(c) If $\mathcal{I}$ *is protoalgebraic, then* $T = T^*$ *if and only if* $T = \bigcap [T]$*.*

Proof:

(a) We have $T^* = \bigcap [\![T]\!]^* \leq \bigcap [T] \leq T$.

(b) If $T^* = T$, then, by Part (a), $T = \bigcap [T]$.

(c) Suppose that $\mathcal{I}$ is protoalgebraic. The necessity is given by Part (b). For the sufficiency, assume that $T = \bigcap [T]$. Since, by Part (a), $T^* \leq T$, by protoalgebraicity, $\Omega^{\mathcal{A}}(T^*) \leq \Omega^{\mathcal{A}}(T)$. Since $T^* \in [\![T]\!]^*$, we get, by definition, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^*)$. Hence, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^*)$ and, therefore, $T^* \in [T]$. Now we conclude that $T = \bigcap [T] \leq T^*$. By Part (a), the reverse inclusion always holds.

■

Proposition 1569 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

(a) $\langle \mathcal{A}, [\![T]\!]^* \rangle \in \mathrm{FStr}(\mathcal{I})$*;*

(b) $\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^*) = \Omega^{\mathcal{A}}(T)$*.*

Proof: By Proposition 1563, $\langle\mathcal{A},[\![T]\!]^*\rangle$ is a full $\mathcal{I}$-structure. Since $T\in[\![T]\!]^*$, it follows that $\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^*)\le\Omega^{\mathcal{A}}(T)$. On the other hand, for all $T'\in[\![T]\!]^*$, $\Omega^{\mathcal{A}}(T)\le\Omega^{\mathcal{A}}(T')$. Thus, $\Omega^{\mathcal{A}}(T)\le\bigcap_{T'\in[\![T]\!]^*}\Omega^{\mathcal{A}}(T')=\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^*)$. ■

It turns out that, for every theory family, its Leibniz counterpart is in fact a Leibniz theory family.

Proposition 1570 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then* $T^*\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$*.*

Proof: By Lemma 1568, we have $(T^*)^*\le T^*$. On the other hand, $T^*\in[\![T]\!]^*$. So, by definition $\Omega^{\mathcal{A}}(T)\le\Omega^{\mathcal{A}}(T^*)$. This shows that $[\![T^*]\!]^*\subseteq[\![T]\!]^*$. This, in turn, yields $T^*=\bigcap[\![T]\!]^*\le\bigcap[\![T^*]\!]^*=(T^*)^*$. We conclude that $(T^*)^*=T^*$ and, hence, $T^*\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

We also have a characterization of Leibniz filter families in terms of full structures.

Proposition 1571 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $T\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ *if and only if, there exists* $\langle\mathcal{A},\mathcal{T}\rangle\in\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$*, such that* $T=\bigcap\mathcal{T}$*.*

Proof: Suppose, first, that $T\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Then $T=T^*=\bigcap[\![T]\!]^*$ and, by Proposition 1569, $\langle\mathcal{A},[\![T]\!]^*\rangle$ is a full $\mathcal{I}$-structure.

Assume, conversely, that $T=\bigcap\mathcal{T}$, with $\langle\mathcal{A},\mathcal{T}\rangle\in\mathrm{FStr}(\mathcal{I})$. Since $T=\bigcap\mathcal{T}\in\mathcal{T}$, we get $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})\le\Omega^{\mathcal{A}}(T)$. Thus, we get

$$[\![T]\!]^*=\Omega^{\mathcal{A}^{-1}}(\Omega^{\mathcal{A}}(T))\subseteq\Omega^{\mathcal{A}^{-1}}(\widetilde{\Omega}^{\mathcal{A}}(T))=\mathcal{T}.$$

So $T=\bigcap\mathcal{T}\le\bigcap[\![T]\!]^*=T^*$. Since, by Lemma 1568, $T^*\le T$, we conclude that $T^*=T$ and, hence, $T\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

Corollary 1554, applied to the Leibniz operator, gives another characterization of Leibniz filter families.

Proposition 1572 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $T\in\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ *if and only if* $T/\Omega^{\mathcal{A}}(T)$ *is the least filter family in* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$*.*

Proof: By specializing Corollary 1554 to the Leibniz operator. ■

Leibniz filter families may also be used in characterizing the reflectivity of the Leibniz operator, which characterizes family reflective π-institutions.

Proposition 1573 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. Ω *is reflective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof: We have that Ω is reflective if and only if, by definition, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad T \le T',$$

if and only if, by definition of $[\![T]\!]^*$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T' \in [\![T]\!]^*$ implies $T \le T'$, if and only if, since $T^* = \min [\![T]\!]^*$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T = T^*$, if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Surjective morphisms between algebraic systems, with isomorphic signature components, that satisfy a compatibility condition, induce order isomorphisms between Leibniz classes, which restrict to order isomorphisms between equi-Leibniz classes.

Theorem 1574 (Correspondence Theorem for Leibniz Classes) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems,* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism, and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. *If* $\langle H, \gamma \rangle$ *is* Ω*-compatible with* T*, then* γ *induces an order isomorphism from* $[\![T]\!]^*$ *onto* $[\![\gamma(T)]\!]^*$*, with inverse* γ^{-1}*. In addition, for all* $T' \in [\![T]\!]^*$, γ *induces an order isomorphism from* $[T']$ *onto* $[\gamma(T')]$.

Proof: The first statement follows from the General Correspondence Theorem 1552 by instantiation to the Leibniz operator. So we undertake the proof of the additional statement. Suppose that $T', T'' \in [\![T]\!]^*$. Since $T' \in [\![T]\!]^*$, we get $[T'] \subseteq [\![T']\!]^* \subseteq [\![T]\!]^*$. Thus, by the first statement, $\gamma^{-1}(\gamma(T')) = T'$ and $\gamma^{-1}(\gamma(T'')) = T''$. Thus, we get

$$\begin{array}{rll} \Omega^{\mathcal{A}}(T'') = \Omega^{\mathcal{A}}(T') & \text{iff} & \Omega^{\mathcal{A}}(\gamma^{-1}(\gamma(T''))) = \Omega^{\mathcal{A}}(\gamma^{-1}(\gamma(T'))) \\ & \text{iff} & \gamma^{-1}(\Omega^{\mathcal{B}}(\gamma(T''))) = \gamma^{-1}(\Omega^{\mathcal{B}}(\gamma(T'))) \\ & \text{iff} & \Omega^{\mathcal{B}}(\gamma(T'')) = \Omega^{\mathcal{B}}(\gamma(T')). \end{array}$$

So $T'' \in [T']$ if and only if $\gamma(T'') \in [\gamma(T')]$. Thus, the order isomorphism $\gamma : [\![T]\!]^* \to [\![\gamma(T)]\!]^*$ restricts to an order isomorphism $\gamma : [T] \to [\gamma(T)]$. ■

As a consequence of Correspondence Theorem, we get a correspondence between Leibniz filter families.

Corollary 1575 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems,* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism, and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. *If* $\langle H, \gamma \rangle$ *is* Ω*-compatible with* T*, then*

$$T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \quad \textit{iff} \quad \gamma(T) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B}).$$

Proof: By Theorem 1574, under the isomorphism $\gamma : [\![T]\!]^* \to [\![\gamma(T)]\!]^*$, the least theory family T^* of $[\![T]\!]^*$ corresponds to the least theory family $\gamma(T)^*$ of $[\![\gamma(T)]\!]^*$. Therefore, $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ if and only if $T = T^*$ if and only if $\gamma(T) = \gamma(T)^*$ if and only if $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B})$. ■

Rephrased in terms of strict surjective morphisms Corollary 1575 yields

Corollary 1576 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ *two* $\mathbf{F}$*-algebraic systems,* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T' \in \mathrm{FiFam}^{\mathcal{A}}(\mathcal{B})$ *and* $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ *a strict surjective morphism, with* H *an isomorphism. Then*

$$T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \quad \textit{iff} \quad T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{B}).$$

Proof: It suffices to show that $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ is Ω-compatible with T. If that is the case, then, since $T = \gamma^{-1}(T')$, we get, $T' = \gamma(\gamma^{-1}(T')) = \gamma(T)$, and the statement follows by applying Corollary 1575. We have, indeed

$$\begin{array}{rcl}\mathrm{Ker}(\langle H, \gamma \rangle) & = & \gamma^{-1}(\Delta^{\mathcal{B}}) \\ & \leq & \gamma^{-1}(\Omega^{\mathcal{B}}(T')) \\ & = & \Omega^{\mathcal{A}}(\gamma^{-1}(T')) \\ & = & \Omega^{\mathcal{A}}(T).\end{array}$$

Therefore, $\langle H, \gamma \rangle$ is indeed compatible with T. ■

The Correspondence Theorem 1574 allows us to formulate a Correspondence Theorem for the special case of protoalgebraic π-institutions that, as it turns out, provides an additional characterization of protoalgebraicity.

Theorem 1577 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ *and every strict surjective morphism* $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$*, with* H *an isomorphism,* γ *induces an order isomorphism from* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *onto* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$*, with inverse* γ^{-1}*.*

Proof: Suppose, first, that $\mathcal{I}$ is protoalgebraic and let $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ be a strict surjective morphism, with H an isomorphism. Then, we get $T = \gamma^{-1}(T')$ and $T' = \gamma(\gamma^{-1}(T')) = \gamma(T)$. So $T = \gamma^{-1}(\gamma(T))$. This implies that $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ is compatible with T. By the Correspondence Theorem for Leibniz Classes 1574, γ induces an order isomorphism $\gamma : [\![T]\!]^* \to [\![T']\!]^*$, with inverse γ^{-1}. But, by protoalgebraicity, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ and $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ are upsets of $[\![T]\!]^*$ and $[\![T']\!]^*$, respectively and T corresponds to T' under γ. Therefore, γ restricts to an order isomorphism $\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$, with inverse γ^{-1}.

Suppose, conversely, that the given condition holds. Let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Consider the quotient morphism $\langle I,\pi\rangle : \mathcal{F} \to \mathcal{F}/\Omega(T)$. It gives a strict surjective morphism

$$\langle I,\pi\rangle : \langle \mathcal{F},T\rangle \to \langle \mathcal{F}/\Omega(T), T/\Omega(T)\rangle.$$

Since, by hypothesis, $\pi : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})^T \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\Omega(T))^{T/\Omega(T)}$ is an order isomorphism. with inverse π^{-1} and, clearly, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})^T$, we get that $\pi(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\Omega(T))^{T/\Omega(T)}$ and $T' = \pi^{-1}(\pi(T'))$. Now we get

$$\begin{array}{rcl}\Omega(T) & = & \mathrm{Ker}(\langle I,\pi\rangle)\\ & = & \pi^{-1}(\Delta^{\mathcal{F}/\Omega(T)})\\ & \leq & \pi^{-1}(\Omega^{\mathcal{F}/\Omega(T)}(\pi(T')))\\ & = & \Omega(\pi^{-1}(\pi(T')))\\ & = & \Omega(T').\end{array}$$

Since Ω is monotone, we conclude that $\mathcal{I}$ is a protoalgebraic π-institution. ■

Now we get a characterization of those full $\mathcal{I}$-structures whose closure families are Leibniz classes.

Proposition 1578 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\langle \mathcal{A},\mathcal{T}\rangle$ *is a full* $\mathcal{I}$*-structure. Then* $\mathcal{T} = [\![T]\!]^*$*, for some* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, if and only if* $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^*(\mathcal{I})$*.*

Proof: Suppose, first, that $\mathcal{T} = [\![T]\!]^*$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, using Proposition 1569, we get

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^*) = \Omega^{\mathcal{A}}(T).$$

Therefore, $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I})$.

Assume, conversely, that $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^*(\mathcal{I})$. By definition, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}))$, such that $\Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}(T) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}$. This equality implies that $[\![T]\!]^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}))$. Now consider the quotient morphism $\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$. Since, by hypothesis $\langle \mathcal{A},\mathcal{T}\rangle$ is a full $\mathcal{I}$-structure, we get

$$\mathcal{T} = \pi^{-1}(\mathcal{T}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})) = \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}))) = \pi^{-1}([\![T]\!]^*).$$

Moreover,

$$\mathrm{Ker}(\langle I,\pi\rangle) = \pi^{-1}(\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}) = \pi^{-1}(\Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}(T)) = \Omega^{\mathcal{A}}(\pi^{-1}(T)).$$

So $\langle I,\pi\rangle$ is Ω-compatible with $\pi^{-1}(T)$. By the Correspondence Theorem for Leibniz Classes 1574, we get an order isomorphism $\pi : [\![\pi^{-1}(T)]\!]^* \to [\![T]\!]^*$. This gives $\mathcal{T} = \pi^{-1}([\![T]\!]^*) = [\![\pi^{-1}(T)]\!]^*$. ■

We get, as a consequence, a characterization of those π-institutions for which all full $\mathcal{I}$-structures are determined by Leibniz classes of $\mathcal{I}$-filter families.

Proposition 1579 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, [\![T]\!]^* \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$ *if and only if* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$*.*

Proof: Suppose, first, that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, [\![T]\!]^* \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$. Since $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$ holds in general, it suffices to show the reverse inclusion. To this end, let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Thus, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Since $[\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, we get, by hypothesis, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $[\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} = [\![T']\!]^*$. Now notice the following:

- $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq [\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}}$, whence $\Omega^{\mathcal{A}}(T') \leq \bigcap_{T \leq T''} \Omega^{\mathcal{A}}(T'') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$;
- $T' \in [\![T']\!]^*$ implies $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

We conclude that $\Omega^{\mathcal{A}}(T') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Hence, we have $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$.

Assume, conversely, that $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. Since, by Proposition 1569, we have, in general, $\{\langle \mathcal{A}, [\![T]\!]^* \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, it suffices to show the reverse inclusion. To this end, let $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. Then $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}(\mathcal{I})$. By hypothesis, $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}^*(\mathcal{I})$. Therefore, by Proposition 1578, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\mathcal{T} = [\![T]\!]^*$. ■

So, one way to characterize π-institutions $\mathcal{I}$ for which $\mathcal{I}$-algebraic systems and $\mathcal{I}^*$-algebraic systems coincide is to look at the form of full $\mathcal{I}$-structures. An alternative characterization uses the Leibniz and Suszko operators.

Proposition 1580 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, there exists* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$*.*

Proof: Assume $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, so that $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{AlgSys}(\mathcal{I})$. By Proposition 1579, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $[\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}} = [\![T']\!]^*$. We now get

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\widetilde{\Omega}^{\mathcal{I}}}) = \widetilde{\Omega}^{\mathcal{A}}([\![T']\!]^*) = \Omega^{\mathcal{A}}(T').$$

Assume, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. By hypothesis, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. We conclude that $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. The reverse inclusion always holds. Therefore, $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. ■

Proposition 1580, gives the following feature of protoalgebraic π-institutions.

Corollary 1581 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is protoalgebraic, then every full* $\mathcal{I}$*-structure is of the form* $\langle \mathcal{A}, [\![T]\!]^* \rangle$*, for some* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and some* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: We know that, if $\mathcal{I}$ is protoalgebraic and $\mathcal{A}$ is an $\mathbf{F}$-algebraic system, then, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T)$. Therefore, by Proposition 1580 and Proposition 1579, every full $\mathcal{I}$-structure has the form claimed in the statement. ∎

This property of the full $\mathcal{I}$-structures in a more precise form, yields a characterization of protoalgebraicity.

Theorem 1582 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is protoalgebraic;*

(ii) Every full $\mathcal{I}$*-structure is of the form* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$*, for some* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and some* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) Every full $\mathcal{I}$*-structure is of the form* $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$*, for some* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and some* $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$*;*

(iv) $[\![T]\!]^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof:

(i)⇒(ii) Suppose that $\mathcal{I}$ is protoalgebraic and let $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. By Proposition 1563, $\mathcal{T} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \leq \Omega^{\mathcal{A}}(T)\}$. By protoalgebraicity, $\mathcal{T}$ is an upset in $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, $\mathcal{T}$ has a least element, $T = \bigcap \mathcal{T}$. Thus, we have $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\cap \mathcal{T}}$.

(ii)⇒(iii) Assume (ii) holds and let $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$. Then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. By Proposition 1571, $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$.

(iii)⇒(iv) Assume (iii) holds and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Proposition 1569, $\langle \mathcal{A}, [\![T]\!]^* \rangle \in \mathrm{FStr}(\mathcal{I})$. By Proposition 1570, $T^* \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ and, by definition $T^* = \bigcap [\![T]\!]^*$. Thus, by (iii), we get $[\![T]\!]^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$.

(iv)⇒(i) Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Then, by Lemma 1568, $T^* \leq T \leq T'$. By hypothesis, $T' \in [\![T]\!]^*$. So we get, by definition of $[\![T]\!]^*$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Since Ω is monotone on every $\mathbf{F}$-algebraic system, we get that $\mathcal{I}$ is protoalgebraic. ∎

21.11 Suszko Operator as an $\mathcal{I}$-Operator

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

The $\widetilde{\Omega}^{\mathcal{I}}$**-class of** T or **Suszko class of** T is

$$[\![T]\!]^{\mathsf{Su}} = \Omega^{\mathcal{A}^{-1}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\}.$$

The **Suszko filter family of** T is

$$T^{\mathsf{Su}} = \bigcap [\![T]\!]^{\mathsf{Su}}.$$

T is a **Suszko filter family** if $T^{\mathsf{Su}} = T$. The collection of all Suszko filter families of $\mathcal{A}$ is denoted by $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$.

The following lemma gives some of the basic properties of Suszko classes and Suszko theory families.

Lemma 1583 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

(a) $T^{\mathsf{Su}} \leq T^* \leq T$*;*

(b) $T^{\mathsf{Su}} = T$ *implies* $T^* = T$*;*

(c) If $T \leq T'$*, then* $[\![T']\!]^{\mathsf{Su}} \subseteq [\![T]\!]^{\mathsf{Su}}$ *and* $T^{\mathsf{Su}} \leq T'^{\mathsf{Su}}$*;*

(d) $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq [\![T]\!]^{\mathsf{Su}} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^{\mathsf{Su}}}$*;*

(e) $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *if and only if* $T^{\mathsf{Su}} = T$*.*

Proof:

(a) We have $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$. Hence $[\![T]\!]^* \subseteq [\![T]\!]^{\mathsf{Su}}$. This gives

$$T^{\mathsf{Su}} = \bigcap [\![T]\!]^{\mathsf{Su}} \leq [\![T]\!]^* = T^*.$$

The last inequality is by Lemma 1568.

(b) If $T = T^{\mathsf{Su}}$, then, by Part (a), $T = T^*$.

(c) If $T \leq T'$, by the monotonicity of the Suszko operator, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Thus, we get $[\![T']\!]^{\mathsf{Su}} \subseteq [\![T]\!]^{\mathsf{Su}}$. Finally, $T^{\mathsf{Su}} = \bigcap [\![T]\!]^{\mathsf{Su}} \leq \bigcap [\![T']\!]^{\mathsf{Su}} = T'^{\mathsf{Su}}$.

(d) Suppose $T \leq T'$. Then $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T')$. So $T' \in [\![T]\!]^{\mathsf{Su}}$. Moreover, if $T' \in [\![T]\!]^{\mathsf{Su}}$, then $T^{\mathsf{Su}} = \bigcap [\![T]\!]^{\mathsf{Su}} \leq T'$.

(e) By specializing Lemma 1533. ∎

For the Suszko classes, we get an analogous result to Proposition 1569, to the effect that they are closure families of full $\mathcal{I}$-structures and their Tarski congruence systems equal the Suszko congruence system of their generating theory family.

Proposition 1584 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

(a) $\langle \mathcal{A}, [\![T]\!]^{\mathsf{Su}} \rangle \in \mathrm{FStr}(\mathcal{I})$*;*

(b) $\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\mathsf{Su}}) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$*.*

Proof: Part (a) is a specialization of Proposition 1526.

Since, by Lemma 1583, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq [\![T]\!]^{\mathsf{Su}}$, we get $\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\mathsf{Su}}) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. On the other hand, if $T' \in [\![T]\!]^{\mathsf{Su}}$, then $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Hence $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \bigcap_{T' \in [\![T]\!]^{\mathsf{Su}}} \Omega^{\mathcal{A}}(T') = \widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\mathsf{Su}})$. Equality now follows. ∎

The mapping $T \mapsto T^{\mathsf{Su}}$ is monotone.

Lemma 1585 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. For all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T \leq T' \quad \textit{implies} \quad T^{\mathsf{Su}} \leq T'^{\mathsf{Su}}.$$

Proof: By Proposition 1529. ∎

Moreover, even though T^{Su} is not necessarily a Suszko theory family, in case it happens to be, it is the largest such below T.

Lemma 1586 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. For all* $T' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$*, such that* $T' \leq T$*, we have* $T' \leq T^{\mathsf{Su}}$*.*

Proof: Suppose $T' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, such that $T' \leq T$. Then, by the hypothesis and Lemma 1585, $T' = T'^{\mathsf{Su}} \leq T^{\mathsf{Su}}$. ∎

As far as characterizing Suszko theory families, we have the following

Proposition 1587 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.* $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$ *if and only if* $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ *is the least* $\mathcal{I}$*-filter family of* $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$*.*

Proof: By Proposition 1530. ∎

It turns out that the collection of Suszko theory families of a π-institution forms a join complete subsemilattice of the lattice of all theory families.

Lemma 1588 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$ *is a join complete subsemilattice of* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof: Suppose $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. By Lemma 1585, we get, for all $i \in I$,

$$T^i = (T^i)^{\mathsf{Su}} \leq (\bigvee_{i \in I} T)^{\mathsf{Su}}.$$

This gives $\bigvee_{i \in I} T^i \leq (\bigvee_{i \in I} T^i)^{\mathsf{Su}}$. But, by Lemma 1583, $(\bigvee_{i \in I} T^i)^{\mathsf{Su}} \leq \bigvee_{i \in I} T^i$. Hence, we conclude that $\bigvee_{i \in I} T^i \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. ∎

For an $\mathbf{F}$-algebraic system $\mathcal{A}$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, it turns out that T is a Suszko $\mathcal{I}$-filter family exactly when it is the least filter family of a full $\mathcal{I}$-structure, whose closure family consists of the upset in the lattice of $\mathcal{I}$-theory families generated by T.

Theorem 1589 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. *The following conditions are equivalent:*

(i) $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$*;*

(ii) $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$*;*

(iii) $T = \bigcap \mathcal{T}$*, where* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *is an upset and* $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}(\mathcal{I})$.

Proof:

(i)⇒(ii) Assume that $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Then, by Lemma 1583, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = [\![T]\!]^{\mathsf{Su}}$ and, moreover, by Proposition 1584, $\langle \mathcal{A}, [\![T]\!]^{\mathsf{Su}} \rangle \in \mathrm{FStr}(\mathcal{I})$.

(ii)⇒(iii) Assume (ii) holds and set $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Then, $T = \bigcap \mathcal{T}$, $\mathcal{T}$ is an upset in $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by hypothesis, $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}(\mathcal{I})$.

(iii)⇒(i) Suppose, finally, that $T = \bigcap \mathcal{T}$, where $\mathcal{T}$ is an upset in $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{T})$ and $\langle \mathcal{A}, \mathcal{T} \rangle$ is a full $\mathcal{I}$-structure. We then have $T = \bigcap \mathcal{T} \in \mathcal{T}$, since $\mathcal{T}$ is a closure family. Hence, since $\mathcal{T}$ is an upset, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq \mathcal{T}$. But, by hypothesis $T = \bigcap \mathcal{T}$, whence $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Thus, we get that $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Since $\langle \mathcal{A}, \mathcal{T} \rangle$ is a full $\mathcal{I}$-structure, we have, by Theorem 1395,

$$\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \leq \Omega^{\mathcal{A}}(T')\}.$$

But $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$, whence $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = [\![T]\!]^{\mathsf{Su}}$. Now we get $T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = \bigcap [\![T]\!]^{\mathsf{Su}} = T^{\mathsf{Su}}$ and $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$.

■

It turns out that requiring that all $\mathcal{I}$-filter families on all $\mathbf{F}$-algebraic systems be Suszko filter families is tantamount to $\mathcal{I}$ being family completely reflective.

Theorem 1590 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is family c-reflective;*

(ii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof:

(i)⇒(iii) Assume that $\mathcal{I}$ is family c-reflective and let $\mathcal{A}$ be an $\mathcal{I}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, for all $T' \in [\![T]\!]^{\mathsf{Su}}$, we have $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. By family c-reflectivity and Lemma 826, we get $T \leq T'$, Thus, $T \leq \bigcap [\![T]\!]^{\mathsf{Su}} = T^{\mathsf{Su}}$. Since, by Lemma 1583, $T^{\mathsf{Su}} \leq T$, we get $T = T^{\mathsf{Su}}$, i.e., $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. We conclude that $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(iii)⇒(ii) Suppose that (iii) holds and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Set $T' \in \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$. Since $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is compatible with T, by Corollary 57, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$. Thus, by definition, $T' \leq T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Thus, we get

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T') \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}.$$

By hypothesis, since $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{AlgSys}(\mathcal{I})$, we get that

$$T', T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)).$$

By Proposition 1528, $T' = T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Thus, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is the least $\mathcal{I}$-theory family on $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Therefore, by Proposition 1587, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$.

(ii)⇒(i) Assume (ii) and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. By definition, $T' \in [\![T]\!]^{\mathsf{Su}}$. Since $T = T^{\mathsf{Su}}$, we get that $T = \bigcap [\![T]\!]^{\mathsf{Su}} \leq T'$. By Lemma 826, $\mathcal{I}$ is family c-reflective. ■

Using Theorem 1590, we get additional characterizations of family c-reflectivity.

Corollary 1591 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is family c-reflective;*

(ii) $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof:

(i)⇒(ii) Assume $\mathcal{I}$ is family c-reflective and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Theorem 1590, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Thus, by Theorem 1589, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$.

(ii)⇒(iii) Assume (ii). Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By hypothesis, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathrm{FStr}(\mathcal{I})$. Thus, by Theorem 1589, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Therefore, by Lemma 1583, $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$.

(iii)⇒(i) Assume (iii). Then, by Lemma 1583, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Therefore, by Theorem 1590, $\mathcal{I}$ is family c-reflective.

■

The condition that all full $\mathcal{I}$-structures are of the form given in Part (ii) of Theorem 1591 is tantamount to weak family algebraizability.

Corollary 1592 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is weakly family algebraizable if and only if* $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proof: By definition $\mathcal{I}$ is WF algebraizable if and only if it is protoalgebraic and family c-reflective, if and only if, by Theorem 1582 and by Corollary 1591, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) \subseteq \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$ and $\{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \subseteq \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, if and only if $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. ■

Moreover, as far as characterizations of WF algberaizability we obtain one that involves both Suszko classes and Suszko filter families.

Proposition 1593 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is weakly family algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$ *and, for every* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}(\mathcal{I})$*, there exists* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\mathcal{T} = [\![T]\!]^{\mathsf{Su}}$*.*

Proof: Suppose that $\mathcal{I}$ is weakly family algebraizable. Since it is protoalgebraic, by Theorem 1582, for every **F**-algebraic system $\mathcal{A}$, if $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$, then $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\mathcal{I}$ is family c-reflective, by Corollary 1591, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T = [\![T]\!]^{\mathsf{Su}}$. Hence, if $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$, then $\mathcal{T} = [\![T]\!]^{\mathsf{Su}}$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Finally, by Theorem 1590, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$.

Suppose, conversely, that the given property holds. Since, for every **F**-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, by Theorem 1590, $\mathcal{I}$ is family c-reflective. By, Corollary 1591, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. By hypothesis, for all $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\mathcal{T} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Hence, by Theorem 1582, $\mathcal{I}$ is also protoalgebraic. We conclude that $\mathcal{I}$ is WF algebraizable. ■

As far as Suszko classes go, we have a special correspondence theorem that follows from the General Correspondence Theorem 1552 for O-classes.

Theorem 1594 (Correspondence Theorem for Suszko Classes) *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$*,* $\mathcal{B} = \langle\mathbf{B},\langle G,\beta\rangle\rangle$ **F***-algebraic systems,* $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism, and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. If* $\langle H,\gamma\rangle$ *is* $\widetilde{\Omega}^{\mathcal{I}}$*-compatible with* T*, then* γ *induces an order isomorphism from* $[\![T]\!]^{\mathsf{Su}}$ *to* $[\![\gamma(T)]\!]^{\mathsf{Su}}$*, with inverse* γ^{-1}*.*

Proof: By Proposition 1544, $\widetilde{\Omega}^{\mathcal{I}}$ is a semi-coherent family of compatibility $\mathcal{I}$-operators, whence, by Theorem 1552, we get the conclusion. ■

Under the hypotheses of Theorem 1594, we also obtain a correspondence between Suszko filter families:

Corollary 1595 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$*,* $\mathcal{B} = \langle\mathbf{B},\langle G,\beta\rangle\rangle$ **F***-algebraic systems,* $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism, and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\langle H,\gamma\rangle$ *is* $\widetilde{\Omega}^{\mathcal{I}}$*-compatible with* T*. Then*

$$T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \quad \textit{iff} \quad \gamma(T) \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{B}).$$

Proof: We have

$$\begin{array}{lll} T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) & \text{iff} & T = T^{\mathsf{Su}} \\ & \text{iff} & T = \bigcap [\![T]\!]^{\mathsf{Su}} \\ & \text{iff} & \gamma(T) = \bigcap [\![\gamma(T)]\!]^{\mathsf{Su}} \quad \text{(by Theorem 1594)} \\ & \text{iff} & \gamma(T) = \gamma(T)^{\mathsf{Su}} \\ & \text{iff} & \gamma(T) \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{B}). \end{array}$$

■

Analogously to Theorem 1577, characterizing protoalgebraicity via a correspondence between posets of filter families of $\mathcal{F}$-algebraic systems related via surjective strict morphisms, we get a correspondence theorem characterizing family c-reflectivity.

Theorem 1596 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family c-reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, *and all strict surjective* $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$, *with* H *an isomorphism, such that* $\langle H, \gamma \rangle$ *is* $\widetilde{\Omega}^{\mathcal{I}}$*-compatible with* T, γ *induces an order isomorphism from* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *onto* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'^{\mathsf{Su}}}$, *with inverse* γ^{-1}.

Proof: Suppose, first, that $\mathcal{I}$ is family c-reflective. Let $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ be a strict surjective morphism, with H an isomorphism, such that $\langle H, \gamma \rangle$ is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T. By Theorem 1594, $\gamma : [\![T]\!]^{\mathsf{Su}} \to [\![T']\!]^{\mathsf{Su}}$ is an order isomorphism with inverse γ^{-1}. By Corollary 1591, $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^T$ and $[\![T']\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$. Moreover, by Theorem 1590, $T' = T'^{\mathsf{Su}}$. Thus, we get the conclusion.

Assume, conversely, that the given condition holds. It suffices, by Theorem 1590, to show that every $\mathcal{I}$-filter family on every $\mathbf{F}$-algebraic system is a Suszko $\mathcal{I}$-filter family. So let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Then $\langle I, \pi \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T), T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \rangle$ is a strict surjective morphism, with I an isomorphism and it is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T. By hypothesis,

$$\pi : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))^{(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))^{\mathsf{Su}}}$$

is an order isomorphism with inverse π^{-1}.

- By Lemma 1557, we get $\widetilde{\Omega}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}$. Thus, by the definition of a Suszko class,

$$[\![T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)),$$

  whence $(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))^{\mathsf{Su}} = \bigcap \mathrm{FiFam}^{\mathcal{I}}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$ and, therefore,

$$\mathrm{FiFam}^{\mathcal{I}}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))^{(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))^{\mathsf{Su}}} = \mathrm{FiFam}^{\mathcal{I}}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)).$$

- By Theorem 1594, $\pi : [\![T]\!]^{\mathsf{Su}} \to [\![T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)]\!]^{\mathsf{Su}}$ is an order isomorphism with inverse π^{-1}.

We conclude that $[\![T]\!]^{\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. By Lemma 1583, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Thus, every $\mathcal{I}$-filter family on every $\mathbf{F}$-algebraic system is a Suszko $\mathcal{I}$-filter family and, by Theorem 1590, $\mathcal{I}$ is family c-reflective. ∎

Along similar lines, for weakly family algebraizable π-institutions, we get the following characterization, which consists of strengthening the condition in Theorem 1596 by requiring that it holds for all strict surjective morphisms with isomorphic signature components, without additional compatibility requirements.

Theorem 1597 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is weakly family algebraizable if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, *and all strict surjective morphisms* $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$, *with* H *an isomorphism,* γ *induces an order isomorphism from* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *onto* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'^{\mathsf{Su}}}$, *with inverse* γ^{-1}.

Proof: Suppose, first, that $\mathcal{I}$ is weakly family algebraizable. On the one hand, it is protoalgberaic, whence, by Theorem 1577, $\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is an order isomorphism with inverse γ^{-1}. On the other hand, it is family c-reflective, whence by Theorem 1590, $T' = T'^{\mathsf{Su}}$. This establishes the conclusion.

Assume, conversely, that the property in the statement holds. Then, by Theorem 1596, $\mathcal{I}$ is family c-reflective. Thus, by Theorem 1590, $T'^{\mathsf{Su}} = T'$. So $\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is an order isomorphism with inverse γ^{-1}. Hence, by Theorem 1577, $\mathcal{I}$ is also protoalgebraic. Therefore, $\mathcal{I}$, being both protoalgebraic and family c-reflective, is weakly family algebraizable. ∎

Next, in analogy with Proposition 1579, we give a characterization of those π-institutions $\mathcal{I}$ all of whose $\mathcal{I}$-structures correspond to closure families consisting of Suszko classes.

Proposition 1598 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *The following conditions are equivalent:*

(i) $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, [\![T]\!]^{\mathsf{Su}} \rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$, *for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*;*

(ii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is surjective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Proof:

(i)⇒(ii) Suppose (i) holds. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. Then, by Corollary 1565, there exists $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\langle \mathcal{A}, \mathcal{T} \rangle \in$

$\mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ and $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \theta$. By hypothesis, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\mathcal{T} = [\![T]\!]^{\mathsf{Su}}$. Now we get, using Proposition 1584,

$$\theta = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\mathsf{Su}}) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Thus, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is indeed surjective.

(ii)⇒(i) Assume that (ii) holds. Since, by Proposition 1584, the right-to-left inclusion in (i) always holds, it suffices to show the reverse inclusion. To this end, let $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$. Then $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{AlgSys}(\mathcal{I})$, which gives that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \in \mathrm{ConSys}^{\mathcal{A}}(\mathcal{A})$. Therefore, by hypothesis, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Since, by Proposition 1584, $\widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^{\mathsf{Su}}) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ and, by Proposition 1584, $\langle\mathcal{A}.[\![T]\!]^{\mathsf{Su}}\rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, we get, by the isomorphism established in Corollary 1565, that $\mathcal{T} = [\![T]\!]^{\mathsf{Su}}$.

■

The next proposition provides a characterization of weakly family algebraizable π-institution inside the class of family c-reflective ones, based on the form of their full $\mathcal{I}$-structures.

Proposition 1599 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a family c-reflective π-institution based on $\mathbf{F}$. $\mathcal{I}$ is weakly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,*

$$\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle\mathcal{A},[\![T]\!]^{\mathsf{Su}}\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.$$

Proof: Suppose, first, that $\mathcal{I}$ is weakly family algebraizable. Since this implies that $\mathcal{I}$ is protoalgebraic, we get that $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. Thus, by Proposition 1579, $\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle\mathcal{A},[\![T]\!]^{\mathsf{Su}}\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

Suppose, conversely, that the condition given in the statement holds and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, by hypothesis and Proposition 1598, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Hence, $[\![T]\!]^* = [\![T']\!]^{\mathsf{Su}}$. Since $\mathcal{I}$ is family c-reflective, by Theorem 1590 and Lemma 1583, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Thus, $T = T^* = T'^{\mathsf{Su}} = T'$. We conclude that $\Omega^{\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. By Proposition 1567, we conclude that $\mathcal{I}$ is protoalgebraic. Since, by hypothesis, it is family c-reflective, we conclude that $\mathcal{I}$ is weakly family algebraizable. ■

We see, next, that family c-reflectivity is characterized by the property that all principal filters in the lattice of filter families are Suszko full classes and, also, by the reflectivity of the Suszko operator on every $\mathbf{F}$-algebraic system.

Proposition 1600 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is family c-reflective;*

(ii) $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ *is Suszko full for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *is order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proof:

(i)⇒(iii) Suppose that $\mathcal{I}$ is family c-reflective and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Then we get

$$\bigcap\{\Omega^{\mathcal{A}}(T'') : T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T').$$

By hypothesis and Lemma 826, $\bigcap\{T'' : T \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \leq T'$, i.e., $T \leq T'$. Thus, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is order reflecting.

(iii)⇒(i) If $\widetilde{\Omega}^{\mathcal{I}}$ is order reflecting, then it is a fortiori injective. Thus, by Theorem 827, $\mathcal{I}$ is family c-reflective.

(ii)⇒(iii) Assume (ii) holds. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')$. Then, by hypothesis,

$$\begin{array}{rcl}\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}^{-1}}(\widetilde{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)) \\ & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}^{-1}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) \\ & = & \{T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T'')\}.\end{array}$$

Similarly, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'} = \{T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T'')\}$. Therefore, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$, i.e., $T \leq T'$ and $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is order reflecting.

(iii)⇒(ii) Assume $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is order reflecting for every $\mathbf{F}$-algebraic system $\mathcal{A}$. Then

$$\begin{array}{l}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}^{-1}}(\widetilde{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T)) \\ \quad = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}^{-1}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) \\ \quad = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T')\} \\ \quad = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T.\end{array}$$

Hence $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ is Suszko full. ■

Finally, we conclude the section with a characterization of protoalgebraicity in terms of the form of full $\mathcal{I}$-structures and, also, by the coincidence of Leibniz and Suszko classes.

Proposition 1601 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is protoalgebraic;*

(ii) $\mathrm{FStr}(\mathcal{I}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I},\widetilde{\Omega}^{\mathcal{I}}}(\mathcal{A})\rangle : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$*;*

(iii) $[\![T]\!]^* = [\![T]\!]^{\mathsf{Su}}$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof:

(i)⇒(ii) Suppose $\mathcal{I}$ is protoalgebraic. Then, by Theorem 1582,

$$\mathrm{FStr}(\mathcal{I}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})\rangle : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}.$$

But, by Lemma 1518, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$, whence, the conclusion follows.

(i)⇒(iii) If $\mathcal{I}$ is protoalgebraic, then, by Lemma 1518, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$. Therefore, $[\![T]\!]^* = [\![T]\!]^{\mathsf{Su}}$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(ii)⇒(i) Suppose (ii) holds. Then, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,

$$\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T\rangle : T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\Omega}^{\mathcal{I}}}(\mathcal{A})\}.$$

So by Theorem 1582, $\mathcal{I}$ is protoalgebraic.

(iii)⇒(i) Assume (iii). Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \le T'$. By Lemma 1583,

$$T' \in [\![T']\!]^{\mathsf{Su}} \subseteq [\![T]\!]^{\mathsf{Su}} = [\![T]\!]^*.$$

So $\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. Thus, Ω is monotone and, therefore, $\mathcal{I}$ is protoalgebraic.

■

21.12 Frege Operator as an $\mathcal{I}$-Operator

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system.

Recall that $\lambda^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$ is given, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, by setting $\lambda^{\mathcal{A}}(T) = \{\lambda^{\mathcal{A}}_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}|}$, where, for all $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\lambda^{\mathcal{A}}_\Sigma(T) = \{\langle \phi, \psi \rangle \in \mathrm{SEN}(\Sigma)^2 : \phi \in T_\Sigma \text{ iff } \psi \in T_\Sigma\}.$$

Its lifting is the operator $\widetilde{\lambda}^{\mathcal{A}} : \mathcal{P}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \to \mathrm{EqvFam}(\mathcal{A})$, given, for all $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\widetilde{\lambda}^{\mathcal{A}}(\mathcal{T}) = \bigcap\{\lambda^{\mathcal{A}}(T') : T' \in \mathcal{T}\}.$$

Its relativization is the operator $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{EqvFam}(\mathcal{A})$, given, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, by

$$\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) = \bigcap\{\lambda^{\mathcal{A}}(T') : T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.$$

Given $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, the $\widetilde{\lambda}^{\mathcal{I}}$**-class of** T or **Frege class of** T is

$$[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}} = \Omega^{\mathcal{A}^{-1}}(\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')\}.$$

Since λ is not a compatibility $\mathcal{I}$-operator, $[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$ may not be the closure family of a full $\mathcal{I}$-structure. But, nevertheless, it is still a closure family on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proposition 1602 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then* $[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$ *is a closure family on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof: This is specialization of Proposition 1525. ∎

Given $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, based on Proposition 1602, we denote by $T^{\widetilde{\lambda}^{\mathcal{I}}}$ the least $\mathcal{I}$-filter family of $[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$, i.e.,

$$T^{\widetilde{\lambda}^{\mathcal{I}}} = \bigcap [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}.$$

Moreover, we say that T is a **Frege filter family** if $T = T^{\widetilde{\lambda}^{\mathcal{I}}}$. The collection of all Frege $\mathcal{I}$-filter families of $\mathcal{A}$ is denoted by $\mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$.

We give, now, a characterization of Frege filter families for π-institutions with theorems.

Lemma 1603 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*, having theorems,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

$$T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A}) \quad \textit{iff} \quad \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T) \quad \textit{iff} \quad T \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}.$$

Proof: The last equivalence is by the definition of $[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$. So it suffices to show the first equivalence.

Suppose, first, that $T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$. Then, we have

$$\begin{array}{lll} T & = & T^{\widetilde{\lambda}^{\mathcal{I}}} \\ & = & \bigcap [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}} \\ & = & \bigcap\{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')\}. \end{array}$$

Thus, taking into account Proposition 1602, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T)$.

Suppose, conversely, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T)$. Let $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T' \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$, i.e., $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. Let $\Sigma \in |\mathbf{Sign}|$ and $t \in C_\Sigma^{\mathcal{I},\mathcal{A}}(\varnothing)$, which exists, since $\mathcal{I}$ is assumed to have theorems. Then, if $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in T_\Sigma$, we get $C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,\phi) = T_\Sigma = C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,t)$. Thus, $\langle\phi,t\rangle \in \widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T) \subseteq \Omega_\Sigma^{\mathcal{A}}(T')$. Since $t \in T'_\Sigma$, by compatibility, $\phi \in T'_\Sigma$. Therefore, $T \le T'$. Now we have

$$\begin{array}{rcll} T & \le & \bigcap [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}} & (T \le T', \text{ for all } T' \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}) \\ & = & T^{\widetilde{\lambda}^{\mathcal{I}}} & (\text{by definition}) \\ & \le & T. & (\text{since } T \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}) \end{array}$$

Hence, we conclude that $T = T^{\widetilde{\lambda}^{\mathcal{I}}}$ and $T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$. ∎

Assuming that the π-institution $\mathcal{I}$ is protoalgebraic, gives the following characterization of Frege filter families.

Corollary 1604 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle\mathbf{F},C\rangle$ be a protoalgebraic π-institution based on $\mathbf{F}$, having theorems, $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

$$T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A}) \quad \textit{iff} \quad \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T).$$

Proof: If $T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$, then

$$\begin{array}{rcll} \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) & \le & \Omega^{\mathcal{A}}(T) & (\text{by Lemma \textbf{??}}) \\ & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) & (\text{by protoalgebraicity}) \\ & \le & \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T). & (\text{by compatibility}) \end{array}$$

Thus, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T)$. The converse is by Lemma 1603. ∎

Each component of any $\mathcal{I}$-filter family is determined by any of its elements modulo the Frege operator.

Proposition 1605 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle\mathbf{F},C\rangle$ be a π-institution based on $\mathbf{F}$, having theorems, $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in T_\Sigma$, $T_\Sigma = \phi/\widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T)$.*

Proof: Suppose that $T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$ and let $\Sigma \in |\mathbf{Sign}|$, $\phi \in T_\Sigma$.

- Let $\psi \in T_\Sigma$. Then, we have $C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,\phi) = T_\Sigma = C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,\psi)$. Thus, $\langle\phi,\psi\rangle \in \widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T)$, i.e., $\psi \in \phi/\widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T)$.
- Conversely, if $\psi \in \phi/\widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T)$, then $\langle\phi,\psi\rangle \in \widetilde{\lambda}_\Sigma^{\mathcal{I},\mathcal{A}}(T)$, which gives $C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,\phi) = C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma,\psi)$. Since $\phi \in T_\Sigma$, we get $\psi \in T_\Sigma$.

We conclude that $T_\Sigma = \phi/\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$. ■

Every Frege filter family is also a Leibniz filter family.

Lemma 1606 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*, having theorems. Then*

$$\mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A}).$$

Proof: Suppose $T \in \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$. Then, by Lemma 1603, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$. Since $T^* \in [\![T]\!]^*$, we also have $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^*)$. Therefore, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^*)$. Thus, by definition, $T^* \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$. Now we have

$$T = T^{\lambda^{\mathcal{I}}} = \bigcap [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}} \leq T^*$$

and, since, by Lemma 1568, $T^* \leq T$ always holds, we get $T = T^*$, i.e., $T \in \mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. ■

We saw that, in general, the Leibniz and Suszko filter families of a given filter family T are included in T, i.e., $T^*, T^{\mathsf{Su}} \leq T$. On the other hand, for Frege filter families, we have the reverse inclusion.

Lemma 1607 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*, having theorems,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system. For all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T \leq T^{\widetilde{\lambda}^{\mathcal{I}}}$*.*

Proof: By Proposition 1602, $T^{\lambda^{\mathcal{I}}} \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$. Thus, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^{\lambda^{\mathcal{I}}})$. Let $\Sigma \in |\mathbf{Sign}|$ and $t \in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)$ and assume $\phi \in T_\Sigma$. Then, we have $C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, t) = T_\Sigma = C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, \phi)$, i.e., $\langle t, \phi\rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$. By the preceding inequality, $\langle t, \phi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T^{\widetilde{\lambda}^{\mathcal{I}}})$. But $t \in T^{\widetilde{\lambda}^{\mathcal{I}}}_\Sigma$, whence, by compatibility, $\phi \in T^{\lambda^{\mathcal{I}}}_\Sigma$. We conclude that $T \leq T^{\widetilde{\lambda}^{\mathcal{I}}}$. ■

Strong Fregeanity is characterized by compatibility of the Frege operator on theory families and, similarly, full strong Fregeanity by the compatibility of the Frege operator on filter families of arbitrary algebraic systems.

Proposition 1608 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is strongly Fregean if and only if* $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}$ *is a compatibility* $\mathcal{I}$*-operator on* $\mathcal{F}$*;*

(b) $\mathcal{I}$ *is fully strongly Fregean if and only if* $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ *is a compatibility* $\mathcal{I}$*-operator on every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proof: We only prove Part (a) in detail. Part (b) may be proved similarly, by working on an arbitrary $\mathbf{F}$-algebraic system $\mathcal{A}$ instead of on $\mathcal{F}$.

Suppose $\mathcal{I}$ is strongly Fregean. Then, by definition, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T) \le \widetilde{\Omega}^{\mathcal{I},\mathcal{F}}(T) \le \Omega^{\mathcal{F}}(T)$. So $\lambda^{\mathcal{I},\mathcal{F}}$ is a compatibility $\mathcal{I}$-operator on $\mathcal{F}$.

Suppose, conversely, that $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}$ is a compatibility $\mathcal{I}$-operator on $\mathcal{F}$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T) \le \Omega^{\mathcal{F}}(T)$. Therefore,

$$\begin{array}{lcll}\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T) & = & \bigcap\{\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T') : T \le T' \in \mathrm{ThFam}(\mathcal{I})\} & (\text{monotonicity of } \widetilde{\lambda}^{\mathcal{I},\mathcal{F}}) \\ & \le & \bigcap\{\Omega^{\mathcal{F}}(T') : T \le T' \in \mathrm{ThFam}(\mathcal{I})\} & (\text{by the hypothesis}) \\ & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{F}}(T). & (\text{by definition})\end{array}$$

Since, by compatibility, $\widetilde{\Omega}^{\mathcal{I},\mathcal{F}}(T) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T)$ always holds, we conclude that $\mathcal{I}$ is strongly Fregean. ■

The characterizations of Proposition 1608 imply that a π-institution if strongly Fregean if and only if every theory family is Frege and that it is fully strongly Fregean if and only if every filter family of any algebraic system is a Frege filter family.

Corollary 1609 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a π-institution based on* $\mathbf{F}$*, having theorems.* $\mathcal{I}$ *is strongly Fregean if and only if* $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThFam}^{\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{I})$.

Proof: Suppose $\mathcal{I}$ is strongly Fregean and let $T \in \mathrm{ThFam}(\mathcal{I})$. By Proposition 1608, $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T) \le \Omega^{\mathcal{F}}(T)$. Thus, by Lemma 1603, $T \in \mathrm{ThFam}^{\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{I})$.

Assume, conversely, that every theory family of $\mathcal{I}$ is Frege. Then, by Lemma 1603, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T) \le \Omega^{\mathcal{F}}(T)$. Thus, by Proposition 1608, $\mathcal{I}$ is strongly Fregean. ■

Corollary 1610 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a π-institution based on* $\mathbf{F}$*, having theorems.* $\mathcal{I}$ *is fully strongly Fregean if and only if* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\widetilde{\lambda}^{\mathcal{I}}}(\mathcal{A})$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Proof: The proof follows along the same lines as that of Corollary 1609, using Proposition 1608 and Lemma 1603, but applied over an arbitrary $\mathbf{F}$-algebraic system $\mathcal{A}$ instead of over $\mathcal{F}$. ■

Our next goal is to show that the Frege operator $\widetilde{\lambda}^{\mathcal{I}}$ is a semi-coherent family of $\mathcal{I}$-operators. But, first, we need to have available an isomorphism theorem involving this operator. So we embark on some preparatory work.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$-algebraic systems, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. A surjective morphism $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ is called **deductive** if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi) \quad \text{implies} \quad C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma, \phi) = C_\Sigma^{\mathcal{I},\mathcal{A}}(T_\Sigma, \psi).$$

Equivalently, $\langle H,\gamma\rangle$ is deductive if and only if

$$\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T),$$

i.e., if and only if $\langle H,\gamma\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with T.

We now show that for a surjective morphism, with an isomorphic signature component, compatibility properties and deductive morphisms are very closely interrelated.

Lemma 1611 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$ $\mathbf{F}$-algebraic systems, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. For a surjective morphism $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$, with H an isomorphism, the following statements are equivalent:*

(i) $\langle H,\gamma\rangle$ *is* $\widetilde{\Omega}^{\mathcal{I}}$*-compatible with* T*;*

(ii) $\langle H,\gamma\rangle$ *is* $\widetilde{\lambda}^{\mathcal{I}}$*-compatible with* T*;*

(iii) $\langle H,\gamma\rangle : \langle \mathcal{A}, T\rangle \to \langle \mathcal{B}, \gamma(T)\rangle$ *is deductive.*

Proof:

(i)⇒(ii) Suppose $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Since, by compatibility, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$, we get that $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$. Thus $\langle H,\gamma\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with T.

(ii)⇒(iii) Suppose $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$. This implies that $\mathrm{Ker}(\langle H,\gamma\rangle)$ is compatible with T. Indeed, if $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$ and $\phi \in T_\Sigma$, then, by the hypothesis, $\langle \phi,\psi\rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$, i.e., $C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma,\phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma,\psi)$. Since $\phi \in T_\Sigma$, we get that $\psi \in T_\Sigma$. Thus, by Corollary 56, $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Moreover, by hypothesis and the comments preceding the lemma, $\langle H,\gamma\rangle : \langle \mathcal{A}, T\rangle \to \langle \mathcal{B}, \gamma(T)\rangle$ is a deductive morphism.

(iii)⇒(i) Suppose that $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$. Then, since, by Corollary 17, $\mathrm{Ker}(\langle H,\gamma\rangle)$ is a congruence system on $\mathcal{A}$ and, by Proposition 1420, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is the largest congruence system on $\mathcal{A}$ included in $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$, we conclude that $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Thus, $\langle H,\gamma\rangle$ is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T.

■

We now show that each deductive morphism, with an isomorphic signature component, induces an order isomorphism between the principal filter of the lattice of filter families generated by the domain and the principal filter of the lattice of theory families generate by its codomain.

Theorem 1612 (Correspondence Theorem for Deductive Morphisms) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$*-algebraic systems,* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ *and* $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ *a deductive morphism, with* H *an isomorphism. Then* γ *induces an order isomorphism from* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$ *onto* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$*, with inverse* γ^{-1}*.*

Proof: By Lemma 1611, $\langle H, \gamma \rangle$ is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T. This implies that, for every $T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$, $\mathrm{Ker}(\langle H, \gamma \rangle)$ is compatible with T''. It follows by Corollary 56 that, for all $T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$, $\gamma(T'') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$. Moreover, the same compatibility property implies that $\gamma^{-1}(\gamma(T'')) = T''$, for all $T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$. Finally, by surjectivity of $\langle H, \gamma \rangle$, we get, for all $T''' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$, $\gamma(\gamma^{-1}(T''')) = T'''$. Therefore, $\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')} \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is a bijection and, since, clearly, both γ and γ^{-1} are order preserving, they are mutually inverse order isomorphisms, as claimed. ∎

Now we are ready to return to the main line of work and establish that $\widetilde{\lambda}^{\mathcal{I}}$ constitutes a semi-coherent family of $\mathcal{I}$-operators.

Theorem 1613 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The Frege operator* $\widetilde{\lambda}^{\mathcal{I}}$ *is a semi-coherent family of* $\mathcal{I}$*-operators.*

Proof: Let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\langle H, \gamma \rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with $\gamma^{-1}(T')$. Then, by Lemma 1611 and Theorem 1612, $\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')} \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is an order isomorphism with inverse γ^{-1}. Thus, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$, $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ and $\gamma^{-1}(\gamma(T)) = T$. Now we get, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rcl}
C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'_{H(\Sigma)}, \gamma_\Sigma(\phi)) & = & C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(\gamma_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)})), \gamma_\Sigma(\phi)) \\
& = & C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(\gamma_\Sigma(C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \phi))) \\
& = & \gamma_\Sigma(C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \phi)).
\end{array}$$

Therefore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ll}
\multicolumn{2}{l}{\langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'))} \\
\text{iff} & \langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T') \\
\text{iff} & C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'_{H(\Sigma)}, \gamma_\Sigma(\phi)) = C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'_{H(\Sigma)}, \gamma_\Sigma(\psi)) \\
\text{iff} & \gamma_\Sigma(C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \phi)) = \gamma_\Sigma(C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \psi)) \\
\text{iff} & C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \psi) \\
\text{iff} & \langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}(T')).
\end{array}$$

We conclude that $\widetilde{\lambda}^{\mathcal{I}}$ is semi-coherent. ∎

It turns out that if we strengthen the semi-coherence condition by requiring that $\widetilde{\lambda}^{\mathcal{I}}$ be commuting over all morphisms, with isomorphic signature components (regardless of compatibility), then we get a characterization of protoalgebraicity.

Theorem 1614 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is protoalgebraic if and only if* $\widetilde{\lambda}^{\mathcal{I}}$ *is a semi-commuting family of* $\mathcal{I}$*-operators.*

Proof: Suppose, first, that $\mathcal{I}$ is protoalgebraic and let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Then, by Corollary 55, $\gamma^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$. Then

$$\begin{aligned}
\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}(T')) & \\
\text{iff} \quad & C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(\gamma^{-1}_\Sigma(T'_{H(\Sigma)}), \psi) \\
\text{iff} \quad & C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'_{H(\Sigma)}, \gamma_\Sigma(\phi)) = C^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T'_{H(\Sigma)}, \gamma_\Sigma(\psi)) \\
\text{iff} \quad & \langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T') \\
\text{iff} \quad & \langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}_{H(\Sigma)}(T')).
\end{aligned}$$

Therefore, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(T'))$ and $\widetilde{\lambda}^{\mathcal{I}}$ is a semi-commuting family of $\mathcal{I}$-operators.

Assume, conversely, that $\widetilde{\lambda}^{\mathcal{I}}$ is semi-commuting and let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$. Since $\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(T') \leq \widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(T')$, we get

$$\gamma^{-1}(\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(T')) \leq \gamma^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(T')) = \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T')).$$

By Corollary 17, $\gamma^{-1}(\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(T'))$ is a congruence system on $\mathcal{A}$. By Proposition 1420, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T'))$ is the largest congruence system below $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T'))$. Therefore, we get $\gamma^{-1}(\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(T')) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T'))$. Since the converse inclusion always holds, $\widetilde{\Omega}^{\mathcal{I}}$ is semi-commuting. Thus, by Corollary 1537, we get that $\widetilde{\Omega}^{\mathcal{I}} = \Omega$ and, therefore, by Lemma 1518, $\mathcal{I}$ is protoalgebraic. ■

We also get a commutativity property with direct images.

Lemma 1615 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$*-algebraic systems,* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. *If* $\langle H, \gamma \rangle$ *is* $\widetilde{\lambda}^{\mathcal{I}}$*-compatible with* T*, then*

$$\gamma(\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)) = \widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T)).$$

Proof: By hypothesis and Lemma 1611, $\langle H, \gamma \rangle$ is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T. Therefore, by Corollary 56, $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, also, $T = \gamma^{-1}(\gamma(T))$. Since, by Theorem 1613, $\widetilde{\lambda}^{\mathcal{I}}$ is semi-coherent, we get

$$\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(\gamma(T))) = \gamma^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T))).$$

Hence, by the surjectivity of $\langle H,\gamma\rangle$, we get $\gamma(\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)) = \widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T))$. ■

In analogy with previous correspondence theorems we have the following one regarding correspondence between Frege classes.

Theorem 1616 (Correspondence Theorem for Frege Classes) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$ $\mathbf{F}$*-algebraic systems,* $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, with* H *an isomorphism and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. If* $\langle H,\gamma\rangle$ *is* $\widetilde{\lambda}^{\mathcal{I}}$*-compatible with* T*, then* γ *induces an order isomorphism from* $[\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$ *onto* $[\![\gamma(T)]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$*, with inverse* γ^{-1}*.*

Proof: Since $\langle H,\gamma\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with T, we get, by Lemma 1611, that $\langle H,\gamma\rangle$ is $\widetilde{\Omega}^{\mathcal{I}}$-compatible with T. Therefore, by Corollary 56, $\gamma(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, also, $T = \gamma^{-1}(\gamma(T))$.

Now, let $T' \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$. Then $\mathrm{Ker}(\langle H,\gamma\rangle) \le \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. As a consequence, we get $\gamma(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and $\gamma^{-1}(\gamma(T')) = T'$. Now we get

$$\begin{array}{rcll}\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T)) & = & \gamma(\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)) & \text{(by Lemma 1615)}\\ & \le & \gamma(\Omega^{\mathcal{A}}(T')) & (\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T'))\\ & = & \Omega^{\mathcal{B}}(\gamma(T')). & \text{(by Lemma 1542).}\end{array}$$

We conclude that $\gamma(T') \in [\![\gamma(T)]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$.

Suppose, conversely, that $T' \in [\![\gamma(T)]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$. Then $\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T)) \le \Omega^{\mathcal{B}}(T')$. By Corollary 55, $\gamma^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by surjectivity, $\gamma(\gamma^{-1}(T')) = T'$. Moreover, $\langle H,\gamma\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with $\gamma^{-1}(\gamma(T)) = T$. Hence, we have

$$\begin{array}{rcll}\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) & = & \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(\gamma(T))) & \\ & = & \gamma^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(T)) & \text{(by Theorem 1613)}\\ & \le & \gamma^{-1}(\Omega^{\mathcal{B}}(T')) & (\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\gamma(T)) \le \Omega^{\mathcal{B}}(T'))\\ & = & \Omega^{\mathcal{A}}(\gamma^{-1}(T')). & \text{(by Proposition 24)}\end{array}$$

Hence, $\gamma^{-1}(T') \in [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$.

Thus, $\gamma : [\![T]\!]^{\widetilde{\lambda}^{\mathcal{I}}} \to [\![\gamma(T)]\!]^{\widetilde{\lambda}^{\mathcal{I}}}$ is a bijection, with inverse γ^{-1}. Since both mappings are order-preserving, we conclude that they form a pair of mutually inverse order isomorphisms. ■

This correspondence theorem allows us to provide characterizations of full self extensionality and full strong Fregeanity in the following two corollaries.

Corollary 1617 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is fully self extensional if and only if, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$*.*

Proof: Suppose, first, that $\mathcal{I}$ is fully self extensional and let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Then we have

$$\begin{array}{lll}\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \\ & & \text{(by full self extensionality)} \\ & = & \Delta^{\mathcal{A}}. \quad (\text{since } \mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}))\end{array}$$

Suppose, conversely, that, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$, and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. Set, for notational convenience and brevity, $\mathcal{B} = \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$, and consider the quotient morphism

$$\langle I,\pi\rangle : \mathcal{A} \to \mathcal{B}.$$

Then $\mathrm{Ker}(\langle I,\pi\rangle) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$, whence $\mathrm{Ker}(\langle I,\pi\rangle)$ is compatible with $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence, we get, by Corollary 56, $\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and $\pi^{-1}(\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is the least $\mathcal{I}$-family of $\mathcal{A}$, it must be a Suszko $\mathcal{I}$-filter family. Hence, by Corollary 1554, $\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$ is the least $\mathcal{I}$-filter family on $\mathcal{B}$, i.e., we have

$$\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B}).$$

Since $\mathrm{Ker}(\langle I,\pi\rangle) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \leq \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$, $\langle I,\pi\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with $\pi^{-1}(\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, since $\mathcal{B} \in \mathrm{AlgSys}(\mathcal{I})$, we get, by hypothesis, $\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})) = \Delta^{\mathcal{B}}$. Now we get

$$\begin{array}{lll}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & = & \mathrm{Ker}(\langle I,\pi\rangle) \quad (\text{definition of } \langle I,\pi\rangle) \\ & = & \pi^{-1}(\Delta^{\mathcal{B}}) \quad (\text{definition of kernel}) \\ & = & \pi^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{B}}(\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})))) \\ & & (\text{shown above}) \\ & = & \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\pi^{-1}(\pi(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})))) \\ & & (\text{Theorem 1614}) \\ & = & \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})).\end{array}$$

We conclude that $\mathcal{I}$ is fully self extensional. ■

Corollary 1618 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is fully strongly Fregean if and only if, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$.

Proof: The left-to-right implication follows directly by the definition of full strong Fregeanity. Assume, conversely, that, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Let $\mathcal{A}$ be an arbitrary $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and consider the quotient morphism

$$\langle I,\pi\rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

$\mathrm{Ker}(\langle I,\pi\rangle)=\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ is compatible with T. Hence $\pi(T)\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$ and $\pi^{-1}(\pi(T))=T$. Moreover, $\mathrm{Ker}(\langle I,\pi\rangle)=\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)\le\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$. Thus, $\langle I,\pi\rangle$ is $\widetilde{\lambda}^{\mathcal{I}}$-compatible with T. Since $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)\in\mathrm{AlgSys}(\mathcal{I})$, we get, by hypothesis,

$$\widetilde{\lambda}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T))=\widetilde{\Omega}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T))=\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}.$$

Now we have

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)&=&\mathrm{Ker}(\langle I,\pi\rangle) & \text{(definition of } \langle I,\pi\rangle)\\ &=&\pi^{-1}(\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}) & \text{(definition of kernel)}\\ &=&\pi^{-1}(\widetilde{\lambda}^{\mathcal{I},\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T))) & \text{(shown above)}\\ &=&\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\pi^{-1}(\pi(T))) & \text{(Theorem 1614)}\\ &=&\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T).\end{array}$$

We conclude that $\mathcal{I}$ is fully strongly Fregean. ■

On the other hand, strong Fregeanity, combined with the existence of natural theorems, implies assertionality.

Corollary 1619 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a π-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is strongly Fregean and has natural theorems, then it is syntactically family assertional.*

Proof: Assume $\mathcal{I}$ is strongly Fregean and has natural theorems. Let $\vartheta^\flat:(\mathrm{SEN}^\flat)^k\to\mathrm{SEN}^\flat$ be a natural theorem. Then define $\tau^\flat:(\mathrm{SEN}^\flat)^{k+1}\to\mathrm{SEN}^\flat$ by

$$\tau^\flat:=\{p^{k+1,0}\approx\vartheta^\flat\circ\langle p^{k+1,1},\dots,p^{k+1,k}\rangle\}.$$

We show, first, that, for all $T\in\mathrm{ThFam}(\mathcal{I})$, all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\vec{\chi},\vec{\chi}'\in\mathrm{SEN}^\flat(\Sigma)$, $\langle\vartheta^\flat_\Sigma(\vec{\chi}),\vartheta^\flat_\Sigma(\vec{\chi}'\rangle\in\Omega_\Sigma(T)$. Since, $\vartheta^\flat$ is a natural theorem, we have, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\vec{\chi},\vec{\chi}'\in\mathrm{SEN}^\flat(\Sigma)$, $\vartheta^\flat_\Sigma(\vec{\chi}),\vartheta^\flat_\Sigma(\vec{\chi}')\in\mathrm{Thm}_\Sigma(\mathcal{I})$. Therefore, we get $\langle\vartheta^\flat_\Sigma(\vec{\chi}),\vartheta^\flat_\Sigma(\vec{\chi}')\rangle\in\widetilde{\lambda}^{\mathcal{I}}_\Sigma(T)$. Thus, by strong Fregeanity, $\langle\vartheta^\flat_\Sigma(\vec{\chi}),\vartheta^\flat_\Sigma(\vec{\chi}')\rangle\in\Omega^{\mathcal{I}}_\Sigma(T)\le\Omega_\Sigma(T)$.

We show, next, that $\mathcal{I}$ is systemic. To this end, let $T\in\mathrm{ThFam}(\mathcal{I})$, $\Sigma,\Sigma'\in|\mathbf{Sign}^\flat|$, $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\phi\in\mathrm{SEN}^\flat(\Sigma)$, such that $\phi\in T_\Sigma$. Let $t\in\mathrm{Thm}_\Sigma(\mathcal{I})$. Then, we have $\langle\phi,t\rangle\in\widetilde{\lambda}^{\mathcal{I}}_\Sigma(T)=\widetilde{\Omega}^{\mathcal{I}}_\Sigma(T)$. Hence, since $\widetilde{\Omega}^{\mathcal{I}}(T)$ is a congruence system, we get $\langle\mathrm{SEN}^\flat(f)(\phi),\mathrm{SEN}^\flat(f)(t)\rangle\in\widetilde{\Omega}^{\mathcal{I}}_{\Sigma'}(T)=\widetilde{\lambda}^{\mathcal{I}}_{\Sigma'}(T)$. But $\mathrm{SEN}^\flat(f)(t)\in\mathrm{Thm}_{\Sigma'}(\mathcal{I})\subseteq T_{\Sigma'}$ and, therefore, by compatibility, $\mathrm{SEN}^\flat(f)(\phi)\in T_{\Sigma'}$. Hence, $T\in\mathrm{ThSys}(\mathcal{I})$ and $\mathcal{I}$ is systemic.

Finally, we show that, for all $T\in\mathrm{ThFam}(\mathcal{I})$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\phi\in\mathrm{SEN}^\flat(\Sigma)$,

$$\phi\in T_\Sigma\quad\text{iff}\quad\tau^\flat_\Sigma[\phi]\le\Omega_\Sigma(T).$$

Assume, first $\phi\in T_\Sigma$. By systemicity, for every $\Sigma'\in|\mathbf{Sign}^\flat|$ and all $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\mathrm{SEN}^\flat(f)(\phi)\in T_{\Sigma'}$. Therefore, for all $\vec{\chi}'\in\mathrm{SEN}^\flat(\Sigma')$, $\langle\mathrm{SEN}^\flat(f)(\phi),\vartheta^\flat_{\Sigma'}(\vec{\chi}')\rangle\in\widetilde{\lambda}^{\mathcal{I}}_{\Sigma'}(T)=\widetilde{\Omega}^{\mathcal{I}}_{\Sigma'}(T)\le\Omega_{\Sigma'}(T)$. If, conversely, for all $\Sigma'\in|\mathbf{Sign}^\flat|$, all $f\in$

$\mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi}' \in \mathrm{SEN}^\flat(\Sigma')$, we have $\langle \mathrm{SEN}^\flat(\phi), \vartheta^\flat_{\Sigma'}(\vec{\chi}')\rangle \in \Omega_{\Sigma'}(T)$, then, in particular for $f = i_\Sigma$, we get, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\langle \phi, \vartheta^\flat_\Sigma(\vec{\chi})\rangle \in \Omega_\Sigma(T)$. Since $\vartheta^\flat_\Sigma(\vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by compatibility, that $\phi \in T_\Sigma$. ■

Finally, combining this work with previously obtained results, we get the following corollary comparing the injectivity of the various $\mathcal{I}$-operators we have studied.

Corollary 1620 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\widetilde{\Omega}^{\mathcal{I}}$ *is injective, then* $\widetilde{\Omega}$ *is injective.*

(b) If Ω *is injective, then* $\widetilde{\lambda}^{\mathcal{I}}$ *is injective.*

Proof:

(a) If $\widetilde{\Omega}^{\mathcal{I}}$ is injective, then, by Theorem 827, Ω is c-reflective. Thus, it is, a fortiori, injective.

(b) If Ω is injective, then, necessarily, $\mathcal{I}$ has theorems. Therefore, by Theorem 495, we get that $\widetilde{\lambda}^{\mathcal{I}}$ is injective.

■

21.13 Leibniz Hierarchy Revisited

Using the Isomorphism Theorem 1408 between full $\mathcal{I}$-structures and $\mathcal{I}$-congruence systems, we obtain, in the case of protoalgebraic π-institutions, the following special isomorphism theorem between Leibniz $\mathcal{I}$-filter families and $\mathcal{I}^*$-congruence systems.

Proposition 1621 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a protoalgebraic* π*-institution based on* $\mathbf{F}$. *Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the Leibniz operator* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism.*

Proof: By Theorem 1408, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,

$$\widetilde{\Omega}^{\mathcal{A}} : \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order isomorphism. By protoalgebraicity and Theorem 1582,

$$\mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) = \{\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T\rangle : T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\}.$$

Moreover, by protoalgebraicity, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) = \Omega^{\mathcal{A}}(T)$ and, also, $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) = \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Therefore, we get that $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. ■

We now show that $\Omega^{\mathcal{A}}$, as a mapping from Leibniz $\mathcal{I}$-filter families to $\mathcal{I}^*$-congruence systems on $\mathcal{I}$-algebraic systems, being an order isomorphism is sufficient to establish that the same mapping is an order isomorphism for all $\mathbf{F}$-algebraic systems.

Proposition 1622 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, the following conditions are equivalent:*

(i) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism;*

(ii) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism.*

Proof: Since (i)⇒(ii) is trivial, assume (ii) holds and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an arbitrary $\mathbf{F}$-algebraic system.

By Proposition 1528, $\Omega^{\mathcal{A}}$ is injective on $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$.

To show surjectivity, assume $\theta \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. By definition, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\theta = \Omega^{\mathcal{A}}(T)$. Consider the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$. Since $\mathrm{Ker}(\langle I, \pi \rangle) = \Omega^{\mathcal{A}}(T)$ is compatible with T, by Corollary 56, $\pi(T) \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. Since $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$, we get, by hypothesis, that there exists $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$, such that $\Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T)) = \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T')$. Now we have

$$\begin{array}{rcll}\Omega^{\mathcal{A}}(T) & = & \Omega^{\mathcal{A}}(\pi^{-1}(\pi(T))) & (\mathrm{Ker}(\langle I, \pi \rangle) \text{ compatible with } T)\\ & = & \pi^{-1}(\Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T))) & \\ & = & \pi^{-1}(\Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T')) & \\ & = & \Omega^{\mathcal{A}}(\pi^{-1}(T')). & \end{array}$$

Since $\mathrm{Ker}(\langle I, \pi \rangle) = \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))$, we get that $\mathrm{Ker}(\langle I, \pi \rangle)$ is compatible with $\pi^{-1}(T')$, and, hence, $\pi(\pi^{-1}(T')) = T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. by Corollary 1575, $\pi^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. We showed that $\theta = \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))$, with $\pi^{-1}(T') \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Therefore, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is surjective.

Next, we turn to monotonicity. To this end, let $T, T' \in \mathrm{Fifam}^{\mathcal{I}*}(\mathcal{A})$, such that $T \leq T'$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

We have $\mathrm{Ker}(\langle I, \pi \rangle) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$ and, also, $\mathrm{Ker}(\langle I, \pi \rangle) = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T')$. Thus, by Corollary 56,

$$\pi(T), \pi(T') \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)).$$

Since $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \text{AlgSys}(\mathcal{I})$, we get, by hypothesis, $\Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T)) \le \Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T'))$. Therefore,

$$\begin{array}{rcll} \Omega^{\mathcal{A}}(T) & = & \Omega^{\mathcal{A}}(\pi^{-1}(\pi(T))) & \text{(compatibility)} \\ & = & \pi^{-1}(\Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T))) & \\ & \le & \pi^{-1}(\Omega^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\pi(T'))) & \\ & = & \Omega^{\mathcal{A}}(\pi^{-1}(\pi(T'))) & \\ & = & \Omega^{\mathcal{A}}(T'). & \end{array}$$

Hence $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is monotone. Finally, by Proposition 1528, $\Omega^{\mathcal{A}}$ is reflective on $\text{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Thus, we conclude that $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. ■

Next, we show that, if $\Omega^{\mathcal{A}}$ from the Leibniz filter families onto the $\mathcal{I}^*$-congruence systems happens to be an order isomorphism on every $\mathcal{I}$-algebraic system, then the class of $\mathcal{I}$-algebraic systems coincides with the class of $\mathcal{I}^*$-algebraic systems.

Lemma 1623 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If, for all* $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism, then $\text{AlgSys}(\mathcal{I}) = \text{AlgSys}^*(\mathcal{I})$*.*

Proof: By Corollary 1405, we know that $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}(\mathcal{I})$ always holds. So it suffices to show the reverse inclusion. To this end, let $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ and let $T^m = \bigcap \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, for all $T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A})$, we have, by the hypothesis, $\Omega^{\mathcal{A}}(T^m) \le \Omega^{\mathcal{A}}(T)$, which yields $[\![T]\!]^* \subseteq [\![T^m]\!]^*$.

Now let $T' \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})$. By hypothesis, there exists $T \in \text{ThFam}^{\mathcal{I}*}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Thus, we get $T' \in [\![T']\!]^* = [\![T]\!]^* \subseteq [\![T^m]\!]^*$. Since this holds for every $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we conclude that $[\![T^m]\!]^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Proposition 1578, we get $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \text{AlgSys}^*(\mathcal{I})$ and, as, by hypothesis, $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ and, hence, $\widetilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$, we get $\mathcal{A} = \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \text{AlgSys}^*(\mathcal{I})$. We conclude that $\text{AlgSys}(\mathcal{I}) \subseteq \text{AlgSys}^*(\mathcal{I})$ and, therefore, the two classes of algebraic systems coincide. ■

The same conclusion may be drawn if we assume that $\Omega^{\mathcal{A}}$ is an order isomorphism from the collection of Suszko $\mathcal{I}$-filter families to the collection of all $\mathcal{I}^*$-congruence systems and, in fact, the proof follows along very similar lines.

Lemma 1624 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If, for all* $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism, then $\text{AlgSys}(\mathcal{I}) = \text{AlgSys}^*(\mathcal{I})$*.*

Proof: By Corollary 1405, we know that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$ always holds. So it suffices to show the reverse inclusion. To this end, let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ and let $T^m = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, for all $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, we have, by the hypothesis, $\Omega^{\mathcal{A}}(T^m) \leq \Omega^{\mathcal{A}}(T)$, which yields $[\![T]\!]^* \subseteq [\![T^m]\!]^*$.

Now let $T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$. By hypothesis, there exists $T \in \mathrm{ThFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Thus, we get $T' \in [\![T']\!]^* = [\![T]\!]^* \subseteq [\![T^m]\!]^*$. Since this holds for every $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we conclude that $[\![T^m]\!]^* = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Proposition 1578, we get $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \mathrm{AlgSys}^*(\mathcal{I})$ and, as, by hypothesis, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ and, hence, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$, we get $\mathcal{A} = \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \mathrm{AlgSys}^*(\mathcal{I})$. We conclude that $\mathrm{AlgSys}(\mathcal{I}) \subseteq \mathrm{AlgSys}^*(\mathcal{I})$ and, therefore, the two classes of algebraic systems coincide. ■

We know that, under protoalgebraicity, $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. The converse is true when family c-reflectivity is also assumed.

Proposition 1625 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a family completely reflective* π*-institution based on* $\mathbf{F}$. *If* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$, *then* $\mathcal{I}$ *is protoalgebraic.*

Proof: Assume that $\mathcal{I}$ is family c-reflective and that $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. By Proposition 1579, every full $\mathcal{I}$-structure on an $\mathbf{F}$-algebraic system $\mathcal{A}$ has the form $\langle \mathcal{A}, [\![T]\!]^* \rangle$, for some $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Proposition 1584, then, for every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $[\![T]\!]^{\mathsf{Su}} = [\![T']\!]^*$. Hence, $T^{\mathsf{Su}} = T'^*$. Now we have

$$\begin{array}{rcll} T & = & T^{\mathsf{Su}} & \text{(by Theorem 1590)} \\ & = & T'^* & \text{(shown above)} \\ & = & T'. & \text{(by Lemma 1583)} \end{array}$$

We conclude that $[\![T]\!]^{\mathsf{Su}} = [\![T]\!]^*$. Since this holds, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{Fifam}^{\mathcal{I}}(\mathcal{A})$, we conclude, by Proposition 1601, that $\mathcal{I}$ is protoalgebraic. ■

By Lemma 1623, we may replace equality of the two classes of algebraic system in Proposition 1625 by the condition that the Leibniz operator be an order isomorphism.

Proposition 1626 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a family completely reflective* π*-institution based on* $\mathbf{F}$. *If, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism, then* $\mathcal{I}$ *is protoalgebraic.*

Proof: By Proposition 1625 and Lemma 1623. ■

We also get a characterization of weak family algebraizability.

Corollary 1627 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is weakly family algebraizable if and only if it is family c-reflective and* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$*.*

Proof: If $\mathcal{I}$ is weakly family algebraizable, then it is, by definition, family c-reflective and protoalgebraic. By protoalgebraicity, $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. On the other hand, if $\mathcal{I}$ is family c-reflective and $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$, then it is family c-reflective and, by Proposition 1625, it is also protoalgebraic. Hence, $\mathcal{I}$ is weakly family algebraizable. ■

If, in Proposition 1626, we drop the hypothesis of $\mathcal{I}$ being family c-reflective, but compensate by assuming that $\Omega^{\mathcal{A}}$ is an order isomorphism between the collection of Suszko filter families and $\mathcal{I}^*$-congruence systems on all $\mathbf{F}$-algebraic systems, then we can still infer the protoalgebraicity of $\mathcal{I}$.

Theorem 1628 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ *is an order isomorphism.*

Proof: By Proposition 1621, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is an order isomorphism. By protoalgebraicity and Theorem 1601, $\mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Therefore, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{I})$ is an order isomorphism.

Conversely, assume that, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is an order isomorphism. By Lemma 1518, it suffices to show that the Leibniz and Suszko operators on an arbitrary $\mathbf{F}$-algebraic system coincide. To this end, let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

- Note that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. By Lemma 1624 and the hypothesis, there exists $T' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Hence, $[\![T]\!]^{\mathsf{Su}} = [\![T']\!]^*$ and, therefore, by Lemma 1583, $T^{\mathsf{Su}} = T'^* = T'$. We conclude that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^{\mathsf{Su}})$.

- Note that $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. Thus, there exists, by hypothesis, $T'' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T'')$. So $[\![T]\!]^* = [\![T'']\!]^*$. Hence, by Lemma 1583, $T^* = T''^* = T''$. This gives $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^*)$. Since $T^* = T'' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, $(T^*)^{\mathsf{Su}} = T^*$. But, by Lemma 1568, $T^* \le T$. Hence, $[\![T]\!]^{\mathsf{Su}} \subseteq [\![T^*]\!]^{\mathsf{Su}}$ and, thus, $T^* = (T^*)^{\mathsf{Su}} \le T^{\mathsf{Su}}$. By Lemma 1583, the reverse inclusion always holds, whence $T^* = T^{\mathsf{Su}}$. Now we get $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^{\mathsf{Su}})$.

Since, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^{\mathsf{Su}}) = \Omega^{\mathcal{A}}(T)$, we get that $\mathcal{I}$ is a protoalgebraic π-institution. ■

Theorem 1628 allows us to give a related characterization of equivalential π-institutions.

Corollary 1629 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *$\mathcal{I}$ is family equivalential if and only if it is family commuting and, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism.*

Proof: Suppose, first, that $\mathcal{I}$ is family equivalential. Then, by definition, $\mathcal{I}$ is family extensional and protoalgebraic. Thus, by Theorem 327, it is family inverse commuting and, by Theorem 325, it is family commuting. Moreover, by Theorem 1628, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism.

Assume, conversely, that $\mathcal{I}$ is family commuting and that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. Then, by Theorem 1628, it is protoalgebraic. Therefore, by Theorem 325, it is family inverse commuting and, by Theorem 327, it is family extensional. Being protoalgebraic and family extensional, it is, by definition, family equivalential. ∎

We turn now to establishing some characterizations of semantic classes in the Leibniz hierarchy via the use of the Suszko operator. First, we show that the family c-reflectivity of the Leibniz operator is equivalent with the universal injectivity of the Suszko operator and, in turn, a sufficient (and, trivially, necessary) condition fr it is the injectivity of the Suszko operator on an $\mathcal{I}$-algebraic systems.

Theorem 1630 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *The following conditions are equivalent:*

(i) *$\mathcal{I}$ is family c-reflective;*

(ii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ *is injective, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$*;*

(iii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ *is injective, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$.

Proof:

(i)⇒(ii) By Proposition 1528, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is injective on $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. By hypothesis and Theorem 1590, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is injective, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$.

(ii)⇒(iii) Trivial.

(iii)⇒(i) We use again Theorem 1590, showing that for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. To this end. let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider $T^m = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$. We have $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{AlgSys}(\mathcal{I})$ and, by Corollary 56, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$.

Hence, by assumption, $T^m \le T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. By monotonicity of the Suszko operator, Proposition 1544 and Lemma 1557,

$$\widetilde{\Omega}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(T^m) \le \widetilde{\Omega}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I}<\mathcal{A}}(T)}(T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}.$$

Hence, by hypothesis, $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = T^m$. Therefore, by Proposition 1587, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. This proves that $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by Theorem 1590, yields that $\mathcal{I}$ is family c-reflective. ∎

As regards protoalgebraicity, we have the following characterization.

Theorem 1631 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is protoalgebraic if and only if* $\widetilde{\Omega}^{\mathcal{I}}$ *is commuting.*

Proof: If $\mathcal{I}$ is protoalgebraic, then, by Lemma 1518, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$ and, by Proposition 24, $\widetilde{\Omega}^{\mathcal{I}}$ is commuting. If, conversely, $\widetilde{\Omega}^{\mathcal{I}}$ is commuting, then, by Corollary 1537, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$. Therefore, by Lemma 1518, $\mathcal{I}$ is protoalgebraic. ∎

We also get characterizations for equivalential, weakly algebraizable and algebraizable π-institutions.

Theorem 1632 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is family equivalential if and only if* $\widetilde{\Omega}^{\mathcal{I}}$ *is commuting and family extensional.*

(b) $\mathcal{I}$ *is weakly family algebraizable if and only if* $\widetilde{\Omega}^{\mathcal{I}}$ *is injective and commuting.*

(c) $\mathcal{I}$ *is family algebraizable if and only if* $\widetilde{\Omega}^{\mathcal{I}}$ *is injective and commuting and family extensional.*

Proof:

(a) Suppose $\mathcal{I}$ is equivalential. Then, by Theorem 334, Ω is monotone and family extensional. By Lemma 1518, $\Omega = \widetilde{\Omega}^{\mathcal{I}}$. Thus, by Proposition 24, $\widetilde{\Omega}^{\mathcal{I}}$ is commuting and family extensional. Conversely, if $\widetilde{\Omega}^{\mathcal{I}}$ is commuting and family extensional, then, by Corollary 1537, $\widetilde{\Omega}^{\mathcal{I}} = \Omega$. Thus, Ω is monotone and family extensional. By Theorem 334, $\mathcal{I}$ is family equivalential.

(b) By Theorems 1630 and 1631.

(c) By Part (a) and Theorem 1630.

■

In general, it is not hard to show that the Suszko operator on an **F**-algebraic system is an order embedding from the collection of Suszko $\mathcal{I}$-filter families into the family of $\mathcal{I}$-congruence systems.

Proposition 1633 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$$

is an order embedding.

Proof: The Suszko operator $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is always into $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. It is monotone by definition, and it is order-reflecting on $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$ by Proposition 1528. Therefore, it is an order embedding, as claimed. ■

Requiring the preceding embedding to be an order isomorphism turns out to be equivalent to the protoalgebraicity of $\mathcal{I}$.

Theorem 1634 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *is protoalgebraic;*

(ii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is an order isomorphism, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*;*

(iii) $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is surjective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proof:

(i)⇒(ii) By hypothesis and Lemma 1518, $\Omega^{\mathcal{A}} = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$. Thus, by Proposition 1580, $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}^*(\mathcal{I})$. It follows that $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) = \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. Now, by Theorem 1628, we get that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism.

(ii)⇒(iii) Trivial.

(iii)⇒(i) Assume (iii). We show that the Leibniz operator $\Omega^{\mathcal{A}}$ is monotone on the $\mathcal{I}$-filter families of every $\mathbf{F}$-algebraic system $\mathcal{A}$. To this end, let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Since $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A}) \subseteq \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, there exists, by hypothesis, $T'' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T'') = \Omega^{\mathcal{A}}(T)$. Thus, we have

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{A}}([\![T'']\!]^{\mathsf{Su}}) & = & \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T'') \\ & = & \Omega^{\mathcal{A}}(T) \\ & = & \widetilde{\Omega}^{\mathcal{A}}([\![T]\!]^*).\end{array}$$

Since $\langle\mathcal{A},[\![T'']\!]^{\mathsf{Su}}\rangle$, $\langle\mathcal{A},[\![T]\!]^*\rangle\in\mathrm{FStr}(\mathcal{I}|)$, by Theorem 1408, $[\![T'']\!]^{\mathsf{Su}}=[\![T]\!]^*$. Moreover, since $T''\in\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, by Lemma 1583, we obtain $[\![T'']\!]^{\mathsf{Su}}=\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T''}$. Since $T\in[\![T]\!]^*=[\![T'']\!]^{\mathsf{Su}}=\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T''}$, we get $T''\le T\le T'$. Thus, $T'\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T''}=[\![T'']\!]^{\mathsf{Su}}=[\![T]\!]^*$. In other words, $\Omega^{\mathcal{A}}(T)\le\Omega^{\mathcal{A}}(T')$. We conclude that $\Omega^{\mathcal{A}}$ is monotone on every $\mathcal{A}$, whence $\mathcal{I}$ is protoalgebraic.

■

In closing the section, we exploit Theorem 1634 to provide characterizations of some of the classes of the semantic Leibniz hierarchy.

Theorem 1635 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) *$\mathcal{I}$ is protoalgebraic if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism;*

(b) *$\mathcal{I}$ is family c-reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding;*

(c) *$\mathcal{I}$ is weakly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism;*

(d) *$\mathcal{I}$ is family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism and $\mathcal{I}$ is family extensional.*

Proof:

(a) By Theorem 1634.

(b) By Proposition 1633, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is always an order embedding. By Theorem 1590, family c-reflectivity implies $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})=\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We conclude that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding. If, conversely, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding, then it is injective on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, whence, by Theorem 1630, $\mathcal{I}$ is family c-reflective.

(c) Assume, first, that $\mathcal{I}$ is weakly family algebraizable. By Theorem 1628, $\Omega^{\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. By Theorem 1590, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})=\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\Omega^{\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. Finally, by protoalgebraicity and Lemma 1518, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}=\Omega^{\mathcal{A}}$, and by protoalgebraicity and Proposition 1580, $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})=\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$. Thus, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism.

If, conversely, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism, then, by Theorem 1630, $\mathcal{I}$ is family c-reflective, whence, by

Theorem 1590, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, hence, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is onto $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Thus, by Theorem 1634, $\mathcal{I}$ is protoalgebraic. We conclude that $\mathcal{I}$ is weakly family algebraizable.

(d) By Part (c) and the definition of family algebraizability.

■

21.14 Suszko Operator and Truth Equationality

Recall that by Proposition 68 and Proposition 28, it makes sense, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, to consider the relative congruence system $\Theta^{\mathcal{I},\mathcal{A}}(R) := \Theta^{\mathrm{AlgSys}(\mathcal{I}),\mathcal{A}}(R)$ on $\mathcal{A}$ generated by a relation family $R \in \mathrm{RelFam}(\mathcal{A})$.

Lemma 1636 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $X \in \mathrm{SenFam}(\mathcal{A})$*, if* $\theta = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X])$ *and* $\langle I, \pi\rangle : \mathcal{A} \to \mathcal{A}/\theta$ *is the quotient morphism, then*

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) = \pi(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^X) \text{ and } \pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^X.$$

Proof: Let us set

$$\mathcal{T} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X]) \le \Omega^{\mathcal{A}}(T)\}.$$

By Proposition 1524, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) = \pi(\mathcal{T})$ and $\pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)) = \mathcal{T}$. But we also have

$$\begin{array}{rcl}
\mathcal{T} & = & \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \theta \le \Omega^{\mathcal{A}}(T)\} \\
 & & \text{(definition of } \mathcal{T}) \\
 & = & \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \tau^{\mathcal{A}}[X] \le \Omega^{\mathcal{A}}(T)\} \\
 & & \text{(since } \theta = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X]) \text{ and } \Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})) \\
 & = & \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : X \le T\} \\
 & & \text{(by family truth equationality)} \\
 & = & \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^X. \quad \text{(definition of } \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^X)
\end{array}$$

The conclusion follows. ■

We show, next that, under the same hypotheses, the Suszko congruence system of an $\mathcal{I}$-filter family generated by a sentence family X equals the least $\mathcal{I}$-congruence system on $\mathcal{A}$ generated by the relation family $\tau^{\mathcal{A}}[X]$.

Proposition 1637 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $X \in \mathrm{SenFam}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(X)) = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X]).$$

In particular, if $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[T])$*.*

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $X \in \mathrm{SenFam}(\mathcal{A})$ and set $\theta = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X])$. Since $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, we have $\mathcal{A}/\theta \in \mathrm{AlgSys}(\mathcal{I})$. Therefore,

$$\widetilde{\Omega}^{\mathcal{A}/\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)) = \Delta^{\mathcal{A}/\theta}.$$

Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\theta.$$

We have

$$\begin{array}{rcll}
\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(X)) & = & \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^X) & \\
& = & \widetilde{\Omega}^{\mathcal{A}}(\pi^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))) & \text{(Lemma 1636)} \\
& = & \pi^{-1}(\widetilde{\Omega}^{\mathcal{A}/\theta}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))) & \\
& = & \pi^{-1}(\Delta^{\mathcal{A}/\theta}) & \\
& = & \theta. &
\end{array}$$

Therefore, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(X)) = \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X])$, as was to be shown. ∎

Proposition 1638 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\Sigma \in |\mathbf{Sign}^\flat|$ *and* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) = \Theta^{\mathcal{I}}(\tau^\flat_\Sigma[\phi]).$$

Proof: Directly from Proposition 1637, letting $X = \{X_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where $X_\Sigma = \{\phi\}$ and $X_{\Sigma'} = \varnothing$, for all $\Sigma' \neq \Sigma$. ∎

Another property is that the Suszko congruence family of the $\mathcal{I}$-filter family generated by a sentence family X can be obtained as the join of the Suszko congruence families of the $\mathcal{I}$-filter families generated by each singleton in X.

Proposition 1639 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $X \in \mathrm{SenFam}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(X)) = \bigvee \{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(\phi)) : \phi \in X_\Sigma, \Sigma \in |\mathbf{Sign}|\}.$$

Proof: Suppose $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. Then, we have, for every **F**-algebraic system $\mathcal{A}$ and all $X \in \mathrm{SenFam}(\mathcal{A})$,

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(X)) & = & \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[X]) \\ & & \text{(by Proposition 1637)} \\ & = & \bigvee\{\Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}_\Sigma[\phi]) : \phi \in X_\Sigma, \Sigma \in |\mathbf{Sign}|\} \\ & & \text{(by Proposition 35)} \\ & = & \bigvee\{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(\phi)) : \phi \in X_\Sigma, \Sigma \in |\mathbf{Sign}|\}. \\ & & \text{(by Proposition 1637)}\end{array}$$

This proves the statement. ∎

More generally, we have

Proposition 1640 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a family truth equational* π*-institution based on* **F**. *For every* **F***-algebraic system* $\mathcal{A}$ *and all* $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigvee_{i\in I}^{\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})} T^i) = \bigvee_{i\in I}^{\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})} \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T^i).$$

Proof: Suppose $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and let $\mathcal{A}$ be an **F**-algebraic system and $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, we have

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigvee_{i\in I} T^i) & = & \widetilde{\Omega}(C^{\mathcal{I},\mathcal{A}}(\bigcup_{i\in I} T^i)) & \text{(joins in } \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) \\ & = & \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[\bigcup_{i\in I} T^i]) & \text{(Proposition 1637)} \\ & = & \Theta^{\mathcal{I},\mathcal{A}}(\bigcup_{i\in I} \tau^{\mathcal{A}}[T^i]) & \\ & = & \bigvee_{i\in I} \Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[T^i]) & \text{(joins in } \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})) \\ & = & \bigvee_{i\in I} \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T^i). & \text{(Proposition 1637)}\end{array}$$

This proves the statement. ∎

Another property is the commutativity of the Suszko operator with surjective morphisms with isomorphic functor components.

Proposition 1641 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a family truth equational* π*-institution based on* **F**. *For all* **F***-algebraic systems* $\mathcal{A}$, $\mathcal{B}$*, all surjective morphisms* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$*, with* H *an isomorphism, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(C^{\mathcal{I},\mathcal{B}}(\gamma(T))) = \Theta^{\mathcal{I},\mathcal{B}}(\gamma(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))).$$

Proof: Suppose $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and let $\mathcal{A}$, $\mathcal{B}$ be **F**-algebraic systems, $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We now get

$$\begin{array}{rcll}\widetilde{\Omega}^{\mathcal{I},\mathcal{B}}(C^{\mathcal{I},\mathcal{B}}(\gamma(T))) & = & \Theta^{\mathcal{I},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(T)]) & \text{(by Proposition 1637)}\\ & = & \Theta^{\mathcal{I},\mathcal{B}}(\gamma(\Theta^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}[T]))) & \text{(by Proposition 34)}\\ & = & \Theta^{\mathcal{I},\mathcal{B}}(\gamma(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))). & \text{(by Proposition 1637)}\end{array}$$

This proves the equality in the statement. ∎

We now build a little further on our work of Section 12.2 in order to give another characterization of family truth equationality.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems and $\mathcal{K} = \langle \mathbf{K}, D\rangle$ and $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ be two π-structures based on $\mathbf{K}$ and $\mathbf{K}'$, respectively. Consider an order embedding

$$h : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}').$$

Recall that $\overleftarrow{h} = \{\overleftarrow{h}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ is defined, for all $\Sigma \in |\mathbf{Sign}|$, by letting

$$\overleftarrow{h}_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SenFam}(\mathbf{K}')$$

be given, for all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\overleftarrow{h}_\Sigma[\phi] = h(D(\phi)).$$

Then we have the following analog of Lemma 894.

Lemma 1642 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}', D'\rangle$ be π-structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $h : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}')$ an order embedding, which preserves suprema. Then $\overleftarrow{h} : \mathcal{K} \to \mathcal{K}'$ is an interpretation.*

Proof: Suppose $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ is an order embedding and let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{rll}\phi \in D_\Sigma(\Phi) & \text{iff} & D(\phi) \leq D(\Phi)\\ & \text{iff} & h(D(\phi)) \leq h(D(\Phi))\\ & \text{iff} & h(D(\phi)) \leq h(\bigvee\{D(\chi) : \chi \in \Phi\})\\ & \text{iff} & h(D(\phi)) \leq \bigvee\{h(D(\chi)) : \chi \in \Phi\}\\ & \text{iff} & \overleftarrow{h}_\Sigma[\phi] \leq \bigvee\{\overleftarrow{h}_\Sigma[\chi] : \chi \in \Phi\}\\ & \text{iff} & \overleftarrow{h}_\Sigma[\phi] \leq D'(\overleftarrow{h}_\Sigma[\Phi]).\end{array}$$

Thus, $\overleftarrow{h} : \mathcal{K}' \to \mathcal{K}$ is indeed an interpretation. ∎

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$ and $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures based on $\mathbf{K}^k$ and $\mathbf{K}^\ell$, respectively. Consider a suprema preserving order embedding

$$h : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}').$$

We say that the order embedding $h : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}')$ is **transformational** if there exists $\tau : \mathrm{SEN}^\omega \to \mathrm{SEN}^\ell$, with k distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$,

$$\overleftarrow{h}_\Sigma[\vec{\phi}] = D'(\tau_\Sigma[\vec{\phi}]).$$

We have the following analog of Lemma 899.

Lemma 1643 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures and $h : \mathbf{ThFam}(\mathcal{K}) \to \mathbf{ThFam}(\mathcal{K}')$ a transformational suprema preserving order embedding induced by $\tau : \mathbf{K}^k \to \mathbf{K}^\ell$. Then, for all $\Sigma \in |\mathbf{Sign}|$, all $\Phi \subseteq \mathrm{SEN}(\Sigma)^k$,*

$$h(D(\Phi)) = D'(\tau_\Sigma[\Phi]).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)^k$,

$$\begin{array}{rcll} h(D(\Phi)) & = & h(\bigvee_{\phi\in\Phi} D(\phi)) & (\text{join in } \mathbf{ThFam}(\mathcal{K})) \\ & = & \bigvee_{\phi\in\Phi} h(D(\phi)) & (h \text{ suprema preserving}) \\ & = & \bigvee_{\phi\in\Phi} D'(\tau_\Sigma[\phi]) & (\overleftarrow{h}_\Sigma[\phi] = D'(\tau_\Sigma[\phi])) \\ & = & D'(\bigcup_{\phi\in\Phi} \tau_\Sigma[\phi]) & (\text{join in } \mathbf{ThFam}(\mathcal{K}')) \\ & = & D'(\tau_\Sigma[\Phi]). & (\text{by definition}) \end{array}$$

This proves the equality of the statement. ∎

Furthermore, we have an analog of Theorem 900:

Theorem 1644 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D\rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D'\rangle$ be two π-structures and $h : \mathbf{ThFam}(\mathcal{K}') \to \mathbf{ThFam}(\mathcal{K})$ a transformational suprema preserving order embedding induced by $\tau : \mathbf{K}^k \to \mathbf{K}^\ell$. Then $\tau : \mathcal{K} \to \mathcal{K}'$ is an interpretation.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}(\Sigma)^k$. We then have:

$$\begin{array}{rll} \phi \in D_\Sigma(\Phi) & \text{iff} & D_\Sigma(\phi) \leq D_\Sigma(\Phi) \\ & \text{iff} & h(D(\phi)) \leq h(D(\Phi)) \quad (h \text{ order embedding}) \\ & \text{iff} & D'(\tau_\Sigma[\phi]) \leq D'(\tau_\Sigma[\Phi]) \quad (\text{Lemma 1643}) \\ & \text{iff} & \tau_\Sigma[\phi] \leq D'(\tau_\Sigma[\Phi]). \end{array}$$

Thus, $\tau : \mathcal{K} \to \mathcal{K}'$ is an interpretation. ∎

Now, we obtain the following theorem characterizing family truth equationality in terms of transformational suprema preserving order embeddings.

Theorem 1645 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family truth equational if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is a transformational suprema preserving order embedding.*

Proof: Suppose, first, that $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$. Then, it is, a fortiori, family c-reflective, whence, by Theorem 1635, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order embedding, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. By Proposition 1637, $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}$ is transformational and, by Proposition 1640, it is suprema preserving.

Assume, conversely, that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is a transformational suprema preserving order embedding. Then, on the one hand, by Theorem 1635, $\mathcal{I}$ is family c-reflective, and, on the other, by definition, there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, such that $\widetilde{\Omega}^{\mathcal{I}} : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{F})$ is induced by $\tau^\flat$. Thus, by Theorem 1644, $\tau^\flat : \mathcal{I} \to \mathcal{Q}^{\mathrm{AlgSys}(\mathcal{I})}$ is an interpretation. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. we have

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Theta^{\mathcal{I},\mathcal{F}}(\tau^\flat_\Sigma[T_\Sigma]) \quad (\tau^\flat \text{ an interpretation}) \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad (\text{by Lemma 1643}) \\ & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \Omega(T). \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{array}$$

If, conversely, $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$, then $\Theta^{\mathcal{I},\mathcal{F}}(\tau^\flat_\Sigma[\phi]) \leq \Omega(T)$, whence, by Lemma 1643, $\widetilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. Thus, by family c-reflectivity and Lemma 1519, $\phi \in T_\Sigma$. Therefore, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \Omega_\Sigma(T).$$

We conclude that $\mathcal{I}$ is family truth-equational, with witnessing transformations $\tau^\flat$. ∎

21.15 Relations With Algebraic Semantics

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Given a class K of $\mathbf{F}$-algebraic systems, recall the definition oof the closure system $C^{\mathsf{K},\tau} = \{C^{\mathsf{K},\tau}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $C^{\mathsf{K},\tau}_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$ is given, for all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, by

$$\phi \in C^{\mathsf{K},\tau}_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq C^{\mathsf{K}}(\tau^\flat_\Sigma[\Phi]).$$

Define the class $\mathsf{K}(\mathcal{I}, \tau)$ of $\mathbf{F}$-algebraic systems by

$$\mathsf{K}(\mathcal{I}, \tau) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : C \leq C^{\mathcal{A},\tau}\}.$$

The following proposition gives a characterization of this class.

Proposition 1646 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$\mathsf{K}(\mathcal{I},\tau) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.$$

Proof: Suppose, first, that $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$. Then, by definition, $\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\Phi)] \leq \Delta^{\mathcal{A}}$. This implies $\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}}$. Since, by hypothesis, $\phi \in C_\Sigma(\Phi)$ and $C \leq C^{\mathcal{A},\tau}$, we get $\alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}$. Equivalently, $\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}}$, i.e., $\alpha_\Sigma(\phi) \in \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$. We conclude that $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. This proves the left-to-right inclusion.

Assume, conversely, that $\mathcal{A}$ is an $\mathbf{F}$-algebraic system, such that $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}}$. Then $\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\Phi)] \leq \Delta^{\mathcal{A}}$, i.e., $\alpha_\Sigma(\Phi) \subseteq \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$. Since, by hypothesis, $\phi \in C_\Sigma(\Phi)$ and $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get $\alpha_\Sigma(\phi) \in \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$, whence $\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}}$ or, equivalently, $\alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}$. We conclude that $\phi \in C^{\mathcal{A},\tau}_\Sigma(\Phi)$ and, hence, $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. ∎

It is readily inferred from the definition that, provided $\mathcal{I}$ has a $\tau^\flat$-algebraic semantics, then the class $\mathsf{K}(\mathcal{I},\tau)$ is the largest such.

Corollary 1647 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *has a* $\tau^\flat$*-algebraic semantics, then* $\mathsf{K}(\mathcal{I},\tau)$ *is its largest* $\tau^\flat$*-algebraic semantics.*

Proof: Suppose K is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$ and let $\mathcal{A} \in \mathsf{K}$. Then, by the definition of $\tau^\flat$-algebraic semantics and taking into account the membership $\mathcal{A} \in \mathsf{K}$, we get $C = C^{\mathsf{K},\tau} \leq C^{\mathcal{A},\tau}$. Therefore, by definition of $\mathsf{K}(\mathcal{I},\tau)$, $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. We conclude that $\mathsf{K} \subseteq \mathsf{K}(\mathcal{I},\tau)$. ∎

we can also show that, if $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat$, then $\mathrm{AlgSys}(\mathcal{I})$ is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$.

Proposition 1648 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family truth equational, with witnessing transformations* $\tau^\flat$*, then* $\mathrm{AlgSys}(\mathcal{I})$ *is a* $\tau^\flat$*-algebraic semantics for* $\mathcal{I}$*.*

Proof: We must show that $C = C^{\mathrm{AlgSys}(\mathcal{I}),\tau}$.

Let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}}$. Since $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, there exists $\mathcal{T} \subseteq$

$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. Hence, we get

$$\begin{array}{rcl}\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}} & \text{iff} & \alpha(\tau^\flat_\Sigma[\Phi]) \leq \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\Phi]) \leq \Omega^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \tau^\flat_\Sigma[\Phi] \leq \Omega(\alpha^{-1}(T)), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \Phi \subseteq \alpha^{-1}_\Sigma(T), \text{ for all } T \in \mathcal{T}, \\ & \text{implies} & \phi \subseteq \alpha^{-1}_\Sigma(T), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \Omega(\alpha^{-1}(T)), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\phi]) \leq \Omega^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T}, \\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\phi]) \leq \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}.\end{array}$$

We conclude that $\phi \in C^{\mathrm{AlgSys}(\mathcal{I}),\tau}_\Sigma(\Phi)$. Therefore, $C \leq C^{\mathrm{AlgSys}(\mathcal{I}),\tau}$.

Suppose, conversely, that $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathrm{AlgSys}(\mathcal{I}),\tau}_\Sigma(\Phi)$ and $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\Phi \subseteq T_\Sigma$. Then, we have $\tau^\flat_\Sigma[\Phi] \leq \Omega(T)$, i.e., $\tau^{\mathcal{F}/\Omega(T)}_\Sigma[\Phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}$. But $\mathcal{F}/\Omega(T) \in \mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. Therefore, since $\phi \in C^{\mathrm{AlgSys}(\mathcal{I}),\tau}_\Sigma(\Phi)$, we get that $\tau^{\mathcal{F}/\Omega(T)}_\Sigma[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}$, whence $\tau^\flat_\Sigma[\phi] \leq \Omega(T)$. Therefore, $\phi \in T_\Sigma$ and we conclude that $\phi \in C_\Sigma(\Phi)$. This proves that $C^{\mathrm{AlgSys}(\mathcal{I}),\tau} \leq C$ and, as a result, equality follows.

We have now shown that $\mathrm{AlgSys}(\mathcal{I})$ is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$. ∎

Corollary 1649 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$, *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is family truth equational, with witnessing transformations* $\tau^\flat$, *then* $\mathrm{AlgSys}(\mathcal{I}) \subseteq \mathsf{K}(\mathcal{I},\tau)$.

Proof: By Proposition 1648 and Corollary 1647. ∎

For family truth equational π-institutions we have the following characterization of the least $\mathcal{I}$-filter families on arbitrary algebraic systems and on $\mathcal{I}$-algebraic systems.

Lemma 1650 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$, *with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$.

(a) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $C^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})) = C^{\mathcal{I},\mathcal{A}}(\varnothing)$;

(b) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = C^{\mathcal{I},\mathcal{A}}(\varnothing)$.

Proof:

(a) Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. We have $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(\varnothing)))$. By family truth equationality, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq C^{\mathcal{I},\mathcal{A}}(\varnothing)$. It follows that $C^{\mathcal{I},\mathcal{A}}(\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})) = C^{\mathcal{I},\mathcal{A}}(\varnothing)$.

(b) Let $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$. Then, by Part (a), $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq C^{\mathcal{I},\mathcal{A}}(\varnothing)$. Assume, conversely, that $\Sigma \in |\mathbf{Sign}|$, $\phi \in \text{SEN}(\Sigma)$, such that $\phi \in C^{\mathcal{I},\mathcal{A}}_{\Sigma}(\varnothing)$. Then, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\phi \in T_\Sigma = \tau^{\mathcal{A}}_{\Sigma}(\Omega^{\mathcal{A}}(T))$, i.e., for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\tau^{\mathcal{A}}_{\Sigma}[\phi] \leq \Omega^{\mathcal{A}}(T)$. We conclude that $\tau^{\mathcal{A}}_{\Sigma}[\phi] \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(\varnothing)) = \Delta^{\mathcal{A}}$. This shows that $\phi \in \tau^{\mathcal{A}}_{\Sigma}(\Delta^{\mathcal{A}})$. Thus, $C^{\mathcal{I},\mathcal{A}}(\varnothing) \leq \tau^{\mathcal{A}}(\Delta^{\mathcal{A}})$. Equality now follows.

■

So in the case of family truth equational π-institutions, we may strengthen the characterization of the class $\mathsf{K}(\mathcal{I},\tau)$ given in Proposition 1646.

Proposition 1651 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat : (\text{SEN}^\flat)^\omega \to (\text{SEN}^\flat)^2$ *in* $N^\flat$*. Then*

$$\mathsf{K}(\mathcal{I},\tau) = \{\mathcal{A} \in \text{AlgSys}(\mathbf{F}) : \tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = C^{\mathcal{I},\mathcal{A}}(\varnothing)\}.$$

Proof: Note that, taking into account Proposition 1646,

$$\begin{aligned}\{\mathcal{A} \in \text{AlgSys}(\mathbf{F}) : \tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = C^{\mathcal{I},\mathcal{A}}(\varnothing)\}&\\ \subseteq \{\mathcal{A} \in \text{AlgSys}(\mathbf{F}) : \tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\}&\\ = \mathsf{K}(\mathcal{I},\tau).&\end{aligned}$$

Assume, conversely, that $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. Then, by Proposition 1646, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by definition of $\mathsf{K}(\mathcal{I},\tau)$, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq C^{\mathcal{I},\mathcal{A}}(\varnothing)$. Hence $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = C^{\mathcal{I},\mathcal{A}}(\varnothing)$. ■

Proposition 1651 has some interesting consequences. First, any two sets of witnessing transformations for truth equationality are, roughly speaking, deductively equivalent over any $\mathcal{I}$-algebraic system.

Corollary 1652 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat \tau'^\flat : (\text{SEN}^\flat)^\omega \to (\text{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family truth equational, with witnessing transformations* $\tau^\flat$ *and* $\tau'^\flat$*, then, for every* $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \text{SEN}^\flat(\Sigma)$*,*

$$C^{\mathcal{A}}(\tau^\flat_\Sigma[\phi]) = C^{\mathcal{A}}(\tau'^\flat_\Sigma[\phi]).$$

Proof: Suppose $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat$ and $\tau'^\flat$ and let $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \text{SEN}^\flat(\Sigma)$, such that $\alpha(\tau'^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}$. This is equivalent to $\tau'^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}}$, i.e., $\alpha_\Sigma(\phi) \in \tau'^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$. By Proposition 1651, $\alpha_\Sigma(\phi) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\varnothing)$. Again by Proposition 1651, $\alpha_\Sigma(\phi) \in \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}})$. Thus, $\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}}$. Hence, $\alpha_\Sigma(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}$. This shows that $\tau^\flat_\Sigma[\phi] \leq C^{\mathcal{A}}(\tau'^\flat_\Sigma[\phi])$. By symmetry, we conclude that $C^{\mathcal{A}}(\tau^\flat_\Sigma[\phi]) = C^{\mathcal{A}}(\tau'^\flat_\Sigma[\phi])$. ■

Finally, the Suszko core $S^\flat$ has a special position among all witnessing transformations. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} =$

$\langle\mathbf{F},C\rangle$ be a π-institution based on $\mathbf{F}$. Recall that the Suszko core of $\mathcal{I}$ is the collection

$$S^{\mathcal{I}}=\{\sigma^\flat\in N^\flat:(\forall T\in\mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[T]\leq\widetilde{\Omega}(T)\}.$$

Recall, also, that, by Lemma 835, if $\mathcal{I}$ is truth equational, with witnessing equations $\tau^\flat\subseteq N^\flat$, then $\tau^\flat\subseteq S^{\mathcal{I}}$.

Corollary 1653 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat:(\mathrm{SEN}^\flat)^\omega\to(\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. Then*

$$\mathsf{K}(\mathcal{I},S^{\mathcal{I}})\subseteq\mathsf{K}(\mathcal{I},\tau).$$

Proof: Suppose $\mathcal{A}\in\mathsf{K}(\mathcal{I},S^{\mathcal{I}})$. By hypothesis and Lemma 835, $\tau^\flat\subseteq S^{\mathcal{I}}$. Hence $S^{\mathcal{I}}(\Delta^{\mathcal{A}})\leq\tau^\flat(\Delta^{\mathcal{A}})$. But, by hypothesis, Theorem 840 and Proposition 1651, $S^{\mathcal{I}}(\Delta^{\mathcal{A}})=C^{\mathcal{I},\mathcal{A}}(\varnothing)$ and, by hypothesis and Lemma 1650, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})\leq C^{\mathcal{I},\mathcal{A}}(\varnothing)$. Hence, we have

$$C^{\mathcal{I},\mathcal{A}}(\varnothing)=S^{\mathcal{I}}(\Delta^{\mathcal{A}})\leq\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})\leq C^{\mathcal{I},\mathcal{A}}(\varnothing).$$

Therefore, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})=C^{\mathcal{I},\mathcal{A}}(\varnothing)$ and, thus, by Proposition 1651, $\mathcal{A}\in\mathsf{K}(\mathcal{I},\tau)$. We conclude that $\mathsf{K}(\mathcal{I},S^{\mathcal{I}})\subseteq\mathsf{K}(\mathcal{I},\tau)$. ■

Corollary 1654 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a family truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat:(\mathrm{SEN}^\flat)^\omega\to(\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. Then* $\mathsf{K}(\mathcal{I},S^{\mathcal{I}})$ *is a* $\tau^\flat$*-algebraic semantics for* $\mathcal{I}$*.*

Proof: Observe that we have

$$\begin{array}{rcll}\mathrm{AlgSys}(\mathcal{I})&\subseteq&\mathsf{K}(\mathcal{I},S^{\mathcal{I}})&\text{(by Theorem 840 and Corollary 1649)}\\&\subseteq&\mathsf{K}(\mathcal{I},\tau).&\text{(by Corollary 1653)}\end{array}$$

Since, by Proposition 1648, $\mathrm{AlgSys}(\mathcal{I})$ is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$ and, by Corollary 1647, $\mathsf{K}(\mathcal{I},\tau)$ is also a $\tau^\flat$-algebraic semantics for $\mathcal{I}$, we conclude that $\mathsf{K}(\mathcal{I},S^{\mathcal{I}})$ is one also. ■

21.16 The $\mathcal{I}$-Operator $\Psi^{\mathsf{K},\tau}$

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, with $\tau^\flat:(\mathrm{SEN}^\flat)^\omega\to(\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I}=\langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$, with a $\tau^\flat$-algebraic semantics K, such that $\mathrm{AlgSys}^*(\mathcal{I})\subseteq\mathsf{K}$. For every $\mathbf{F}$-algebraic system $\mathcal{A}$, we define the operator

$$\Psi^{\mathsf{K},\tau,\mathcal{A}}:\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\to\mathrm{EqvFam}(\mathcal{A})$$

by setting, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\Psi^{\mathsf{K},\tau,\mathcal{A}}(T) = \Theta^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T]).$$

Note that, by the hypotheses and Proposition 28, $\Psi^{\mathsf{K},\tau,\mathcal{A}}$ is well-defined, since $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$-congruence systems on $\mathcal{A}$ form a closure system on $\mathcal{A}^2$.

It is the case that if a class K of $\mathbf{F}$-algebraic systems is a $\tau^\flat$-algebraic semantics for a π-institution $\mathcal{I}$, then so is the larger class $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$.

Proposition 1655 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If a class K of $\mathbf{F}$-algebraic systems is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$, then so is $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$.*

Proof: First, observe that $\mathsf{K} \subseteq \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$, whence $C^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\tau} \leq C^{\mathsf{K},\tau} = C$. To show the converse, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. Let

$$\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

be a subdirect intersection, with $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$, and assume that $\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}}$. Since, by definition $\Delta^{\mathcal{A}} = \bigcap_{i\in I}\mathrm{Ker}(\langle H^i, \gamma^i\rangle)$, we get that $\alpha(\tau^\flat_\Sigma[\Phi]) \leq \mathrm{Ker}(\langle H^i, \gamma^i\rangle)$, for all $i \in I$, i.e., $\gamma^i(\alpha(\tau^\flat_\Sigma[\Phi])) \leq \Delta^{\mathcal{A}^i}$, $i \in I$, or, equivalently, $\alpha^i(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}^i}$, $i \in I$. Since $\phi \in C_\Sigma(\Phi)$, $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$ and K is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$, we get $\alpha^i(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}^i}$, for all $i \in I$. We now reverse the steps above. We get $\gamma^i(\alpha(\tau^\flat_\Sigma[\phi])) \subseteq \Delta^{\mathcal{A}^i}$, $i \in I$, then $\alpha(\tau^\flat_\Sigma[\phi]) \leq \mathrm{Ker}(\langle H^i, \gamma^i\rangle)$, $i \in I$, and, finally, $\alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}}$. Thus, $\phi \in C^{\mathcal{A},\tau}_\Sigma(\Phi)$. Since, for all $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$, $C \leq C^{\mathcal{A},\tau}$, we conclude that $C \leq C^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\tau}$. Therefore, $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$ is also a $\tau^\flat$-algebraic semantics for $\mathcal{I}$. ■

Tying the operator $\Psi^{\mathsf{K},\tau,\mathcal{A}}$ with our preceding work in this Chapter, we show that it is a congruential monotone compatibility $\mathcal{I}$-operator on $\mathcal{A}$.

Proposition 1656 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$, with a $\tau^\flat$-algebraic semantics K, such that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K}$. For every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Psi^{\mathsf{K},\tau,\mathcal{A}}$ is a congruential, monotone, compatibility $\mathcal{I}$-operator on $\mathcal{A}$.*

Proof: $\Psi^{\mathsf{K},\tau,mcA}$ is, by definition, an $\mathcal{I}$-operator on $\mathcal{A}$. It is congruential, since, again by definition, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Theta^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T]) \in \mathrm{ConSys}(\mathcal{A})$. It is monotone, since, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, we get $\tau^{\mathcal{A}}[T] \leq \tau^{\mathcal{A}}[T']$ and, therefore, $\Theta^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T]) \leq \Theta^{\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T'])$.

To see that it is also a compatibility $\mathcal{I}$-operator, consider $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Note, first, that

$$\begin{array}{rcll}\mathrm{AlgSys}(\mathcal{I}) & = & \overset{\triangleleft}{\mathbb{P}}(\mathrm{AlgSys}^*(\mathcal{I}) & \text{(by Theorem 1404)}\\ & \subseteq & \overset{\triangleleft}{\mathbb{P}}(\mathsf{K}). & \text{(since } \mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K})\end{array}$$

Thus, we get $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) \subseteq \mathrm{ConSys}^{\overset{\triangleleft}{\mathbb{P}}(\mathsf{K})}(\mathcal{A})$. Since, by Corollary 824, $\tau^{\mathcal{A}}[T] \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$, we get

$$\Theta^{\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T]) \leq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T).$$

Therefore, $\Psi^{\mathsf{K},\tau,\mathcal{A}}$ is also a compatibility $\mathcal{I}$-operator on $\mathcal{A}$. ■

It turns out that $\Psi^{\mathsf{K},\tau} = \{\Psi^{\mathsf{K},\tau,\mathcal{A}} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$ is also semi-coherent. To show this, we formulate two technical lemmas on the way.

Lemma 1657 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$. *For all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$, $\mathcal{B}$, *every surjective morphism* $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$, *with* H *an isomorphism, and all* $T' \in \mathrm{SenFam}(\mathcal{B})$,

(a) $\tau^{\mathcal{B}}[T'] = \gamma(\tau^{\mathcal{A}}[\gamma^{-1}(T')])$;

(b) $\tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \gamma^{-1}(\tau^{\mathcal{B}}[T'])$.

Proof: First, note that, for all $T \in \mathrm{SenFam}(\mathcal{A})$, we have, taking into account the fact that $\langle H, \gamma\rangle$ is a surjective morphism, $\gamma(\tau^{\mathcal{A}}[T]) = \tau^{\mathcal{B}}[\gamma(T)]$. Now, we set $T = \gamma^{-1}(T')$. This gives

$$\gamma(\tau^{\mathcal{A}}[\gamma^{-1}(T')]) = \tau^{\mathcal{B}}[\gamma(\gamma^{-1}(T'))] = \tau^{\mathcal{B}}[T'],$$

which conclude the proof of Part (a). For Part (b), we have, using Part (a),

$$\tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \gamma^{-1}(\gamma(\tau^{\mathcal{A}}[\gamma^{-1}(T')])) = \gamma^{-1}(\tau^{\mathcal{B}}[T']).$$

■

Lemma 1658 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$, *and* K *a class of* $\mathbf{F}$*-algebraic systems, such that* $\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}) \subseteq \mathsf{K}$. *For all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$, $\mathcal{B}$, *every surjective morphism* $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$, *with* H *an isomorphism, and all* $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\begin{array}{l}\{\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) : \mathrm{Ker}(\langle H, \gamma\rangle) \leq \theta \text{ and } \tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \theta\}\\ \qquad = \{\gamma^{-1}(\theta') : \theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B}) \text{ and } \tau^{\mathcal{B}}[T'] \leq \theta'\}.\end{array}$$

Proof: Suppose K is closed under subdirect intersections and let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{SenFam}(\mathcal{B})$.

(⊆) Let $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, such that $\mathrm{Ker}(\langle H,\gamma\rangle) \leq \theta$ and $\tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \theta$. By Lemma 1657, $\tau^{\mathcal{B}}[T'] = \gamma(\tau^{\mathcal{A}}[\gamma^{-1}(T')]) \leq \gamma(\theta)$. By Proposition 33, $\gamma(\theta) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B})$. Finally, by Lemma 25, $\theta = \gamma^{-1}(\gamma(\theta))$. Hence, we get

$$\theta = \gamma^{-1}(\gamma(\theta)) \in \{\gamma^{-1}(\theta') : \theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B}) \text{ and } \tau^{\mathcal{B}}[T'] \leq \theta'\}.$$

(⊇) Suppose, now, $\theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B})$, such that $\tau^{\mathcal{B}}[T'] \leq \theta'$. By Lemma 1657, $\tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \gamma^{-1}(\tau^{\mathcal{B}}[T']) \leq \gamma^{-1}(\theta')$. Finally, $\mathrm{Ker}(\langle H,\gamma\rangle) = \gamma^{-1}(\Delta^{\mathcal{B}}) \leq \gamma^{-1}(\theta')$. So we get

$$\gamma^{-1}(\theta') \in \{\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) : \mathrm{Ker}(\langle H,\gamma\rangle) \leq \theta \text{ and } \tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \theta\}.$$ ■

Now, for the main theorem to the effect that $\Psi^{\mathsf{K},\tau}$ is a semi-coherent family of congruential monotone compatibility $\mathcal{I}$-operators.

Theorem 1659 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$, with a $\tau^\flat$-algebraic semantics K, such that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K}$. $\Psi^{\mathsf{K},\tau}$ is a semi-coherent family of congruential monotone compatibility $\mathcal{I}$-operators.*

Proof: Let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\langle H,\gamma\rangle$ is $\Psi^{\mathsf{K},\tau}$-compatible with $\gamma^{-1}(T')$. Then, by definition,

$$\mathrm{Ker}(\langle H,\gamma\rangle) \leq \Psi^{\mathsf{K},\tau,\mathcal{A}}(\gamma^{-1}(T')) = \Theta^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[\gamma^{-1}(T')]).$$

So we have

$$\begin{array}{rcl}
\Psi^{\mathsf{K},\tau,\mathcal{A}}(\gamma^{-1}(T')) & = & \Theta^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[\gamma^{-1}(T')]) \\
& = & \bigcap\{\theta \in \mathrm{ConSys}^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K})}(\mathcal{A}) : \\
& & \qquad \mathrm{Ker}(\langle H,\gamma\rangle) \leq \theta \text{ and } \tau^{\mathcal{A}}[\gamma^{-1}(T')] \leq \theta\} \\
& = & \bigcap\{\gamma^{-1}(\theta') : \theta' \in \mathrm{ConSys}^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K})}(\mathcal{B}) \text{ and } \tau^{\mathcal{B}}[T'] \leq \theta'\} \\
& = & \gamma^{-1}(\bigcap\{\theta' \in \mathrm{ConSys}^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K})}(\mathcal{B}) : \tau^{\mathcal{B}}[T'] \leq \theta'\}) \\
& = & \gamma^{-1}(\Theta^{\overset{\triangleleft}{\mathrm{II}}(\mathsf{K}),\mathcal{B}}(\tau^{\mathcal{B}}[T'])) \\
& = & \gamma^{-1}(\Psi^{\mathsf{K},\tau,\mathcal{B}}(T')).
\end{array}$$

This proves that $\Psi^{\mathsf{K},\tau}$ is also semi-coherent (the remaining properties having been demonstrated in Proposition 1656). ■

Since, by Proposition 1648, every family truth equational π-institution $\mathcal{I}$ has $\mathrm{AlgSys}(\mathcal{I})$ as a $\tau^\flat$-algebraic semantics and $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$, setting $\mathsf{K} := \mathrm{AlgSys}(\mathcal{I})$, we get that $\Psi^{\mathsf{K},\tau}$ is a semi-coherent family of monotone congruential compatibility $\mathcal{I}$-operators.

Our last result shows that the classes of **F**-algebraic systems associated with $\Psi^{\mathsf{K},\tau}$ (which are equal by Proposition 1558) coincide with $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$.

First, however, we show that, for any π-institution $\mathcal{I}$, with $\tau^\flat$ in $N^\flat$, the class $\mathsf{K}(\mathcal{I},\tau)$ is closed under subdirect intersections.

Lemma 1660 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}(\mathcal{I},\tau)) \subseteq \mathsf{K}(\mathcal{I},\tau).$$

Proof: Let $\mathcal{A}^i \in \mathsf{K}(\mathcal{I},\tau)$, for all $i \in I$, and

$$\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

be a subdirect intersection. Then, we have, by definition of subdirect intersection, $\bigcap_{i\in I} \mathrm{Ker}(\langle H^i,\gamma^i\rangle) = \Delta^{\mathcal{A}}$ and, by Proposition 1646, $\tau^{\mathcal{A}^i}(\Delta^{\mathcal{A}^i}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i)$, for all $i \in I$. These give

$$\begin{array}{rcl}
\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) & = & \tau^{\mathcal{A}}(\bigcap_{i\in I}\mathrm{Ker}(\langle H^i,\gamma^i\rangle))\\
& = & \bigcap_{i\in I}\tau^{\mathcal{A}}(\mathrm{Ker}(\langle H^i,\gamma^i\rangle))\\
& = & \bigcap_{i\in I}\tau^{\mathcal{A}}((\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}))\\
& = & \bigcap_{i\in I}(\gamma^i)^{-1}(\tau^{\mathcal{A}^i}(\Delta^{\mathcal{A}^i}))\\
& \in & \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}),
\end{array}$$

where membership follows from the fact that $\tau^{\mathcal{A}^i}(\Delta^{\mathcal{A}^i}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i)$, for all $i \in I$, by Corollary 55 and by closure of $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ under intersections. We conclude, using again Proposition 1646, that $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. ■

Recall the classes of **F**-algebraic systems

$$\begin{array}{rcl}
\mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) & = & \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Psi^{\mathsf{K},\tau,\mathcal{A}}(T) = \Delta^{\mathcal{A}})\};\\
\mathrm{AlgSys}^{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) & = & \{\mathcal{A}/\Psi^{\mathsf{K},\tau,\mathcal{A}}(T) : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.
\end{array}$$

Proposition 1661 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*, with a* $\tau^\flat$*-algebraic semantics* K*, such that* $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K}$*. Then*

$$\mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) = \mathrm{AlgSys}^{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) = \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}).$$

Proof: First, by Proposition 1558, $\mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) = \mathrm{AlgSys}^{\Psi^{\mathsf{K},\tau}}(\mathcal{I})$. So it suffices to show that $\mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) = \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$.

Suppose, first, that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$. By Corollary 1647, $\mathsf{K} \subseteq \mathsf{K}(\mathcal{I},\tau)$. By Lemma 1660, $\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}) \subseteq \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}(\mathcal{I},\tau)) \subseteq \mathsf{K}(\mathcal{I},\tau)$, whence $\mathcal{A} \in \mathsf{K}(\mathcal{I},\tau)$. Thus, by

Proposition 1646, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, $\Delta^{\mathcal{A}} \in \mathrm{ConSys}^{\overset{\triangleleft}{\amalg}(\mathsf{K})}(\mathcal{A})$. We now get

$$\Psi^{\mathsf{K},\tau,\mathcal{A}}(\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})) = \Theta^{\overset{\triangleleft}{\amalg}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})]) \leq \Theta^{\overset{\triangleleft}{\amalg}(\mathsf{K}),\mathcal{A}}(\Delta^{\mathcal{A}}) = \Delta^{\mathcal{A}}.$$

We conclude that $\mathcal{A} \in \mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I})$.

Suppose, conversely, that $\mathcal{A} \in \mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I})$. Then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Psi^{\mathsf{K},\tau,\mathcal{A}}(T) = \Delta^{\mathcal{A}}$, that is, $\Theta^{\overset{\triangleleft}{\amalg}(\mathsf{K}),\mathcal{A}}(\tau^{\mathcal{A}}[T]) = \Delta^{\mathcal{A}}$. This shows that $\Delta^{\mathcal{A}}$ is an $\overset{\triangleleft}{\amalg}(\mathsf{K})$-congruence system on $\mathcal{A}$. Hence $\mathcal{A} \in \overset{\triangleleft}{\amalg}(\mathsf{K})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$, with a $\tau^\flat$-algebraic semantics K, such that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K}$. Then we have

$$\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K} \subseteq \mathsf{K}(\mathcal{I},\tau).$$

Assume, now, that $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat$. By Proposition 1648, $\mathrm{AlgSys}(\mathcal{I})$ is a $\tau^\flat$-algebraic semantics for $\mathcal{I}$ and, by Proposition 65, $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. Thus, in the case of truth equationality $\mathcal{I}$ has a $\tau^\flat$-algebraic semantics K, such that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathsf{K} \subseteq \mathsf{K}(\mathcal{I},\tau)$.

- If $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I})$, then, by Proposition 1637 and Theorem 1404, we would have $\Psi^{\mathsf{K},\tau} = \widetilde{\Omega}^{\mathcal{I}}$;
- At the other extreme, if $\mathsf{K} = \mathsf{K}(\mathcal{I},\tau)$, then, we get, by Proposition 1661 and Lemma 1660, a semi-coherent family of congruential monotone compatibility $\mathcal{I}$-operators $\Psi^{\mathsf{K},\tau}$, such that, similarly, $\mathrm{AlgSys}_{\Psi^{\mathsf{K},\tau}}(\mathcal{I}) = \mathsf{K}(\mathcal{I},\tau)$.

Chapter 22

The Strong Version of a π-Institution

22.1 The Strong Version of a π-Institution

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define the following classes of $\mathcal{I}$-matrix families.

$$\begin{array}{rcl} \mathsf{M}^{\mathcal{I}*} & = & \{\langle \mathcal{A}, T\rangle : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\}; \\ \mathsf{M}^{\mathcal{I},\mathsf{Su}} & = & \{\langle \mathcal{A}, T\rangle : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})\}; \\ \mathsf{M}^{\mathcal{I},m} & = & \{\langle \mathcal{A}, T\rangle : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}. \end{array}$$

We show that all three classes of $\mathcal{I}$-matrix families generate the same closure system on $\mathbf{F}$.

Proposition 1662 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Then $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}}$.*

Proof: By Lemma 1568, we have that, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Thus, $\mathsf{M}^{\mathcal{I},m} \subseteq \mathsf{M}^{\mathcal{I}*}$. This implies that $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} \leq \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}}$. To show the converse, assume that $\langle \mathcal{A}, T\rangle \in \mathsf{M}^{\mathcal{I}*}$ and consider the quotient morphism $\langle I, \pi\rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$. By Corollary 1554, $\pi(T^*)$ is the least $\mathcal{I}$-filter family of $\mathcal{A}/\Omega^{\mathcal{A}}(T)$. By hypothesis $T = T^*$, whence $\pi(T) = \pi(T^*)$ and, hence, since $\langle I, \pi\rangle : \langle \mathcal{A}, T\rangle \to \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), \pi(T)\rangle$ is a strict surjective morphism,, we get that

$$\mathcal{I}^{\langle \mathcal{A}, T\rangle} = \mathcal{I}^{\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), \pi(T)\rangle} = \mathcal{I}^{\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), \pi(T^*)\rangle}$$

and $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), \pi(T^*)\rangle \in \mathsf{M}^{\mathcal{I},m}$. Putting things together, we finally obtain

$$\begin{array}{rcl} \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}} & \leq & \bigcap \{\mathcal{I}^{\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), \pi(T^*)\rangle} : T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\} \\ & = & \bigcap \{\mathcal{I}^{\langle \mathcal{A}, T\rangle} : T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\} \\ & = & \mathcal{I}^{\mathsf{M}^{\mathcal{I}*}}. \end{array}$$

Therefore, $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}}$. ∎

Proposition 1662 enables us to show that $\mathsf{M}^{\mathcal{I}*}$ and $\mathsf{M}^{\mathcal{I},\mathsf{Su}}$ also generate the same closure system on $\mathbf{F}$.

Corollary 1663 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Then $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},\mathsf{Su}}}$.*

Proof: By Lemma 1583, $\mathsf{M}^{\mathcal{I},\mathsf{Su}} \subseteq \mathsf{M}^{\mathcal{I}*}$. Also by Lemma 1583, $\mathsf{M}^{\mathcal{I},m} \subseteq \mathsf{M}^{\mathcal{I},\mathsf{Su}}$. So we get $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} \leq \mathcal{I}^{\mathsf{M}^{\mathcal{I},\mathsf{Su}}} \leq \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}}$. Therefore, by Proposition 1662, $\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},\mathsf{Su}}}$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Taking into account Proposition 1662 and Corollary 1663, we define the **strong version of** $\mathcal{I}$, denoted by $\mathcal{I}^+ = \langle \mathbf{F}, C^+\rangle$, by

$$\mathcal{I}^+ := \mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},\mathsf{Su}}} = \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}}.$$

There are even more ways to characterize the π-institution $\mathcal{I}^+$. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Given a class K of $\mathbf{F}$-algebraic systems, we define

$$\begin{array}{rcl}\mathsf{M}_\mathsf{K}^{\mathcal{I},m} & = & \{\langle \mathcal{A}, T \rangle : \mathcal{A} \in \mathsf{K}, T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\};\\ \mathsf{M}_\mathsf{K}^{\mathcal{I}*} & = & \{\langle \mathcal{A}, T \rangle : \mathcal{A} \in \mathsf{K}, T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\};\\ \mathsf{M}_\mathsf{K}^{\mathcal{I},\mathsf{Su}} & = & \{\langle \mathcal{A}, T \rangle : \mathcal{A} \in \mathsf{K}, T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})\}.\end{array}$$

Proposition 1664 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I})$ or $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$. Then*

$$\mathcal{I}^+ = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},m}} = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},\mathsf{Su}}}.$$

Proof: By definition and Lemma 1583, we have

$$\mathsf{M}_\mathsf{K}^{\mathcal{I},m} \subseteq \mathsf{M}_\mathsf{K}^{\mathcal{I},\mathsf{Su}} \subseteq \mathsf{M}_\mathsf{K}^{\mathcal{I}*} \subseteq \mathsf{M}^{\mathcal{I}*}.$$

Therefore, we get

$$\mathcal{I}^+ \le \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I}*}} \le \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},\mathsf{Su}}} \le \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},m}}.$$

For the converse, suppose $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. By Proposition 1572, $T/\Omega^{\mathcal{A}}(T)$ is the least $\mathcal{I}$-filter family of $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. Therefore, we get

$$\begin{array}{rcl}\mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},m}} & \le & \bigcap\{\mathcal{I}^{\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\}\\ & = & \bigcap\{\mathcal{I}^{\langle \mathcal{A}, T\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})\}\\ & = & \mathcal{I}^+.\end{array}$$

We conclude that $\mathcal{I}^+ = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},m}} = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I}*}} = \mathcal{I}^{\mathsf{M}_\mathsf{K}^{\mathcal{I},\mathsf{Su}}}$. ■

The following proposition lists some of the properties of the strong version $\mathcal{I}^+$ of a π-institution $\mathcal{I}$.

Proposition 1665 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I} \le \mathcal{I}^+$;

(b) $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, *for every $\mathbf{F}$-algebraic system $\mathcal{A}$;*

(c) $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, *for every $\mathbf{F}$-algebraic system $\mathcal{A}$;*

(d) If $\mathcal{I}$ is family reflective, then $\mathcal{I}^+ = \mathcal{I}$.

Proof:

(a) Since $\mathsf{M}^{\mathcal{I},m} \subseteq \mathrm{MatFam}(\mathcal{I})$, we get $\mathcal{I} = \mathcal{I}^{\mathrm{MatFam}(\mathcal{I})} \le \mathcal{I}^{\mathsf{M}^{\mathcal{I},m}} = \mathcal{I}^+$.

(b) Since, by Part (a), $\mathcal{I} \leq \mathcal{I}^+$, we get that $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$.

(c) By definition of $\mathcal{I}^+$, we have, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, all $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ and all $T' \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, $C^+ \leq C^{\langle \mathcal{A},T\rangle}$ and $C^+ \leq C^{\langle \mathcal{A},T'\rangle}$. Moreover, by Lemma 1583, every Suszko filter family is a Leibniz filter family. We conclude that $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$.

(d) By the hypothesis and Proposition 1573, $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. Therefore, $\mathcal{I}^+ = \mathcal{I}^{\mathsf{M}^{\mathcal{I}*}} = \mathcal{I}^{\mathrm{MatFam}(\mathcal{I})} = \mathcal{I}$. ■

It turns out that the strong version $\mathcal{I}^+$ is mostly interesting when $\mathcal{I}$ itself has theorems. In the absence of theorems $\mathcal{I}^+$ has only trivial theory families.

Proposition 1666 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *does not have theorems, then* $\mathcal{I}$ *is almost inconsistent.*

Proof: Assume that $\mathcal{I}$ does not have theorems. Then, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\varnothing \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, by definition $\mathcal{I}^+ = \bigcap\{\mathcal{I}^{\langle \mathcal{A},\varnothing\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})\}$. This implies that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we have, vacuously, for all $\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\psi \in C^+_\Sigma(\phi)$. Therefore, the only Σ-theory families of $\mathcal{I}^+$ are $\varnothing$ and $\mathrm{SEN}^\flat(\Sigma)$. So $\mathcal{I}^+$ is almost inconsistent. ■

The least $\mathcal{I}$-filter family on every algebraic system $\mathcal{A}$ coincides with the least $\mathcal{I}^+$-filter family. As a consequence $\mathcal{I}$ and $\mathcal{I}^+$ share the same theorems.

Lemma 1667 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \bigcap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}).$$

In particular, $\mathrm{ThFam}(\mathcal{I}^+) = \mathrm{ThFam}(\mathcal{I})$.

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By Proposition 1665, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, we have $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \leq \bigcap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. On the other hand, by Lemma 1568, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, whence, by Proposition 1665, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Therefore, $\bigcap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \leq \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Equality now follows. ■

Lemma 1667 implies the idempotency of the strong version operator on π-institutions.

Corollary 1668 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then* $(\mathcal{I}^+)^+ = \mathcal{I}^+$.

Proof: We have

$$\begin{array}{rcl}(\mathcal{I}^+)^+ & = & \bigcap\{\mathcal{I}^{\langle\mathcal{A},T\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T = \bigcap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{I})\}\\ & = & \bigcap\{\mathcal{I}^{\langle\mathcal{A},T\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}), T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{I})\}\\ & = & \mathcal{I}^+.\end{array}$$

The first and last equalities follow by the definition of $^+$, and the main equality is due to Lemma 1667. ∎

The next proposition provides sufficient conditions for recognizing that a given π-institution is the strong version of another π-institution based on the same algebraic system.

Proposition 1669 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$, $\mathcal{I}' = \langle\mathbf{F}, C'\rangle$ *π-institutions based on* $\mathbf{F}$*, such that*

1. *$\mathcal{I}'$ is family reflective;*
2. $\mathrm{AlgSys}(\mathcal{I}') = \mathrm{AlgSys}(\mathcal{I})$*;*
3. *For all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}')$, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \bigcap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$.

Then $\mathcal{I}' = \mathcal{I}^+$.

Proof: We have

$$\begin{array}{rcl}\mathcal{I}' & = & \mathcal{I}'^+ \quad \text{(by 1 and Proposition 1665)}\\ & = & \bigcap\{\mathcal{I}^{\langle\mathcal{A},T\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}'), T = \bigcap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})\}\\ & & \text{(by Proposition 1664)}\\ & = & \bigcap\{\mathcal{I}^{\langle\mathcal{A},T\rangle} : \mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}), T = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}\\ & & \text{(by 2 and 3)}\\ & = & \mathcal{I}^+. \quad \text{(by Proposition 1664)}\end{array}$$

This proves the claim. ∎

We now show that Suszko and Leibniz $\mathcal{I}$-filter families form subclasses, respectively, of the classes of Suszko and Leibniz $\mathcal{I}^+$-filter families on every $\mathbf{F}$-algebraic system.

Proposition 1670 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A}) \quad \text{and} \quad \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}).$$

Proof: By Proposition 1665, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FFam}^{\mathcal{I}}(\mathcal{A})$. Thus, for all $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, $[\![T]\!]^{\mathcal{I}^+*} \subseteq [\![T]\!]^{\mathcal{I}*}$ and $[\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} \subseteq [\![T]\!]^{\mathcal{I},\mathsf{Su}}$.

Suppose that $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Then, by Proposition 1665, $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and, moreover, $T = \bigcap [\![T]\!]^{\mathcal{I},\mathsf{Su}} \leq \bigcap [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}}$. Thus, since $T \in [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}}$, we get that $T = \bigcap [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} \in \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A})$.

The second inclusion may be shown similarly. ∎

But the Leibniz counterpart of an $\mathcal{I}^+$-filter family is identical whether it be considered with respect to $\mathcal{I}$ or with respect to $\mathcal{I}^+$.

Lemma 1671 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, and all* $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$*,* $T^{\mathcal{I}*} = T^{\mathcal{I}^+*}$*.*

Proof: By Proposition 1665, $[\![T]\!]^{\mathcal{I}^+*} \subseteq [\![T]\!]^{\mathcal{I}*}$. Therefore, $T^{\mathcal{I}*} \leq T^{\mathcal{I}^+*}$. On the other hand,

$$\begin{array}{lll} T^{\mathcal{I}*} & \in & \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \quad \text{(by Proposition 1570)} \\ & \subseteq & \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \quad \text{(by Proposition 1670)} \end{array}$$

and, since $T^{\mathcal{I}*} \in [\![T]\!]^{\mathcal{I}*}$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^{\mathcal{I}*})$. Thus, $T^{\mathcal{I}*} \subseteq [\![T]\!]^{\mathcal{I}^+*}$, which gives $T^{\mathcal{I}^+*} \leq T^{\mathcal{I}*}$. We conclude that $T^{\mathcal{I}*} = T^{\mathcal{I}^+*}$. ■

And this implies that the Leibniz $\mathcal{I}$-filter families and the Leibniz $\mathcal{I}^+$-filter families coincide on every $\mathbf{F}$-algebraic system.

Corollary 1672 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: The right-to-left inclusion was shown in Proposition 1670. For the reverse, assume that $T \in \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A})$. Then, by Proposition 1665, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by Lemma 1671, $T = T^{\mathcal{I}^+*} = T^{\mathcal{I}*}$. Therefore, $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

22.2 Leibniz and Suszko $\mathcal{I}^+$-Filter Families

There is a relation between the $\mathcal{I}^+$-filter families on algebraic systems and the Leibniz and Suszko $\mathcal{I}$-filter families on the same algebraic systems. The following proposition shows how these relations interplay with family c-reflectivity.

Proposition 1673 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- *(a) If, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$*,* $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$*, then* $\mathcal{I}^+$ *is family c-reflective.*
- *(b) If* $\mathcal{I}^+$ *is family c-reflective, then* $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$*, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A}$*.*

Proof:

(a) Suppose, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By Proposition 1670, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A})$. Hence, by hypothesis, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A})$. Thus, $\mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. By Theorem 1590, $\mathcal{I}^+$ is family c-reflective.

(b) Suppose $\mathcal{I}^+$ is family c-reflective and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By Theorem 1590, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A})$. Since, by Lemma 1583 and Corollary 1672, $\mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, we get that $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. The reverse inclusion holds by Proposition 1665.

■

A necessary and sufficient condition for the $\mathcal{I}^+$-filter families to coincide with the Leibniz $\mathcal{I}$-filter families is the universal reflectivity of the Leibniz operator on $\mathcal{I}^+$-filter families.

Proposition 1674 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$$

if and only if, for every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\Omega^{\mathcal{A}}$ *is order reflecting on* $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$*.*

Proof: By Corollary 1672, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. By Proposition 1573, $\Omega^{\mathcal{A}}$ is reflective on $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, for all $\mathcal{A}$, if and only if $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A})$, for all $\mathcal{A}$. Thus, we get that $\Omega^{\mathcal{A}}$ is reflective on $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, for all $\mathcal{A}$, if and only if $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, for all $\mathcal{A}$. ■

Under the stipulation that the strong version of $\mathcal{I}$ be protoalgebraic, the identification of $\mathcal{I}^+$-filter families with the Leibniz $\mathcal{I}$-families have several characterizations.

Proposition 1675 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, such that* $\mathcal{I}^+$ *is protoalgebraic. The following conditions are equivalent:*

(i) $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*;*

(ii) $\mathrm{ThFam}(\mathcal{I}^+) = \mathrm{ThFam}^*(\mathcal{I})$*;*

(iii) $\mathcal{I}^+$ *is weakly family algebraizable;*

(iv) $\mathcal{I}^+$ *is family c-reflective;*

Proof:

(i)⇒(ii) Trivial.

(ii)⇒(iii) Suppose that $\mathrm{ThFam}(\mathcal{I}^+) = \mathrm{ThFam}^*(\mathcal{I})$. By Proposition 1528, Ω is injective on $\mathrm{ThFam}^*(\mathcal{I})$. By definition it is onto $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{F})$. Thus, by hypothesis and Corollary 1672, $\Omega : \mathrm{FiFam}(\mathcal{I}^+) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{F})$ is a bijection. By hypothesis it is monotone and, by Proposition 1528, it is order reflecting. Therefore, it is an order isomorphism. By Theorem 296, $\mathcal{I}^+$ is weakly family algebraizable.

(iii)⇒(iv) Every weakly family algebraizable π-institution is a fortiori family c-reflective.

(iv)⇒(i) By hypothesis, $\mathcal{I}^+$ is protoalgebraic, whence, by Proposition 1601 and Corollary 1672,

$$\mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

By hypothesis and Theorem 1590, $\mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Therefore, we get that $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

We close the section by looking at various consequences of the condition imposed on a π-institution $\mathcal{I}$ that $\Omega^{\mathcal{A}}$ be an order isomorphism from the Leibniz $\mathcal{I}$-filter families of $\mathcal{A}$ onto the $\mathcal{I}^*$-congruence systems on $\mathcal{A}$, for every $\mathcal{I}$-algebraic system $\mathcal{A}$. First, we show that this condition ensures that $\mathcal{I}$-algebraic systems, $\mathcal{I}^*$-algebraic systems, $\mathcal{I}^+$-algebraic systems and $(\mathcal{I}^+)^*$-algebraic systems all coincide.

Lemma 1676 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathcal{I}$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{AlgSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. Then

$$\mathrm{AlgSys}(\mathcal{I}^+) = \mathrm{AlgSys}^*(\mathcal{I}^+) = \mathrm{AlgSys}^*(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}).$$

Proof: We show, first, that $\mathrm{AlgSys}^*(\mathcal{I}^+) = \mathrm{AlgSys}^*(\mathcal{I})$. The left-to-right inclusion holds because, by Proposition 1665, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, for every $\mathbf{F}$-algebraic system $\mathcal{I}$. Assume, conversely, that $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. Then $\Delta^{\mathcal{A}} \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. By hypothesis, then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. By Proposition 1665 again, $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Hence, $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I}^+)$.

Now we have

$$\begin{array}{rcll}
\mathrm{AlgSys}(\mathcal{I}) & = & \mathrm{AlgSys}^*(\mathcal{I}) & \text{(by Lemma 1623)}\\
& = & \mathrm{AlgSys}^*(\mathcal{I}^+) & \text{(shown above)}\\
& \subseteq & \mathrm{AlgSys}(\mathcal{I}^+) & \text{(by Proposition 65)}\\
& \subseteq & \mathrm{AlgSys}(\mathcal{I}). & \text{(by Proposition 1665).}
\end{array}$$

We conclude that all four classes of algebraic system coincide. ∎

Next we show that, under the same hypothesis the Leibniz congruence systems of a filter family and its Leibniz counterpart coincide and that the Suszko congruence system of a filter family coincides with the Leibniz congruence system of its Suszko counterpart.

Proposition 1677 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathcal{I}$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{AlgSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. Then, for every $\mathbf{F}$*-algebraic system and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^*) \quad \text{and} \quad \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^{\mathcal{I},\mathsf{Su}}).$$

Proof: By Proposition 1622, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism.

Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$, there exists $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Hence, $[\![T]\!]^* = [\![T']\!]^*$, which gives $T^* = T'^* = T'$. Thus, we get $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T^*)$.

By hypothesis and Lemma 1623, $\mathrm{AlgSys}^*(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I})$. Since we have $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$, there exists $T'' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T'') = \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. Thus, we get $[\![T]\!]^{\mathsf{Su}} = [\![T'']\!]^*$ and, therefore, $T^{\mathcal{I},\mathsf{Su}} = T''^* = T''$. This gives $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T'') = \Omega^{\mathcal{A}}(T^{\mathcal{I},\mathsf{Su}})$. ∎

Under the same hypothesis, it turns out that the coincidence of the class of Leibniz filter families with Suszko filter families on every algebraic system characterizes protoalgebraicity.

Corollary 1678 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathcal{I}$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{AlgSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. $\mathcal{I}$ *is protoalgebraic if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$*.*

Proof: If $\mathcal{I}$ is protoalgebraic, then, by Proposition 1601, Leibniz and Suszko classes coincide and, therefore, $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$.

Suppose, conversely, that, for all $\mathbf{F}$-algebraic systems $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Lemma 1583, $T^{\mathcal{I},\mathsf{Su}} \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. By the hypothesis and Lemma 1586, $T^{\mathcal{I},\mathsf{Su}}$ is the largest Leibniz $\mathcal{I}$-filter family included in T. Since, by Lemma

1583, $T^{\mathcal{I},\mathsf{Su}} \le T^* \le T$ and, by Proposition 1570, T^* is a Leibniz $\mathcal{I}$-filter family, we get $T^{\mathcal{I},\mathsf{Su}} = T^*$. Therefore, using Proposition 1570, we get

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T^{\mathcal{I},\mathsf{Su}}) = \Omega^{\mathcal{A}}(T^*) = \Omega^{\mathcal{A}}(T).$$

Thus, on every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Suszko and the Leibniz operators coincide and, therefore, by Lemma 1518, $\mathcal{I}$ is protoalgebraic. ■

We already have the tools to show that the property that $\Omega^{\mathcal{A}}$ be an isomorphism between Leibniz filter families and reduced algebraic systems is bequeathed by a π-institution $\mathcal{I}$ to its strong version $\mathcal{I}^+$.

Lemma 1679 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathcal{I}$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{AlgSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. Then, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ *is also an order isomorphism.*

Proof: By Corollary 1672, we have $\mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. By Lemma 1676, $\mathrm{AlgSys}^*(\mathcal{I})) = \mathrm{AlgSys}^*(\mathcal{I}^+)$. Now, taking into account the hypothesis, we get the conclusion. ■

In a proposition analogous to Proposition 1675, we provide under our working hypothesis, of the Leibniz operator being an order isomorphism, a characterization of the property of $\mathcal{I}^+$ being weakly family algebraizable.

Proposition 1680 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathcal{I}$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{AlgSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. The following conditions are equivalent:

(i) $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$*, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*;*

(ii) $\mathrm{ThFam}(\mathcal{I}^+) = \mathrm{ThFam}^*(\mathcal{I})$*;*

(iii) $\mathcal{I}^+$ *is weakly family algebraizable;*

(iv) $\mathcal{I}^+$ *is family c-reflective;*

(v) Ω *is injective on the collection of reduced* $\mathcal{I}^+$*-filter families.*

Proof:

(i)⇒(ii) Trivial.

(ii)⇒(iii) By hypothesis and Lemma 1676, $\Omega : \mathrm{ThFam}(\mathcal{I}^+) \to \mathrm{ConSys}^{\mathcal{I}^{+*}}(\mathcal{F})$ is an order isomorphism. Thus Ω is both monotone and family c-reflective, whence $\mathcal{I}^+$ is weakly family algebraizable.

(iii)⇒(iv) Weak family algebraizability implies family c-reflectivity.

(iv)⇒(v) If $\mathcal{I}^+$ is family c-reflective, then it is a fortiori injective. Therefore, by Theorem 214, $\Omega^{\mathcal{A}}$ is injective on the $\mathcal{I}$-filter families of every $\mathbf{F}$-algebraic system $\mathcal{A}$.

(v)⇒(i) Suppose (v) holds and let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$. By Proposition 1665, we have $\mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. So it suffices to prove the reverse inclusion. To this end, suppose $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T).$$

$\mathrm{Ker}(\langle I, \pi \rangle) = \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T^*)$, the last inclusion, since, by Proposition 1525, $T^* \in [\![T]\!]^{\mathcal{I}^*}$. Hence, by Corollary 56,

$$\pi(T), \pi(T^*) \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$$

and, by compatibility, $\pi^{-1}(\pi(T)) = T$ and $\pi^{-1}(\pi(T^*)) = T^*$. By Corollary 1554, $\pi(T^*) = \pi(T)^*$. Now we get

$$\begin{array}{rcll} \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)} & = & \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T)) & \text{(by Lemma 1557)} \\ & = & \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T)^*) & \text{(by Proposition 1677)} \\ & = & \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T^*)). & \end{array}$$

This, both $\pi(T)$ and $\pi(T^*)$ are reduced $\mathcal{I}^+$-filter families and, therefore, by the injectivity hypothesis, $\pi(T) = \pi(T^*)$. Now we conclude that $T = \pi^{-1}(\pi(T)) = \pi^{-1}(\pi(T^*)) = T^*$. This proves that, for all $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. Equality now follows.

■

22.3 Full $\mathcal{I}^+$-Structures

We now explore the relation between full $\mathcal{I}$-structures and full $\mathcal{I}^+$-structures.

Proposition 1681 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system.* $\langle \mathcal{A}, \mathcal{D} \rangle \in \mathrm{FStr}^{\mathcal{I}^+}(\mathcal{A})$ *if and only if, there exists* $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, such that* $\langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$ *and* $\mathcal{D} = \mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$*, i.e.,*

$$\mathrm{FStr}(\mathcal{I}^+) = \{\langle \mathcal{A}, \mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \rangle : \langle \mathcal{A}, \mathcal{T} \rangle \in \mathrm{FStr}(\mathcal{I})\}.$$

Proof:

($\Rightarrow$) Suppose that $\langle\mathcal{A},\mathcal{D}\rangle \in \mathrm{FStr}(\mathcal{I}^+)$. Set

$$\mathcal{T} = \{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T)\}.$$

If $T \in \mathcal{D}$, then $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T)$ and $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(T)$. Thus, $T \in \mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. On the other hand, let $T \in \mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Then $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T)$ and, since $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and $\langle\mathcal{A},\mathcal{D}\rangle \in \mathrm{FStr}(\mathcal{I}^+)$, we must have, by Theorem 1395, $T \in \mathcal{D}$. We conclude that $\mathcal{D} = \mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Thus, it only remains to show that $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$.

To this end, let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \Omega^{\mathcal{A}}(T)$. Then, we get $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \bigcap_{T'\in\mathcal{D}}\Omega^{\mathcal{A}}(T') = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T)$. Thus, by definition, $T \in \mathcal{T}$. We conclude, using Theorem 1395, that $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$.

($\Leftarrow$) Suppose, now, that $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$ and $\mathcal{D} = \mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Since, by Proposition 1563, the least element of a full $\mathcal{I}$-structure is a Leibniz $\mathcal{I}$-filter family, we get that $\bigcap\mathcal{T} \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. To see that $\langle\mathcal{A},\mathcal{D}\rangle$ is a dull $\mathcal{I}^+$-structure, let $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T)$. Then, we infer

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \le \Omega^{\mathcal{A}}(T).$$

Since $\langle\mathcal{A},\mathcal{T}\rangle \in \mathrm{FStr}(\mathcal{I})$, then, by Theorem 1395, $T \in \mathcal{T}$. Since, in addition, by hypothesis, $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, we get $T \in \mathcal{D}$. Thus, again by Theorem1395, $\langle\mathcal{A},\mathcal{D}\rangle \in \mathrm{FStr}(\mathcal{I}^+)$.

■

Next, we show that the association

$$\langle\mathcal{A},\mathcal{T}\rangle \mapsto \langle\mathcal{A},\mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})\rangle$$

of full $\mathcal{I}^+$-structures to full $\mathcal{I}$-structures, given in Proposition 1681, is one-to-one, provided that $\mathcal{I}$- and $\mathcal{I}^+$-algebraic systems coincide.

Proposition 1682 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*, such that* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}^+)$*, and* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system. For all* $\langle\mathcal{A},\mathcal{T}\rangle, \langle\mathcal{A},\mathcal{T}'\rangle \in \mathrm{FStr}(\mathcal{I})$*,*

$$\mathcal{T}\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathcal{T}'\cap\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \quad \textit{implies} \quad \mathcal{T} = \mathcal{T}'.$$

Proof: We start with some preparatory remarks. Suppose $\mathcal{A}$ is an $\mathbf{F}$-algebraic system. Since, by hypothesis, $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}^+)$, we get that $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) = \mathrm{ConSys}^{\mathcal{I}^+}(\mathcal{A})$. Now, using Theorem 1408 (or, alternatively, Corollary 1565), we have that $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A}) \cong \mathrm{FStr}^{\mathcal{I}^+}(\mathcal{A})$, through

$$\mathcal{T} \mapsto \overline{\mathcal{T}} = \{T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \Omega^{\mathcal{A}}(T)\}.$$

This is obtained, by applying Theorem 1408 to get an isomorphism

$$\begin{array}{rcl}\gamma : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) & \to & \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}); \\ \mathcal{T} & \overset{\gamma}{\mapsto} & \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}),\end{array}$$

then, applying Theorem 1408 to get an isomorphism

$$\begin{array}{rcl}\delta : \mathrm{ConSys}^{\mathcal{I}^+}(\mathcal{A}) & \to & \mathrm{FStr}^{\mathcal{I}^+}(\mathcal{A}); \\ \theta & \overset{\delta}{\mapsto} & \{T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \theta \le \Omega^{\mathcal{A}}(T)\}\end{array}$$

and, finally, composing these two, taking into account the hypothesis.

Now let $\mathcal{T}, \mathcal{T}' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\langle \mathcal{A}, \mathcal{T}\rangle$, $\langle \mathcal{A}, \mathcal{T}'\rangle \in \mathrm{FStr}^{\mathcal{I}}(\mathcal{A})$, and suppose that $\mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathcal{T}' \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$.

Claim 1: $\overline{\mathcal{T}} = \mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and $\overline{\mathcal{T}'} = \mathcal{T}' \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$.

We show the first equality. The second one is shown in exactly the same way. First, if $T \in \overline{\mathcal{T}}$, then $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \Omega^{\mathcal{A}}(T)$. Since $\langle \mathcal{A}, \mathcal{T}\rangle$ is a full $\mathcal{I}$-structure, by Theorem 1395, $T \in \mathcal{T}$. Thus, $T \in \mathcal{Y} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. If, on the other hand, $T \in \mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, then $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and $T \in \mathcal{T}$. Thus, $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$ and $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \Omega^{\mathcal{A}}(T)$. Therefore, $T \in \overline{\mathcal{T}}$.

Claim 2: $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}})$ and $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}') = \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}'})$.

Again, it suffices to show the first equality, since the second is proven in exactly the same way. By Claim 1 and Proposition 1681, $\langle \mathcal{A}, \overline{\mathcal{T}}\rangle \in \mathrm{FStr}^{\mathcal{I}^+}(\mathcal{A})$. Therefore, by Theorem 1395, $\overline{\mathcal{T}} = \{T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}}) \le \Omega^{\mathcal{A}}(T)\}$. Thus, we get $\delta(\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})) = \delta(\gamma(\mathcal{T})) = \overline{\mathcal{T}} = \delta(\widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}}))$. Since δ is an isomorphism, we get that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}})$.

To finish the proof, we get $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}}) = \widetilde{\Omega}^{\mathcal{A}}(\overline{\mathcal{T}'}) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}')$. Therefore, by Theorem 1408, $\mathcal{T} = \mathcal{T}'$. ■

Now we can formulate an order isomorphism between full $\mathcal{I}$- and full $\mathcal{I}^+$-structures, subject to the condition that $\mathcal{I}$- and $\mathcal{I}^+$-algebraic systems coincide.

Corollary 1683 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*, such that* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}^+)$*, and* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system.*

$$\begin{array}{rcl}h : \mathrm{FStr}^{\mathcal{I}}(\mathcal{A}) & \to & \mathrm{FStr}^{\mathcal{I}^+}(\mathcal{A}); \\ \langle \mathcal{A}, \mathcal{T}\rangle & \overset{h}{\mapsto} & \langle \mathcal{A}, \mathcal{T} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})\rangle\end{array}$$

is an order isomorphism.

Proof: By Propositions 1681 and 1682. ■

We turn next to relationships between full classes of filter families with respect to a π-institution $\mathcal{I}$ and its strong version $\mathcal{I}^+$. Recall that, given any

$\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, we have $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. So we get immediately the following inclusions, for all $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$.

$$\begin{array}{rcl}[\![T]\!]^{\mathcal{I}^+*} & = & \{T' \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & \subseteq & \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & = & [\![T]\!]^{\mathcal{I}*}.\end{array}$$

Moreover, taking into account

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \leq \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})^T) = \widetilde{\Omega}^{\mathcal{I}^+,\mathcal{A}}(T),$$

we infer

$$\begin{array}{rcl}[\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} & = & \{T' \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I}^+,\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & \subseteq & \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & = & [\![T]\!]^{\mathcal{I},\mathsf{Su}}.\end{array}$$

These relationships may be strengthened to apply to all extensions to a π-institution rather that only its strong version. More precisely, we obtain

Lemma 1684 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *and* $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *be* π*-institutions based on* $\mathbf{F}$*, such that* $\mathcal{I} \leq \mathcal{I}'$*,* $\mathcal{A}$ *be an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$*. Then*

$$[\![T]\!]^{\mathcal{I}'*} = [\![T]\!]^{\mathcal{I}*} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) \quad \text{and} \quad [\![T]\!]^{\mathcal{I}',\mathsf{Su}} \subseteq [\![T]\!]^{\mathcal{I},\mathsf{Su}} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}).$$

Proof: We have, mimicking the process preceding the statement, applied to the extension $\mathcal{I}'$ rather than specifically $\mathcal{I}^+$:

$$\begin{array}{rcl}[\![T]\!]^{\mathcal{I}'*} & = & \{T' \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & = & \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) \\ & = & [\![T]\!]^{\mathcal{I}*} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}).\end{array}$$

Moreover, taking into account

$$\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \leq \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})^T) = \widetilde{\Omega}^{\mathcal{I}',\mathcal{A}}(T),$$

we infer

$$\begin{array}{rcl}[\![T]\!]^{\mathcal{I}',\mathsf{Su}} & = & \{T' \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I}',\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \\ & \subseteq & \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) \\ & = & [\![T]\!]^{\mathcal{I},\mathsf{Su}} \cap \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}).\end{array}$$

Thus, we have the equality and the inclusion claimed. ■

Since $\mathcal{I}^+$ is an extension of $\mathcal{I}$, then we immediately deduce

Corollary 1685 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$*. Then*

$$[\![T]\!]^{\mathcal{I}^+*} = [\![T]\!]^{\mathcal{I}*} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \quad \text{and} \quad [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} \subseteq [\![T]\!]^{\mathcal{I},\mathsf{Su}} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}).$$

Proof: By Lemma 1684, since $\mathcal{I} \leq \mathcal{I}^+$. ■

Finally, we strengthen the preceding relation between Suszko classes to an equality, in the special case, where T happens to be a Suszko $\mathcal{I}$-filter family of $\mathcal{I}$ (recalling that $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{I}) \subseteq \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$).

Lemma 1686 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$*. Then* $[\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} = [\![T]\!]^{\mathcal{I},\mathsf{Su}} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$*.*

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. Then, by Lemma 1583, $[\![T]\!]^{\mathcal{I},\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Since $T = \bigcap [\![T]\!]^{\mathcal{I},\mathsf{Su}}$, $[\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} \subseteq [\![T]\!]^{\mathcal{I},\mathsf{Su}}$ and $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$, we get $T = \bigcap [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}}$. Hence $T \in \mathrm{FiFam}^{\mathcal{I}^+,\mathsf{Su}}(\mathcal{A})$. Again, using Lemma 1583, we get $[\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} = \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})^T$. Therefore, we conclude that

$$\begin{array}{rcl} [\![T]\!]^{\mathcal{I}^+,\mathsf{Su}} & = & \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})^T \\ & = & \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \\ & = & [\![T]\!]^{\mathcal{I},\mathsf{Su}} \cap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}). \end{array}$$

■

22.4 Leibniz Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **Leibniz truth equational** if there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, such that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T^* = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T)),$$

i.e., for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T^*_\Sigma \quad \text{iff} \quad \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T).$$

It follows directly by the definition that, if $\mathcal{I}$ is Leibniz truth equational, then, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \quad \text{iff} \quad T = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T)).$$

Moreover, we can easily see that family truth equationality implies Leibniz truth equationality.

Lemma 1687 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family truth equational, then* $\mathcal{I}$ *is Leibniz truth equational.*

Proof: Suppose that $\mathcal{I}$ is family truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. Thus, by Theorem 848, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. We have

$$\begin{array}{rcll} \phi \in T_\Sigma & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\phi] \leq \Omega^{\mathcal{A}}(T) & (\mathcal{I} \text{ truth equational}) \\ & \text{implies} & \tau^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T^*) & (T^* \in [\![T]\!]^*) \\ & \text{iff} & \phi \in T^*_\Sigma. & (\mathcal{I} \text{ truth equational}) \end{array}$$

Thus, we get $T \leq T^*$. On the other hand, by Lemma 1568, $T^* \leq T$, whence $T - T^*$. This gives $T^* = T$ and, hence $T^* = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$, showing that $\mathcal{I}$ is Leibniz truth equational. ■

If $\mathcal{I}$ is Leibniz truth equational, then the collection of all its Leibniz filters on every algebraic system forms a closure family.

Proposition 1688 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ *is closed under signature-wise intersections and, hence, forms a closure family on* $\mathcal{A}$*.*

Proof: Suppose $\mathcal{I}$ is Leibniz truth-equational, with witnssing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$ be a collection of Leibniz $\mathcal{I}$-filter families. Then

$$\begin{array}{rcll} \bigcap_{i\in I} T^i & = & \bigcap_{i\in I} (T^i)^* & (T^i \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})) \\ & = & \bigcap_{i\in I} \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T^i)) & (\mathcal{I} \text{ Leibniz truth equational}) \\ & \leq & \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i)) & (\bigcap_{i\in I} \Omega^{\mathcal{A}}(T^i) \leq \Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i)) \\ & = & (\bigcap_{i\in I} T^i)^*. & (\mathcal{I} \text{ Leibniz truth equational}) \end{array}$$

Since, by Lemma 1568, $(\bigcap_{i\in I} T^i)^* \leq \bigcap_{i\in I} T^i$, we get that $(\bigcap_{i\in I} T^i)^* = \bigcap_{i\in I} T^i$ and, therefore, $\bigcap_{i\in I} T^i \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

The next proposition shows that to check that a given π-institution $\mathcal{I}$ is Leibniz truth equational, it is sufficient to work with $\mathcal{I}^*$-algebraic systems only. That is, if the defining property holds for all Leibniz filters of $\mathcal{I}^*$-algebraic systems, then it extends to Leibniz filters over arbitrary $\mathbf{F}$-algebraic systems.

Proposition 1689 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is Leibniz truth equational if and only if, there exists* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T^* = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$*.*

Proof: The implication left-to-right follows from the definition of Leibniz truth equationality. Suppose, conversely, that there exists $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, such that, for all $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T^* = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. Let $\mathcal{A}$ be an arbitrary **F**-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, and consider the quotient morphism $\langle I, \pi\rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T)$. Then, by Corollary 1554, $\pi(T^*) = \pi(T)^*$ and, by Proposition 1530, $\pi(T)^*$ is the least $\mathcal{I}$-filter family on $\mathcal{A}/\Omega^{\mathcal{A}}(T)$. Since $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I})$, we get, by hypothesis,

$$\pi(T)^* = \tau^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \tau^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}).$$

Hence, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll} \phi \in T^*_\Sigma & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \pi_\Sigma(T^*_\Sigma) \quad (\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^*)) \\ & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \pi(T)^*_\Sigma \\ & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \tau_\Sigma^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}) \\ & \text{iff} & \phi \in \tau^{\mathcal{A}}_\Sigma(\Omega^{\mathcal{A}}(T)). \end{array}$$

Thus, $\mathcal{I}$ is Leibniz truth equational. ∎

A fortiori, it suffices to show that the condition in the statement of Proposition 1689 holds for all $\mathcal{I}$-algebraic systems, since this class encompasses all $\mathcal{I}^*$-algebraic systems.

Corollary 1690 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is Leibniz truth equational if and only if, there exists* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T^* = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$.

Proof: The conclusion follows from Proposition 1689, taking into account the fact that $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$. ∎

Next, we provide another characterization of Leibniz truth equationality by showing that it is equivalent to $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}})$ being the least $\mathcal{I}$-filter family on every $\mathcal{I}$- (or $\mathcal{I}\star$-)algebraic system.

Proposition 1691 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. The following conditions are equivalent.*

(i) $\mathcal{I}$ *is Leibniz truth equational, with witnessing transformations* $\tau^\flat$*;*

(ii) For all $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(iii) For all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof:

(i)⇒(iii) Suppose $\mathcal{I}$ is Leibniz truth equational, with witnessing transformations $\tau^\flat$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$ and $T^m = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Lemma 1568, $T^m \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Since $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T^m))$, we get, by hypothesis, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) \leq T^m$. On the other hand, since $T^m = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T^m \leq T^*$, whence, by hypothesis, $T^m \leq \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. Since, this holds for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get, taking into account that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$,

$$T^m \leq \tau^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \tau^{\mathcal{A}}(\Delta^{\mathcal{A}}).$$

Therefore, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = T^m$.

(iii)⇒(ii) Trivial, since $\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I})$.

(ii)⇒(i) Suppose, for all $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T).$$

Then, $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I})$ and, by Corollary 1554, $\pi(T^*) = \pi(T)^*$ and, by Proposition 1530, $\pi(T)^* = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. Thus, by hypothesis, $\pi(T^*) = \tau^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)})$. Therefore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll} \phi \in T^*_\Sigma & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \pi_\Sigma(T^*_\Sigma) \\ & \text{iff} & \phi/\Omega^{\mathcal{A}}_\Sigma(T) \in \tau_\Sigma^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}) \\ & \text{iff} & \phi \in \tau^{\mathcal{A}}_\Sigma(\Omega^{\mathcal{A}}(T)). \end{array}$$

Hence, $\tau^\flat$ witnesses the Leibniz truth equationality of $\mathcal{I}$.

■

If $\mathcal{I}$-algebraic systems and $\mathcal{I}^+$-algebraic systems coincide, then truth equationality of $\mathcal{I}^+$ guarantees the Leibniz truth equationality of $\mathcal{I}$.

Proposition 1692 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. If* $\mathcal{I}^+$ *is family truth equational, with witnessing transformations* $\tau^\flat$ *and* $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}^+)$*, then* $\mathcal{I}$ *is Leibniz truth equational, with witnessing transformations* $\tau^\flat$*.*

Proof: We use Proposition 1691. Suppose $\mathcal{I}^+$ is family truth equational via $\tau^\flat$ and $\mathrm{AlgSys}(\mathcal{I}) = \mathrm{AlgSys}(\mathcal{I}^+)$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Since, by hypothesis $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$, we get, by hypothesis, Lemma 1687 and Proposition 1691, $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. By Lemma 1667, $\bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \bigcap \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. Hence, we get $\tau^{\mathcal{A}}(\Delta^{\mathcal{A}}) = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, whence, by Proposition 1691, $\mathcal{I}$ is Leibniz truth equational via $\tau^\flat$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ and K a class of $\mathbf{F}$-algebraic systems. We define, as before, on $\mathbf{F}$ the closure system $C^{\mathsf{K},\tau} = \{C^{\mathsf{K},\tau}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $C^{\mathsf{K},\tau}_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$ is given, for all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, by

$$\phi \in C^{\mathsf{K},\tau}_\Sigma(\Phi) \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq C^{\mathsf{K}}(\tau^\flat_\Sigma[\Phi]).$$

Then we say that K is a **$\tau^\flat$-algebraic semantics for** $\mathcal{I}$ if $C = C^{\mathsf{K},\tau}$.

We show that, if a π-institution $\mathcal{I}$ is Leibniz truth equational, with witnessing transformations $\tau^\flat$, then any of the four classes $\mathrm{AlgSys}^*(\mathcal{I}^+)$, $\mathrm{AlgSys}(\mathcal{I}^+)$, $\mathrm{AlgSys}^*(\mathcal{I})$ or $\mathrm{AlgSys}(\mathcal{I})$ serves as a $\tau^\flat$-algebraic semantics for $\mathcal{I}^+$.

Theorem 1693 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a Leibniz truth equational π-institution based on $\mathbf{F}$, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. Set $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I}^+)$ or $\mathrm{AlgSys}(\mathcal{I}^+)$ or $\mathrm{AlgSys}^*(\mathcal{I})$ or $\mathrm{AlgSys}(\mathcal{I})$. Then K is a $\tau^\flat$-algebraic semantics for $\mathcal{I}^+$.*

Proof: Let, first, $K = \mathrm{AlgSys}^*(\mathcal{I})$ or $\mathrm{AlgSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then, we have $\phi \in C^+_\Sigma(\Phi)$ if and only if, by Proposition 1664, $\phi \in C^{\mathsf{M}^{\mathcal{I},m}_{\mathsf{K}}}_\Sigma(\Phi)$ if and only if, for all $\mathcal{A} \in \mathsf{K}$,

$$\alpha_\Sigma(\Phi) \subseteq C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\varnothing) \quad \text{implies} \quad \alpha_\Sigma(\phi) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\varnothing).$$

if and only if, by hypothesis and Proposition 1691,

$$\alpha_\Sigma(\Phi) \subseteq \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}}) \quad \text{implies} \quad \alpha_\Sigma(\phi) \in \tau^{\mathcal{A}}_{F(\Sigma)}(\Delta^{\mathcal{A}}),$$

if and only if

$$\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\Phi)] \leq \Delta^{\mathcal{A}} \quad \text{implies} \quad \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}},$$

if and only if

$$\alpha(\tau^\flat_\Sigma[\Phi]) \leq \Delta^{\mathcal{A}} \quad \text{implies} \quad \alpha(\tau^\flat_\Sigma[\phi]) \leq \Delta^{\mathcal{A}},$$

if and only if $\tau^\flat_\Sigma[\phi] \leq C^{\mathsf{K}}(\tau^\flat_\Sigma[\Phi])$ if and only if $\phi \in C^{\mathsf{K},\tau}_\Sigma(\Phi)$. Thus, K is a $\tau^\flat$-algebraic semantics of $\mathcal{I}^+$.

Finally, note that, by hypothesis and Lemma 1671, $\mathcal{I}^+$ is Leibniz truth equational via $\tau^\flat$, as well. Moreover, by Corollary 1668, $(\mathcal{I}^+)^+ = \mathcal{I}^+$. Applying, therefore, what was shown above to $\mathcal{I}^+$, we get the result for $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I}^+)$ or $\mathrm{AlgSys}(\mathcal{I}^+)$. ∎

Theorem 1693 implies that for $\mathrm{AlgSys}(\mathcal{I})$ to be a $\tau^\flat$-algebraic semantics of a Leibniz truth equational π-institution $\mathcal{I}$, where $\tau^\flat$ is a set of witnessing transformations, $\mathcal{I}$ and $\mathcal{I}^+$ must be identical.

Corollary 1694 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$. $\mathrm{AlgSys}(\mathcal{I})$ *is a* $\tau^\flat$*-algebraic semantics for* $\mathcal{I}$ *if and only if* $\mathcal{I} = \mathcal{I}^+$.

Proof: By Theorem 1693, $C^+ = C^{\mathrm{AlgSys}(\mathcal{I}),\tau}$. Therefore, we get that $\mathrm{AlgSys}(\mathcal{I})$ is a $\tau^\flat$-algebraic semantics of $\mathcal{I}$ if and only if, by definition $C = C^{\mathrm{AlgSys}(\mathcal{I}),\tau}$ if and only if $C = C^+$. ■

Moreover, we can show that Leibniz truth equationality of $\mathcal{I}$ implies the family truth equationality of $\mathcal{I}^+$.

Corollary 1695 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is Leibniz truth equational, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$*, then* $\mathcal{I}^+$ *is family truth equational via* $\tau^\flat$.

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A})$. By hypothesis and Theorem 1693, $\mathcal{I}^+$ has a $\tau^\flat$-algebraic semantics. Therefore, by Corollary 824, $T = \tau^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{I}^+,\mathcal{A}}(T)) \leq \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. Conversely, by hypothesis and the fact that, by Proposition 1665, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get, using Lemma 1568, $\tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T)) = T^* \leq T$. We now conclude that $T = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$. Thus, $\mathcal{I}^+$ is family truth equational, with witnessing transformations $\tau^\flat$. ■

As another consequence, we get that, under Leibniz truth equationality, $\mathcal{I}^+$ filter families coincide with Leibniz $\mathcal{I}$-filter families on any algebraic system.

Corollary 1696 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is Leibniz truth equational, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$.

Proof: Suppose $\mathcal{I}$ is Leibniz truth equational. Then, by Corollary 1695, $\mathcal{I}^+$ is family truth equational. Thus, by Proposition 1673, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a Leibniz truth equational π-institution, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. Let, also, $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by definition $T^{\mathcal{I},\mathsf{Su}} = \bigcap [\![T]\!]^{\mathcal{I},\mathsf{Su}}$ and, by Proposition 1584, $\langle \mathcal{A}, [\![T]\!]^{\mathcal{I},\mathsf{Su}} \rangle \in \mathrm{FStr}(\mathcal{I})$. Thus, by Proposition 1584, $T^{\mathcal{I},\mathsf{Su}} \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Now it follows, by hypothesis, that

$$T^{\mathcal{I},\mathsf{Su}} = \tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T^{\mathcal{I},\mathsf{Su}})).$$

There is also an additional characterization of the Suszko filter family, using the Suszko operator.

Proposition 1697 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T^{\mathcal{I},\mathsf{Su}} = \tau^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)).$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T).$$

Then $\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \in \mathrm{AlgSys}(\mathcal{I})$. Moreover, by Lemma 1557, $\pi(T^{\mathcal{I},\mathsf{Su}}) = \pi(T)^{\mathcal{I},\mathsf{Su}}$ and, by Proposition 1587, $\pi(T)^{\mathcal{I},\mathsf{Su}} = \bigcap \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T))$. Thus, by Proposition 1691,

$$\pi(T^{\mathcal{I},\mathsf{Su}}) = \tau^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}).$$

Now we get

$$\begin{array}{rcl}
T^{\mathcal{I},\mathsf{Su}} & = & \pi^{-1}(\pi(T^{\mathcal{I},\mathsf{Su}})) \\
& = & \pi^{-1}(\tau^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}(\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)})) \\
& = & \tau^{\mathcal{A}}(\pi^{-1}(\Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)})) \\
& = & \tau^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)).
\end{array}$$

This proves the statement. ■

Proposition 1697 enables us to characterize the Suszko filter counterpart $T^{\mathcal{I},\mathsf{Su}}$ of a given filter family T as the intersection of all Leibniz filter family companions of filter families in the upset of T.

Corollary 1698 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T^{\mathcal{I},\mathsf{Su}} = \bigcap \{T'^* : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{array}{rcl}
T^{\mathcal{I},\mathsf{Su}} & = & \tau^{\mathcal{A}}(\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) \quad \text{(by Proposition 1697)} \\
& = & \tau^{\mathcal{A}}(\bigcap\{\Omega^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}) \\
& & \text{(definition of } \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) \\
& = & \bigcap\{\tau^{\mathcal{A}}(\Omega^{\mathcal{A}}(T')) : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}) \\
& = & \bigcap\{T'^* : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}. \\
& & \text{(Leibniz truth equationality)}
\end{array}$$

This proves the corollary. ■

We now get immediately

Corollary 1699 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{I}) \quad \textit{iff} \quad T \le T'^*, \textit{ for all } T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T.$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$ if and only if, by definition, $T = T^{\mathcal{I},\mathsf{Su}}$ if and only if, by Corollary 1698, $T = \bigcap\{T'^* : T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T\}$, if and only if, taking into account that $T^* \le T$, $T \le T'^*$, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. ■

We close the section with a characterization of weak family algebraizability of the strong version of $\mathcal{I}$ among those π-institutions that are Leibniz truth equational.

Proposition 1700 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*.* $\mathcal{I}^+$ *is weakly family algebraizable if and only if, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ *is an order isomorphism.*

Proof: If $\mathcal{I}^+$ is weakly family algebraizable, then it is, a fortiori, protoalgebraic. Therefore, by Proposition 1621, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ is an order isomorphism.

Assume, conversely, that the condition in the statement holds. Then, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,

$$\begin{array}{rcll} \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) & = & \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) & \text{(by Corollary 1672)} \\ & = & \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}). & \text{(by Corollary 1696)} \end{array}$$

Thus, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ is an order isomorphism. Hence, by Theorem 296, $\mathcal{I}^+$ is weakly family algebraizable. ■

Proposition 1700 gives a sufficient condition for the weak family algbebraizability of $\mathcal{I}^+$ that involves only $\mathcal{I}$-algebraic systems.

Corollary 1701 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz truth equational* π*-institution, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. If, for every* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism, then* $\mathcal{I}^+$ *is weakly family algebraizable.*

Proof: By hypothesis and Lemma 1679, for every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ is an order isomorphism. Hence, by Proposition 1700, $\mathcal{I}^+$ is weakly family algebraizable. ■

22.5 Leibniz Definability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **Leibniz definable** if, there exists $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T^* = \mu^{\mathcal{A}}(T),$$

i.e., for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\phi \in T^*_\Sigma \quad \text{iff} \quad \mu^{\mathcal{A}}_\Sigma[\phi] \leq T.$$

We show that it suffices to consider only $\mathcal{I}^*$-algebraic systems to establish Leibniz definability.

Proposition 1702 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is Leibniz definable if and only if, there exists $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for all $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T^* = \mu^{\mathcal{A}}(T)$.*

Proof: The "only if" is trivial. For the "if", suppose the stated condition holds and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T).$$

Then $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \mathrm{AlgSys}^*(\mathcal{I})$ and, moreover, $\mathrm{Ker}(\langle I, \pi \rangle) = \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T^*)$, since $T^* \in [\![T]\!]^*$. Now we have

$$\begin{array}{rcll} T^* & = & \pi^{-1}(\pi(T^*)) & (\mathrm{Ker}(\langle I, \pi \rangle) \text{ compatible with } T^*) \\ & = & \pi^{-1}(\pi(T)^*) & (\text{by Lemma 1557}) \\ & = & \pi^{-1}(\mu^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(\pi(T))) & (\text{by hypothesis}) \\ & = & \mu^{\mathcal{A}}(\pi^{-1}(\pi(T))) & (\text{algebra and surjectivity of } \langle I, \pi \rangle) \\ & = & \mu^{\mathcal{A}}(T). & (\mathrm{Ker}(\langle I, \pi \rangle) \text{ compatible with } T) \end{array}$$

Therefore, $\mathcal{I}$ is Leibniz definable via $\mu^\flat$. ∎

Leibniz definability ensures that the mapping sending a filter family to it Leibniz counterpart is monotone and this, in turn, implies that T^* is the largest Leibniz filter family below T.

Lemma 1703 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a Leibniz definable π-institution based on $\mathbf{F}$, with witnessing transformations $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$. For every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T \leq T' \quad \textit{implies} \quad T^* \leq T'^*.$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Then $T^* = \mu^{\mathcal{A}}(T) \leq \mu^{\mathcal{A}}(T') = T'^*$. ∎

Corollary 1704 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* T^* *is the largest Leibniz filter family below* T*.*

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Suppose $T' \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, such that $T' \leq T$. Then we have $T' = T'^* \leq T^*$, where the last inclusion is due to Lemma 1703. ■

Under Leibniz definability, the condition that $\Omega^{\mathcal{A}}$ be an order isomorphism from Leibniz filter families of $\mathcal{A}$ onto $\mathcal{I}^*$-congruence systems on $\mathcal{A}$, for every $\mathcal{I}$-algebraic system yields protoalgebraicity.

Proposition 1705 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*. If, for every* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism, then* $\mathcal{I}$ *is protoalgebraic.*

Proof: Suppose the stated condition holds and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{aligned}
\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) &= \bigcap\{\Omega^{\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\
&\quad \text{(definition of } \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)) \\
&= \bigcap\{\Omega^{\mathcal{A}}(T'^*) : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\
&\quad \text{(by Proposition 1677)} \\
&= \Omega^{\mathcal{A}}(\bigcap\{T'^* : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}) \\
&\quad \text{(by the hypothesis)} \\
&= \Omega^{\mathcal{A}}(T^*) \quad \text{(by Lemma 1703)} \\
&= \Omega^{\mathcal{A}}(T). \quad \text{(by Proposition 1677)}
\end{aligned}$$

Hence, the Leibniz and Suszko operators on every $\mathbf{F}$-algebraic system coincide, whence, by Lemma 1518, $\mathcal{I}$ is protoalgebraic. ■

We show, next, that, under Leibniz definability, the collection of Leibniz $\mathcal{I}$-filter families on every $\mathbf{F}$-algebraic system is closed under morphic images and preimages and under intersections.

Proposition 1706 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*.*

(a) $\mathbb{M}(\mathsf{M}^{\mathcal{I}*}) \subseteq \mathsf{M}^{\mathcal{I}^*}$ *and* $\mathbb{M}^{-1}(\mathsf{M}^{\mathcal{I}*}) \subseteq \mathsf{M}^{\mathcal{I}^*}$*;*

(b) $\mathbb{II}(\mathsf{M}^{\mathcal{I}*}) \subseteq \mathsf{M}^{\mathcal{I}^*}$.

Proof:

(a) Let $\mathcal{A}$, $\mathcal{B}$ be $\mathbf{F}$-algebraic systems, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$ and $\langle H, \gamma \rangle : \langle \mathcal{A}, T \rangle \to \langle \mathcal{B}, T' \rangle$ a strict surjective morphism. We then have

$$\begin{array}{rll} T = T^* & \text{iff} & T = \mu^{\mathcal{A}}(T) \\ & \text{iff} & \gamma^{-1}(T') = \mu^{\mathcal{A}}(\gamma^{-1}(T')) \\ & \text{iff} & \gamma^{-1}(T') = \gamma^{-1}(\mu^{\mathcal{B}}(T')) \\ & \text{iff} & T' = \mu^{\mathcal{B}}(T') \\ & \text{iff} & T' = T'^*. \end{array}$$

Thus, $\langle \mathcal{A}, T \rangle \in \mathsf{M}^{\mathcal{I}*}$ if and only if $\langle \mathcal{B}, T' \rangle \in \mathsf{M}^{\mathcal{I}*}$.

(b) Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Then we have

$$\begin{array}{rcl} \bigcap_{i \in I} T^i & = & \bigcap_{i \in I} (T^i)^* \\ & = & \bigcap_{i \in I} \mu^{\mathcal{A}}(T^i) \\ & = & \mu^{\mathcal{A}}(\bigcap_{i \in I} T^i) \\ & = & (\bigcap_{i \in I} T^i)^*. \end{array}$$

Therefore $\bigcap_{i \in I} T^i \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Thus, if $\langle \mathcal{A}, T^i \rangle \in \mathsf{M}^{\mathcal{I}*}$, for all $i \in I$, then $\langle \mathcal{A}, \bigcap_{i \in I} T^i \rangle \in \mathsf{M}^{\mathcal{I}*}$.

■

Proposition 1706, in conjunction with the characterization Theorem 1787 of the $\mathcal{I}^{\mathsf{M}}$-matrix families for a class M of $\mathbf{F}$-matrix families, allow us to prove that, under Leibniz definability, $\mathcal{I}^+$-filter families and Leibniz $\mathcal{I}$-filter families on any $\mathbf{F}$-algebraic system coincide.

Theorem 1707 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* $\mu^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: We have

$$\begin{array}{rcl} \mathrm{MatFam}(\mathcal{I}^+) & = & \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}^{\mathcal{I}*}}) \quad (\mathcal{I}^+ = \mathcal{I}^{\mathsf{M}^{\mathcal{I}*}}, \text{ by definition}) \\ & = & \mathbb{M}\mathbb{I}\mathbb{P}\mathbb{I}\mathbb{M}^{-1}(\mathsf{M}^{\mathcal{I}*}) \quad (\text{by Theorem 1787}) \\ & \subseteq & \mathsf{M}^{\mathcal{I}*}. \quad (\text{by Proposition 1706}) \end{array}$$

This shows that $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. But, by Proposition 1665, the reverse inclusion always holds. Therefore, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. ■

We give several conditions involving the strong version of $\mathcal{I}$ that turn out to characterize both the protoalebraicity of $\mathcal{I}$ and the protoalgebraicity of $\mathcal{I}^+$, under the proviso that $\mathcal{I}$ be Leibniz definable.

Corollary 1708 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}^+$ *is protoalgebraic;*

(ii) $\mathcal{I}$ *is protoalgebraic;*

(iii) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is an order isomorphism;*

(iv) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}^+)$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ *is an order isomorphism;*

(v) $\mathcal{I}^+$ *is weakly family algebraizable.*

Proof:

(i)⇒(ii) Suppose $\mathcal{I}^+$ is protoalgebraic. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. By Lemma 1703, $T^* \leq T'^*$. Hence, by Proposition 1665 and the hypothesis, $\Omega^{\mathcal{A}}(T^*) \leq \Omega^{\mathcal{A}}(T'^*)$. By hypothesis, Proposition 1621 and Proposition 1677, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Thus, the Leibniz operator is monotone on the $\mathcal{I}$-filter families of every $\mathbf{F}$-algebraic system and, therefore, $\mathcal{I}$ is protoalgebraic.

(ii)⇒(iii) By Proposition 1621.

(iii)⇒(iv) By Lemma 1679.

(iv)⇒(v) We have, for every $\mathbf{F}$-algebraic system $\mathcal{A}$,

$$\begin{array}{rcll} \mathrm{FiFam}^{\mathcal{I}^+*}(\mathcal{A}) & = & \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) & \text{(by Corollary 1672)} \\ & = & \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}). & \text{(by Theorem 1707)} \end{array}$$

Therefore, by hypothesis, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}^+}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^+*}(\mathcal{A})$ is an order isomorphism. By Theorem 296, $\mathcal{I}^+$ is weakly family algebraizable.

(v)⇒(i) If $\mathcal{I}^+$ is weakly family algebraizable, then it is, a fortiori, protoalgebraic. ■

Finally, we give some consequences of imposing both Leibniz definability and Leibniz truth equationality. The combination is strong enough to guarantee that Leibniz filter families and Suszko filter families coincide.

Proposition 1709 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable and Leibniz truth equational* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T^* = T^{\mathcal{I},\mathsf{Su}}.$$

Proof: Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then

$$\begin{array}{lll} T^{\mathcal{I},\mathsf{Su}} & = & \bigcap\{T'^* : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \quad \text{(by Corollary 1698)} \\ & = & T^*. \quad \text{(by Lemma 1703)} \end{array}$$

This proves the statement. ∎

Corollary 1710 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Leibniz definable and Leibniz truth equational* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,*

$$\mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A}) = \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}).$$

Proof: Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$. By Lemma 1583, $\mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$. On the other hand, if $T \in \mathrm{FiFam}^{\mathcal{I}*}(\mathcal{A})$, then, by Proposition 1709, $T = T^* = T^{\mathcal{I},\mathsf{Su}}$. Thus, $T \in \mathrm{FiFam}^{\mathcal{I},\mathsf{Su}}(\mathcal{A})$. ∎

Chapter 23

The Frege Hierarchy

23.1 The Frege Hierarchy

23.2 Self Extensionality and Implication

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ a binary natural transformation in $N^\flat$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

We say that $\to^\flat$ has the **Deduction Detachment Property in** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}(\Sigma)$,

$$\psi \in C_\Sigma(\Phi, \phi) \quad \text{iff} \quad \phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi).$$

$\mathcal{I}$ has the **Uniterm Deduction Detachment Property with respect to** $\to^\flat$ if $\to^\flat$ has the Deduction Detachment Property in $\mathcal{I}$. $\mathcal{I}$ has the **Uniterm Deduction Detachment Property** if it has the Uniterm Deduction Detachment Property with respect to some $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

If a π-institution has the Uniterm Deduction Detachment Theorem with respect to two different binary natural transformations in $N^\flat$, then the two must be interderivable in the following precise sense.

Lemma 1711 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat, \to'^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *has the Uniterm Deduction Detachment Property with respect to both* $\to^\flat$ *and* $\to'^\flat$*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$C_\Sigma(\phi \to^\flat_\Sigma \psi) = C_\Sigma(\phi \to'^\flat_\Sigma \psi).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. We have $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi)$. By the Uniterm Deduction Detachment Property with respect to $\to^\flat$, we get $\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi)$. By the Uniterm Deduction Detachment Property with respect to $\to'^\flat$, we get $\phi \to'^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi)$. Using symmetry, we obtain that $C_\Sigma(\phi \to^\flat_\Sigma \psi) = C_\Sigma(\phi \to'^\flat_\Sigma \psi)$. ■

Thus, for self extensional π-institutions, we get immediately

Corollary 1712 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat, \to'^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a self extensional* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *has the Uniterm Deduction Detachment Property with respect to both* $\to^\flat$ *and* $\to'^\flat$*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi \to^\flat_\Sigma \psi, \phi \to'^\flat_\Sigma \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. By Lemma 1711, $\langle \phi \to^\flat_\Sigma \psi, \phi \to'^\flat_\Sigma \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$. But, by self extensionality, $\widetilde{\lambda}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I})$. This yields the conclusion. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a class of $\mathbf{F}$-algebraic systems. The class K is said to be **Hilbert based with respect to** $\to^\flat$ if, for all $\mathcal{A} \in \mathsf{K}$, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$,

H1. $\phi \to^{\mathcal{A}}_\Sigma \phi = \psi \to^{\mathcal{A}}_\Sigma \psi$;

H2. $(\phi \to^{\mathcal{A}}_\Sigma \phi) \to^{\mathcal{A}}_\Sigma \phi = \phi$;

H3. $\phi \to^{\mathcal{A}}_\Sigma (\psi \to^{\mathcal{A}}_\Sigma \chi) = (\phi \to^{\mathcal{A}}_\Sigma \psi) \to^{\mathcal{A}}_\Sigma (\phi \to^{\mathcal{A}}_\Sigma \chi)$;

H4. $(\phi \to^{\mathcal{A}}_\Sigma \psi) \to^{\mathcal{A}}_\Sigma ((\psi \to^{\mathcal{A}}_\Sigma \phi) \to^{\mathcal{A}}_\Sigma \psi) = (\psi \to^{\mathcal{A}}_\Sigma \phi) \to^{\mathcal{A}}_\Sigma ((\phi \to^{\mathcal{A}}_\Sigma \psi) \to^{\mathcal{A}}_\Sigma \phi)$.

These equations are commonly referred to as the **Hilbert equations**. The class K is **Hilbert based** if it is Hilbert based with respect to $\to^\flat$, for some $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

A class K of $\mathbf{F}$-algebraic systems is called **pointed** if there exists $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, such that, for all $\mathcal{A} \in \mathsf{K}$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$,

$$\top^{\mathcal{A}}_\Sigma(\vec{\phi}) = \top^{\mathcal{A}}_\Sigma(\vec{\psi}).$$

$\top^\flat$ is then called a **constant in** K and we sometimes write $\top^{\mathcal{A}}_\Sigma$ for $\top^{\mathcal{A}}_\Sigma(\vec{\phi})$, since this value is independent of the argument $\vec{\phi} \in \mathrm{SEN}(\Sigma)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a Hilbert based class with respect to $\to^\flat$. Then, by the Hilbert equation H1, the natural transformation $\top^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ in $N^\flat$ defined by

$$\top^\flat := \to^\flat \circ \langle p^{1,0}, p^{1,0} \rangle$$

(in abbreviated more readable form $\top^\flat(x) := x \to^\flat x$) is a constant in K. So in this case, it makes sense to write $\top^{\mathcal{A}}_\Sigma$ for the constant defined by this natural transformation in $\mathcal{A} \in \mathsf{K}$, for $\Sigma \in |\mathbf{Sign}|$.

Moreover, for $\mathcal{A} \in \mathsf{K}$, we define the relation family $\leq^{\mathcal{A}} = \{\leq^{\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ on $\mathcal{A}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \leq^{\mathcal{A}}_\Sigma \psi \quad \text{iff} \quad \phi \to^{\mathcal{A}}_\Sigma \psi = \top^{\mathcal{A}}_\Sigma.$$

It is not difficult to see that this is actually a partial order system on $\mathcal{A}$.

Lemma 1713 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a Hilbert based class with respect to* $\to^\flat$*. For all* $\mathcal{A} \in \mathsf{K}$*,* $\leq^{\mathcal{A}}$ *is a posystem on* $\mathcal{A}$*.*

Proof: We show, first, that, for all $\Sigma \in |\mathbf{Sign}|$, $\leq^{\mathcal{A}}_\Sigma$ is a partial order on $\mathrm{SEN}(\Sigma)$. Let $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$.

- By definition $\phi \to^{\mathcal{A}}_\Sigma \phi = \top^{\mathcal{A}}_\Sigma$, whence $\phi \leq^{\mathcal{A}}_\Sigma \phi$ and $\leq^{\mathcal{A}}_\Sigma$ is reflexive;

- Suppose $\phi \le^{\mathcal{A}}_\Sigma \psi$ and $\psi \le^{\mathcal{A}}_\Sigma \phi$. Then, we get $\phi \to^{\mathcal{A}}_\Sigma \psi = \psi \to^{\mathcal{A}}_\Sigma \phi = \top^{\mathcal{A}}_\Sigma$. Thus, we get

$$\begin{array}{rcl}\phi & = & \top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma \phi \quad \text{(by H2)}\\ & = & \top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma (\top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma \phi) \quad \text{(by H2)}\\ & = & \top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma (\top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma \psi) \quad \text{(by H4)}\\ & = & \top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma \psi \quad \text{(by H2)}\\ & = & \psi. \quad \text{(by H2)}\end{array}$$

  Hence, $\le^{\mathcal{A}}_\Sigma$ is antisymmetric;

- Suppose $\phi \le^{\mathcal{A}}_\Sigma \psi$ and $\psi \le^{\mathcal{A}}_\Sigma \chi$. Then $\phi \to^{\mathcal{A}}_\Sigma \psi = \psi \to^{\mathcal{A}}_\Sigma \chi = \top^{\mathcal{A}}_\Sigma$. Thus, we get

$$\begin{array}{rcl}\phi \to^{\mathcal{A}}_\Sigma \chi & = & \top^{\mathcal{A}}_\Sigma \to^{\mathcal{A}}_\Sigma (\phi \to^{\mathcal{A}}_\Sigma \chi) \quad \text{(by H2)}\\ & = & (\phi \to^{\mathcal{A}}_\Sigma \psi) \to^{\mathcal{A}}_\Sigma (\phi \to^{\mathcal{A}}_\Sigma \chi) \quad \text{(hypothesis)}\\ & = & \phi \to^{\mathcal{A}}_\Sigma (\psi \to^{\mathcal{A}}_\Sigma \chi) \quad \text{(by H3)}\\ & = & \phi \to^{\mathcal{A}}_\Sigma \top^{\mathcal{A}}_\Sigma \quad \text{(hypothesis)}\\ & = & \phi \to^{\mathcal{A}}_\Sigma (\phi \to^{\mathcal{A}}_\Sigma \phi) \quad \text{(definition)}\\ & = & (\phi \to^{\mathcal{A}}_\Sigma \phi) \to^{\mathcal{A}}_\Sigma (\phi \to^{\mathcal{A}}_\Sigma \phi) \quad \text{(by H3)}\\ & = & \top^{\mathcal{A}}_\Sigma. \quad \text{(definition)}\end{array}$$

  So $\le^{\mathcal{A}}_\Sigma$ is also transitive.

Thus, $\le^{\mathcal{A}}$ is a partial order family on $\mathcal{A}$. We show that, in addition, it is a system, i.e., it is invariant under signature morphisms. To this end, suppose $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \le^{\mathcal{A}}_\Sigma \psi$. Then $\phi \to^{\mathcal{A}}_\Sigma \psi = \top^{\mathcal{A}}_\Sigma$. Hence, $\mathrm{SEN}(f)(\phi \to^{\mathcal{A}}_\Sigma \psi) = \mathrm{SEN}(f)(\top^{\mathcal{A}}_\Sigma)$. This gives

$$\mathrm{SEN}(f)(\phi) \to^{\mathcal{A}}_{\Sigma'} \mathrm{SEN}(f)(\psi) = \top^{\mathcal{A}}_{\Sigma'}.$$

We conclude that $\mathrm{SEN}(f)(\phi) \le^{\mathcal{A}}_{\Sigma'} \mathrm{SEN}(f)(\psi)$. Therefore, $\le^{\mathcal{A}}$ is indeed a posystem on $\mathcal{A}$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a Hilbert based class with respect to $\to^\flat$, $\mathcal{A} \in \mathsf{K}$ and $T \in \mathrm{SenFam}(\mathcal{A})$. We say that T is an **$\to^\flat$-implicative filter family of $\mathcal{A}$** if

- $\top^{\mathcal{A}}_\Sigma \in T_\Sigma$, for all $\Sigma \in |\mathbf{Sign}|$;
- $\phi \to^{\mathcal{A}}_\Sigma \psi \in T_\Sigma$ and $\phi \in T_\Sigma$ imply $\psi \in T_\Sigma$, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$.

We write $\mathrm{FiFam}^{\to}(\mathcal{A})$ for the collection of all $\to^\flat$-implicative filter families on $\mathcal{A}$.

Next, we show that in any $\mathbf{F}$-algebraic system $\mathcal{A}$ in a Hilbert based class K, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi_0, \dots, \phi_{n-1}, \phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{l}\phi_0 \to^{\mathcal{A}}_\Sigma (\phi_1 \to^{\mathcal{A}}_\Sigma \cdots \to^{\mathcal{A}}_\Sigma (\phi_{n-1} \to^{\mathcal{A}}_\Sigma \phi)\cdots) = \top^{\mathcal{A}}_\Sigma\\ \qquad \text{iff} \quad \phi_{\pi(0)} \to^{\mathcal{A}}_\Sigma (\phi_{\pi(1)} \to^{\mathcal{A}}_\Sigma \cdots \to^{\mathcal{A}}_\Sigma (\phi_{\pi(n-1)} \to^{\mathcal{A}}_\Sigma \phi)\cdots) = \top^{\mathcal{A}}_\Sigma,\end{array}$$

where π is any permutation of $\{0, \dots, n-1\}$.

Lemma 1714 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a Hilbert based class of* $\mathbf{F}$*-algebraic systems with respect to* $\to^\flat$*. For all* $\mathcal{A} \in \mathsf{K}$*, all* $\Sigma \in |\mathbf{Sign}|$*, all* $\phi_0, \phi_1, \ldots, \phi_{n-1}, \phi \in \mathrm{SEN}(\Sigma)$ *and every permutation* π *of* $\{0, 1, \ldots, n-1\}$*,*

$$\begin{aligned}&\phi_0 \to^{\mathcal{A}}_\Sigma (\phi_1 \to^{\mathcal{A}}_\Sigma \cdots \to^{\mathcal{A}}_\Sigma (\phi_{n-1} \to^{\mathcal{A}}_\Sigma \phi)\cdots) = \top^{\mathcal{A}}_\Sigma \\ &\quad \textit{iff} \quad \phi_{\pi(0)} \to^{\mathcal{A}}_\Sigma (\phi_{\pi(1)} \to^{\mathcal{A}}_\Sigma \cdots \to^{\mathcal{A}}_\Sigma (\phi_{\pi(n-1)} \to^{\mathcal{A}}_\Sigma \phi)\cdots) = \top^{\mathcal{A}}_\Sigma.\end{aligned}$$

Proof:

■

Lemma 1714 allows us to write

$$\vec{\vec{\Phi}} \to^{\mathcal{A}}_\Sigma \phi = \top^{\mathcal{A}}_\Sigma$$

for $\phi_0 \to^{\mathcal{A}}_\Sigma (\phi_1 \to^{\mathcal{A}}_\Sigma \cdots \to^{\mathcal{A}}_\Sigma (\phi_{n-1} \to^{\mathcal{A}}_\Sigma \phi)\cdots) = \top^{\mathcal{A}}_\Sigma$, where $\Phi = \{\phi_0, \ldots, \phi_{n-1}\}$, when appropriate, since the equation does not depend on the order in which the elements of Φ are arranged in the implication expression. Moreover, for convenience, if $\Phi = \varnothing$, we take

$$\vec{\vec{\Phi}} \to^{\mathcal{A}}_\Sigma \phi := \phi.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a Hilbert based class with respect to $\to^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a *finitary* π-institution based on $\mathbf{F}$. $\mathcal{I}$ is called **Hilbert based with respect to** K **and** $\to^\flat$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \text{for all } \mathcal{A} \in \mathsf{K},\ \alpha_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}.$$

We say that $\mathcal{I}$ is **Hilbert based** if there exists $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$ and a Hilbert based class K of $\mathbf{F}$-algebraic systems with respect to $\to^\flat$, such that $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$.

Corollary 1715 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* K *a Hilbert based class with respect to* $\to^\flat$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* K *and* $\to^\flat$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$C_\Sigma(\phi) = C_\Sigma(\psi) \quad \textit{iff} \quad \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K}).$$

Proof: Suppose $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $C_\Sigma(\phi) = C_\Sigma(\psi)$ if and only if, by definition, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\phi \to^\flat_\Sigma \psi) = \alpha_\Sigma(\psi \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}$, if and only if, by Lemma 1713, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$, if and only if, $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. ■

It is not difficult to see that if a π-institution is Hilbert based with respect to a Hilbert based class K, then it is also Hilbert based with respect to the semantic variety generated by K.

Lemma 1716 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* K *a Hilbert based class with respect to* $\to^\flat$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* K *and* $\to^\flat$*. Then* $\mathcal{I}$ *is also Hilbert based with respect to* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ *and* $\to^\flat$*.*

Proof: Assume that $\mathcal{I}$ is Hilbert based with respect K and $\to^\flat$. First, note that, since, for all $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{A})$, all $\mathbf{F}$-algebraic systems in $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ satisfy the Hilbert equations and, hence, $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ is a Hilbert based class with respect to $\to^\flat$.

Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$.

Suppose $\phi \in C_\Sigma(\Phi)$ and let $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. By hypothesis $\langle \vec{\vec{\Phi}} \to^\flat_\Sigma \phi, \top^\flat_\Sigma \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Since $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{A})$. Therefore, $\langle \vec{\vec{\Phi}} \to^\flat_\Sigma \phi, \top^\flat_\Sigma \rangle \in \mathrm{Ker}_\Sigma(\mathcal{A})$. This shows that $\alpha_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}$. Conversely, if, for all $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\alpha_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}$, then this holds, a fortiori, for all $\mathcal{A} \in \mathsf{K}$ and, hence, by the hypothesis $\phi \in C_\Sigma(\Phi)$.

Thus, $\mathcal{I}$ is Hilbert based both with respect to $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ and $\to^\flat$. ∎

Corollary 1717 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* K *a Hilbert based class with respect to* $\to^\flat$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* K *and* $\to^\flat$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$C_\Sigma(\phi) = C_\Sigma(\psi) \quad \textit{iff} \quad \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})).$$

Proof: By Corollary 1715 and Lemma 1716. ∎

We can also show that, if K and K' are two Hilbert based classes of $\mathbf{F}$-algebraic systems with respect to binary transformations $\to^\flat$ and $\to'^\flat$ in $N^\flat$, respectively, and a π-institution $\mathcal{I}$ happens to be Hilbert based with respect to both K and $\to^\flat$ and K' and $\to'^\flat$, then, the two classes K and K' generate the same semantic variety of $\mathbf{F}$-algebraic systems.

Proposition 1718 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat, \to'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* K *a Hilbert class with respect to* $\to^\flat$ *and* K' *a Hilbert class with respect to* $\to'^\flat$*. If* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *is a* π*-institution that is Hilbert based with respect to* K *and* $\to^\flat$ *and Hilbert based with respect to* K' *and* $\to'^\flat$*, then* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}')$*.*

Proof: We show that $\mathsf{K}' \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Then the conclusion will follow by symmetry. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$, and $\mathcal{A}' \in \mathsf{K}'$. By hypothesis, for all $\mathcal{A}$, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Hence, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\phi \to^\flat_\Sigma \psi) = \alpha_\Sigma(\psi \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}$. Thus, since $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, we get $C_\Sigma(\phi) = C_\Sigma(\psi)$. But, by hypothesis, $\mathcal{I}$ is also Hilbert based with respect to K' and $\to'^\flat$, whence $\alpha'_\Sigma(\phi \to'^\flat_\Sigma \psi) = \alpha'_\Sigma(\psi \to'^\flat_\Sigma \phi) = \top^{\mathcal{A}'}_{F'(\Sigma)}$. Hence, by Lemma 1713, $\alpha'_\Sigma(\phi) = \alpha'_\Sigma(\psi)$ or, equivalently, $\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathcal{A}')$. This shows that $\mathcal{A}' \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Thus, $\mathsf{K}' \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. ■

We conclude that, if $\mathcal{I} = \langle\mathbf{F}, C\rangle$ is a Hilbert based π-institution, there is a unique semantic variety of $\mathbf{F}$-algebraic systems, with respect to which it is Hilbert based. We denote this semantic variety by $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})$ and call it the **semantic variety of** $\mathcal{I}$.

A key result is that every Hilbert based π-institution is self extensional and has the Deduction Detachment Property. We also show that the semantic variety of $\mathcal{I}$ coincides with the class $\mathsf{K}^{\mathcal{I}}$, the semantic variety of $\mathcal{I}$.

Proposition 1719 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$, K *a Hilbert based class with respect to* $\to^\flat$, *and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a Hilbert based* π*-institution with respect to* K *and* $\to^\flat$.

(a) $\mathcal{I}$ *is self extensional;*

(b) $\mathcal{I}$ *has the Deduction Detachment Property with respect to* $\to^\flat$*;*

(c) $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$*; Thus,* $\mathcal{I}$ *is Hilbert based with respect to* $\mathsf{K}^{\mathcal{I}}$ *and* $\to^\flat$.

Proof:

(a) We must show that $\widetilde{\Lambda}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I})$. Since $\widetilde{\Omega}(\mathcal{I})$ is the largest congruence system on $\mathbf{F}$ that is included in $\widetilde{\lambda}(\mathcal{I})$, it suffices to show that $\widetilde{\lambda}(\mathcal{I})$ is a congruence system. To this end, let $\sigma^\flat$ be a natural transformation in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi_i,\psi_i\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$, for all $i < k$. Hence, by definition, $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$, for all $i \in I$. Since $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, we get, by Corollary 1715, $\langle\phi_i,\psi_i\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$, for all $i < k$. But $\mathrm{Ker}(\mathsf{K})$ is a congruence system on $\mathbf{F}$, whence $\langle\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Again, by Corollary 1715, $C_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(\sigma^\flat_\Sigma(\vec{\psi}))$ and, therefore, $\langle\sigma^\flat_\Sigma(\vec{\phi}), \sigma^\flat_\Sigma(\vec{\psi})\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$. We conclude that $\widetilde{\lambda}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I})$ and, hence, $\mathcal{I}$ is self extensional.

(b) Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi,\psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$.

- Suppose that $\psi \in C_\Sigma(\Phi,\phi)$. Since $\mathcal{I}$ is finitary, there exists $\Phi' \subseteq_f \Phi$, such that $\psi \in C_\Sigma(\Phi',\phi)$. Since $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, we get $\langle\vec{\Phi}' \to^\flat_\Sigma (\phi \to^\flat_\Sigma \psi), \top^\flat_\Sigma\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Thus, again, since $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi') \subseteq C_\Sigma(\Phi)$.
- Suppose, conversely, that $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi)$. Again, by finitarity, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi')$. Hence, since $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, $\langle\vec{\Phi}' \to^\flat_\Sigma (\phi \to^\flat_\Sigma \psi), \top^\flat_\Sigma\rangle \in$

$\mathrm{Ker}_\Sigma(\mathsf{K})$. But, again by the fact that $\mathcal{I}$ is Hilbert based with respect to K and $\to^\flat$, we get that $\psi \in C_\Sigma(\Phi', \phi) \subseteq C_\Sigma(\Phi, \phi)$.

Hence $\mathcal{I}$ has the Deduction Detachment Property with respect to $\to^\flat$.

(c) Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{llll} \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})) & \text{iff} & C_\Sigma(\phi) = C_\Sigma(\psi) & \text{(by Corollary 1717)} \\ & \text{iff} & \langle \phi, \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) & \text{(by definition)} \\ & \text{iff} & \langle \phi, \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}) & \text{(by Part (a))} \\ & \text{iff} & \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K}^{\mathcal{I}}). & \text{(by definition)} \end{array}$$

Therefore, since $\mathsf{K}^{\mathcal{I}}$ is a semantic variety by definition, we get that $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$. The last statement follows now by Lemma 1716. ■

If $\mathcal{I}$ is Hilbert based, not only is the semantic variety with respect to which it is Hilbert based unique, but, in addition, any two binary natural transformations that serve as the Hilbert implications are in a sense interderivable and, hence, indistinguishable modeulo the Tarski congruence system of $\mathcal{I}$.

Corollary 1720 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat$, $\to'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* $\to^\flat$ *and with respect to* $\to'^\flat$. *Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

(a) $C_\Sigma(\phi \to^\flat_\Sigma \psi) = C_\Sigma(\phi \to'^\flat_\Sigma \psi)$;

(b) $\langle \phi \to^\flat_\Sigma \psi, \phi \to'^\flat_\Sigma \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$.

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{llll} \phi \to^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi) & \text{iff} & \psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi) & \text{(Proposition 1719)} \\ & \text{iff} & \phi \to'^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi). & \text{(Proposition 1719)} \end{array}$$

Therefore, $\phi \to'^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi)$. By symmetry, we get the conclusion of Part (a). Part (b) follows by Proposition 1719, which asserts that $\mathcal{I}$ is self extensional. ■

If $\mathcal{I}$ is self extensional and has the Deduction Detachment Property with respect to $\to^\flat$, it turns out that the singleton class $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$, consisting of the Lindenbaum-Tarski $\mathbf{F}$-algebraic system of $\mathcal{I}$, is Hilbert based with respect to $\to^\flat$.

Lemma 1721 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary self extensional* π*-institution, having the Deduction Detachment Property with respect to* $\to^\flat$. *The class* $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$ *is Hilbert based with respect to* $\to^\flat$.

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$.

(H1) By the Deduction Detachment Property with respect to $\to^\flat$, we get $C_\Sigma(\phi \to^\flat_\Sigma \phi) = C_\Sigma(\psi \to^\flat_\Sigma \psi) = C_\Sigma(\varnothing)$. Therefore, by self extensionality, $\langle \phi \to^\flat_\Sigma \phi, \psi \to^\flat_\Sigma \psi\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$;

(H2) We have $\phi \to^\flat_\Sigma \phi \in C_\Sigma(\phi \to^\flat_\Sigma \phi)$, whence $\phi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \phi)$ and, hence, $(\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi \in C_\Sigma(\phi)$.

On the other hand, $(\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi \in C_\Sigma((\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi)$, whence $\phi \in C_\Sigma((\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi, \phi \to^\flat_\Sigma \phi)$ and, since $\phi \to^\flat_\Sigma \phi \in C_\Sigma(\varnothing)$, $\phi \in C_\Sigma((\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi)$.

This shows that $C_\Sigma((\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi) = C_\Sigma(\phi)$ and, hence, by self extensionality, $\langle (\phi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \phi, \phi\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$.

(H3) By the Deduction Detachment Property with respect to $\to^\flat$, we get $\chi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi, (\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$. Thus, since $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\psi)$, we get $\chi \in C_\Sigma(\phi, \psi, (\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$. This gives $\psi \to^\flat_\Sigma \chi \in C_\Sigma(\phi, (\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$ and, hence, $\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi) \in C_\Sigma((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$.

On the other hand, $\chi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi, \phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi))$. Therefore, $\phi \to^\flat_\Sigma \chi \in C_\Sigma(\phi \to^\flat_\Sigma \psi, \phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi))$, whence $(\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi) \in C_\Sigma(\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi))$.

We conclude that $C_\Sigma(\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi)) = C_\Sigma((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$. Thus, by self extensionality, $\langle \phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi), (\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi)\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$.

(H4) By the Deduction Detachment Property with respect to $\to^\flat$,

$$\psi \in C_\Sigma(\psi \to^\flat_\Sigma \phi, \phi \to^\flat_\Sigma \psi, (\psi \to^\flat_\Sigma \phi) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma \phi)).$$

Therefore, $(\psi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi, (\psi \to^\flat_\Sigma \phi) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma \phi))$, whence $(\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma ((\psi \to^\flat_\Sigma \phi) \to^\flat_\Sigma \psi) \in C_\Sigma((\psi \to^\flat_\Sigma \phi) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma \phi))$. The other inclusion follows similarly and, then, we get the conclusion by self extensionality.

Therefore, $\{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$ is Hilbert based with respect to $\to^\flat$. ■

Now we can fully characterize those finitary π-institutions which are Hilbert based.

Theorem 1722 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat$ be an algebraic system and $\mathcal{I}$ a finitary π-institution based on $\mathbf{F}$. $\mathcal{I}$ is Hilbert based if and only if it is self extensional and has the Uniterm Deduction Detachment Property.*

Proof: The left-to-right implication is given by Proposition 1719. Assume, conversely, that $\mathcal{I}$ is self extensional and has the Uniterm Deduction Detachment Property with respect to some $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. Consider $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$. By Lemma 1721, K is Hilbert based with respect to $\to^\flat$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{llr}\phi \in C_\Sigma(\Phi) & \text{iff} \;\; \vec{\vec{\Phi}} \to^\flat_\Sigma \phi \in C_\Sigma(\varnothing) & \text{(Deduction Detachment)}\\ & \text{iff} \;\; \langle \vec{\vec{\Phi}} \to^\flat_\Sigma \phi, \top^\flat_\Sigma\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) & \text{(definition of } \widetilde{\lambda}(\mathcal{I}))\\ & \text{iff} \;\; \langle \vec{\vec{\Phi}} \to^\flat_\Sigma \phi, \top^\flat_\Sigma\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}). & \text{(self extensionality)}\end{array}$$

Therefore, $\mathcal{I}$ is Hilbert based with respect to K and, hence, by Lemma 1716, with respect to $\mathsf{K}^{\mathcal{I}} = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, and $\to^\flat$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat$ be an algebraic system, with $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$ and K a Hilbert based semantic variety with respect to $\to^\flat$. We define the *finitary* π-**institution**

$$\mathcal{I}^{\mathsf{K},\to} = \langle \mathbf{F}, C^{\mathsf{K},\to}\rangle,$$

associated with K and $\to^\flat$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C^{\mathsf{K},\to}_\Sigma(\Phi) \quad \text{iff} \quad \langle \vec{\vec{\Phi}} \to^\flat_\Sigma \phi, \top^\flat_\Sigma\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K}).$$

We can see easily from the definition that $\mathcal{I}^{\mathsf{K},\to}$ is Hilbert based with respect to K and $\to^\flat$.

Corollary 1723 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a Hilbert based semantic variety with respect to $\to^\flat$. Then $\mathcal{I}^{\mathsf{K},\to}$ is Hilbert based with respect to K and $\to^\flat$ and, moreover, $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}^{\mathsf{K},\to}) = \mathsf{K}$.*

Proof: This follows directly from the definition of $\mathcal{I}^{\mathsf{K},\to}$ and by taking into account Lemma 1716 and the definition of $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}^{\mathsf{K},\to})$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat$ be an algebraic system, with $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. Our next goal is to establish that the two mappings

$$\begin{array}{ccc}\mathcal{I} & \longmapsto & \mathbb{V}^{\mathsf{Sem}}(\mathcal{I})\\ \mathcal{I}^{\mathsf{K},\to} & \longleftarrow\!\!\!\dashv & \mathsf{K}\end{array}$$

form a dual order isomorphism from the collection of Hilbert based π-institutions with respect to $\to^\flat$, under $\leq$, and Hilbert based semantic varieties with respect to $\to^\flat$, under $\subseteq$.

We first show that the Frege operator is both monotone and order reflecting on Hilbert based π-institutions with respect to $\to^\flat$.

Proposition 1724 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$*,* $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *be Hilbert based* π*-institutions with respect to* $\to^\flat$*. Then*

$$\mathcal{I} \le \mathcal{I}' \quad \textit{iff} \quad \widetilde{\lambda}(\mathcal{I}) \le \widetilde{\lambda}(\mathcal{I}').$$

Proof: The left-to-right implication (monotonicity) is given by Lemma 1416. For the right-to-left implication, suppose $\widetilde{\lambda}(\mathcal{I}) \le \widetilde{\lambda}(\mathcal{I}')$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll} \phi \in C_\Sigma(\Phi) & \text{iff} & C_\Sigma(\overset{\Rightarrow}{\Phi} \to^\flat_\Sigma \phi) = C_\Sigma(\varnothing) \quad \text{(by Theorem 1722)} \\ & \text{iff} & \langle \overset{\Rightarrow}{\Phi} \to^\flat_\Sigma \phi, \top^\flat_\Sigma \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) \quad \text{(definition)} \\ & \text{implies} & \langle \overset{\Rightarrow}{\Phi} \to^\flat_\Sigma \phi, \top^\flat_\Sigma \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}') \quad \text{(hypothesis)} \\ & \text{iff} & C'_\Sigma(\overset{\Rightarrow}{\Phi} \to^\flat_\Sigma \phi) = C'_\Sigma(\varnothing) \quad \text{(definition)} \\ & \text{iff} & \phi \in C'_\Sigma(\Phi). \quad \text{(by Theorem 1722)} \end{array}$$

We conclude that $\mathcal{I} \le \mathcal{I}'$ and, hence $\widetilde{\lambda}$ is also order reflecting. ∎

Now we present the preannounced order isomorphism theorem. For an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, with $\to^\flat$ a binary natural transformation in $N^\flat$, we let

$$\mathsf{K}^{\mathbf{F},\to}$$

be the semantic variety consisting of all $\mathbf{F}$-algebraic systems satisfying the Hilbert equations with respect to $\to^\flat$.

Theorem 1725 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, There exists a dual order isomorphism between the collection of all Hilbert based* π*-institutions with respect to* $\to^\flat$*, ordered under* $\le$*, and the collection of all semantic subvarieties of the semantic variety* $\mathsf{K}^{\mathbf{F},\to}$*, ordered under* $\subseteq$*, given by* $\mathcal{I} \mapsto \mathsf{K}^{\mathcal{I}}$*.*

Proof: The given mapping is onto, since, by Corollary 1723, for $\mathsf{K} \subseteq \mathsf{K}^{\mathbf{F},\to}$ a semantic subvariety of $\mathsf{K}^{\mathbf{F},\to}$, $\mathsf{K} = \mathsf{K}^{\mathcal{I}^{\mathsf{K},\to}}$. Moreover, it is 1-1, since $\mathsf{K}^{\mathcal{I}} = \mathsf{K}^{\mathcal{I}'}$ implies that $\widetilde{\lambda}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I}) = \widetilde{\Omega}(\mathcal{I}') = \widetilde{\lambda}(\mathcal{I}')$ and, hence, by Proposition 1724, $\mathcal{I} = \mathcal{I}'$. Finally, monotonicity and order reflectivity are both given by

$$\begin{array}{lll} \mathcal{I} \le \mathcal{I}' & \text{iff} & \widetilde{\lambda}(\mathcal{I}) \le \widetilde{\lambda}(\mathcal{I}') \quad \text{(Proposition 1724)} \\ & \text{iff} & \widetilde{\Omega}(\mathcal{I}) \le \widetilde{\Omega}(\mathcal{I}') \quad \text{(Theorem 1722)} \\ & \text{iff} & \mathcal{F}/\widetilde{\Omega}(\mathcal{I}') \in \mathbb{V}^{\mathsf{Sem}}(\mathcal{F}/\widetilde{\Omega}(\mathcal{I})) \\ & \text{iff} & \mathsf{K}^{\mathcal{I}'} \subseteq \mathsf{K}^{\mathcal{I}}. \end{array}$$

This establishes the order isomorphism. ∎

Our next goal is to show that Hilbert based π-institutions, i.e., finitary self extensional π-institutions that have the Uniterm Deduction Detachment Property (by Theorem 1722) are fully self extensional.

We start by proving that on every $\mathbf{F}$-algebraic system in the Hilbert class $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$, $\mathcal{I}$-filter families and implicative filter families coincide.

Lemma 1726 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* $\to^\flat$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$*,*

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiFam}^{\to}(\mathcal{A}).$$

Proof: Let $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$.

Suppose that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

- We have $\phi \in C_\Sigma(\phi)$, whence, by Proposition 1719, $\phi \to^\flat_\Sigma \phi \in C_\Sigma(\varnothing)$. Hence, $\top^{\mathcal{A}}_{F(\Sigma)} \in T_{F(\Sigma)}$;
- Assume $\alpha_\Sigma(\phi \to^\flat_\Sigma \psi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. Since, again by Proposition 1719, $\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi)$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$.

Therefore, taking into account the surjectivity of $\langle F, \alpha \rangle$, $T \in \mathrm{FiFam}^{\to}(\mathcal{A})$.

Suppose, conversely, that $T \in \mathrm{FiFam}^{\to}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. By Proposition 1719, $\vec{\vec{\Phi}} \to^\flat_\Sigma \phi \in C_\Sigma(\varnothing)$. Therefore, $C_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) = C_\Sigma(\top^\flat_\Sigma)$. Thus, by Proposition 1719 and the fact that $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, we get that $\alpha_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) = \top^{\mathcal{A}}_{F(\Sigma)}$. Since, by hypothesis, $T \in \mathrm{FiFam}^{\to}(\mathcal{A})$, $\alpha_\Sigma(\vec{\vec{\Phi}} \to^\flat_\Sigma \phi) \in T_{F(\Sigma)}$. Thus, by the fact that $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$ and $T \in \mathrm{FiFam}^{\to}(\mathcal{A})$, we get that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. We conclude that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, be an algebraic system, K be a Hilbert based class of $\mathbf{F}$-algebraic systems with respect to $\to^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a Hilbert based π-institution with respect to K and $\to^\flat$. For all $\mathcal{A} \in \mathsf{K}$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, define $T^{\langle \Sigma, \phi \rangle} = \{T^{\langle \Sigma, \phi \rangle}_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}|}$ by setting, for all $\Sigma' \in |\mathbf{Sign}|$,

$$T^{\langle \Sigma, \phi \rangle}_\Sigma = \{\chi \in \mathrm{SEN}(\Sigma) : \phi \to^{\mathcal{A}}_\Sigma \chi = \top^{\mathcal{A}}_\Sigma\}$$

and

$$T^{\langle \Sigma, \phi \rangle}_{\Sigma'} = \{\top^{\mathcal{A}}_{\Sigma'}\}, \quad \text{for all } \Sigma' \neq \Sigma.$$

It is not difficult to see that $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^{\to}(\mathcal{A})$.

Lemma 1727 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$*, with* $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, be an algebraic system,* K *be a Hilbert based class of* $\mathbf{F}$*-algebraic systems with respect to* $\to^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a Hilbert based* π*-institution with respect to* K *and* $\to^\flat$*. For all* $\mathcal{A} \in \mathsf{K}$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi \in \mathrm{SEN}(\Sigma)$*,* $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^{\to}(\mathcal{A})$*.*

Proof: Consider, first, $\Sigma' \neq \Sigma$. By definition, $\top^{\mathcal{A}}_{\Sigma'} \in T^{\langle\Sigma,\phi}_{\Sigma'}$. Moreover, if $\top^{\mathcal{A}}_{\Sigma'} \to^{\mathcal{A}}_{\Sigma'} \in T^{\langle\Sigma,\phi\rangle}_{\Sigma'}$, then, by H2, $\phi \in T^{\langle\Sigma,\phi\rangle}_{\Sigma'}$.

Consider, next, $\Sigma' = \Sigma$. Note that we have

$$\begin{array}{rcl}\phi \to^{\mathcal{A}}_{\Sigma} \top^{\mathcal{A}}_{\Sigma} & = & \phi \to^{\mathcal{A}}_{\Sigma} (\phi \to^{\mathcal{A}}_{\Sigma} \phi) \quad \text{(definition)}\\ & = & (\phi \to^{\mathcal{A}}_{\Sigma} \phi) \to^{\mathcal{A}}_{\Sigma} (\phi \to^{\mathcal{A}}_{\Sigma} \phi) \quad \text{(by H3)}\\ & = & \top^{\mathcal{A}}_{\Sigma} \to^{\mathcal{A}}_{\Sigma} \top^{\mathcal{A}}_{\Sigma} \quad \text{(definition)}\\ & = & \top^{\mathcal{A}}_{\Sigma}. \quad \text{(by H2)}\end{array}$$

Hence, $\top^{\mathcal{A}}_{\Sigma} \in T^{\langle\Sigma,\phi\rangle}_{\Sigma}$. Moreover, if $\psi, \psi \to^{\mathcal{A}}_{\Sigma} \chi \in T^{\langle\Sigma,\phi\rangle}_{\Sigma}$, then, we get, by definition, $\phi \to^{\mathcal{A}}_{\Sigma} \psi = \top^{\mathcal{A}}_{\Sigma}$ and $\phi \to^{\mathcal{A}}_{\Sigma} (\psi \to^{\mathcal{A}}_{\Sigma} \chi) \in \top^{\mathcal{A}}_{\Sigma}$. Therefore, we get

$$\begin{array}{rcl}\phi \to^{\mathcal{A}}_{\Sigma} \chi & = & \top^{\mathcal{A}}_{\Sigma} \to^{\mathcal{A}}_{\Sigma} (\phi \to^{\mathcal{A}}_{\Sigma} \chi) \quad \text{(by H2)}\\ & = & (\phi \to^{\mathcal{A}}_{\Sigma} \psi) \to^{\mathcal{A}}_{\Sigma} (\phi \to^{\mathcal{A}}_{\Sigma} \chi) \quad \text{(hypothesis)}\\ & = & \phi \to^{\mathcal{A}}_{\Sigma} (\psi \to^{\mathcal{A}}_{\Sigma} \chi) \quad \text{(by H3)}\\ & = & \top^{\mathcal{A}}_{\Sigma}, \quad \text{(hypothesis)}\end{array}$$

We conclude that $\chi \in T^{\langle\Sigma,\phi\rangle}_{\Sigma}$. Thus, $T^{\langle\Sigma,\phi\rangle} \in \mathrm{FiFam}^{\to}(\mathcal{A})$. ∎

We can now prove that the Frege equivalence system of every full $\mathcal{I}$-structure of the form $\langle\mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$, with $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, is the identity congruence system. This shows, in particular that every **F**-algebraic system in $\mathsf{K}^{\mathcal{I}}$ is an $\mathcal{I}$-algebraic system and, moreover, satisfies the Congruence Property.

Lemma 1728 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a Hilbert based* π*-institution based on* $\mathbf{F}$*. For every* $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$*,* $\widetilde{\lambda}^{\mathcal{I}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$*. Thus,* $\langle\mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ *is reduced and satisfies the Congruence Property.*

Proof: Let $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \notin \Delta^{\mathcal{A}}_{\Sigma}$. Thus, $\phi \neq \psi$. Taking into account Lemma 1727, consider $T^{\langle\Sigma,\phi\rangle}, T^{\langle\Sigma,\psi\rangle} \in \mathrm{FiFam}^{\to}(\mathcal{A})$. By Lemma 1726, $T^{\langle\Sigma,\phi\rangle}, T^{\langle\Sigma,\psi\rangle} \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, by definition, $\phi \in T^{\langle\Sigma,\phi\rangle}_{\Sigma}$ and $\psi \in T^{\langle\Sigma,\psi\rangle}_{\Sigma}$. On the other hand, if it was the case that $\psi \in T^{\langle\Sigma,\phi\rangle}_{\Sigma}$ and $\phi \in T^{\langle\Sigma,\psi\rangle}_{\Sigma}$, then, by definition, $\phi \to^{\mathcal{A}}_{\Sigma} \psi = \psi \to^{\mathcal{A}}_{\Sigma} \phi = \top^{\mathcal{A}}_{\Sigma}$, whence, by Lemma 1713, $\phi = \psi$, contrary to hypothesis. Thus, it must be the case that $\psi \notin T^{\langle\Sigma,\phi\rangle}_{\Sigma}$ or $\phi \notin T^{\langle\Sigma,\psi\rangle}_{\Sigma}$. We can now conclude that $\langle\phi,\psi\rangle \notin \widetilde{\lambda}^{\mathcal{A}}_{\Sigma}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$. This shows that $\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$. Since $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \leq \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$, we get that $\langle\mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced $\mathcal{I}$-structure and that it satisfies the Congruence Property. ∎

Lemma 1728 allows us to conclude that, for Hilbert based π-institutions $\mathcal{I}$, the semantic variety of $\mathcal{I}$ coincides with the class of all $\mathcal{I}$-algebraic systems.

Theorem 1729 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a Hilbert based* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathrm{AlgSys}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}} = \mathbb{V}^{\mathsf{Sem}}(\mathcal{I})$*;*

(b) AlgSys($\mathcal{I}$) *is a semantic variety;*

(c) $\mathcal{I}$ *is Hilbert based with respect to* AlgSys($\mathcal{I}$).

Proof: By Proposition 65, we have $\mathrm{AlgSys}(\mathcal{I}) \subseteq \mathsf{K}^{\mathcal{I}}$. On the other hand, Lemma 1728 gives $\mathsf{K}^{\mathcal{I}} \subseteq \mathrm{AlgSys}(\mathcal{I})$. Therefore, $\mathrm{AlgSys}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$. Since $\mathsf{K}^{\mathcal{I}}$ is a semantic variety, we conclude that AlgSys($\mathcal{I}$) is also a semantic variety. Finally, since, by Proposition 1719, $\mathcal{I}$ is Hilbert based with respect to $\mathsf{K}^{\mathcal{I}}$, we conclude that $\mathcal{I}$ is Hilbert based with respect to AlgSys($\mathcal{I}$). ∎

In one of the main theorems of the section, we show that a finitary self extensional π-institution with the Uniterm Deduction Detachment Property is necessarily fully self extensional.

Theorem 1730 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary self extensional π-institution with the Uniterm Deduction Detachment Property. Then $\mathcal{I}$ is fully self extensional.*

Proof: Suppose that $\mathcal{I}$ is finitary self extensional and that it has the Uniterm Deduction Detachment Property with respect to $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. By Theorem 1722 and Proposition 1719, $\mathcal{I}$ is Hilbert based with respect to $\mathsf{K}^{\mathcal{I}}$ and $\to^\flat$. By Theorem 1729, $\mathsf{K}^{\mathcal{I}} = \mathrm{AlgSys}(\mathcal{I})$, whence, by Lemma 1728, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$,

$$\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}.$$

Now to prove full self extensionality, we use Proposition 1428. To this end, assume $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a full $\mathcal{I}$-structure. Then $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \in \mathrm{AlgSys}(\mathcal{I})$ and, by definition,

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})).$$

Thus, by what was shown above,

$$\widetilde{\lambda}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))}.$$

By Proposition 1426, we infer that $\langle \mathcal{A}.\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ also has the Congruence Property. We now conclude, by Proposition 1428, that $\mathcal{I}$ is fully self extensional. ∎

We finish the section by looking at some connections with the theory of Gentzen π-institutions, that is presented in another chapter.

Recall that, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a finitary π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$, a finitary Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ is said to be **adequate for** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \Phi \vdash_\Sigma \phi \in G_\Sigma(\varnothing).$$

We say that the Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ has the **Congruence Property** if, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma^\flat_\Sigma(\vec{\phi}) \vdash \sigma^\flat_\Sigma(\vec{\psi}) \in G_\Sigma(\{\phi_i \vdash_\Sigma \psi_i,\ \psi_i \vdash_\Sigma \phi_i : i \in I\}).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a finitary Gentzen π-institution based on $\mathbf{F}$. We say that:

- $\mathfrak{G}$ has the **Deduction Rule with respect to** $\to^\flat$, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi, \psi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\Phi \vdash_\Sigma \phi \to^\flat_\Sigma \psi \in G_\Sigma(\Phi, \phi \vdash_\Sigma \psi);$$

- $\mathfrak{G}$ has the **Detachment Rule with respect to** $\to^\flat$, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi, \psi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

$$\Phi, \phi \vdash_\Sigma \psi \in G_\Sigma(\Phi \vdash_\Sigma \phi \to^\flat_\Sigma \psi);$$

- $\mathfrak{G}$ has the **Deduction Detachment Rule with respect to** $\to^\flat$, if it has both the Deduction and the Detachment Property with respect to $\to^\flat$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary self extensional π-institution, having the Deduction Detachment Property with respect to $\to^\flat$.

- Define $\mathrm{Ax}^{\mathcal{I}} = \{\mathrm{Ax}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Ax}^{\mathcal{I}}_\Sigma = \{\Phi \vdash_\Sigma \phi : \phi \in C_\Sigma(\Phi)\};$$

- Define $\mathrm{Ir}^{\mathcal{I}} = \{\mathrm{Ir}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\begin{aligned}\mathrm{Ir}^{\mathcal{I}}_\Sigma \;=\; & \{\langle \{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i \in I\}, \sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \rangle : \\ & \qquad\qquad \sigma^\flat \in N^\flat, \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)\} \\ & \cup \{\langle \{\Phi, \phi \vdash_\Sigma \psi\}, \Phi \vdash_\Sigma \phi \to^\flat_\Sigma \psi \rangle : \Phi \cup \{\phi, \psi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)\} \\ & \cup \{\langle \{\Phi \vdash_\Sigma \phi \to^\flat_\Sigma \psi\}, \Phi, \phi \vdash_\Sigma \psi \rangle : \Phi \cup \{\phi, \psi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)\}.\end{aligned}$$

- $R^{\mathcal{I}} := \mathrm{Ax}^{\mathcal{I}} \cup \mathrm{Ir}^{\mathcal{I}}$.

Finally, define $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, C^{\mathcal{I}} \rangle := \mathfrak{G}^{R^{\mathcal{I}}}$ be the Gentzen π-institution generated by the system $R^{\mathcal{I}}$ of Gentzen rules. Recall, by Proposition 1482, that $G^{\mathcal{I}} = \Xi^{R^{\mathcal{I}}}$.

We are almost ready to establish the existence of a fully adequate Gentzen π-institution for any given Hilbert based π-institution. Recall, again, from work in a different chapter, that a Gentzen π-institution $\mathfrak{G}$ is **fully adequate**

for a π-institution $\mathcal{I}$ (with theorems) if, for every $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}$ is a full $\mathcal{I}$-structure if and only if it is a $\mathfrak{G}$-structure.

For Hilbert based π-institutions, it turns out that any $\mathcal{I}$-structure whose Frege equivalence system is the identity is of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, for some $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$.

Lemma 1731 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a Hilbert based π-institution based on $\mathbf{F}$. If $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathcal{I})$, such that $\widetilde{\lambda}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$, then $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$.*

Proof: Let $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathcal{I})$, such that $\widetilde{\lambda}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$. Then, we have

$$\widetilde{\Omega}^{\mathcal{A}}(D) \leq \widetilde{\lambda}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}},$$

i.e., $\widetilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$ and, therefore, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I}) \subseteq \mathsf{K}^{\mathcal{I}}$.

Suppose, next, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By Lemma 1726, $T \in \mathrm{FiFam}^{\rightarrow}(\mathcal{A})$, where $\rightarrow^\flat$ in $N^\flat$ is the binary transformation with respect to which $\mathcal{I}$ is Hilbert based. Let $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(T_\Sigma)$. By finitarity and Proposition 114, there exists $\Phi \subseteq_f T_\Sigma$, such that $\phi \in D_\Sigma(\Phi)$. Thus, by the hypothesis, Proposition 1719 and Corollary 1440, $\vec{\vec{\Phi}} \rightarrow^{\mathcal{A}}_\Sigma \phi \in D_\Sigma(\top^{\mathcal{A}}_\Sigma)$, i.e., $D_\Sigma(\vec{\vec{\Phi}} \rightarrow^{\mathcal{A}}_\Sigma \phi) = D_\Sigma(\top^{\mathcal{A}}_\Sigma)$. By hypothesis, $\vec{\vec{\Phi}} \rightarrow^{\mathcal{A}}_\Sigma \phi = \top^{\mathcal{A}}_\Sigma$. Since $T \in \mathrm{FiFam}^{\rightarrow}(\mathcal{A})$, we have $\vec{\vec{\Phi}} \rightarrow^{\mathcal{A}}_\Sigma \phi \in T_\Sigma$ and, since, also, $\Phi \subseteq T_\Sigma$, we infer that $\phi \in T_\Sigma$. Therefore, $T = D(T)$, showing that $T \in \mathcal{D}$ and, hence, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

We finally show that any Hilbert based π-institution $\mathcal{I}$ has a fully adequate Gentzen π-institution, namely, the π-institution $\mathfrak{G}^{\mathcal{I}}$, generated by the Gentzen rules $R^{\mathcal{I}}$, which encode the rules of $\mathcal{I}$, the Congruence Property and the Deduction Detachment Property.

Theorem 1732 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$, having the Uniterm Deduction Detachment Property. $\mathcal{I}$ is self extensional if and only if the Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$ if fully adequate for $\mathcal{I}$.*

Proof: Suppose that $\mathfrak{G}^{\mathcal{I}}$ is fully adequate for $\mathcal{I}$. We know that $\langle \mathcal{F}, C \rangle$ is a full $\mathcal{I}$-structure. Thus, by full adequacy, $\langle \mathcal{F}, C \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$. Therefore, $\langle \mathcal{F}, C \rangle$ satisfies all the Gentzen rules that hold in $\mathfrak{G}^{\mathcal{I}}$. In particular, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \subseteq \mathrm{SEN}^\flat(\Sigma)$, $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$, for all $i \in I$, imply $C_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(\sigma^\flat_\Sigma(\vec{\psi}))$. Thus, $\widetilde{\lambda}(\mathcal{I})$ is a congruence system and, hence $\mathcal{I}$ is self extensional.

Suppose, conversely, that $\mathcal{I}$ is self extensional. By Theorem 1730, it is fully self extensional. Let $\langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. Then, by Theorem 1444 and the definition of $\mathfrak{G}^{\mathcal{I}}$, we get that $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$. Assume, conversely, that $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$. By considering, if necessary, $\langle \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(D), \mathcal{D}/\widetilde{\Omega}^{\mathcal{A}}(D) \rangle$, we may assume that $\widetilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$ and must show that $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. By the definition of $\mathfrak{G}^{\mathcal{I}}$, we get $\langle\mathcal{A}, D\rangle \in \mathrm{Str}(\mathcal{I})$. For the same reason, $\langle\mathcal{A}, D\rangle$ satisfies the Congruence Property. Therefore, $\widetilde{\lambda}^{\mathcal{A}}(D) = \widetilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$. Since, by hypothesis, it has the Deduction Detachment Property, we get, by Theorem 1722, that it is Hilbert based. Now, applying Lemma 1731, we conclude that $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\langle\mathcal{A}, \mathcal{D}\rangle \in \mathrm{FStr}(\mathcal{I})$.

This shows that $\mathrm{FStr}(\mathcal{I}) = \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$ and, hence, $\mathfrak{G}^{\mathcal{I}}$ is, indeed, fully adequate for $\mathcal{I}$. ∎

23.3 Self Extensionality and Conjunction

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ has the **Conjunction Property with respect to** $\wedge^\flat$ and that $\wedge^\flat$ is a **conjunction for** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

- $\phi \wedge^\flat_\Sigma \psi \in C_\Sigma(\phi, \psi)$;
- $\phi, \psi \in C_\Sigma(\phi \wedge^\flat_\Sigma \psi)$.

Equivalently, $\wedge^\flat$ is a conjunction for $\mathcal{I}$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C_\Sigma(\phi \wedge^\flat_\Sigma \psi) = C_\Sigma(\phi, \psi).$$

We say $\mathcal{I}$ is **conjunctive** if it has the Conjunction Property with respect to some $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

If a π-institution has the Conjunction Property with respect to two different binary natural transformations in $N^\flat$, then the two concjunctions must be interderivable in an obvious sense.

Lemma 1733 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat, \wedge'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Conjunction Property with respect to both $\wedge^\flat$ and $\wedge'^\flat$, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$C_\Sigma(\phi \wedge^\flat_\Sigma \psi) = C_\Sigma(\phi \wedge'^\flat_\Sigma \psi).$$

Proof: Suppose that $\wedge^\flat$ and $\wedge'^\flat$ are both conjunctions for $\mathcal{I}$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\psi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rcll} C_\Sigma(\phi \wedge^\flat_\Sigma \psi) & = & C_\Sigma(\phi, \psi) & (\wedge^\flat \text{ a conjunction}) \\ & = & C_\Sigma(\phi \wedge'^\flat_\Sigma \psi). & (\wedge'^\flat \text{ a conjunction}) \end{array}$$

This proves the statement. ∎

Corollary 1734 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat, \wedge'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is self extensional and has the Conjunction Property with respect to both* $\wedge^\flat$ *and* $\wedge'^\flat$*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi \wedge^\flat_\Sigma \psi, \phi \wedge'^\flat_\Sigma \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}).$$

Proof: Suppose that $\mathcal{I}$ is self extensional and $\wedge^\flat$ and $\wedge'^\flat$ are both conjunctions for $\mathcal{I}$. Then, if $\Sigma \in |\mathbf{Sign}^\flat|$, $\psi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, by Lemma 1733, $\langle \phi \wedge^\flat_\Sigma \psi, \phi \wedge'^\flat_\Sigma \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$, whence, by self extensionality, $\langle \phi \wedge^\flat_\Sigma \psi, \phi \wedge'^\flat_\Sigma \psi \rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I})$. ∎

We also know, by Proposition 1434 that the Conjunction Property transfers from a π-institution $\mathcal{I}$ to all $\mathcal{I}$-structures.

Corollary 1735 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, having the Conjunction Property with respect to* $\wedge^\flat$*. For every* $\mathcal{I}$*-structure* $\langle \mathcal{A}, D \rangle$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$D_\Sigma(\phi \wedge^{\mathcal{A}}_\Sigma \psi) = D_\Sigma(\phi, \psi).$$

Proof: This is simply a restatement of Proposition 1434. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a class of $\mathbf{F}$-algebraic systems. K is **semilattice based with respect to** $\wedge^\flat$ if, for all $\mathcal{A} \in \mathsf{K}$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$,

- L1. $\phi \wedge^{\mathcal{A}}_\Sigma \phi = \phi$;
- L2. $\phi \wedge^{\mathcal{A}}_\Sigma \psi = \psi \wedge^{\mathcal{A}}_\Sigma \phi$;
- L3. $(\phi \wedge^{\mathcal{A}}_\Sigma \psi) \wedge^{\mathcal{A}}_\Sigma \chi = \phi \wedge^{\mathcal{A}}_\Sigma (\psi \wedge^{\mathcal{A}}_\Sigma \chi)$.

L1-L3 are referred to as the **semilattice equations**. We say that K is **semilattice based** if it is semilattice based with respect to some $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

If a class of $\mathbf{F}$-algebraic systems is semilattices based, then the semantic variety generated by the class is also semilattice based with respect to the same binary natural transformation.

Lemma 1736 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a class of* $\mathbf{F}$*-algebraic systems. If* K *is semilattice based with respect to* $\wedge^\flat$*, then* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ *is also semilattice based with respect to* $\wedge^\flat$*.*

Proof: Let $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. We show $\mathcal{A}$ satisfies L2. The work for L1 and L3 follows along the same lines. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Since K is semilattice based with respect to $\wedge^\flat$, $\langle \phi \wedge^\flat_\Sigma \psi, \psi \wedge^\flat_\Sigma \phi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Since, by hypothesis, $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, we get $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$, whence $\langle \phi \wedge^\flat_\Sigma \psi, \psi \wedge^\flat_\Sigma \phi \rangle \in \mathrm{Ker}_\Sigma(\mathcal{A})$. This shows that $\alpha_\Sigma(\phi \wedge^\flat_\Sigma \psi) = \alpha_\Sigma(\psi \wedge^\flat_\Sigma \phi)$, i.e., $\alpha_\Sigma(\phi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi) = \alpha_\Sigma(\psi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$. Thus, by the surjectivity of $\langle F, \alpha \rangle$, we conclude that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\phi \wedge^{\mathcal{A}}_\Sigma \psi = \psi \wedge^{\mathcal{A}}_\Sigma \phi$. Therefore, $\mathcal{A}$ satisfies L2. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$. For every $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, define the relation family $\leq^{\mathcal{A}} = \{\leq^{\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ on $\mathcal{A}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \leq^{\mathcal{A}}_\Sigma \psi \quad \text{iff} \quad \phi \wedge^{\mathcal{A}}_\Sigma \psi = \phi.$$

It is easily shown that $\leq^{\mathcal{A}}$ is a partial order system on $\mathcal{A}$.

Lemma 1737 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a semilattice based class with respect to $\wedge^\flat$. For all $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\leq^{\mathcal{A}}$ is a posystem on $\mathcal{A}$.*

Proof: First, fix $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\Sigma \in |\mathbf{Sign}|$. We show that $\leq^{\mathcal{A}}_\Sigma$ is a partial order on $\mathrm{SEN}(\Sigma)$. To this end, let $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$.

- By L1, $\phi = \phi \wedge^{\mathcal{A}}_\Sigma \phi$, whence, by definition, $\phi \leq^{\mathcal{A}}_\Sigma \phi$ and $\leq^{\mathcal{A}}_\Sigma$ is reflexive;
- If $\phi \leq^{\mathcal{A}}_\Sigma \psi$ and $\psi \leq^{\mathcal{A}}_\Sigma \phi$, then, we get

$$\begin{array}{lll} \phi & = & \phi \wedge^{\mathcal{A}}_\Sigma \psi \quad (\phi \leq^{\mathcal{A}}_\Sigma \psi) \\ & = & \psi \wedge^{\mathcal{A}}_\Sigma \phi \quad (\text{by L2}) \\ & = & \psi. \quad (\psi \leq^{\mathcal{A}}_\Sigma \phi) \end{array}$$

  Thus, $\leq^{\mathcal{A}}_\Sigma$ is antisymmetric.
- If $\phi \leq^{\mathcal{A}}_\Sigma \psi$ and $\psi \leq^{\mathcal{A}}_\Sigma \chi$, then

$$\begin{array}{lll} \phi & = & \phi \wedge^{\mathcal{A}}_\Sigma \psi \quad (\phi \leq^{\mathcal{A}}_\Sigma \psi) \\ & = & \phi \wedge^{\mathcal{A}}_\Sigma (\psi \wedge^{\mathcal{A}}_\Sigma \chi) \quad (\psi \leq^{\mathcal{A}}_\Sigma \chi) \\ & = & (\phi \wedge^{\mathcal{A}}_\Sigma \psi) \wedge^{\mathcal{A}}_\Sigma \chi \quad (\text{by L3}) \\ & = & \phi \wedge^{\mathcal{A}}_\Sigma \chi. \quad (\phi \leq^{\mathcal{A}}_\Sigma \psi) \end{array}$$

  Hence $\phi \leq^{\mathcal{A}}_\Sigma \chi$ and $\leq^{\mathcal{A}}_\Sigma$ is also transitive.

Thus, $\leq^{\mathcal{A}}$ is a partial order on $\mathrm{SEN}(\Sigma)$. Suppose, now, that $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \leq^{\mathcal{A}}_\Sigma \psi$. Then, by definition, $\phi = \phi \wedge^{\mathcal{A}}_\Sigma \psi$. Thus, $\mathrm{SEN}^\flat(f)(\phi) = \mathrm{SEN}^\flat(f)(\phi \wedge^{\mathcal{A}}_\Sigma \psi) = \mathrm{SEN}^\flat(f)(\phi) \wedge^{\mathcal{A}}_{\Sigma'} \mathrm{SEN}^\flat(f)(\psi)$.

This shows that $\mathrm{SEN}^\flat(f)(\phi) \leq^{\mathcal{A}}_{\Sigma'} \mathrm{SEN}^\flat(f)(\psi)$. Thus, $\leq^{\mathcal{A}}$ is a partial order system on $\mathcal{A}$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$, $\mathcal{A} \in \mathsf{K}$ and $T \in \mathrm{SenFam}(\mathcal{A})$. We say that T is a **semilattice filter family of** $\mathcal{A}$ if the following conditions hold, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$:

- $T_\Sigma \neq \varnothing$;
- $\phi, \psi \in T_\Sigma$ implies $\phi \wedge^{\mathcal{A}}_\Sigma \psi \in T_\Sigma$;
- $\phi \in T_\Sigma$ and $\phi \leq^{\mathcal{A}}_\Sigma \psi$ imply $\psi \in T_\Sigma$.

We denote by $\mathrm{FiFam}^\wedge(\mathcal{A})$ the collection of all semilattice filter families on $\mathcal{A}$. Moreover, we write $\mathrm{FiFam}^{\wedge,\varnothing}(\mathcal{A})$ for the same collection augmented by those sentence families resulting from semilattice filter families after one or more components are replaced by the empty set.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$, $\mathcal{A} \in \mathsf{K}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Define

$$T^{\langle \Sigma, \phi \rangle} = \{T^{\langle \Sigma, \phi \rangle}_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}|}$$

by setting,

- $T^{\langle \Sigma, \phi \rangle}_\Sigma = \{\chi \in \mathrm{SEN}(\Sigma) : \phi \leq^{\mathcal{A}}_\Sigma \chi\}$;
- $T^{\langle \Sigma, \phi \rangle}_{\Sigma'} = \begin{cases} \{\chi \in \mathrm{SEN}(\Sigma) : 1_\Sigma \leq^{\mathcal{A}}_\Sigma \chi\}, & \text{if } 1_\Sigma \text{ is a maximum in } \leq^{\mathcal{A}}_\Sigma \\ \varnothing, & \text{if } \leq^{\mathcal{A}}_\Sigma \text{ has no maximum} \end{cases}$, for all $\Sigma \neq \Sigma' \in |\mathbf{Sign}|$,

We show that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^\wedge(\mathcal{A})$ or $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^{\wedge,\varnothing}(\mathcal{A})$.

Lemma 1738 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$, $\mathcal{A} \in \mathsf{K}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then, $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^\wedge(\mathcal{A})$ or $T^{\langle \Sigma, \phi \rangle} \in \mathrm{FiFam}^{\wedge,\varnothing}(\mathcal{A})$.*

Proof: It suffices to show that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, the collection $\{\chi \in \mathrm{SEN}(\Sigma) : \phi \leq^{\mathcal{A}}_\Sigma \chi\}$ is an upset under $\leq^{\mathcal{A}}_\Sigma$, closed under $\wedge^{\mathcal{A}}_\Sigma$. Let $\psi, \chi \in \mathrm{SEN}(\Sigma)$.

- If $\psi, \chi \in T^{\langle \Sigma, \phi \rangle}_\Sigma$, then, by definition, $\phi \leq^{\mathcal{A}}_\Sigma \psi$ and $\phi \leq^{\mathcal{A}}_\Sigma \chi$. Thus, we get

$$\begin{array}{rcll} \phi & = & \phi \wedge^{\mathcal{A}}_\Sigma \chi & (\phi \leq^{\mathcal{A}}_\Sigma \chi) \\ & = & (\phi \wedge^{\mathcal{A}}_\Sigma \psi) \wedge^{\mathcal{A}}_\Sigma \chi & (\phi \leq^{\mathcal{A}}_\Sigma \psi) \\ & = & \phi \wedge^{\mathcal{A}}_\Sigma (\psi \wedge^{\mathcal{A}}_\Sigma \chi). & (\text{by L3}) \end{array}$$

Therefore, $\phi \leq^{\mathcal{A}}_\Sigma \psi \wedge^{\mathcal{A}}_\Sigma \chi$ and, hence $\psi \wedge^{\mathcal{A}}_\Sigma \chi \in T^{\langle \Sigma, \phi \rangle}_\Sigma$.

- If $\psi \in T_\Sigma^{\langle\Sigma,\phi\rangle}$ and $\psi \leq_\Sigma^{\mathcal{A}} \chi$, then $\phi \leq_\Sigma^{\mathcal{A}} \psi$ and $\psi \leq_\Sigma^{\mathcal{A}} \chi$, whence, by Lemma 1737, $\phi \leq_\Sigma^{\mathcal{A}} \chi$, i.e., $\chi \in T_\Sigma^{\langle\Sigma,\phi\rangle}$.

Thus, $T^{\langle\Sigma,\phi\rangle} \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$ or $T^{\langle\Sigma,\phi\rangle} \in \mathrm{FiFam}^{\wedge,\varnothing}(\mathcal{A})$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a *finitary* π-institution based on $\mathbf{F}$. We say $\mathcal{I}$ is **semilattice based with respect to** K and $\wedge^\flat$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, with $\Phi \neq \varnothing$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \text{for all } \mathcal{A} \in \mathsf{K},\ \textstyle\bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi).$$

We say that $\mathcal{I}$ is **semilattice based** if it is semilattice based with respect to K and $\wedge^\flat$, for some semilattice based class K with respect to some $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

We get immediately from the definition that interderivability in $\mathcal{I}$ is reflected into equality in all algebraic systems in the defining class K.

Lemma 1739 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a semilattice based π-institution with respect to K and $\wedge^\flat$. For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$C_\Sigma(\phi) = C_\Sigma(\psi) \quad \textit{iff} \quad \textit{for all } \mathcal{A} \in \mathsf{K},\ \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).$$

Proof: By the definition, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $C_\Sigma(\phi) = C_\Sigma(\psi)$ iff, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi)$ and $\alpha_\Sigma(\psi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$ iff, by Lemma 1737, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. ∎

Moreover, in case $\mathcal{I}$ is semilattice based with respect to a class K, then it is also semilattice based with respect to the semantic variety generated by K, with respect to the same binary transformation.

Lemma 1740 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, K a semilattice based class of $\mathbf{F}$-algebraic systems with respect to $\wedge^\flat$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a semilattice based π-institution with respect to K and $\wedge^\flat$. Then $\mathcal{I}$ is semilattice based with respect to $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ and $\wedge^\flat$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Since $\mathcal{I}$ is semilattice based with respect to K and $\wedge^\flat$, $\langle \bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi, \bigwedge^\flat_\Sigma \Phi\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Since $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, we get $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$. This gives $\bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi) = \bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi)$, and, therefore, $\bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$.

Conversely, if, for all $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, $\bigvee^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$, then, a fortiori, for all $\mathcal{A} \in \mathsf{K}$, we have $\bigvee^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$. Therefore, by hypothesis, $\phi \in C_\Sigma(\Phi)$. We conclude that $\mathcal{I}$ is semilattice based with respect to $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ and $\wedge^\flat$. ■

We can now show that, if a π-institution is semilattice based with respect to two different classes of semilattice based $\mathbf{F}$-algebraic systems, then, they both have to generate the same semantic variety.

Lemma 1741 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat, \wedge'^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*,* K *a semilattice based class with respect to* $\wedge^\flat$ *and* K' *a semilattice based class with respect to* $\wedge'^\flat$*. If* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *is a semilattice based* π*-institution both with respect to* K *and* $\wedge^\flat$ *and with respect to* K' *and* $\wedge'^\flat$*, then* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}')$*.*

Proof: Suppose $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a semilattice based π-institution both with respect to K and $\wedge^\flat$ and with respect to K' and $\wedge'^\flat$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$ and $\mathcal{A} \in \mathsf{K}'$. Then, since $\mathcal{I}$ is semilattice based with respect to K, by Lemma 1739, $C_\Sigma(\phi) = C_\Sigma(\psi)$. Thus, since $\mathcal{I}$ is semilattice based with respect to K', again, by Lemma 1739, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Hence, $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$, which gives that $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. We conclude that $\mathsf{K}' \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ and, by symmetry, $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}')$. ■

Thus, if $\mathcal{I}$ is semilattice based with respect to some K and $\wedge^\flat$, it makes sense, based on Lemma 1741 and Lemma 1740, to denote by $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})$ the unique semantic variety of $\mathbf{F}$-algebraic systems with respect to which it is semilattice based.

In one of the cornerstone results of the section, we show that, if a π-institution is semilattice based, then it is self extensional and has the Conjunction Property, and, in addition, its semantic variety coincides with the semantic variety $\mathsf{K}^{\mathcal{I}}$ generated by the Lindenbaum-Tarski algebraic system of $\mathcal{I}$.

Proposition 1742 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\wedge^\flat$ *in* $N^\flat$*,* K *a semilattice based class with respect to* $\wedge^\flat$*,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a semilattice based* π*-institution with respect to* K *and* $\wedge^\flat$*.*

(a) $\mathcal{I}$ *is self extensional;*

(b) $\mathcal{I}$ *has the Conjunction Property with respect to* $\wedge^\flat$*;*

(c) $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$*; Hence* $\mathcal{I}$ *is semilattice based with respect to* $\mathsf{K}^{\mathcal{I}}$*.*

Proof:

(a) For self extensionality, it suffices to show that the Frege equivalence system $\widetilde{\lambda}(\mathcal{I})$ is a congruence system. To this end, let $\sigma^\flat$ be in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi_i, \psi_i \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$, for all $i < k$. By definition, we get $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$, for all $i < k$. Hence, since

$\mathcal{I}$ is semilattice based with respect to K and $\wedge^\flat$, $\langle\phi_i,\psi_i\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$, for all $i < k$. But $\mathrm{Ker}(\mathsf{K})$ is a congruence system on $\mathbf{F}$, whence, $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. By Lemma 1739, $C_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(\sigma^\flat_\Sigma(\vec{\psi}))$, whence $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})$. Therefore, $\widetilde{\lambda}(\mathcal{I})$ is a congruence system on $\mathbf{F}$ and $\mathcal{I}$ is self extensional.

(b) Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $\mathcal{A} \in \mathsf{K}$,

$$\alpha_\Sigma(\phi \wedge^\flat_\Sigma \psi) = \alpha_\Sigma(\phi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi),\alpha_\Sigma(\psi).$$

Thus, since $\mathcal{I}$ is semilattice based with respect to K and $\wedge^\flat$, we get that $\phi \wedge^\flat_\Sigma \psi \in C_\Sigma(\phi,\psi)$ and $\phi,\psi \in C_\Sigma(\phi \wedge^\flat_\Sigma \psi)$. Hence, $\wedge^\flat$ is a conjunction for $\mathcal{I}$.

(c) We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})) & \text{iff} & \langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})) \\ & & \text{(definition of } \mathbb{V}^{\mathsf{Sem}}(\mathcal{I})) \\ & \text{iff} & \langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K}) \\ & & \text{(definition of } \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})) \\ & \text{iff} & C_\Sigma(\phi) = C_\Sigma(\psi) \\ & & \text{(Lemma 1739)} \\ & \text{iff} & \langle\phi,\psi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) \\ & & \text{(definition of } \widetilde{\lambda}(\mathcal{I})) \\ & \text{iff} & \langle\phi,\psi\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}) \\ & & \text{(Part (a))} \\ & \text{iff} & \langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathsf{K}^{\mathcal{I}}). \\ & & \text{(definition of } \mathsf{K}^{\mathcal{I}})\end{array}$$

Therefore, since both classes are semantic varieties, we conclude that $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$.

■

If $\mathcal{I}$ is a finitary self extensional π-institution $\mathcal{I}$, having the Conjunction Property with respect to $\wedge^\flat$, then the singleton class $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$, consisting of its Lindenbaum-Tarski $\mathbf{F}$-algebraic system $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$, is semilattice based with respect to $\wedge^\flat$.

Lemma 1743 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a finitary self extensional π-institution, having the Conjunction Property with respect to $\wedge^\flat$. Then the class $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$ is semilattice based with respect to $\wedge^\flat$.*

Proof: We have to verify that the class K satisfies the semilattice identities. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi,\chi \in \mathrm{SEN}^\flat(\Sigma)$.

- By the Conjunction Property, $C_\Sigma(\phi \wedge^\flat_\Sigma \phi) = C_\Sigma(\phi)$. Thus, using self extensionality, $\langle\phi \wedge^\flat_\Sigma \phi,\phi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) = \widetilde{\Omega}_\Sigma(\mathcal{I})$. Hence K satisfies L1.

- By the Conjunction Property, $C_\Sigma(\phi \wedge^\flat_\Sigma \psi) = C_\Sigma(\phi,\psi) = C_\Sigma(\psi \wedge^\flat_\Sigma \phi)$. Thus, again using self extensionality, $\langle \phi \wedge^\flat_\Sigma \psi, \psi \wedge^\flat_\Sigma \phi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) = \widetilde{\Omega}_\Sigma(\mathcal{I})$. Hence K satisfies L2.

- Finally, we have
$$\begin{array}{rcl} C_\Sigma((\phi \wedge^\flat_\Sigma \psi) \wedge^\flat_\Sigma \chi) & = & C_\Sigma(\phi \wedge^\flat_\Sigma \psi, \chi) \\ & = & C_\Sigma(\phi,\psi,\chi) \\ & = & C_\Sigma(\phi, \psi \wedge^\flat_\Sigma \chi) \\ & = & C_\Sigma(\phi \wedge^\flat_\Sigma (\psi \wedge^\flat_\Sigma \chi)). \end{array}$$
Thus, again using self extensionality,
$$\langle (\phi \wedge^\flat_\Sigma \psi) \wedge^\flat_\Sigma \chi, \phi \wedge^\flat_\Sigma (\psi \wedge^\flat_\Sigma \chi)\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) = \widetilde{\Omega}_\Sigma(\mathcal{I})$$
and K also satisfies L3.

Thus, K is semilattice based with respect to $\wedge^\flat$. ■

In one of our main theorems, we characterize semilattice based π-institutions as those that are self extensional and conjunctive.

Theorem 1744 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a finitary* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is semilattice based if and only if it is self extensional and conjunctive.*

Proof: The left-to-right implication is by Proposition 1742. Suppose, conversely, that $\mathcal{I}$ is self extensional and conjunctive, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$ a conjunction for $\mathcal{I}$. By Lemma 1743, $\mathsf{K} = \{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})\}$ is semilattice based with respect to $\wedge^\flat$. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,
$$\begin{array}{rll} \phi \in C_\Sigma(\Phi) & \text{iff} & \phi \in C_\Sigma(\bigwedge^\flat_\Sigma \Phi) \quad \text{(Conjunction Property)} \\ & \text{iff} & C_\Sigma(\bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi) = C_\Sigma(\bigwedge^\flat_\Sigma \Phi) \quad \text{(Conjunction Property)} \\ & \text{iff} & \langle \bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi, \bigwedge^\flat_\Sigma \Phi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) \quad \text{(definition of } \widetilde{\lambda}(\mathcal{I})) \\ & \text{iff} & \langle \bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi, \bigwedge^\flat_\Sigma \Phi\rangle \in \widetilde{\Omega}_\Sigma(\mathcal{I}) \quad \text{(self extensionality)} \\ & \text{iff} & \bigwedge_\Sigma^{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})} \Phi/\widetilde{\Omega}_\Sigma(\mathcal{I}) \leq_\Sigma^{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})} \phi/\widetilde{\Omega}_\Sigma(\mathcal{I}). \quad \text{(def. of } \leq^{\mathcal{F}/\widetilde{\Omega}(\mathcal{I})}) \end{array}$$
Therefore, $\mathcal{I}$ is indeed semilattice based with respect to K and $\wedge^\flat$. ■

In some contexts it is desirable to have a specification of the theorems of a π-institution under discussion. However, the hypothesis that $\mathcal{I}$ is semilattice based by itself does not provide information about the theorems of $\mathcal{I}$, since it only specifies, based on properties of the defining class K, entailments with non empty sets of hypotheses. We discuss the *property of being non psudo-axiomatic*, which serves to streamline this ambiguity concerning theorems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **non pseudo-axiomatic** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Thm}_\Sigma(\mathcal{I}) = \bigcap\{C_\Sigma(\phi) : \phi \in \mathrm{SEN}^\flat(\Sigma)\}.$$

The property may be equivalently expressed by the condition

$$\mathrm{Thm}(\mathcal{I}) = \bigcap\{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma \neq \varnothing)\}.$$

Non pseudo-axiomatic semilattice based π-institutions form a generalization of π-institutions with theorems.

Lemma 1745 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a semilattice based π-institution with theorems, based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is non pseudo-axiomatic;

(b) For all $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha_\Sigma(\phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(t).$$

Proof:

(a) Let $\Sigma \in |\mathbf{Sign}^\flat|$. On the one hand, $\mathrm{Thm}_\Sigma(\mathcal{I}) \subseteq \bigcap\{C_\Sigma(\phi) : \phi \in \mathrm{SEN}^\flat(\Sigma)\}$. On the other, $\bigcap\{C_\Sigma(\phi) : \phi \in \mathrm{SEN}^\flat(\Sigma)\} \subseteq \bigcap\{C_\Sigma(\phi) : \phi \in \mathrm{Thm}_\Sigma(\mathcal{I})\} = \mathrm{Thm}_\Sigma(\mathcal{I})$. Hence, $\mathcal{I}$ is non pseudo-axiomatic.

(b) Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $t \in C_\Sigma(\phi)$. Since, by Proposition 1742, $\mathcal{I}$ is semilattice based with respect to $\mathsf{K}^{\mathcal{I}}$, we get that, for all $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, $\alpha_\Sigma(\phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(t)$. ■

By Lemma 1739, for all $\Sigma \in |\mathbf{Sign}^\flat|$, and all $t, t' \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$, for all $\mathcal{A} \in \mathsf{K}$. Furthermore, the common value of all theorems in $\mathrm{SEN}(\Sigma)$ is, by Lemma 1745, a maximum element under $\leq^{\mathcal{A}}_\Sigma$. This element will be denoted by $1^{\mathcal{A}}_\Sigma$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a semilattice based semantic variety with respect to $\wedge^\flat$. We assume that K is **conditionally max natural**, i.e., for all $\mathcal{A} \in \mathsf{K}$, either for no $\Sigma \in |\mathbf{Sign}|$ is there a maximum under $\leq^{\mathcal{A}}_\Sigma$ or, for every $\Sigma \in |\mathbf{Sign}|$, there exists a maximum $1^{\mathcal{A}}_\Sigma$ under $\leq^{\mathcal{A}}_\Sigma$, and moreover, $1^{\mathcal{A}} = \{1^{\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ is natural, i.e., it satisfies, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(1^{\mathcal{A}}_\Sigma) = 1^{\mathcal{A}}_{\Sigma'}.$$

Define a finitary closure system

$$C^{\mathsf{K},\wedge} : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$$

on $\mathbf{F}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$,

- $\phi \in C^{\mathsf{K},\wedge}_\Sigma(\varnothing)$ if and only if, for all $\mathcal{A} \in \mathsf{K}$ and all $\chi \in \mathrm{SEN}(F(\Sigma))$, $\chi \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$;
- $\phi \in C^{\mathsf{K},\wedge}_\Sigma(\Phi)$ if and only if, for all $\mathcal{A} \in \mathsf{K}$, $\bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$.

We note that conditional max naturality is essential in guaranteeing the structurality of $C^{\mathsf{K},\wedge}$.

Lemma 1746 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a conditionally max natural semilattice based semantic variety with respect to $\wedge^\flat$. Then $\mathcal{I}^{\mathsf{K},\wedge} = \langle \mathbf{F}, C^{\mathsf{K},\wedge}\rangle$ is a non pseudo-axiomatic π-institution.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \bigcap\{C_\Sigma(\psi) : \psi \in \mathrm{SEN}^\flat(\Sigma)\}$. Then, by definition, for all $\mathcal{A} \in \mathsf{K}$, $\alpha_\Sigma(\psi) \leq \alpha_\Sigma(\phi)$, for all $\psi \in \mathrm{SEN}^\flat(\Sigma)$. By the surjectivity of $\langle F, \alpha\rangle$, we get that $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}^{\mathsf{K},\wedge})$. Therefore, $\mathcal{I}^{\mathsf{K},\wedge}$ is non pseudo-axiomatic. ∎

The semantic variety of $\mathcal{I}^{\mathsf{K},\wedge}$ turns out to be the class K.

Proposition 1747 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a conditionally max natural semilattice based semantic variety with respect to $\wedge^\flat$. Then $\mathcal{I}^{\mathsf{K},\wedge} = \langle \mathbf{F}, C^{\mathsf{K},\wedge}\rangle$ is semilattice based with respect to K and $\wedge^\flat$ and $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}^{\mathsf{K},\wedge}) = \mathsf{K}$.*

Proof: By the second condition in the definition of $C^{\mathsf{K},\wedge}$, we conclude that $\mathcal{I}^{\mathsf{K},\wedge}$ is semilattice based with respect to K and $\wedge^\flat$. Then, by definition $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}^{\mathsf{K},\wedge}) = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$, since, by hypothesis, K is a semantic variety. ∎

Proposition 1748 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a semilattice based non pseudo-axiomatic π-institution. Then $\mathcal{I}^{\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}),\wedge} = \mathcal{I}$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, with $\Phi \neq \varnothing$. Then, we have:

$$\begin{array}{lll}
\phi \in C^{\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}),\wedge}_\Sigma(\varnothing) & \text{iff} & \text{for all } \mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathcal{I}), \chi \in \mathrm{SEN}(F(\Sigma)),\\
& & \chi \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi),\\
& \text{iff} & \text{for all } \mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathcal{I}), \psi \in \mathrm{SEN}^\flat(\Sigma),\\
& & \alpha_\Sigma(\psi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi),\\
& \text{iff} & \text{for all } \mathcal{A} \in \mathsf{K}, \psi \in \mathrm{SEN}^\flat(\Sigma),\\
& & \alpha_\Sigma(\psi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi),\\
& \text{iff} & \phi \in \bigcap\{C_\Sigma(\psi) : \psi \in \mathrm{SEN}^\flat(\Sigma)\}\\
& \text{iff} & \phi \in C_\Sigma(\varnothing).
\end{array}$$

Moreover,

$$\begin{array}{lll}\phi \in C_\Sigma^{\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}),\wedge}(\Phi) & \text{iff} & \text{for all } \mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathcal{I}),\\ & & \bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)\\ & \text{iff} & \text{for all } \mathcal{A} \in \mathsf{K},\\ & & \bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)\\ & \text{iff} & \phi \in C_\Sigma(\Phi).\end{array}$$

Thus, we get $\mathcal{I}^{\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}),\wedge} = \mathcal{I}$. ∎

For non pseudo-axiomatic semilattice based π-institutions on the same algebraic system, the Frege relations reflect the $\leq$ ordering on their closure systems.

Proposition 1749 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$, $\mathcal{I}' = \langle \mathbf{F}, C'\rangle$ *non pseudo-axiomatic semilattice based* π*-institutions with respect to* $\wedge^\flat$. *Then*

$$\mathcal{I} \leq \mathcal{I}' \quad \textit{iff} \quad \widetilde{\lambda}(\mathcal{I}) \leq \widetilde{\lambda}(\mathcal{I}').$$

Proof: The left-to-right implication is by Lemma 1416. Assume, conversely, that $\mathcal{I}$, $\mathcal{I}'$ are non pseudo-axiomatic semilattice based with respect to $\wedge^\flat$, such that $\widetilde{\lambda}(\mathcal{I}) \leq \widetilde{\lambda}(\mathcal{I}')$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, with $\Phi \neq \varnothing$,

$$\begin{array}{lll}\phi \in C_\Sigma(\Phi) & \text{iff} & \phi \in C_\Sigma(\bigwedge^\flat_\Sigma \Phi)\\ & \text{iff} & C_\Sigma(\bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi) = C_\Sigma(\bigwedge^\flat_\Sigma \Phi)\\ & \text{iff} & \langle \bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi, \bigwedge^\flat_\Sigma \Phi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I})\\ & \text{implies} & \langle \bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi, \bigwedge^\flat_\Sigma \Phi\rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}')\\ & \text{iff} & C'_\Sigma(\bigwedge^\flat_\Sigma \Phi \wedge^\flat_\Sigma \phi) = C'_\Sigma(\bigwedge^\flat_\Sigma \Phi)\\ & \text{iff} & \phi \in C'_\Sigma(\bigwedge^\flat_\Sigma \Phi)\\ & \text{iff} & \phi \in C'_\Sigma(\Phi).\end{array}$$

Moreover, taking into account what was just demonstrated,

$$\begin{array}{lll}\phi \in C_\Sigma(\varnothing) & \text{iff} & \phi \in \bigcap\{C_\Sigma(\psi) : \psi \in \mathrm{SEN}^\flat(\Sigma)\}\\ & \text{implies} & \phi \in \bigcap\{C'_\Sigma(\psi) : \psi \in \mathrm{SEN}^\flat(\Sigma)\}\\ & \text{iff} & \phi \in C'_\Sigma(\varnothing).\end{array}$$

We conclude that $\mathcal{I} \leq \mathcal{I}'$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. Denote by $\mathsf{K}^{\mathbf{F},\wedge}$ the semantic variety of $\mathbf{F}$-algebraic systems generated by the semilattice equations L1-L4.

Theorem 1750 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$. *There exists a dual isomorphism between the collection of semilattice based non pseudo-axiomatic* π*-institutions with respect to* $\wedge^f lat$, *ordered under* $\leq$, *and the collection of all conditionally max natural semantic subvarieties of* $\mathsf{K}^{\mathbf{F},\wedge}$, *ordered under* $\subseteq$, *given by* $\mathcal{I} \mapsto \mathsf{K}^{\mathcal{I}}$.

Proof: Consider the mapping $\mathcal{I} \mapsto \mathsf{K}^{\mathcal{I}}$.

Suppose, first, that $\mathcal{I}, \mathcal{I}'$ are non pseudo-axiomatic and semilattice based with respect to $\wedge^\flat$, such that $\mathsf{K}^{\mathcal{I}} = \mathsf{K}^{\mathcal{I}'}$. Then $\mathcal{I}^{\mathsf{K}^{\mathcal{I}},\wedge} = \mathcal{I}^{\mathsf{K}^{\mathcal{I}'},\wedge}$. By Proposition 1742 and Proposition 1748, we get $\mathcal{I} = \mathcal{I}'$. Therefore, the mapping is one-to-one.

Assume, now, that K is conditionally max natural and semilattice based with respect to $\wedge^\flat$. Then, by Lemma 1746 and Proposition 1747, $\mathcal{I}^{\mathsf{K},\wedge}$ is a non pseudo-axiomatic and semilattice based π-institution with respect to K and $\wedge^\flat$, such that $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}^{\mathsf{K},\wedge}) = \mathsf{K}$. Therefore, by Proposition 1742, $\mathsf{K}^{\mathcal{I}^{\mathsf{K},\wedge}} = \mathsf{K}$ and the mapping is also onto. Thus, it is a bijection from the collection of semilattice based non pseudo-axiomatic π-institutions with respect to $\wedge^f lat$ onto the collection of all conditionally max natural semantic subvarieties of $\mathsf{K}^{\mathbf{F},\wedge}$.

Finally, for all non pseudo-axiomatic and semilattice based π-institutions $\mathcal{I}, \mathcal{I}'$, with respect to $\wedge^\flat$, we have

$$\begin{array}{lll}\mathcal{I} \leq \mathcal{I}' & \text{iff} & \widetilde{\lambda}(\mathcal{I}) \leq \widetilde{\lambda}(\mathcal{I}') \quad \text{(by Proposition 1749)}\\ & \text{iff} & \widetilde{\Omega}(\mathcal{I}) \leq \widetilde{\Omega}(\mathcal{I}') \quad \text{(by Proposition 1742)}\\ & \text{iff} & \mathsf{K}^{\mathcal{I}'} \leq \mathsf{K}^{\mathcal{I}}. \quad \text{(definition of } \mathsf{K}^{\mathcal{I}}, \mathsf{K}^{\mathcal{I}'})\end{array}$$

Thus, the bijection is also order reversing and dual order reflecting and, therefore, it is a dual order isomorphism, as claimed. ■

Our next goal is to show that for semilattice based π-institutions, their semantic variety coincides with the class of all $\mathcal{I}$-algebraic systems. We start by showing that, for such a π-institution, the $\mathcal{I}$-filter families on any algebraic system in their semantic variety coincides (roughly) with the collection of all semilattice filter families.

Lemma 1751 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a semilattice based* π*-institution based on* $\mathbf{F}$*. For all* $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$*,*

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \begin{cases} \mathrm{FiFam}^{\wedge}(\mathcal{A}), & \textit{if } \mathcal{I} \textit{ has theorems}\\ \mathrm{FiFam}^{\wedge,\varnothing}(\mathcal{A}), & \textit{otherwise}\end{cases}$$

Proof: It suffices to show that, for all $T \in \mathrm{SenFam}(\mathcal{A})$, such that $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}|$, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ if and only if $T \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$.

Suppose, first, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

- Suppose that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then, since $\phi \wedge^\flat_\Sigma \psi \in C_\Sigma(\phi, \psi)$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get $\alpha_\Sigma(\phi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi) = \alpha_\Sigma(\phi \wedge^\flat_\Sigma \psi) \in T_{F(\Sigma)}$;
- If $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi)$, then $\alpha_\Sigma(\phi \wedge^\flat_\Sigma \psi) = \alpha_\Sigma(\phi) \wedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\psi) = \alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. Since $\psi \in C_\Sigma(\phi \wedge^\flat_\Sigma \psi)$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$.

Taking into account the surjectivity of $\langle F,\alpha\rangle$, we get $T \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$.

Assume, conversely, that $T \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$ and let $\Sigma \in |\mathbf{Sign}^{\flat}|$, $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^{\flat}(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Since, by Proposition 1742, $\mathcal{I}$ is semilattice based with respect to $\mathsf{K}^{\mathcal{I}}$, we get that $\bigwedge^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\Phi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Since, by hypothesis, $T \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$, $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$.

Finally, if $\phi \in C_\Sigma(\varnothing)$, then $\phi \in C_\Sigma(\psi)$, for all $\psi \in \mathrm{SEN}^{\flat}(\Sigma)$. Since $\mathcal{I}$ has theorems, $T_{F(\Sigma)} \neq \varnothing$, whence, by the surjectivity of $\langle F,\alpha\rangle$, for some $\psi \in \mathrm{SEN}^{\flat}(\Sigma)$, $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. For this chosen ψ, we also have, since $\mathcal{I}$ is semilattice based with respect to $\mathsf{K}^{\mathcal{I}}$, that $\alpha_\Sigma(\psi) \leq^{\mathcal{A}}_{F(\Sigma)} \alpha_\Sigma(\phi)$. Thus, since $T \in \mathrm{FiFam}^{\wedge}(\mathcal{A})$, we conclude that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$.

Since in all cases $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$ imply $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ∎

In the next step, we show that, for a semilattice based π-institution, the Frege congruence system of any $\mathcal{I}$-structure of the form $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$, with $\mathcal{A}$ in the semantic variety of $\mathcal{I}$, is reduced.

Lemma 1752 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat}\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a semilattice based π-institution based on $\mathbf{F}$. For every $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$,*

$$\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}.$$

Hence, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is reduced.

Proof: Let $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi,\psi\rangle \notin \Delta^{\mathcal{A}}_\Sigma$. Then, by definition, $\phi \neq \psi$ and, by Lemma 1737 and Proposition 1742, we get $\psi \notin T^{\langle \Sigma,\phi\rangle}_\Sigma$ or $\phi \in T^{\langle \Sigma,\psi\rangle}_\Sigma$. Since, by Lemmas 1738 and 1751, $T^{\langle \Sigma,\phi\rangle}, T^{\langle \Sigma,\psi\rangle} \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that $\langle \phi,\psi\rangle \notin \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$. Thus, $\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$.

Finally, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \leq \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))$, whence, $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$ and, therefore, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is a reduced $\mathcal{I}$-structure. ∎

In the last step before the main theorem, we show that for a semilattice based π-institution $\mathcal{I}$, if $\langle \mathcal{A}, D\rangle$ is any $\mathcal{I}$-structure, such that $\widetilde{\lambda}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$, then $\mathcal{D}$ is either $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, if $\mathcal{I}$ has theorems, or $\mathcal{D}^{\varnothing}$ is $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, if $\mathcal{I}$ does not have theorems, where $\mathcal{D}^{\varnothing}$ consists of the filter families in $\mathcal{D}$, (potentially) augmented by filter families in $\mathcal{D}$, in which one or more components have been replaced by $\varnothing$.

Lemma 1753 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat}\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a semilattice based π-institution based on $\mathbf{F}$, and $\langle \mathcal{A}, D\rangle \in \mathrm{Str}(\mathcal{I})$, such that $\widetilde{\lambda}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$. If $\mathcal{I}$ has theorems, then $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. If $\mathcal{I}$ does not have theorems, then $\mathcal{D}^{\varnothing} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and suppose $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}|$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(T_\Sigma)$. By Proposition 114, there exists $\Phi \subseteq_f T_\Sigma$, such that $\phi \in D_\Sigma(\Phi)$. Since $\langle \mathcal{A}, D\rangle \in \mathrm{Str}(\mathcal{I})$, by Corollary 1735, $D_\Sigma(\bigwedge_\Sigma^{\mathcal{A}} \Phi \wedge_\Sigma^{\mathcal{A}} \phi) = D_\Sigma(\bigwedge_\Sigma^{\mathcal{A}} \Phi)$. Hence, by hypothesis, $\bigwedge_\Sigma^{\mathcal{A}} \Phi \wedge_\Sigma^{\mathcal{A}} \phi = \bigwedge_\Sigma^{\mathcal{A}} \Phi$. Since $\Phi \subseteq_f T_\Sigma$ and, by Lemma 1751, $T \in \mathrm{FiFam}^\wedge(\mathcal{A})$, $\bigwedge_\Sigma^{\mathcal{A}} \Phi \in T_\Sigma$. By the preceding equation, $\bigwedge_\Sigma^{\mathcal{A}} \Phi \wedge_\Sigma^{\mathcal{A}} \phi \in T_\Sigma$ and, therefore, $\phi \in T_\Sigma$. We conclude that $T = D(T)$ and, hence, $T \in \mathcal{D}$.

If $\mathcal{I}$ has theorems, then, for every $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T_\Sigma \neq \varnothing$, for all $\Sigma \in |\mathbf{Sign}|$. By what was proven above, $\mathcal{D} = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. On the other hand, if $\mathcal{I}$ does not have theorems, then any of the components of $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is allowed to be empty and, therefore, $\mathcal{D}^\varnothing = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

In one of the main theorems, we show that, for a semilattice based π-institution $\mathcal{I}$, the semantic variety $\mathsf{K}^{\mathcal{I}}$ of $\mathcal{I}$ coincides with the class $\mathrm{AlgSys}(\mathcal{I})$ of all $\mathcal{I}$-algebraic systems.

Theorem 1754 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a semilattice based* π*-institution based on* $\mathbf{F}$.

(a) $\mathrm{AlgSys}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$;

(b) $\mathrm{AlgSys}(\mathcal{I})$ *is a semantic variety;*

(c) $\mathcal{I}$ *is semilattice based with respect to* $\mathrm{AlgSys}(\mathcal{I})$.

Proof: We have, by Proposition 65, that, in general, $\mathrm{AlgSys}(\mathcal{I}) \subseteq \mathsf{K}^{\mathcal{I}}$. Suppose, conversely, that $\mathcal{A} \in \mathsf{K}^{\mathcal{I}}$. Then, by Lema 1752, $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$ is reduced. Therefore, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. We conclude that $\mathrm{AlgSys}(\mathcal{I}) = \mathsf{K}^{\mathcal{I}}$. Since $\mathsf{K}^{\mathcal{I}}$ is, by definition, a semantic variety, then so is $\mathrm{AlgSys}(\mathcal{I})$. Finally, since, by Proposition 1742, $\mathcal{I}$ is semilattice based with respect to $\mathsf{K}^{\mathcal{I}}$, it is semilattice based with respect to $\mathrm{AlgSys}(\mathcal{I})$. ■

In another main theorem, it is shown that a finitary self extensional and conjunctive π-institution $\mathcal{I}$ is necessarily fully self extensional, i.e., that every $\langle \mathcal{A}, D\rangle \in \mathrm{FStr}(\mathcal{I})$ satisfies the Congruence Property.

Theorem 1755 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a finitary* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is self extensional and conjunctive, then it is fully self extensional.*

Proof: Suppose that $\mathcal{I}$ is finitary, self extensional and has the Conjunction Property with respect to $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. By Theorem 1744 and Proposition 1742, $\mathcal{I}$ is semilattice based with respect to $\mathsf{K}^{\mathcal{I}}$ and $\wedge^\flat$. By Proposition 65, $\mathrm{AlgSys}(\mathcal{I}) \subseteq \mathsf{K}^{\mathcal{I}}$, whence, by Lemma 1752, if $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, then $\widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$.

Suppose, now, that $\langle \mathcal{A}, D\rangle \in \mathrm{FStr}(\mathcal{I})$. Then, by definition,

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(D)) = \mathcal{D}/\widetilde{\Omega}^{\mathcal{A}}(D).$$

Since $\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \in \mathrm{AlgSys}(\mathcal{I})$, by what was shown in the preceding paragraph,

$$\widetilde{\lambda}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(D)}(\mathcal{D}/\widetilde{\Omega}^{\mathcal{A}}(D)) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(D)}.$$

Therefore, we get that $\langle \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(D), \mathcal{D}/\widetilde{\Omega}^{\mathcal{A}}(D)\rangle$ has the Congruence Property. Therefore, by Proposition 1426, $\langle \mathcal{A}, D\rangle$ also has the Congruence Property. We conclude that $\mathcal{I}$ is fully self extensional. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a finitary Gentzen π-institution based on $\mathbf{F}$.

$\mathfrak{G}$ **has congruence** if, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \in G_\Sigma(\{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i < k\}).$$

Moreover, $\mathfrak{G}$ **has conjunction with respect to** $\wedge^\flat$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi, \psi \vdash_\Sigma \phi \wedge^\flat_\Sigma \psi,\ \ \phi \wedge^\flat_\Sigma \psi \vdash_\Sigma \phi,\ \ \phi \wedge^\flat_\Sigma \psi \vdash_\Sigma \psi \in G_\Sigma(\varnothing).$$

Let, also, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a finitary π-institutuon based on $\mathbf{F}$. Recall that:

- If $\mathcal{I}$ has theorems, $\mathfrak{G}$ is **fully adequate for** $\mathcal{I}$ if $\mathrm{Str}(\mathfrak{G}) = \mathrm{FStr}(\mathcal{I})$;
- If $\mathcal{I}$ does not have theorems, then $\mathfrak{G}$ is **fully adequate for** $\mathcal{I}$ if $\mathrm{Str}(\mathfrak{G})^\varnothing = \mathrm{FStr}(\mathcal{I})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a finitary self extensional π-institution, having the Conjunction Property with respect to $\wedge^\flat$.

- Define $\mathrm{Ax}^{\mathcal{I}} = \{\mathrm{Ax}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Ax}^{\mathcal{I}}_\Sigma = \{\Phi \vdash_\Sigma \phi : \phi \in C_\Sigma(\Phi)\};$$
- Define $\mathrm{Ir}^{\mathcal{I}} = \{\mathrm{Ir}^{\mathcal{I}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\begin{aligned}\mathrm{Ir}^{\mathcal{I}}_\Sigma \ = \ \{\langle\{\phi_i \vdash_\Sigma \psi_i, \psi_i \vdash_\Sigma \phi_i : i \in I\}, \sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi})\rangle :\\ \sigma^\flat \in N^\flat, \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)\}.\end{aligned}$$
- $R^{\mathcal{I}} \coloneqq \mathrm{Ax}^{\mathcal{I}} \cup \mathrm{Ir}^{\mathcal{I}}$.

Finally, define $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, C^{\mathcal{I}}\rangle \coloneqq \mathfrak{G}^{R^{\mathcal{I}}}$ as the Gentzen π-institution generated by the system $R^{\mathcal{I}}$ of Gentzen rules. Recall, by Proposition 1482, that $G^{\mathcal{I}} = \Xi^{R^{\mathcal{I}}}$.

This Gentzen π-institution turns out to be fully adequate for the π-institution $\mathcal{I}$:

Theorem 1756 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary conjunctive* π*-institution.* $\mathcal{I}$ *is self extensional if and only if* $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$ *is fully adequate for* $\mathcal{I}$.

Proof: Suppose, first, that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. Since $\langle \mathcal{F}, C \rangle \in \mathrm{FStr}(\mathcal{I})$, we get that $\langle \mathcal{F}, C \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$, if $\mathcal{I}$ has theorems, and that $\langle \mathcal{F}, C \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})^\varnothing$, otherwise. Since, by definition, $\mathfrak{G}^{\mathcal{I}}$ has congruence, we get that $\langle \mathcal{F}, C \rangle$ has the Congruence Property, which amounts to $\mathcal{I}$ having the Congruence Property. Thus, $\mathcal{I}$ is self extensional.

Assume, conversely, that $\mathcal{I}$ is finitary, self extensional and has the Conjunction Property with respect to $\wedge^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$.

- Suppose, first, that $\langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$. Then, by Theorem 1755, $\langle \mathcal{A}, D \rangle$ has the Congruence Property. Moreover, by definition, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)$, if $\phi \in C_\Sigma(\Phi)$, then, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. We conclude that, if $\mathcal{I}$ has theorems, then $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$ and that, otherwise, $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})^\varnothing$.

- Suppose, conversely, that $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})$, if $\mathcal{I}$ has theorems, or $\langle \mathcal{A}, D \rangle \in \mathrm{Str}(\mathfrak{G}^{\mathcal{I}})^\varnothing$, otherwise. Consider the reduction

  $$\langle \mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})), \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))\rangle.$$

  This reduction is an $\mathcal{I}$-structure and, by hypothesis and Proposition 1426, it has the Congruence Property. Thus, we get

  $$\widetilde{\lambda}^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))}.$$

  Now Lemma 1753 allows us to conclude that

  $$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}/\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))).$$

  Therefore, $\langle \mathcal{A}, D \rangle \in \mathrm{FStr}(\mathcal{I})$.

We conclude that $\mathfrak{G}^{\mathcal{I}}$ is fully adequate for $\mathcal{I}$. ■

23.4 Fregeanity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with a binary natural transformation $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is called:

- **strongly Fregean** if, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\lambda}(T) = \widetilde{\Omega}(T)$, i.e., if and only if the strong Frege equivalence family $\widetilde{\lambda}(T)$ is a congruence system;

- **congruential** if, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\lambda}(T)$ satisfies the congruence property, i.e., $\widetilde{\lambda}(T)$ is a congruence family (but not necessarily a system);

- **Fregean** if, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\Lambda}(T) = \widetilde{\Omega}(T)$, i.e., if its Frege equivalence system $\widetilde{\Lambda}$ is a congruence system.

Strong Fregeanity implies congruentiality, which, in turn, implies Fregeanity.

Recall, also, that $\mathcal{I}$ is said to have the **Deduction Detachment Theorem with respect to** $\to^\flat$ if, for every $\Sigma \in |\mathbf{Sign}^\flat|$, all $\Phi \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\psi \in C_\Sigma(\Phi, \phi) \quad \text{iff} \quad \phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi).$$

In the following proposition, it is shown that every strongly Fregean π-institution with the Deduction Detachment Theorem satisfies certain axioms and the rule of Modus Ponens.

Proposition 1757 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with a binary natural transformation $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a congruential π-institution having the Deduction Detachment Theorem with respect to $\to^\flat$. Then, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi, \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,*

(a) $\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \phi) \in C_\Sigma(\varnothing)$;

(b) $(\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi)) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi)) \in C_\Sigma(\varnothing)$;

(c) $(\phi_0 \to^\flat_\Sigma \psi_0) \to^\flat_\Sigma ((\psi_0 \to^\flat_\Sigma \phi_0) \to^\flat_\Sigma (\cdots((\phi_{k-1} \to^\flat_\Sigma \psi_{k-1}) \to^\flat_\Sigma ((\psi_{k-1} \to^\flat_\Sigma \phi_{k-1}) \to^\flat_\Sigma (\sigma^\flat_\Sigma(\vec{\phi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\psi}))))\cdots)) \in C_\Sigma(\varnothing)$;

(d) $\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi)$.

Proof:

(a) We have, by inflationarity, $\phi \in C_\Sigma(\phi, \psi)$, whence, by two applications of the Deduction Theorem, $\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \phi) \in C_\Sigma(\varnothing)$.

(b) We have, using the Detachment Theorem,

$$\chi \in C_\Sigma(\psi, \psi \to^\flat_\Sigma \chi) \subseteq C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi, \phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi)).$$

Thus, using the Deduction Theorem, we get

$$(\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi)) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi)) \in C_\Sigma(\varnothing).$$

(c) Since $\mathcal{I}$ is congruential, we get, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$C_\Sigma(T_\Sigma, \phi_i) = C_\Sigma(T_\Sigma, \psi_i),\ i < k, \\ \text{imply} \quad C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\psi})).$$

But $C_\Sigma(T_\Sigma, \phi_i) = C_\Sigma(T_\Sigma, \psi_i)$ is equivalent, by the Deduction Detachment Theorem, to $\phi \to^\flat_\Sigma \psi$, $\psi \to^\flat_\Sigma \phi \in C_\Sigma(T_\Sigma) = T_\Sigma$. Similarly,

$$C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\psi}))$$

is equivalent to $\sigma^\flat_\Sigma(\vec{\phi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\psi})$, $\sigma^\flat_\Sigma(\vec{\psi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\phi}) \in C_\Sigma(T_\Sigma) = T_\Sigma$. Therefore, we get

$$\sigma^\flat_\Sigma(\vec{\phi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \in C_\Sigma(\{\phi_i \to^\flat_\Sigma \psi_i, \psi_i \to^\flat_\Sigma \phi_i : i < k\}).$$

Now (c) follows by several applications of the Deduction Theorem.

(d) By inflationarity, $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\phi \to^\flat_\Sigma \psi)$, whence by the Detachment Theorem, $\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi)$.

■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$. Define $\mathrm{Ax}^0 = \{\mathrm{Ax}^0_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, Ax^0_Σ is the set consisting, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi, \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,

- $\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \phi)$;
- $(\phi \to^\flat_\Sigma (\psi \to^\flat_\Sigma \chi)) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \psi) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \chi))$;
- $(\phi_0 \to^\flat_\Sigma \psi_0) \to^\flat_\Sigma ((\psi_0 \to^\flat_\Sigma \phi_0) \to^\flat_\Sigma (\cdots((\phi_{k-1} \to^\flat_\Sigma \psi_{k-1}) \to^\flat_\Sigma ((\psi_{k-1} \to^\flat_\Sigma \phi_{k-1}) \to^\flat_\Sigma (\sigma^\flat_\Sigma(\vec{\phi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\psi}))))\cdots))$.

Furthermore, define $\mathrm{Ir}^0 = \{\mathrm{Ir}^0_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Ir}^0_\Sigma = \{\langle \{\phi, \phi \to^\flat_\Sigma \psi\}, \psi \rangle : \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\}.$$

Finally, let $R^0 = \mathrm{Ax}^0 \cup \mathrm{Ir}^0$. Set $\mathcal{I}^0 = \langle \mathbf{F}, C^0 \rangle$ be the finitary π-institution, based on $\mathbf{F}$, with $C^0 = C^{R^0}$ the closure system on $\mathbf{F}$ generated by the collection R^0 of $\mathbf{F}$-axioms and $\mathbf{F}$-rules of inference.

Our work in Proposition 1757 allows us to formalize the fact that a congruential finitary π-institution having the Deduction Detachment Theorem with respect to $\to^\flat$ is an axiomatic extension of $\mathcal{I}^0$. Recall that $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is an axiomatic extension of $\mathcal{I}^0$ if there exists an axiom family Ax', such that $C = C^{R^0 \cup \mathrm{Ax}'}$.

Theorem 1758 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with a binary natural transformation $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a congruential finitary π-institution having the Deduction Detachment Theorem with respect to $\to^\flat$. Then $\mathcal{I}$ is an axiomatic extension of $\mathcal{I}^0$.*

Proof: Since $\mathcal{I}$ is finitary, its closure system is specified by a collection $R = \mathrm{Ax} \cup \mathrm{Ir}$ of $\mathbf{F}$-axioms and $\mathbf{F}$-rules. We define $R' = \mathrm{Ax}' \cup \mathrm{Ir}'$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

- $\mathrm{Ax}'_\Sigma = \mathrm{Ax}_\Sigma \cup \{\phi_0 \to^\flat_\Sigma (\phi_i \to^\flat_\Sigma \cdots \to^\flat_\Sigma (\phi_{n-1} \to^\flat_\Sigma \phi)\cdots) : \langle\{\phi_0,\ldots,\phi_{n-1}\},\phi\rangle \in \mathrm{Ir}_\Sigma\}$;
- $\mathrm{Ir}'_\Sigma = \{\langle\{\langle\phi, \phi \to^\flat_\Sigma \psi\},\psi\rangle : \phi,\psi \in \mathrm{SEN}^\flat(\Sigma)\}$.

Note that, by the Deduction Theorem of $\mathcal{I}$, for every $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathrm{Ax}'_\Sigma \subseteq C_\Sigma(\varnothing)$. Moreover, by the Detachment Theorem for $\mathcal{I}$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi)$. Therefore, we conclude that $C^{\mathrm{R}'} \leq C$.

Conversely, note that, by definition, $\mathrm{Ax} \leq \mathrm{Ax}'$. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\langle\{\phi_0,\ldots,\phi_{n-1}\},\phi\rangle \in \mathrm{Ir}_\Sigma$,

$$\phi \in C^{R'}_\Sigma(\Phi, \phi_0 \to^\flat_\Sigma (\phi_1 \to^\flat_\Sigma \cdots \to^\flat_\Sigma (\phi_{n-1} \to^\flat_\Sigma \phi)\cdots)) \subseteq C^{R'}_\Sigma(\Phi).$$

Hence, $C = C^R \leq C^{R'}$. We now conclude that $C = C^{R'}$. ■

Next, we show that, if $\mathcal{I}$ is an axiomatic extension of $\mathcal{I}^0$, then it has the Deduction Detachment Theorem with respect to $\to^\flat$.

Proposition 1759 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with a binary natural transformation $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ an axiomatic extension of $\mathcal{I}^0$. Then $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\to^\flat$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi,\psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi)$. Then, since, by hypothesis, $C^{R^0} \leq C$, we get

$$\psi \in C_\Sigma(\phi, \phi \to^\flat_\Sigma \psi) \subseteq C_\Sigma(\Phi, \phi).$$

Suppose, conversely, that $\psi \in C_\Sigma(\Phi,\phi)$. Then, there exists in $\mathcal{I}$ a proof $\phi_0,\phi_1,\ldots,\phi_n = \psi$ of ψ from premises $\Phi \cup \{\phi\}$. We show by induction on $k \leq n$ that there exists a proof in $\mathcal{I}$ of $\phi \to^\flat_\Sigma \psi$ from premises Φ in $\mathcal{I}$.

- If $k = 0$, then $\phi_0 \in \mathrm{Ax}_\Sigma$ or $\phi_0 \in \Phi \cup \{\phi\}$.
  - If $\phi_0 \in \mathrm{Ax}_\Sigma$, then $\phi_0 \to^\flat_\Sigma (\phi \to^\flat_\Sigma \phi_0), \phi_0, \phi \to^\flat_\Sigma \phi_0$ is a proof in $\mathcal{I}$ of $\phi \to^\flat_\Sigma \phi_0$ from Φ;
  - If $\phi_0 \in \Phi$, then $\phi_0 \to^\flat_\Sigma (\phi \to^\flat_\Sigma \phi_0), \phi_0, \phi \to^\flat_\Sigma \phi_0$ is a proof in $\mathcal{I}$ of $\phi \to^\flat_\Sigma \phi_0$ from premises Φ.
  - If $\phi_0 = \phi$, then

$$\begin{array}{l}(\phi_0 \to^\flat_\Sigma ((\phi_0 \to^\flat_\Sigma \phi_0) \to^\flat_\Sigma \phi_0)) \\ \qquad\qquad \to^\flat_\Sigma ((\phi_0 \to^\flat_\Sigma (\phi_0 \to^\flat_\Sigma \phi_0)) \to^\flat_\Sigma (\phi_0 \to^\flat_\Sigma \phi_0)) \\ \phi_0 \to^\flat_\Sigma ((\phi_0 \to^\flat_\Sigma \phi_0) \to^\flat_\Sigma \phi_0) \\ (\phi_0 \to^\flat_\Sigma (\phi_0 \to^\flat_\Sigma \phi_0)) \to^\flat_\Sigma (\phi_0 \to^\flat_\Sigma \phi_0) \\ \phi_0 \to^\flat_\Sigma (\phi_0 \to^\flat_\Sigma \phi_0) \\ \phi_0 \to^\flat_\Sigma \phi_0\end{array}$$

    is a proof in $\mathcal{I}$ of $\phi_0 \to^\flat_\Sigma \phi_0$ from Φ

- If $k > 0$, assume that, for all $\ell < k$, $\phi \to^\flat_\Sigma \phi_\ell \in C_\Sigma(\Phi)$. If ϕ_k is either an axiom or in $\Phi \cup \{\phi\}$, then the treatment is the same as in the Induction Basis. So assume, for the final case, that ϕ_k follows from preceding Σ-sentences in the sequel by an application of the only **F**-rule available, i.e., that, for some $i, j < k$, $\phi_i = \phi_j \to^\flat_\Sigma \phi_k$. Then, by the Induction Hypothesis, $\phi \to^\flat_\Sigma (\phi_j \to^\flat_\Sigma \phi_k) \in C_\Sigma(\Phi)$ and $\phi \to^\flat_\Sigma \phi_j \in C_\Sigma(\Phi)$. Then by adjoining the following Σ-sentences to the sequence consisting of the proofs in $\mathcal{I}$ from Φ of $\phi \to^\flat_\Sigma (\phi_j \to^\flat_\Sigma \phi_k)$ and $\phi \to^\flat_\Sigma \phi_j$, we obtain a proof in $\mathcal{I}$ from Φ of $\phi \to^\flat_\Sigma \phi_k$:

$$\begin{array}{l} \vdots \\ \phi \to^\flat_\Sigma (\phi_j \to^\flat_\Sigma \phi_k) \\ \vdots \\ \phi \to^\flat_\Sigma \phi_j \\ (\phi \to^\flat_\Sigma (\phi_j \to^\flat_\Sigma \phi_k)) \to^\flat_\Sigma ((\phi \to^\flat_\Sigma \phi_j) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \phi_k)) \\ (\phi \to^\flat_\Sigma \phi_j) \to^\flat_\Sigma (\phi \to^\flat_\Sigma \phi_k) \\ \phi \to^\flat_\Sigma \phi_k \end{array}$$

  This completes the Induction Step.

Thus, we conclude that $\phi \to^\flat_\Sigma \psi \in C_\Sigma(\Phi)$ and, therefore, $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\to^\flat$. ■

Moreover, under the same hypotheses, $\mathcal{I}$ turns out to be strongly Fregean.

Proposition 1760 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary natural transformation* $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *an axiomatic extension of* $\mathcal{I}^0$*. Then* $\mathcal{I}$ *is congruential.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ be in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, such that $C_\Sigma(T_\Sigma, \phi_i) = C_\Sigma(T_\Sigma, \psi_i)$, for all $i < k$. Then, by Proposition 1759, we get that

$$\phi_i \to^\flat_\Sigma \psi_i, \psi_i \to^\flat_\Sigma \phi_i \in C_\Sigma(T_\Sigma) = T_\Sigma,\ i < k.$$

Since $C^{R^0} \le C$, we get, by multiple applications of the Detachment Theorem, $\sigma^\flat_\Sigma(\vec{\phi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\psi}), \sigma^\flat_\Sigma(\vec{\psi}) \to^\flat_\Sigma \sigma^\flat_\Sigma(\vec{\phi}) \in C_\Sigma(T_\Sigma)$. Hence, $C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\phi})) = C_\Sigma(T_\Sigma, \sigma^\flat_\Sigma(\vec{\psi}))$. Thus, $\widetilde{\lambda}(T)$ is a congruence family on $\mathbf{F}$ and, therefore, $\mathcal{I}$ is congruential. ■

Thus, we have obtained an exact characterization of those π-institutions that are congruential and possess the Deduction Detachment Property with respect to a binary natural transformation $\to^\flat$.

Theorem 1761 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with a binary natural transformation* $\to^\flat: (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is congruential and has the Deduction Detachment Theorem with respect to* $\to^\flat$ *if and only if it is an axiomatic extension of* $\mathcal{I}^0$*.*

Proof: The implication left-to-right is by Theorem 1758. The converse is given by Propositions 1759 and 1760. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. Recall that a Σ-**sequent** is an expression of the form $\Phi \vdash_\Sigma \phi$, where $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. It is **finite** if Φ is a finite set. Moreover, a **Gentzen F-rule** is an expression of the form

$$\langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle,$$

where $\Phi_i \vdash_\Sigma \phi_i$, $i \in I$, and $\Phi \vdash_\Sigma \phi$ are Σ-sequents. We say the rule is **finitary** if I is finite and all sequents in the rule are finite.

Let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be an **F**-structure, $\Sigma \in |\mathbf{Sign}^\flat|$, $s = \Phi \vdash_\Sigma \phi$ a Σ-sequent and $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ a Gentzen **F**-rule.

- $\mathbb{L}$ **satisfies** s or s is **true** or **valid** or **holds in** $\mathbb{L}$, written $\mathbb{L} \vDash_\Sigma s$, if $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$;
- $\mathbb{L}$ **satisfies** r or r is **true** or **valid** or **holds in** $\mathbb{L}$, written $\mathbb{L} \vDash_\Sigma r$, if

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

These definitions are extended in the ordinary way to sets of rules and sets of structures.

Let M be a class of **F**-structures. We say that M is a (**finitary**) **Gentzen class** if it is specified by a collection $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of (finitary) Gentzen **F**-rules (including sequents, viewed as rules with empty sets of premises).

The following examples illustrate the definition.

- The class of all finitary **F**-structures having the Deduction Detachment Theorem with respect to a binary natural transformation $\to^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ in $N^\flat$ is a finitary Gentzen class specified by $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}|^\flat|}$, where

$$\begin{array}{rcl} R_\Sigma & = & \{\phi, \phi \to^\flat_\Sigma \psi \vdash_\Sigma \psi : \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\} \\ & & \cup \{\langle \{\Phi, \phi \vdash_\Sigma \psi\}, \Phi \vdash_\Sigma \phi \to^\flat_\Sigma \psi \rangle : \Phi \cup \{\phi, \psi\} \subseteq_f \mathrm{SEN}^\flat(\Sigma)\}. \end{array}$$

- The class of all finitary self extensional **F**-structures is also a finitary Gentzen class specified by $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$\begin{array}{r} R_\Sigma = \{\langle \{\phi_i \vdash_\Sigma \psi_i,\ \psi_i \vdash_\Sigma \phi_i : i < k\}, \sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \rangle : \\ \sigma^\flat \in N^\flat, \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)\}. \end{array}$$

- The class of all finitary congruential **F**-structures is also a finitary Gentzen class specified by $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$\begin{array}{r} R_\Sigma = \{\langle \{\Phi, \phi_i \vdash_\Sigma \psi_i,\ \Phi, \psi_i \vdash_\Sigma \phi_i : i < k\},\ \Phi, \sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi}) \rangle : \\ \sigma^\flat \in N^\flat, \Phi \subseteq_f \mathrm{SEN}^\flat(\Sigma), \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)\}. \end{array}$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\Sigma \in |\mathbf{Sign}^\flat|$ and $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ a finitary Gentzen $\mathbf{F}$-rule. The **accumulation of** r, denoted $\mathrm{acm}(r)$, is the collection of finitary Gentzen $\mathbf{F}$-rules

$$\mathrm{acm}(r) = \{\langle \{X, \Phi_i \vdash_\Sigma \phi_i : i \in I\},\ X, \Phi \vdash_\Sigma \phi \rangle : X \subseteq_f \mathrm{SEN}^\flat(\Sigma)\}.$$

We say that a collection R of Gentzen rules is **accumulative** if it is the union of accumulations. We say that a class M of $\mathbf{F}$-structures is an **accumulative class** if it is a Gentzen class specified by an accumulative collection of Gentzen $\mathbf{F}$-rules.

Note, e.g., that both the class of all finitary $\mathbf{F}$-structures having the Deduction Detachment Theorem with respect to $\rightarrow^\flat$ and the class of congruential finitary $\mathbf{F}$-structures are accumulative classes. On the other hand, the class of of all self extensional finitary $\mathbf{F}$-structures is not accumulative.

It is not difficult to see that satisfaction of Gentzen $\mathbf{F}$-rules is preserved under bilogical morphisms between $\mathbf{F}$-structures.

Proposition 1762 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*,* $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ *two* $\mathbf{F}$*-structures,* $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ *a bilogical morphism,* $\Sigma \in |\mathbf{Sign}^\flat|$ *and* $r = \langle \{\Phi_i \vdash \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ *a Gentzen* $\mathbf{F}$*-rule. Then*

$$\mathbb{L} \vDash_\Sigma r \quad \textit{iff} \quad \mathbb{L}' \vDash_\Sigma r.$$

Proof: We have, by the definition of satisfaction and that of bilogical morphism, $\mathbb{L} \vDash_\Sigma r$ if and only if

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi)),$$

if and only if

$$\begin{aligned} &\gamma_{F(\Sigma)}(\alpha_\Sigma(\phi_i)) \in D'_{H(F(\Sigma))}(\gamma_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))),\ i \in I, \\ &\qquad\qquad \text{imply} \quad \gamma_{F(\Sigma)}(\alpha_\Sigma(\phi)) \in D'_{H(F(\Sigma))}(\gamma_{F(\Sigma)}(\alpha_\Sigma(\Phi))), \end{aligned}$$

if and only if

$$\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i)),\ i \in I, \quad \text{imply} \quad \alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi)),$$

if and only if $\mathbb{L}' \vDash_\Sigma r$. ∎

Additionally, we can show that the accumulation of a Gentzen rule holding in a finitary $\mathbf{F}$-structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ necessarily holds in all structures of the form $\mathbb{L}^T = \langle \mathcal{A}, D^T \rangle$, where, for all $T \in \mathrm{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in D^T_\Sigma(\Phi) \quad \text{iff} \quad \phi \in D_\Sigma(T_\Sigma, \Phi).$$

Lemma 1763 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\Sigma \in |\mathbf{Sign}^\flat|$, $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ *be an* $\mathbf{F}$*-rule and* $\mathbb{L} = \langle \mathcal{A}, D \rangle$ *a finitary* $\mathbf{F}$*-structure. If* $\mathbb{L} \vDash_\Sigma \mathrm{acm}(r)$*, then, for all* $T \in \mathrm{ThFam}(\mathbb{L})$*,* $\mathbb{L}^T \vDash_\Sigma \mathrm{acm}(r)$*.*

Proof: Let $X \subseteq_f \mathrm{SEN}^\flat(\Sigma)$ and assume $\alpha_\Sigma(\phi_i) \in D^T_{F(\Sigma)}(\alpha_\Sigma(X), \alpha_\Sigma(\Phi_i))$, for all $i \in I$. By definition,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(T_\Sigma, \alpha_\Sigma(X), \alpha_\Sigma(\Phi_i)),\ i \in I.$$

But $\langle F, \alpha \rangle$ is surjective, whence there exists $\Psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\Psi) = T_\Sigma$. Therefore, we get

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Psi), \alpha_\Sigma(X), \alpha_\Sigma(\Phi_i)),\ i \in I.$$

By finitarity of $\mathbb{L}$, we get that there exists $\Psi' \subseteq_f \Psi$, such that

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Psi'), \alpha_\Sigma(X), \alpha_\Sigma(\Phi_i)),\ i \in I.$$

By the hypothesis, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Psi'), \alpha_\Sigma(X), \alpha_\Sigma(\Phi))$. Since $\Psi' \subseteq \Psi$, we get $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Psi), \alpha_\Sigma(X), \alpha_\Sigma(\Phi))$. Thus,

$$\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(T_\Sigma, \alpha_\Sigma(X), \alpha_\Sigma(\Phi)),$$

i.e., $\alpha_\Sigma(\phi) \in D^T_{F(\Sigma)}(\alpha_\Sigma(X), \alpha_\Sigma(\Phi)$. We conclude that $\mathbb{L}^T \vDash_\Sigma \mathrm{acm}(r)$. ■

Proposition 1764 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *an accumulative class of finitary* $\mathbf{F}$*-structures. If* $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathsf{M}$*, then, for all* $T \in \mathrm{ThFam}(\mathbb{L})$*,* $\mathbb{L}^T = \langle \mathcal{A}, D^T \rangle \in \mathsf{M}$*.*

Proof: Directly by Lemma 1763. ■

Next, we show that, if $\mathcal{I}$ is an accumulative protoalgebraic finitary π-institution, then all full $\mathcal{I}$-structures satisfy the defining Gentzen $\mathbf{F}$-rules of $\mathcal{I}$.

Theorem 1765 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *an accumulative class of finitary* $\mathbf{F}$*-structures. If* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *is a protoalgebraic* π*-institution in* M*, then the full* $\mathcal{I}$*-structures of the form* $\mathbb{L} = \langle \mathcal{A}, D \rangle$*, where* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* F *an isomorphism, are in* M*.*

Proof: Suppose $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a protoalgebraic π-institution in M. By Proposition 1762, it suffices to show that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, $\mathbb{L} = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \in \mathsf{M}$. By protoalgebraicity and Theorem 1577, we get

$$\alpha^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \mathrm{ThFam}(\mathcal{I})^T,$$

where $T = \alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(\varnothing))$. But

$$\langle F,\alpha\rangle : \langle \mathcal{F}, \alpha^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))\rangle \to \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\rangle$$

is a bilogical morphism. Since, by the hypothesis and Proposition 1764, we have $\langle \mathcal{F}, \mathrm{ThFam}(\mathcal{I})^T\rangle \in \mathsf{M}$, we get, by Proposition 1762. $\mathbb{L} \in \mathsf{M}$. ∎

Now we get easily the following results concerning the Deduction Detachment Theorem and congruentiality, respectively.

Corollary 1766 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\to^\flat$: $(\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ a binary natural transformations in $N^\flat$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a finitary π-institution based on $\mathbf{F}$ that has the Deduction Detachment Theorem with respect to $\to^\flat$. Then, every full $\mathcal{I}$-structure of the form $\mathbb{L} = \langle \mathcal{A}, D\rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with F an isomorphism, has the Deduction Detachment Theorem with respect to $\to^\flat$.*

Proof: This follows from Theorem 1765 once it is show that if $\mathcal{I}$ has the Deduction Detachment Property with respect to $\to^\flat$, then it is protoalgebraic. Suppose $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \le T'$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi,\psi\rangle \in \Omega_\Sigma(T)$. Then, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, we have

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \in T_{\Sigma'}.$$

But, by the Deduction Detachment Theorem, this holds if and only if,

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \to^\flat_{\Sigma'} \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}),\\ \qquad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \to^\flat_{\Sigma'} \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in T_{\Sigma'}.\end{array}$$

Since $T \le T'$, we get that

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \to^\flat_{\Sigma'} \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}),\\ \qquad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \to^\flat_{\Sigma'} \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in T'_{\Sigma'}.\end{array}$$

Hence, again by the Deduction Detachment Theorem,

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}) \in T'_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}) \in T'_{\Sigma'}.$$

This gives $\langle \phi,\psi\rangle \in \Omega_\Sigma(T')$. Therefore, $\Omega(T) \le \Omega(T')$ and, hence, $\mathcal{I}$ is protoalgebraic. ∎

Corollary 1767 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a protoalgebraic finitary π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is congruential, then the full $\mathcal{I}$-structures of the form $\mathbb{L} = \langle \mathcal{A}, D\rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with F an isomorphism, are also congruential.*

Proof: This follows from Theorem 1765 and the fact that the class of all congruential finitary **F**-structures is accumulative. ∎

Now we look at the converse, in a certain sense, of the inheritance problem of properties specified by Gentzen **F**-rules. Namely, we identify a type of properties that are bequeathed to the π-institution specified by classes of **F**-structures, when all structures in the class satisfy the property.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and M be a class of **F**-structures. Recall that the π-institution $\mathcal{I}^\mathsf{M} = \langle \mathbf{F}, C^\mathsf{M} \rangle$ determined by, or specified by or generated by, M is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in C^\mathsf{M}_\Sigma(\Phi) & \text{iff} & \text{for all } \langle \mathcal{A}, D \rangle \in \mathsf{M}, \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'),\\ & & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in D_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))).\end{array}$$

Let, now, $\Sigma \in |\mathbf{Sign}^\flat|$ and $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ be a Gentzen **F**-rule. The **structure of** r, denoted $\mathrm{str}(r)$ is the family of all Gentzen **F**-rules of the form

$$\begin{array}{rl}\mathrm{SEN}^\flat(f)(r) := \langle \{ & \!\!\!\mathrm{SEN}^\flat(f)(\Phi_i) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi_i) : i \in I\},\\ & \mathrm{SEN}^\flat(f)(\Phi) \vdash_{\Sigma'} \mathrm{SEN}^\flat(f)(\phi)\rangle,\end{array}$$

where $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. We say that a collection R of Gentzen **F**-rules is **structural** if it is the union of structures. We say that a class M of **F**-structures is a **structural class** if it is a Gentzen class specified by a structural collection of Gentzen **F**-rules.

Lemma 1768 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\Sigma \in |\mathbf{Sign}^\flat|$, $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ *a Gentzen* **F***-rule and* M *a class* **F***-structures. If* $\mathsf{M} \vDash \mathrm{str}(r)$*, then* $\mathrm{str}(r)$ *holds in* $\mathcal{I}^\mathsf{M}$.

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $r = \langle \{\Phi_i \vdash_\Sigma \phi_i : i \in I\}, \Phi \vdash_\Sigma \phi \rangle$ and suppose $\mathsf{M} \vDash \mathrm{str}(r)$ and $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, such that

$$\mathrm{SEN}^\flat(f)(\phi_i) \in C^\mathsf{M}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi_i)), \ i \in I.$$

Then, by definition of $\mathcal{I}^\mathsf{M}$, for all $\langle \mathcal{A}, D \rangle \in \mathsf{M}$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{\ f\ } \Sigma' \xrightarrow{\ g\ } \Sigma''$$

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\phi_i))) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\Phi_i)))), \ i \in I,$$

i.e.,

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi_i)) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\Phi_i))), \ i \in I.$$

Since, by hypothesis, $\mathsf{M} \vDash \mathrm{str}(r)$ and $\langle \mathcal{A}, D\rangle \in \mathsf{M}$, we get

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi)) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\Phi)))$$

and, thus,

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\phi))) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\Phi)))).$$

By the definition of $\mathcal{I}^{\mathsf{M}}$, we conclude that $\mathrm{SEN}^\flat(f)(\phi) \in C^{\mathsf{M}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$. Therefore, $\mathcal{I}^{\mathsf{M}} \vDash \mathrm{str}(r)$. ■

Theorem 1769 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* P *a structural class* $\mathbf{F}$*-structures. If* $\mathsf{M} \subseteq \mathsf{P}$*, then* $\mathcal{I}^{\mathsf{M}} \in \mathsf{P}$*.*

Proof: Suppose that $\mathrm{str}(r)$ is a rule of P. Since $\mathsf{M} \subseteq \mathsf{P}$, $\mathrm{str}(r)$ is a rule of M. Therefore, by Lemma 1768, $\mathrm{str}(r)$ is a rule of $\mathcal{I}^{\mathsf{M}}$. Thus, $\mathcal{I}^{\mathsf{M}}$ satisfies all Gentzen $\mathbf{F}$-rules determining P (since all of them are, by hypothesis, structural) and, therefore, $\mathcal{I}^{\mathsf{M}} \in \mathsf{P}$. ■

An application of Theorem 1769 gives that, if all $\mathbf{F}$-structures in a class M are congruential, then the π-institution determined by the class is also congruential.

Corollary 1770 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* M *a class of congruential* $\mathbf{F}$*-structures. Then* $\mathcal{I}^{\mathsf{M}}$ *is congruential.*

Proof: It suffices, by Theorem 1769 to show that the class of congruential $\mathbf{F}$-structures is a structural class. This is easily seen by observing that it is the class of $\mathbf{F}$-structures specified by $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$\begin{aligned} R_\Sigma = \{\langle \{\Phi, \phi_i \vdash_\Sigma \psi_i,\ \Phi, \psi_i \vdash_\Sigma \phi_i : i < k\},\ \Phi, \sigma^\flat_\Sigma(\vec{\phi}) \vdash_\Sigma \sigma^\flat_\Sigma(\vec{\psi})\rangle :\\ \sigma^\flat \in N^\flat, \Phi \subseteq \mathrm{SEN}^\flat(\Sigma), \vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)\}.\end{aligned}$$

It is easy to check that R is a structural class of Gentzen $\mathbf{F}$-rules, whence the class of all congruential $\mathbf{F}$-structures is a structural class. ■

23.5 Fregeanity and Congruence Orderability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a $\top^\flat$-pointed guasivariety of $\mathbf{F}$-algebraic systems.

We say that K is **congruence orderable** if, for all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathsf{K}$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned} \phi = \psi \quad \text{if} \quad & \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'),\\ & \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}^\flat(f)(\phi), \top^{\mathcal{A}}_{\Sigma'}) = \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}^\flat(f)(\psi), \top^{\mathcal{A}}_{\Sigma'}).\end{aligned}$$

Moreover, we say that K is **Fregean** if it is both relatively point regular and congruence orderable.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, and K a $\top^\flat$-pointed guasivariety of $\mathbf{F}$-algebraic systems. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, define the relation family

$$\leq^{\mathsf{K},\mathcal{A}} = \{\leq^{\mathsf{K},\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$$

on $\mathcal{A}$ by letting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll} \phi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \psi & \text{iff} & \text{for all } \Sigma' \in |\mathbf{Sign}, f \in \mathbf{Sign}(\Sigma, \Sigma'), \\ & & \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\phi), \top^{\mathcal{A}}_{\Sigma'}) \geq \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\psi), \top^{\mathcal{A}}_{\Sigma'}). \end{array}$$

We show that $\leq^{\mathsf{K},\mathcal{A}}$ is in fact a quasiordering system (**qosystem**, for short) on $\mathcal{A}$.

Proposition 1771 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a* $\top^\flat$*-pointed guasivariety of* $\mathbf{F}$*-algebraic systems. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\leq^{\mathsf{K},\mathcal{A}}$ *is a quasiordering system on* $\mathcal{A}$.

Proof: Let $\Sigma \in |\mathbf{Sign}|$. Since, for all $\phi \in \mathrm{SEN}(\Sigma)$, all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\phi), \top^{\mathcal{A}}_{\Sigma'}) = \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\phi), \top^{\mathcal{A}}_{\Sigma'})$, we get that $\phi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \phi$ and $\leq^{\mathsf{K},\mathcal{A}}$ is reflexive. Since, for all $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$, if $\phi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \psi$ and $\psi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \chi$ imply, by definition, that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

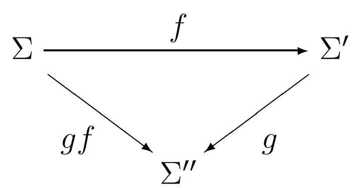
$$\Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\phi), \top^{\mathcal{A}}_{\Sigma'}) \geq \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\psi), \top^{\mathcal{A}}_{\Sigma'}) \geq \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\chi), \top^{\mathcal{A}}_{\Sigma'}),$$

we, get, again by definition, $\phi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \chi$. Thus, $\leq^{\mathsf{K},\mathcal{A}}$ is also transitive.

Finally, suppose $\phi \leq^{\mathsf{K},\mathcal{A}}_\Sigma \psi$ and let $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$. Then, by definition, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $h \in \mathbf{Sign}(\Sigma, \Sigma'')$, we get

$$\Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(h)(\phi), \top^{\mathcal{A}}_{\Sigma''}) \geq \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(h)(\psi), \top^{\mathcal{A}}_{\Sigma''}).$$

In particular, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$,



$$\Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\phi)), \top^{\mathcal{A}}_{\Sigma''}) \geq \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\psi)), \top^{\mathcal{A}}_{\Sigma''}),$$

i.e., $\mathrm{SEN}(f)(\phi) \leq^{\mathsf{K},\mathcal{A}}_{\Sigma'} \mathrm{SEN}(f)(\psi)$ and $\leq^{\mathsf{K},\mathcal{A}}$ is a system. ■

Corollary 1772 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a* $\top^\flat$*-pointed guasivariety of* $\mathbf{F}$*-algebraic systems. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the qosystem* $\leq^{\mathsf{K},\mathcal{A}}$ *is a posystem if and only if* K *is congruence orderable.*

Proof: Clear, by Proposition 1772 and the definitions of $\leq^{\mathsf{K},\mathcal{A}}$ and of congruence orderability. ■

Recall the assertional π-institution $\mathcal{I}^{\mathsf{K},\top}$ associated with a $\top^\flat$-pointed guasivariety K of $\mathbf{F}$-algebraic systems. Recall, also, that, if $\mathcal{I}^{\mathsf{K},\top}$ is family regular, protoalgebraic, with $\top^\flat$ a natural theorem, then the guasivariety K is relatively point regular.

We show, next, that, if $\mathcal{I}^{\mathsf{K},\top}$ is strongly Fregean, protoalgebraic, with $\top^\flat$ a natural theorem, then it is also family regular. Thus, the property of being strongly Freagean, protoalgebraic, with $\top^\flat$ a natural theorem is stronger than being family regular, protoalgebraic, with $\top^\flat$ a natural theorem. In terms of the $\top^\flat$-pointed guasivariety K, this is reflected, as we shall see in the following theorem, in the fact that, in additional to being relatively point regular, it is also congruence orderable, i.e., it is a Fregean guasivariety of $\mathbf{F}$-algebraic systems.

Lemma 1773 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a* $\top^\flat$*-pointed guasivariety of* $\mathbf{F}$*-algebraic systems. If* $\mathcal{I}^{\mathsf{K},\top} = \langle \mathbf{F}, C^{\mathsf{K},\top} \rangle$ *is Fregean, then it is also family regular.*

Proof: Suppose $\mathcal{I}^{\mathsf{K},\top}$ is Fregean. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and consider the theory family $C^{\mathsf{K},\top}(\phi, \psi)$. We have, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$C^{\mathsf{K},\top}_{\Sigma'}(C^{\mathsf{K},\top}_{\Sigma'}(\phi,\psi), \mathrm{SEN}^\flat(f)(\phi)) = C^{\mathsf{K},\top}_{\Sigma'}(\phi,\psi) = C^{\mathsf{K},\top}_{\Sigma'}(C^{\mathsf{K},\top}_{\Sigma'}(\phi,\psi), \mathrm{SEN}^\flat(f)(\psi)).$$

Therefore, we get

$$\begin{array}{rcll}\langle \phi, \psi \rangle & \in & \widetilde{\Lambda}_\Sigma(C^{\mathsf{K},\top}(\phi,\psi)) & \\ & = & \widetilde{\Omega}_\Sigma(C^{\mathsf{K},\top}(\phi,\psi)) & \text{(by Fregeanity)} \\ & \subseteq & \Omega_\Sigma(C^{\mathsf{K},\top}(\phi,\psi)). & \end{array}$$

This shows that $\mathcal{I}^{\mathsf{K},\top}$ is family regular. ■

Theorem 1774 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, and* K *a* $\top^\flat$*-pointed guasivariety of* $\mathbf{F}$*-algebraic systems. If* $\mathcal{I}^{\mathsf{K},\top} = \langle \mathbf{F}, C^{\mathsf{K},\top} \rangle$ *is Fregean, protoalgebraic, with* $\top^\flat$ *a natural theorem, then* K *is Fregean.*

Proof: Since $\mathcal{I}^{\mathsf{K},\top}$ is Fregean, by Lemma 1774, it is family regular. Since $\mathcal{I}^{\mathsf{K},\top}$ is family regular, protoalgebraic, with $\top^\flat$ a natural theorem, by Theorem 1356, K is a relatively point regular guasivariety of **F**-algebraic systems. Thus, to show that K ir Fregean, it suffices, by definition, to show that it is also congruence orderable.

To this end, assume that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathsf{K}$, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\phi), \top^{\mathcal{A}}_{\Sigma'}) = \Theta^{\mathsf{K},\mathcal{A}}(\mathrm{SEN}(f)(\psi), \top^{\mathcal{A}}_{\Sigma'}).$$

This is equivalent to asserting that

$$C_\Sigma^{\mathcal{I}^{\mathsf{K},\top},\mathcal{A}}(\phi) = C_\Sigma^{\mathcal{I}^{\mathsf{K},\top},\mathcal{A}}(\psi).$$

Thus, we obtain

$$\begin{array}{lll}\langle \phi, \psi\rangle & \in & \widetilde{\Lambda}^{\mathcal{A}}_\Sigma(\mathrm{FiFam}^{\mathcal{I}^{\mathsf{K},\top}}(\mathcal{A})) \quad \text{(definition of Frege relation)}\\ & = & \widetilde{\Omega}^{\mathcal{A}}_\Sigma(\mathrm{FiFam}^{\mathcal{I}^{\mathsf{K},\top}}(\mathcal{A})) \quad \text{(Fregeanity)}\\ & = & \Omega^{\mathcal{A}}_\Sigma(\{\top^{\mathcal{A}}\}) \quad \text{(protoalgebraicity)}\\ & = & \Delta^{\mathcal{A}}_\Sigma.\end{array}$$

We conclude that $\phi = \psi$ and, therefore, K is also congruence orderable. ∎

To conclude the section, we would like to prove the converse of Theorem 1774, i.e., that, if K is a Fregean class of **F**-algebraic systems, then the assertional π-institution $\mathcal{I}^{\mathsf{K},top}$ of K is a Fregean, protoalgebraic π-institution with $\top^\flat$ a natural theorem. Parts of the conclusion, we have already obtained in Theorem 1356. To obtain the full conclusion, we work towards the only remaining subgoal, expressed in the following proposition.

Proposition 1775 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a* $\top^\flat$*-pointed class of* **F***-algebraic systems. If* K *is Fregean, then the assertional* π*-institution* $\mathcal{I}^{\mathsf{K},\top} = \langle \mathbf{F}, C^{\mathsf{K},\top}\rangle$ *of* K *is Fregean.*

Proof: Suppose K is a Fregean guasivariety of **F**-algebraic systems, i.e., relatively point regular and congruence orderable. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$, $\widetilde{\Lambda}^{\mathcal{I}^{\mathsf{K},\top}}(T) = \widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}(T)$. Let $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{K},\top})$. Since $\widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}(T) \leq \widetilde{\Lambda}^{\mathcal{I}^{\mathsf{K},\top}}(T)$ always holds, it suffices to show the reverse inclusion, i.e., that $\widetilde{\Lambda}^{\mathcal{I}^{\mathsf{K},\top}}(T) \leq \widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}(T)$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi\rangle \notin \widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}_\Sigma(T)$. Equivalently, $\phi/\widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}_\Sigma(T) \neq \psi/\widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}_\Sigma(T)$. Let us denote, for the sake of brevity $\theta := \widetilde{\Omega}^{\mathcal{I}^{\mathsf{K},\top}}(T)$. Then, by Lemma 1351 and Proposition 1352, $\mathcal{F}/\theta \in \mathsf{K}$. Thus,y congruence orderability, there exists $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, such that

$$\Theta^{\mathsf{K},\mathcal{F}/\theta}(\mathrm{SEN}^\flat(f)(\phi)/\theta_{\Sigma'}, \top^{\mathcal{F}/\theta}_{\Sigma'}) \neq \Theta^{\mathsf{K},\mathcal{F}/\theta}(\mathrm{SEN}^\flat(f)(\psi)/\theta_{\Sigma'}, \top^{\mathcal{F}/\theta}_{\Sigma'}).$$

Thus, by relative point regularity, we must have

$$\top^{\mathcal{F}/\theta}/\Theta^{\mathsf{K},\mathcal{F}/\theta}(\mathrm{SEN}^\flat(f)(\phi)/\theta_{\Sigma'},\top_{\Sigma'}^{\mathcal{F}/\theta}) \neq \top^{\mathcal{F}/\theta}/\Theta^{\mathsf{K},\mathcal{F}/\theta}(\mathrm{SEN}^\flat(f)(\psi)/\theta_{\Sigma'},\top_{\Sigma'}^{\mathcal{F}/\theta}).$$

This gives that

$$C_\Sigma^{\mathsf{K},\top}(\mathrm{SEN}^\flat(f)(\phi),\top^\flat_{\Sigma'}/\Omega_{\Sigma'}(T)) \neq C_\Sigma^{\mathsf{K},\top}(\mathrm{SEN}^\flat(f)(\phi),\top^\flat_{\Sigma'}/\Omega_{\Sigma'}(T)),$$

which translates to $\langle\phi,\psi\rangle \notin \widetilde{\Lambda}_\Sigma^{\mathcal{I}^{\mathsf{K},\top}}(T)$. We conclude that $\mathcal{I}^{\mathsf{K},\top}$ is Fregean. ■

Finally, putting this together, we get

Theorem 1776 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems. If K is Fregean, then $\mathcal{I}^{\mathsf{K},\top} = \langle\mathbf{F},C^{\mathsf{K},\top}\rangle$ is a Fregean, protoalgebraic π-institution, with $\top^\flat$ a natural theorem.*

Proof: By Proposition 1348, $\top^\flat$ is a natural theorem of $\mathcal{I}^{\mathsf{K},\top}$. By Proposition 1352, $\mathcal{I}^{\mathsf{K},\top}$ is protoalgebraic. Finally, by Proposition 1775, $\mathcal{I}^{\mathsf{K},\top}$ is Fregean. ■

The main result proven in this section is summarized in

Theorem 1777 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and K a $\top^\flat$-pointed class of $\mathbf{F}$-algebraic systems. K is Fregean if and only if $\mathcal{I}^{\mathsf{K},\top} = \langle\mathbf{F},C^{\mathsf{K},\top}\rangle$ is a Fregean, protoalgebraic π-institution, with $\top^\flat$ a natural theorem.*

Proof: The "if" by Theorem 1774. The "only if" by Theorem 1776. ■

Chapter 24

Special Topics

24.1 Rule Based π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system.

An **F-rule** is a pair $\langle P, \rho \rangle$, where $P \cup \{\rho\} : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ is a finite set of natural transformations in $N^\flat$. If $P = \varnothing$, then $\langle \varnothing, \rho \rangle$ is called an **F-axiom** and it is ordinarily identified with ρ.

Let $R = \langle P, \rho \rangle$ be an **F**-rule, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. We say ϕ R-**follows from** Φ, written $\Phi \to^R_\Sigma \phi$, if there exists $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$P_\Sigma(\vec{\chi}) \subseteq \Phi \quad \text{and} \quad \rho_\Sigma(\vec{\chi}) = \phi.$$

Consider, now, a set $\mathcal{R}$ of **F**-rules. For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, we say ϕ is $\mathcal{R}$-**provable from** Φ, written $\phi \in C^{\mathcal{R}}_\Sigma(\Phi)$ or $\Phi \vdash^{\mathcal{R}}_\Sigma \phi$, if there exists a sequence

$$\phi_0, \phi_1, \phi_2, \dots, \phi_{n-1}, \phi_n$$

in $\mathrm{SEN}^\flat(\Sigma)$, such that $\phi_n = \phi$ and, for all $i \le n$,

- $\phi_i \in \Phi$ or
- ϕ_i R-follows from $\{\phi_0, \phi_1, \dots, \phi_{i-1}\}$, for some $R \in \mathcal{R}$.

A sequence $\phi_0, \phi_1, \dots, \phi_n$ witnessing $\Phi \vdash^{\mathcal{R}}_\Sigma \phi$ is called an $\mathcal{R}$-**proof** of ϕ from Φ.

We show that $C^{\mathcal{R}}$, as defined here, is indeed a closure system on the base algebraic system **F**.

Proposition 1778 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{R}$ *a collection of* **F***-rules. Then* $C^{\mathcal{R}} = \{C^{\mathcal{R}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ *is a closure system on* **F**.

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$.

(i) If $\phi \in \Phi$, then ϕ is an $\mathcal{R}$-proof of ϕ from Φ. So $\phi \in C^{\mathcal{R}}_\Sigma(\Phi)$ and $C^{\mathcal{R}}$ is inflationary.

(ii) If $\Phi \subseteq \Psi$ and $\phi \in C^{\mathcal{R}}_\Sigma(\Phi)$, then, there exists an $\mathcal{R}$-proof of ϕ from Φ. The same sequence is then an $\mathcal{R}$-proof of ϕ from Ψ. So $\phi \in C^{\mathcal{R}}_\Sigma(\Psi)$ and $C^{\mathcal{R}}$ is monotone.

(iii) Suppose $\phi \in C^{\mathcal{R}}_\Sigma(C^{\mathcal{R}}_\Sigma(\Phi))$. Then, there exists an $\mathcal{R}$-proof of ϕ from $C^{\mathcal{R}}_\Sigma(\Phi)$, say

$$\phi_0, \phi_1, \dots, \phi_{n-1}, \phi_n = \phi.$$

Then, for each $\phi_i \in C^{\mathcal{R}}_\Sigma(\Phi)$, there exists an $\mathcal{R}$-proof of ϕ_i from Φ. For each such ϕ_i, we insert its $\mathcal{R}$-proof from Φ in its place in the sequence. The new sequence is an $\mathcal{R}$-proof of ϕ from Φ. Thus, we get that $\phi \in C^{\mathcal{R}}_\Sigma(\Phi)$ and $C^{\mathcal{R}}$ is also idempotent.

(iv) Finally, it remains to show structurality. Let $\Sigma,\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathcal{R}}_\Sigma(\Phi)$. Let $\phi_0,\phi_1,\ldots,\phi_{n-1},\phi_n = \phi$ be an $\mathcal{R}$-proof of ϕ from Φ. We consider the sequence

$$\mathrm{SEN}^\flat(f)(\phi_0),\mathrm{SEN}^\flat(f)(\phi_1),\ldots,\mathrm{SEN}^\flat(f)(\phi_{n-1}),\mathrm{SEN}^\flat(f)(\phi_n).$$

Then $\mathrm{SEN}^\flat(f)(\phi_n) = \mathrm{SEN}^\flat(f)(\phi)$ and, moreover, for all $i \le n$, if $\phi_i \in \Phi$, then $\mathrm{SEN}^\flat(f)(\phi_i) \in \mathrm{SEN}^\flat(f)(\Phi)$, and, if ϕ_i R-follows from $\{\phi_0,\phi_1,\ldots,\phi_{i-1}\}$, for some $R \in \mathcal{R}$, then $\mathrm{SEN}^\flat(f)(\phi_i)$ R-follows from $\{\mathrm{SEN}^\flat(f)(\phi_0),\mathrm{SEN}^\flat(f)(\phi_1),\ldots,\mathrm{SEN}^\flat(f)(\phi_{i-1})\}$ because of the naturality of R. So, the displayed sequence is an $\mathcal{R}$-proof of $\mathrm{SEN}^\flat(f)(\phi)$ from $\mathrm{SEN}^\flat(f)(\Phi)$ and $C^{\mathcal{R}}$ is also structural.

We conclude that $C^{\mathcal{R}}$ is a closure system on $\mathbf{F}$. ■

We denote by $\mathcal{I}^{\mathcal{R}} = \langle \mathbf{F}, C^{\mathcal{R}}\rangle$ the π-institution corresponding to $C^{\mathcal{R}}$.

In general, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, we say that $\mathcal{I}$ is **rule based** if there exists a collection $\mathcal{R}$ of $\mathbf{F}$-rules, such that $C = C^{\mathcal{R}}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{R}$ a collection of $\mathbf{F}$-rules, $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, an $\mathbf{F}$-algebraic system and $T \in \mathrm{SenFam}(\mathcal{A})$. We say that T is **closed under** $\mathcal{R}$ or is $\mathcal{R}$-**closed** if, for all $R = \langle P,\rho\rangle \in \mathcal{R}$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$,

$$P^{\mathcal{A}}_\Sigma(\vec{\chi}) \subseteq T_\Sigma \quad \text{implies} \quad \rho^{\mathcal{A}}_\Sigma(\vec{\chi}) \in T_\Sigma.$$

This terminology allows the following elegant characterization of $\mathcal{I}^{\mathcal{R}}$-filter families of $\mathcal{A}$.

Proposition 1779 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{R}$ *a collection of* $\mathbf{F}$*-rules,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*, an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{SenFam}(\mathcal{A})$*. Then* $T \in \mathrm{FiFam}^{\mathcal{I}^{\mathcal{R}}}(\mathcal{A})$ *if and only if* T *is* $\mathcal{R}$*-closed.*

Proof: Assume, first, that $T \in \mathrm{FiFam}^{\mathcal{I}^{\mathcal{R}}}(\mathcal{A})$, $R = \langle P,\rho\rangle \in \mathcal{R}$ and, using surjectivity of $\langle F,\alpha\rangle$, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$P^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}.$$

Then we get $\alpha_\Sigma(P_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}$. Since, by the definition of $C^{\mathcal{I}^{\mathcal{R}}}$, $\rho_\Sigma(\vec{\chi}) \in C^{\mathcal{I}^{\mathcal{R}}}_\Sigma(P_\Sigma(\vec{\chi}))$ and, by hypothesis, $T \in \mathrm{FiFam}^{\mathcal{I}^{\mathcal{R}}}(\mathcal{A})$, we get $\alpha_\Sigma(\rho_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$ or, equivalently, $\rho^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$. Thus, T is $\mathcal{R}$-closed.

Suppose, conversely, that $T \in \mathrm{SenFam}(\mathcal{A})$ is $\mathcal{R}$-closed. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^{\mathcal{I}^{\mathcal{R}}}_\Sigma(\Phi)$ and consider $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, such that

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}.$$

Since $\phi \in C_\Sigma^{\mathcal{I}^\mathcal{R}}(\Phi)$, there exists an $\mathcal{R}$-proof of ϕ from Φ, say

$$\phi_0, \phi_1, \dots, \phi_{n-1}, \phi_n = \phi.$$

We prove by induction on $i \le n$ that, every member of the sequence

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_0)), \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_1)), \dots, \\ \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_{n-1})), \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_n))$$

belongs to $T_{F(\Sigma')}$. The case $i = n$, will yield the desired conclusion.

First, if $\phi_i \in \Phi$, then $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_i)) \in \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}$, where the latter inclusion holds by hypothesis.

Suppose, on the other hand, that ϕ_i R-follows from $\{\phi_0, \phi_1, \dots, \phi_{i-1}\}$, for some $R = \langle P, \rho\rangle \in \mathcal{R}$. Thus, there exists $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$P_\Sigma(\vec{\chi}) \subseteq \{\phi_0, \phi_1, \dots, \phi_{i-1}\} \quad \text{and} \quad \rho_\Sigma(\vec{\chi}) = \phi_i.$$

But then

$$\begin{array}{rcl} P^\mathcal{A}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\chi}))) & = & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(P_\Sigma(\vec{\chi}))) \\ & \subseteq & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\{\phi_0, \dots, \phi_{i-1}\})) \\ & \subseteq & T_{F(\Sigma')}, \end{array}$$

where the last inclusion follows by the induction hypothesis, and, hence, since T is $\mathcal{R}$-closed, we get that $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_i)) = \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\rho_\Sigma(\vec{\chi}))) = \rho^\mathcal{A}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\chi}))) \in T_{F(\Sigma')}$. This concludes the induction step and shows that, for all $i \le n$, $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_i)) \in T_{F(\Sigma')}$. ■

In addition, we can characterize $\mathcal{I}^\mathcal{R}$-filter families generated by a given sentence family as follows.

Proposition 1780 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{R}$ *a collection of* $\mathbf{F}$*-rules,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*, an* $\mathbf{F}$*-algebraic system and* $X \in \mathrm{SenFam}(\mathcal{A})$*. Then, for all* $\Sigma \in |\mathbf{Sign}|$*,*

$$C_\Sigma^{\mathcal{I}^\mathcal{R}, \mathcal{A}}(X) = \{\phi \in \mathrm{SEN}(\Sigma) : X_\Sigma \vdash_\Sigma^\mathcal{R} \phi\}.$$

Proof: Define $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, by letting, for all $\Sigma \in |\mathbf{Sign}|$,

$$T_\Sigma = \{\phi \in \mathrm{SEN}(\Sigma) : X_\Sigma \vdash_\Sigma^\mathcal{R} \phi\}.$$

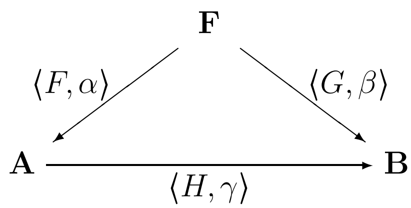
It is not difficult to see that $X \le T$ and T is $\mathcal{R}$-closed. Thus, by Proposition 1779, $C^{\mathcal{I}^\mathcal{R}, \mathcal{A}}(X) \le T$. On the other hand, if $T' \in \mathrm{SenFam}(\mathcal{I})$ contains X and is $\mathcal{R}$-closed, then $T \le T'$. Therefore, we conclude that $T \le C^{\mathcal{I}^\mathcal{R}, \mathcal{A}}(X)$. Equality now follows. ■

24.2 Operators on Classes of Matrix Families

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system. Recall that an $\mathbf{F}$-algebraic system is a pair $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, where $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ is an $N^\flat$-algebraic system and $\langle F, \alpha \rangle : \mathbf{F} \to \mathbf{A}$ is a surjective $N^\flat$-algebraic system morphism. Recall, also, that an $\mathbf{F}$-matrix family is a pair $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, where $\mathcal{A}$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{SenFam}(\mathbf{A})$ is a sentence family on $\mathbf{A}$.

We define now some class operators on classes of $\mathbf{F}$-matrix families, i.e., operators that, given, as input a class of $\mathbf{F}$-matrix families, produce a new class of $\mathbf{F}$-matrix families.

Given $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, and $\mathbf{F}$-matrix families $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $\mathfrak{B} = \langle \mathcal{B}, T' \rangle$, we say that $\mathfrak{B}$ is a **morphic image** of $\mathfrak{A}$ and write $\mathfrak{B} \in \mathbb{M}(\mathfrak{A})$, if there exists a surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ (that is, such that $\langle G, \beta \rangle = \langle H, \gamma \rangle \circ \langle F, \alpha \rangle$)



such that

$$\gamma^{-1}(T') = T.$$

In this case, we call $\mathfrak{A}$ an **inverse morphic image** or a **morphic preimage** of $\mathfrak{B}$ and write $\mathfrak{A} \in \mathbb{M}^{-1}(\mathfrak{B})$.

Given a class M of $\mathbf{F}$-matrix families, we write $\mathfrak{B} \in \mathbb{M}(\mathsf{M})$ if there exists $\mathfrak{A} \in \mathsf{M}$, such that $\mathfrak{B} \in \mathbb{M}(\mathfrak{A})$.

Similarly, we write $\mathfrak{A} \in \mathbb{M}^{-1}(\mathsf{M})$ if there exists $\mathfrak{B} \in \mathsf{M}$, such that $\mathfrak{A} \in \mathbb{M}^{-1}(\mathfrak{B})$.

It is not difficult to show that both $\mathbb{M}$ and $\mathbb{M}^{-1}$ are closure operators on the collection of all $\mathbf{F}$-matrix families.

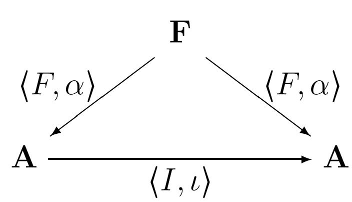
Lemma 1781 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*

$$\mathbb{M}, \mathbb{M}^{-1} : \mathcal{P}(\mathrm{MatFam}(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}(\mathbf{F}))$$

are closure operators on $\mathrm{MatFam}(\mathbf{F})$.

Proof: We prove the statement for $\mathbb{M}$ in detail. The proof for $\mathbb{M}^{-1}$ is similar.

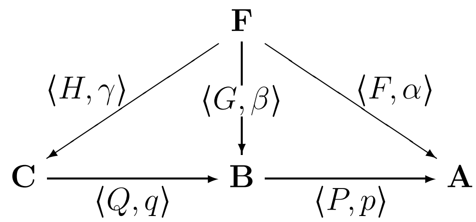
Suppose, first, that M is a class of $\mathbf{F}$-matrix families and $\mathfrak{A} \in \mathsf{M}$. Then, the diagram



where $\langle I, \iota\rangle : \mathcal{A} \to \mathcal{A}$ is the identity morphism, shows that $\mathfrak{A} \in \mathbb{M}(\mathsf{M})$. Therefore, $\mathbb{M}$ is inflationary.

Monotonicity is obvious, since, if M, N are classes of $\mathbf{F}$-matrix families, such that $\mathsf{M} \subseteq \mathsf{N}$, and $\mathfrak{A} \in \mathbb{M}(\mathsf{M})$, then, by definition, $\mathfrak{A} \in \mathbb{M}(\mathfrak{B})$, with $\mathcal{B} \in \mathsf{M}$. But then, since $\mathsf{M} \subseteq \mathsf{N}$, $\mathfrak{A} \in \mathbb{M}(\mathfrak{B})$, with $\mathcal{B} \in \mathsf{N}$ and, again, by definition, $\mathfrak{A} \in \mathbb{M}(\mathsf{N})$. Thus, we have $\mathbb{M}(\mathsf{M}) \subseteq \mathbb{M}(\mathsf{N})$.

Finally, assume that M is a class of $\mathbf{F}$-matrix families and $\mathfrak{A} \in \mathbb{M}(\mathbb{M}(\mathsf{M}))$. Then, there exists $\mathfrak{B} \in \mathbb{M}(\mathsf{M})$, such that $\mathfrak{A} \in \mathbb{M}(\mathfrak{B})$. Furthermore, there exists $\mathfrak{C} \in \mathsf{M}$, such that $\mathfrak{B} \in \mathbb{M}(\mathfrak{C})$. But these two statements combined reveal the existence of the following diagram, in which the two small triangles commute.



As a result, the big triangle also commutes and this ensures that $\mathfrak{A} \in \mathbb{M}(\mathfrak{C})$, which yields $\mathfrak{A} \in \mathbb{M}(\mathsf{M})$. ■

Next, we introduce another class operator on classes of $\mathbf{F}$-matrix families.

Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\mathfrak{A}^i = \langle \mathcal{A}, T^i\rangle$, $i \in I$, a collection of $\mathbf{F}$-matrix families, all over $\mathcal{A}$. Define the **intersection** of the $\mathfrak{A}^i$, $i \in I$, as the $\mathbf{F}$-matrix family, with the same underlying $\mathbf{F}$-algebraic system $\mathcal{A}$ and with filter family the intersection of the T^i's; more formally

$$\bigcap_{i\in I} \mathfrak{A}^i = \langle \mathcal{A}, \bigcap_{i\in I} T^i\rangle.$$

Given a class M of $\mathbf{F}$-matrix families and an $\mathbf{F}$-matrix family $\mathfrak{B}$, we write $\mathfrak{B} \in \mathbb{I}(\mathsf{M})$ if $\mathfrak{B}$ is the intersection of members of M, i.e., $\mathfrak{B} = \bigcap_{i\in I} \mathfrak{A}^i$, with $\mathfrak{A}^i \in \mathsf{M}$, for all $i \in I$.

Again, it is not difficult to show that $\mathbb{I}$ is a closure operator on the collection of $\mathbf{F}$-matrix families.

Lemma 1782 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system. Then*

$$\mathbb{I} : \mathcal{P}(\mathrm{MatFam}(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}(\mathbf{F}))$$

is a closure operator on $\mathrm{MatFam}(\mathbf{F})$.

Proof: To show inflationarity, notice that, trivially, for all $\mathfrak{A} \in \mathsf{M}$, $\mathfrak{A} = \bigcap\{\mathfrak{A}\}$, whence $\mathfrak{A} \in \mathbb{I}(\mathsf{M})$.

Monotonicity is straightforward, since, if $\mathsf{M} \subseteq \mathsf{N}$ and $\mathfrak{A} \in \mathbb{I}(\mathsf{M})$, then $\mathfrak{A} = \bigcap_{i\in I} \mathfrak{A}^i$, with $\mathfrak{A}^i \in \mathsf{M}$, for all $i \in I$, and, hence, $\mathfrak{A} = \bigcap_{i\in I} \mathfrak{A}^i$, with $\mathfrak{A}^i \in \mathsf{N}$, for all $i \in I$. So $\mathfrak{A} \in \mathbb{I}(\mathsf{N})$.

Finally, for transitivity, if $\mathfrak{A} \in \mathbb{I}\mathbb{I}(\mathbb{I}\mathbb{I}(\mathsf{M}))$, then $\mathfrak{A} = \bigcap_{i\in I}\mathfrak{A}^i$, where $\mathfrak{A}^i \in \mathbb{I}\mathbb{I}(\mathsf{M})$, for all $i \in I$. Thus, for all $i \in I$, $\mathfrak{A}^i = \bigcap_{j\in J_i}\mathfrak{A}^{ij}$, where $\mathfrak{A}^{ij} \in \mathsf{M}$, for all $j \in J_i$. Therefore, we get

$$\mathfrak{A} = \bigcap_{i\in I}\mathfrak{A}^i = \bigcap_{i\in I}\bigcap_{j\in J_i}\mathfrak{A}^{ij},$$

where $\mathfrak{A}^{ij} \in \mathsf{M}$, for all $i \in I$, $j \in J_i$, and, hence, $\mathfrak{A} \in \mathbb{I}\mathbb{I}(\mathsf{M})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and M a class of $\mathbf{F}$-matrix families. Recall the closure system $C^{\mathsf{M}} : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$ on $\mathbf{F}$ generated by M. It is defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, by $\phi \in C^{\mathsf{M}}_\Sigma(\Phi)$ if and only if, for all $\mathfrak{A} = \langle \mathcal{A}, T\rangle \in \mathsf{M}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}.$$

$\mathcal{I}^{\mathsf{M}} = \langle \mathbf{F}, C^{\mathsf{M}}\rangle$ denotes the corresponding π-institution generated by M.

Now, given a π-institution $\mathcal{I}$, one can consider its matrix family models, i.e., those $\mathbf{F}$-matrix families $\mathfrak{A}$, such that

$$\mathcal{I} \le \mathcal{I}^{\mathfrak{A}}.$$

Doing this for the specific π-institution $\mathcal{I}^{\mathsf{M}}$, generated by the class M of $\mathbf{F}$-matrix families, we consider the class $\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})$ of $\mathcal{I}^{\mathsf{M}}$-matrix families. Clearly, since, for every $\mathfrak{A} \in \mathsf{M}$, $C^{\mathsf{M}} \le C^{\mathfrak{A}}$,

$$\mathsf{M} \subseteq \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}).$$

In the spirit of many classical problems in universal algebraic logic, the following question naturally arises:

> Characterize $\mathrm{MathFam}(\mathcal{I}^{\mathsf{M}})$, i.e., find a list of operators on classes of $\mathbf{F}$-matrix families so that, when applied to M consecutively, they generate the class $\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})$.

Our goal here is to show that the list of operators that are needed consists of $\mathbb{M}\mathbb{I}\mathbb{I}\mathbb{M}^{-1}$, i.e., that, given any class M of $\mathbf{F}$-matrix families, we have

$$\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}) = \mathbb{M}\mathbb{I}\mathbb{I}\mathbb{M}^{-1}(\mathsf{M}).$$

We start by showing that applying each of the three operators to classes of matrix family models of a π-institution $\mathcal{I}$ always results in classes of the same character.

Proposition 1783 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

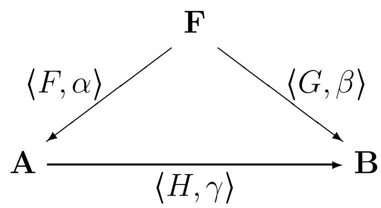
(a) $\mathbb{I}\mathbb{M}(\text{MatFam}(\mathcal{I})) \subseteq \text{MatFam}(\mathcal{I})$*;*

(b) $\mathbb{I}\mathbb{I}(\text{MatFam}(\mathcal{I})) \subseteq \text{MatFam}(\mathcal{I})$*;*

(c) $\mathbb{I}\mathbb{M}^{-1}(\text{MatFam}(\mathcal{I})) \subseteq \text{MatFam}(\mathcal{I})$*.*

Proof:

(a) Let $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \text{MatFam}(\mathcal{I})$ and consider a surjective morphism $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{B}$, where $\mathfrak{B} = \langle \mathcal{B}, T' \rangle$, as in the diagram.



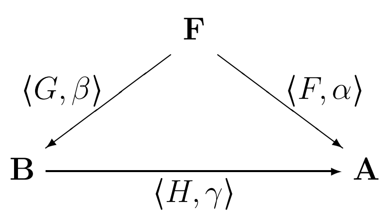
We now have

$$\beta^{-1}(T') = \alpha^{-1}(\gamma^{-1}(T')) = \alpha^{-1}(T) \in \text{ThFam}(\mathcal{I}),$$

where the last membership follows by the hypothesis and Lemma 51. Thus, again by Lemma 51, we get that $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, hence, $\mathfrak{B} \in \text{MatFam}(\mathcal{I})$.

(b) Suppose, next, that $\mathfrak{A}^i = \langle \mathcal{A}, T^i \rangle$, $i \in I$, are $\mathcal{I}$-matrix families. Then $T^i \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, for all $i \in I$. Since the collection $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$ forms a closure system on $\mathcal{A}$, it follows that $\bigcap_{i \in I} T^i \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, we get that $\bigcap_{i \in I} \mathfrak{A}^i \in \text{MatFam}(\mathcal{I})$. So $\text{MatFam}(\mathcal{I})$ is closed under $\mathbb{I}\mathbb{I}$.

(c) Let $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \text{MatFam}(\mathcal{I})$ and consider a surjective morphism $\langle H, \gamma \rangle : \mathfrak{B} \to \mathfrak{A}$, where $\mathfrak{B} = \langle \mathcal{B}, T' \rangle$, as in the diagram.



We now have

$$\beta^{-1}(T') = \beta^{-1}(\gamma^{-1}(T)) = \alpha^{-1}(T) \in \text{ThFam}(\mathcal{I}),$$

where the last membership follows by the hypothesis and Lemma 51. Thus, again by Lemma 51, we get that $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, hence, $\mathfrak{B} \in \text{MatFam}(\mathcal{I})$.

■

Proposition 1783 gives

Corollary 1784 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$\mathbb{M}\mathbb{\Pi}\mathbb{I}\mathbb{M}^{-1}(\mathrm{MatFam}(\mathcal{I})) \subseteq \mathrm{MatFam}(\mathcal{I}).$$

Proof: We have, using Proposition 1783,

$$\begin{array}{rcl}\mathbb{M}\mathbb{\Pi}\mathbb{I}\mathbb{M}^{-1}(\mathrm{MatFam}(\mathcal{I})) & \subseteq & \mathbb{M}\mathbb{\Pi}(\mathrm{MatFam}(\mathcal{I})) \\ & \subseteq & \mathbb{M}(\mathrm{MatFam}(\mathcal{I})) \\ & \subseteq & \mathrm{MatFam}(\mathcal{I}).\end{array}$$

■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that a Lindenbaum $\mathcal{I}$-matrix family is an $\mathcal{I}$-matrix family of the form $\langle \mathcal{F}, T \rangle$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and $T \in \mathrm{ThFam}(\mathcal{I})$. We show, next, that the class of all $\mathcal{I}$-matrix families can be obtained by applying the $\mathbb{M}$ operator on the class of all Lindenbaum matrix families, i.e., $\mathrm{MatFam}(\mathcal{I}) = \mathbb{M}(\mathrm{LMatFam}(\mathcal{I}))$.

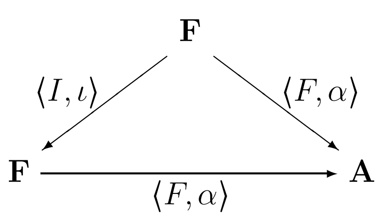
Lemma 1785 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$\mathrm{MatFam}(\mathcal{I}) = \mathbb{M}(\mathrm{LMatFam}(\mathcal{I})).$$

Proof: First, observe that, since $\mathrm{LMatFam}(\mathcal{I}) \subseteq \mathrm{MatFam}(\mathcal{I})$, we have, by Proposition 1783,

$$\mathbb{M}(\mathrm{LMatFam}(\mathcal{I})) \subseteq \mathbb{M}(\mathrm{MatFam}(\mathcal{I})) \subseteq \mathrm{MatFam}(\mathcal{I}).$$

Suppose, conversely, that $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}(\mathcal{I})$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$. Then, we have, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Hence, $\langle \mathcal{F}, \alpha^{-1}(T) \rangle \in \mathrm{LMatFam}(\mathcal{I})$. Now, it suffices to consider the surjective morphism $\langle F, \alpha \rangle : \langle \mathcal{F}, \alpha^{-1}(T) \rangle \to \mathfrak{A}$



to conclude that $\mathfrak{A} \in \mathbb{M}(\mathrm{LMatFam}(\mathcal{I}))$. Therefore, we obtain $\mathrm{MatFam}(\mathcal{I}) \subseteq \mathbb{M}(\mathrm{LMatFam}(\mathcal{I}))$. ■

Now, to complete our task, we turn again to the specific π-institution $\mathcal{I}^{\mathsf{M}}$, generated by a given class M of $\mathbf{F}$-matrix families. We show that all its Lindenbaum matrix families, i.e., all matrix families of the form $\langle \mathcal{F}, T \rangle$, where $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{M}})$, can be obtained by applying the operator $\mathbb{\Pi}\mathbb{I}\mathbb{M}^{-1}$ on the class M.

Lemma 1786 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of* $\mathbf{F}$*-matrix families. Then*

$$\mathrm{LMatFam}(\mathcal{I}^{\mathsf{M}}) \subseteq \mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}).$$

Proof: Let $\mathfrak{F} = \langle \mathcal{F}, T \rangle \in \mathrm{LMatFam}(\mathcal{I}^{\mathsf{M}})$, i.e., $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{M}})$. Thus, there exist $\mathfrak{A}^i = \langle \mathcal{A}^i, T^i \rangle \in \mathsf{M}$, with $\mathcal{A} = \langle \mathbf{A}^i, \langle F^i, \alpha^i \rangle \rangle$, $i \in I$, such that

$$T = \bigcap_{i \in I} (\alpha^i)^{-1}(T^i).$$

Consider the collection $\mathfrak{F}^i = \langle \mathcal{F}, (\alpha^i)^{-1}(T^i) \rangle$, $i \in I$. Taking into account the surjective morphisms $\langle F^i, \alpha^i \rangle : \mathfrak{F}^i \to \mathfrak{A}^i$, $i \in I$, and the fact that $\mathfrak{A}^i \in \mathsf{M}$, we conclude that $\mathfrak{F}^i \in \mathbb{M}^{-1}(\mathsf{M})$, for all $i \in I$. Finally, observing that $\mathfrak{F} = \bigcap_{i \in I} \mathfrak{F}^i$, we get that $\mathfrak{F} \in \mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$. Therefore, $\mathrm{LMatFam}(\mathcal{I}^{\mathsf{M}}) \subseteq \mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$. ∎

Now we are ready to provide the promised characterization of $\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})$ in terms of M and the class operators $\mathbb{M}$, $\mathbb{\Pi}$ and $\mathbb{M}^{-1}$, introduced in this section.

Theorem 1787 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of* $\mathbf{F}$*-matrix families. Then*

$$\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}) = \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}).$$

Proof: First, since $\mathsf{M} \subseteq \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})$, we have, using Corollary 1784,

$$\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}) \subseteq \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})) \subseteq \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}).$$

Conversely, let $\mathfrak{A} \in \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})$. Then, by Lemmas 1785 and 1786,

$$\mathfrak{A} \in \mathbb{M}(\mathrm{LMatFam}(\mathcal{I}^{\mathsf{M}})) \subseteq \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}).$$

Therefore, $\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}) \subseteq \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$. ∎

As a consequence of this characterization, we can also show that the operator $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}$ is a closure operator on classes of $\mathbf{F}$-matrix families and, moreover, given any such class M, applying the operator to the class results in the smallest class of $\mathbf{F}$-matrix systems that contains M and is closed under the operations $\mathbb{M}$, $\mathbb{\Pi}$ and $\mathbb{M}^{-1}$.

Theorem 1788 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of* $\mathbf{F}$*-matrix families.*

(a) $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1} : \mathcal{P}(\mathrm{MatFam}(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}(\mathbf{F}))$ *is a closure operator;*

(b) $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$ *is the smallest class of* $\mathbf{F}$*-matrix families containing* M *and closed under the operators* $\mathbb{M}$*,* $\mathbb{\Pi}$ *and* $\mathbb{M}^{-1}$*.*

Proof:

(a) Inflationarity and monotonicity follow from the corresponding properties of the three operators, which were established in Lemmas 1781 and 1782. For idempotency, we have

$$\begin{array}{rcl}\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})) & = & \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})) \\ & & \text{(by Theorem 1787)} \\ & \subseteq & \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}) \\ & & \text{(by Corollary 1784)} \\ & = & \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}). \\ & & \text{(again by Theorem 1787)}\end{array}$$

(b) By Part (a), $\mathsf{M} \subseteq \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$. Moreover, if $\mathbb{O} \in \{\mathbb{M}, \mathbb{\Pi}, \mathbb{M}^{-1}\}$, then

$$\begin{array}{rcll}\mathbb{O}(\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})) & = & \mathbb{O}(\mathrm{MatFam}(\mathcal{I}^{\mathsf{M}})) & \text{(by Theorem 1787)} \\ & \subseteq & \mathrm{MatFam}(\mathcal{I}^{\mathsf{M}}) & \text{(by Corollary 1784)} \\ & = & \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}). & \text{(by Theorem 1787)}\end{array}$$

Hence, $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$ is closed under all three operators. If N is a class of $\mathbf{F}$-matrix families such that $\mathsf{M} \subseteq \mathsf{N}$ and N closed under the three operators, then, clearly, $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M}) \subseteq \mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{N}) = \mathsf{N}$. Therefore, $\mathbb{M}\mathbb{\Pi}\mathbb{M}^{-1}(\mathsf{M})$ is the smallest class satisfying these properties. ∎

24.3 Classes of Reduced Matrix Families

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathrm{LMatFam}^*(\mathcal{I})$ is the class of all reduced Lindenbaum $\mathcal{I}$-matrix families, i.e., all $\mathbf{F}$-matrix families of the form $\langle \mathcal{F}^{\Omega(T)}, T/\Omega(T) \rangle$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and $T \in \mathrm{ThFam}(\mathcal{I})$, and that $\mathcal{I}$ is complete with respect to $\mathrm{LMatFam}^*(\mathcal{I})$.

Recall, also, that $\mathrm{MatFam}^*(\mathcal{I})$ is the collection of all reduced $\mathcal{I}$-matrix families, i.e., $\mathbf{F}$-matrix families of the form $\langle \mathcal{A}, T \rangle$, where $\mathcal{A}$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Moreover, $\mathcal{I}$ is also complete with respect to $\mathrm{MatFam}^*(\mathcal{I})$.

Our first goal is to show that the class $\mathrm{MatFam}^*(\mathcal{I})$ is, in fact, the class generated by applying the morphic image operator $\mathbb{M}$, introduced in the previous section, on the class $\mathrm{LMatFam}^*(\mathcal{I})$.

We prove, first, that the operator

$$\mathbb{M} : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})),$$

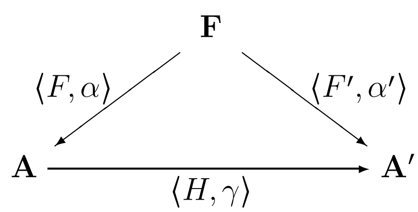
i.e., the operator $\mathbb{M}$, introduced in Section 24.2, restricted to reduced $\mathbf{F}$-matrix families, is also a closure operator.

Proposition 1789 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*

$$\mathbb{M} : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$$

is a closure operator on $\mathrm{MatFam}^*(\mathbf{F})$.

Proof: Since we know, by Lemma 1781, that $\mathbb{M}$ is inflationary, monotone and idempotent, it suffices to show that it is well-defined, i.e., that, when applied to collections of reduced $\mathbf{F}$-matrix families, it produces collections of the same kind. In turn, it suffices to show that, given a reduced $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, an $\mathbf{F}$-matrix family $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$, with $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, and a strict surjective morphism $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{A}'$, then $\mathfrak{A}'$ is also reduced.



Taking into account the surjectivity of $\langle F', \alpha' \rangle$, we reason as follows. For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we have

$$\begin{array}{rl} \multicolumn{2}{l}{\langle \alpha'_\Sigma(\phi), \alpha'_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}'}_{F'(\Sigma)}(T')} \\ \text{iff} & \langle \gamma_{F(\Sigma)}(\alpha_\Sigma(\phi)), \gamma_{F(\Sigma)}(\alpha_\Sigma(\psi)) \rangle \in \Omega^{\mathcal{A}'}_{G(F(\Sigma))}(T') \\ \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \gamma^{-1}_{F(\Sigma)}(\Omega^{\mathcal{A}'}_{G(F(\Sigma))}(T')) \\ \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(\gamma^{-1}(T')) \\ \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T) \\ \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Delta^{\mathcal{A}}_{F(\Sigma)}(T) \\ \text{iff} & \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi) \\ \text{implies} & \gamma_{F(\Sigma)}(\alpha_\Sigma(\phi)) = \gamma_{F(\Sigma)}(\alpha_\Sigma(\psi)) \\ \text{iff} & \alpha'_\Sigma(\phi) = \alpha'_\Sigma(\psi). \end{array}$$

Therefore $\Omega^{\mathcal{A}'}(T') = \Delta^{\mathcal{A}'}$ and, hence $\mathfrak{A}'$ is also reduced. ■

Next, we show that, given π-institution $\mathcal{I}$, the class $\mathrm{MatFam}^*(\mathcal{I})$ is obtained by applying the operator $\mathbb{M}$ on the class $\mathrm{LMatFam}^*(\mathcal{I})$.

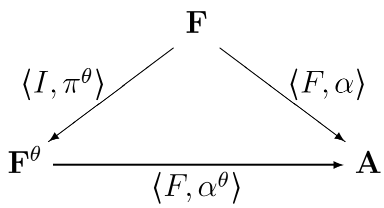
Proposition 1790 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then*

$$\mathrm{MatFam}^*(\mathcal{I}) = \mathbb{M}(\mathrm{LMatFam}^*(\mathcal{I})).$$

Proof: The inclusion $\mathbb{M}(\mathrm{LMatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I})$ is obtained by observing that $\mathrm{LMatFam}^*(\mathcal{I}) \subseteq \mathrm{MatFam}^*(\mathcal{I})$ and applying $\mathbb{M}$:

$$\begin{array}{rcll} \mathbb{M}(\mathrm{LMatFam}^*(\mathcal{I})) & \subseteq & \mathbb{M}(\mathrm{MatFam}^*(\mathcal{I})) & \text{(Lemma 1781)} \\ & \subseteq & \mathrm{MatFam}^*(\mathcal{I}). & \text{(Propositions 1783 and 1789)} \end{array}$$

Suppose, conversely, that $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, is a reduced $\mathcal{I}$-matrix family. Let $\theta = \mathrm{Ker}(\langle F, \alpha \rangle)$ and consider the commutative diagram



where, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha^\theta_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\phi).$$

It now suffices to show that $\mathfrak{F} := \langle \mathcal{F}^\theta, \alpha^{-1}(T)/\theta \rangle \in \mathrm{LMatFam}^*(\mathcal{I})$. First, note that since $\mathfrak{A} \in \mathrm{MatFam}^*(\mathcal{I}) \subseteq \mathrm{MatFam}(\mathcal{I})$, then

$$\mathfrak{F} \in \mathbb{M}^{-1}(\mathrm{MatFam}(\mathcal{I})) \subseteq \mathrm{MatFam}(\mathcal{I}),$$

by Proposition 1783. So it suffices to show that $\Omega^{\mathcal{F}^\theta}(\alpha^{-1}(T)/\theta) = \Delta^{\mathcal{F}^\theta}$. We have

$$\begin{array}{rcl}\Omega^{\mathcal{F}^\theta}(\alpha^{-1}(T)/\theta) & = & \Omega^{\mathcal{F}^\theta}((\alpha^\theta)^{-1}(T)) \\ & = & (\alpha^\theta)^{-1}(\Omega^{\mathcal{A}}(T)) \\ & = & (\alpha^\theta)^{-1}(\Delta^{\mathcal{A}}) \\ & = & \mathrm{Ker}(\langle F, \alpha^\theta \rangle) = \Delta^{\mathcal{F}^\theta}.\end{array}$$

Now we conclude that $\mathfrak{A} \in \mathbb{M}(\mathrm{LMatFam}^*(\mathcal{I}))$. ∎

Consider, again, a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a collection M of reduce $\mathbf{F}$-matrix families. We pose now a problem similar to that posed in Section 24.2, but for classes of reduced matrix families.

> Characterize the class $\mathrm{MatFam}^*(\mathcal{I})$, i.e., find a list of operators on classes of reduced $\mathbf{F}$-matrix families so that, when applied to M consecutively, they generate the class $\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})$.

Unlike the operator $\mathbb{M}$ that, when applied to reduced matrix families yields reduced matrix families, the other two operators that we considered in Section 24.2, namely $\mathbb{\Pi}$ and $\mathbb{M}^{-1}$, do not share this property. So to "localize" them to reduced matrix families, we must take the output classes of $\mathbf{F}$-matrix families that they produce and "reduce" them so that the output produced becomes a collection of reduced $\mathbf{F}$-matrix families. According to this scheme, we consider the following operators, induced by the operators $\mathbb{\Pi}$ and $\mathbb{M}^{-1}$ on class of matrix families, introduced in Section 24.2.

- $\mathbb{\Pi}^* : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$ is given, by setting, for all $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$,

$$\mathbb{\Pi}^*(\mathsf{M}) = \{\mathfrak{A}^* : \mathfrak{A} \in \mathbb{\Pi}(\mathsf{M})\};$$

- $\mathbb{M}^{-1*} : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$ is given, by setting, for all $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$,
$$\mathbb{M}^{-1*}(\mathsf{M}) = \{\mathfrak{A}^* : \mathfrak{A} \in \mathbb{M}^{-1}(\mathsf{M})\}.$$

It is not very difficult to prove that both $\mathbb{I}\mathbb{I}^*$ and $\mathbb{M}^{-1*}$ are closure operators on the class of reduced $\mathbf{F}$-matrix families.

Proposition 1791 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*
$$\mathbb{I}\mathbb{I}^* : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$$
is a closure operator on $\mathrm{MatFam}^*(\mathbf{F})$.

Proof: Let $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and $\mathfrak{A} \in \mathsf{M}$. Then, by Proposition 1782, $\mathfrak{A} \in \mathbb{I}\mathbb{I}(\mathsf{M})$ and, as $\mathfrak{A}$ is reduced, we get $\mathfrak{A} \in \mathbb{I}\mathbb{I}^*(\mathsf{M})$. Thus, $\mathbb{I}\mathbb{I}^*$ is inflationary.

Suppose, next, that $\mathsf{M} \subseteq \mathsf{N} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and $\mathfrak{A} \in \mathbb{I}\mathbb{I}^*(\mathsf{M})$. Then $\mathfrak{A} = (\bigcap_{i\in I} \mathfrak{A}^i)^*$, with $\mathfrak{A}^i \in \mathsf{M}$, for all $i \in I$. But then, since $\mathsf{M} \subseteq \mathsf{N}$, $\mathfrak{A} = (\bigcap_{i\in I} \mathfrak{A}^i)^*$, with $\mathfrak{A}^i \in \mathsf{N}$, for all $i \in I$, and, hence, $\mathfrak{A} \in \mathbb{I}\mathbb{I}^*(\mathsf{N})$. Therefore $\mathbb{I}\mathbb{I}^*$ is also monotone.

Suppose, finally, that $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and that $\mathfrak{A} \in \mathbb{I}\mathbb{I}^*(\mathbb{I}\mathbb{I}^*(\mathsf{M}))$. Then $\mathfrak{A} = (\bigcap_{i\in I} \mathfrak{A}^i)^*$, where $\mathfrak{A}^i \in \mathbb{I}\mathbb{I}^*(\mathsf{M})$. Hence, for all $i \in I$, $\mathfrak{A}^i = (\bigcap_{j\in J_i} \mathfrak{A}^{ij})^*$, where $\mathfrak{A}^{ij} \in \mathsf{M}$, for all $i \in I$ and all $j \in J_i$. Now note the following:

- For every $i \in I$, for $\bigcap_{j\in J_i} \mathfrak{A}^{ij}$ to be defined, we must have $\mathfrak{A}^{ij} = \langle \mathcal{A}^i, T^{ij} \rangle$, for all $j \in J_i$.
- For $\bigcap_{i\in I} \mathcal{A}^i = \bigcap_{i\in I} (\bigcap_{j\in J_i} \mathfrak{A}^{ij})^*$ to be defined, we must have, for all $i \in I$, $\mathcal{A}^i = \mathcal{A}$, for some $\mathbf{F}$-algebraic system $\mathcal{A}$, and, moreover, for all $i \in I$, $\Omega^{\mathcal{A}}(\bigcap_{j\in J_i} T^{ij}) = \theta$, for some $\theta \in \mathrm{ConSys}(\mathcal{A})$.

Under these restrictions, it is easy to show that
$$\langle I, \pi \rangle : \langle \mathcal{A}, \bigcap_{i\in I} \bigcap_{j\in J_i} T^{ij} \rangle \to \mathcal{A}^\theta / \Omega^{\mathcal{A}^\theta}(\bigcap_{i\in I} ((\bigcap_{j\in J_i} T^{ij})/\theta))$$
defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by
$$\pi_\Sigma(\phi) = (\phi/\theta_\Sigma)/\Omega^{\mathcal{A}^\theta}_\Sigma(\bigcap_{i\in I} ((\bigcap_{j\in J_i} T^{ij})/\theta)),$$
is a strict surjective matrix morphism, with kernel
$$\mathrm{Ker}(\langle I, \pi \rangle) = \Omega^{\mathcal{A}}(\bigcap_{i\in I} \bigcap_{j\in J_i} T^{ij}).$$
Therefore, we get an isomorphism
$$\mathfrak{A}/\Omega^{\mathcal{A}}(\bigcap_{i\in I} \bigcap_{j\in J_i} T^{ij}) \cong (\mathfrak{A}^\theta)(\Omega^{\mathcal{A}^\theta}(\bigcap_{i\in I} ((\bigcap_{j\in J_i} T^{ij})/\theta))).$$
We conclude that $\mathfrak{A} \in \mathbb{I}\mathbb{I}^*(\mathsf{M})$ and, therefore, $\mathbb{I}\mathbb{I}^*$ is also idempotent. ■

To show that $\mathbb{M}^{-1*}$ is a closure operator, we employ a lemma to the effect that, given a class M of reduced $\mathbf{F}$-matrix families, $\mathbb{M}^{-1*}(\mathsf{M}) \subseteq \mathbb{M}^{-1}(\mathsf{M})$.

Lemma 1792 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. For every* $\mathbf{F}$*-matrix family* $\mathfrak{A} = \langle \mathcal{A}, T \rangle$*, every reduced* $\mathbf{F}$*-matrix family* $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$ *and strict surjective morphism* $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{A}'$*, there exists a strict surjective morphism* $\langle H, \gamma^* \rangle : \mathfrak{A}^* \to \mathfrak{A}'$*, such that the following triangle commutes,*

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathfrak{A}' \\ & {\scriptstyle \langle I, \pi \rangle} \searrow \quad \nearrow {\scriptstyle \langle H, \gamma^* \rangle} & \\ & \mathfrak{A}^* & \end{array}$$

where $\langle I, \pi \rangle : \mathfrak{A} \to \mathfrak{A}^*$ *is the quotient morphism.*

Proof: We define $\gamma^* : \mathrm{SEN}^* \to \mathrm{SEN}' \circ H$ by setting, for all $\Sigma \in |\mathbf{Sign}|$, and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\gamma^*_\Sigma(\phi^*) = \gamma_\Sigma(\phi).$$

This makes sense, since, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi^* = \psi^*$, we have $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T) = \Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))$, whence $\langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))$ and, hence, $\langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \Delta^{\mathcal{A}'}_{H(\Sigma)}$, i.e., $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$.

Moreover, $\gamma : \mathrm{SEN}^* \to \mathrm{SEN} \circ H$ is a natural transformation, since, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc} \mathrm{SEN}^*(\Sigma) & \xrightarrow{\gamma^*_\Sigma} & \mathrm{SEN}'(H(\Sigma)) \\ {\scriptstyle \mathrm{SEN}^*(f)} \downarrow & & \downarrow {\scriptstyle \mathrm{SEN}'(H(f))} \\ \mathrm{SEN}^*(\Sigma') & \xrightarrow[\gamma^*_{\Sigma'}]{} & \mathrm{SEN}'(H(\Sigma')) \end{array}$$

$$\begin{array}{rcl} \mathrm{SEN}'(H(f))(\gamma^*_\Sigma(\phi^*)) & = & \mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)) \\ & = & \gamma_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \\ & = & \gamma^*_{\Sigma'}(\mathrm{SEN}(f)(\phi)^*) \\ & = & \gamma^*_{\Sigma'}(\mathrm{SEN}^*(g)(\phi^*)). \end{array}$$

Further, the triangle commutes, by the definition of $\langle H, \gamma^* \rangle$ and, finally, $\langle H, \gamma^* \rangle : \mathfrak{A}^* \to \mathfrak{A}'$ is strict since $\pi^{-1}((\gamma^*)^{-1}(T')) = \gamma^{-1}(T') = T$ and, therefore, $(\gamma^*)^{-1}(T') = \pi(T) = T^*$. ■

Now, we show $\mathbb{M}^{-1*}$ is a closure operator.

Proposition 1793 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*

$$\mathbb{M}^{-1*} : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$$

is a closure operator on $\mathrm{MatFam}^*(\mathbf{F})$*.*

Proof: Suppose, first, that $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and $\mathfrak{A} \in \mathsf{M}$. Then, we have, by Proposition 1781, $\mathfrak{A} \in \mathbb{M}^{-1}(\mathsf{M})$ and, since $\mathfrak{A}$ is reduced, we get $\mathfrak{A} \in \mathbb{M}^{-1*}(\mathsf{M})$. So $\mathbb{M}^{-1*}$ is inflationary.

Suppose, next, that $\mathsf{M} \subseteq \mathsf{N} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and $\mathfrak{A} \in \mathbb{M}^{-1*}(\mathsf{M})$. Then $\mathfrak{A} = \mathfrak{B}^*$, with $\mathfrak{B} \in \mathbb{M}^{-1}(\mathsf{M})$. Thus, by Proposition 1781, we get $\mathfrak{A} = \mathfrak{B}^*$, with $\mathfrak{B} \in \mathbb{M}^{-1}(\mathsf{N})$. We conclude that $\mathfrak{A} \in \mathbb{M}^{-1*}(\mathsf{N})$ and, therefore, $\mathbb{M}^{-1*}$ is also monotone.

Finally, suppose that $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$ and that $\mathfrak{A} \in \mathbb{M}^{-1*}(\mathbb{M}^{-1*}(\mathsf{M}))$. Then, using Lemma 1792, we get

$$\mathfrak{A} \in \mathbb{M}^{-1*}(\mathbb{M}^{-1*}(\mathsf{M})) \subseteq \mathbb{M}^{-1}(\mathbb{M}^{-1*}(\mathsf{M})) \subseteq \mathbb{M}^{-1}(\mathbb{M}^{-1}(\mathsf{M})) \subseteq \mathbb{M}^{-1}(\mathsf{M}),$$

and, since $\mathfrak{A}$ is reduced, we get $\mathfrak{A} \in \mathbb{M}^{-1*}(\mathsf{M})$. Therefore $\mathbb{M}^{-1*}$ is also idempotent. ■

We need one more operator on reduced classes of $\mathbf{F}$-matrix families.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. We define

$$\overleftarrow{\mathbb{P}}^* : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$$

by setting, for all $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$,

$$\overleftarrow{\mathbb{P}}^*(\mathsf{M}) = (\mathbb{P}\mathbb{M}^{-1}(\mathsf{M}))^*.$$

Note that this operator dominates both $\mathbb{P}^*$ and $\mathbb{M}^{-1*}$.

Proposition 1794 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. Then, for all $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathbf{F})$,*

$$\mathbb{P}^*(\mathsf{M}) \subseteq \overleftarrow{\mathbb{P}}^*(\mathsf{M}) \quad \textit{and} \quad \mathbb{M}^{-1*}(\mathsf{M}) \subseteq \overleftarrow{\mathbb{P}}^*(\mathsf{M}).$$

Proof: The proofs of both statements are parallel. We have

$$\begin{aligned} \mathbb{P}^*(\mathsf{M}) &= (\mathbb{P}(\mathsf{M}))^* & \qquad \mathbb{M}^{-1}(\mathsf{M}) &= (\mathbb{M}^{-1}(\mathsf{M}))^* \\ &\subseteq (\mathbb{P}\mathbb{M}^{-1}(\mathsf{M}))^* & &\subseteq (\mathbb{P}\mathbb{M}^{-1}(\mathsf{M}))^* \\ &= \overleftarrow{\mathbb{P}}^*(\mathsf{M}) & &= \overleftarrow{\mathbb{P}}^*(\mathsf{M}) \end{aligned}$$

where the inclusions follow from Lemmas 1781 and 1782, respectively. ■

Our next goal is to show that the list of operators that are needed to obtain the class of all reduced $\mathcal{I}^{\mathsf{M}}$-matrix families from a class M of reduced $\mathbf{F}$-matrix families generating a closure operator C^{M} (of a π-institution $\mathcal{I}^{\mathsf{M}} = \langle \mathbf{F}, C^{\mathsf{M}} \rangle$) consists of $\mathbb{M}\overleftarrow{\mathbb{P}}^*$, i.e., that, given any class M of reduced $\mathbf{F}$-matrix families, we have

$$\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) = \mathbb{M}\overleftarrow{\mathbb{P}}^*(\mathsf{M}).$$

We start by showing that applying each of these operators to classes of reduced matrix family models of a π-institution $\mathcal{I}$ always results in classes of the same character. This forms an analog of Proposition 1783.

Proposition 1795 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathbb{M}(\mathrm{MatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I})$;

(b) $\overleftarrow{\mathbb{IP}}^*(\mathrm{MatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I})$.

Proof:

(a) We have

$$\begin{array}{rcl}\mathbb{M}(\mathrm{MatFam}^*(\mathcal{I})) & \subseteq & \mathbb{M}(\mathrm{MatFam}(\mathcal{I})) \cap \mathbb{M}(\mathrm{MatFam}^*(\mathbf{F}))\\ & & \text{(Proposition 1781)}\\ & \subseteq & \mathrm{MatFam}(\mathcal{I}) \cap \mathrm{MatFam}^*(\mathbf{F})\\ & & \text{(Propositions 1783 and 1789)}\\ & = & \mathrm{MatFam}^*(\mathcal{I}). \quad \text{(Definition)}\end{array}$$

(b) Similarly,

$$\begin{array}{rcl}\overleftarrow{\mathbb{IP}}^*(\mathrm{MatFam}^*(\mathcal{I})) & = & (\mathbb{IPM}^{-1}(\mathrm{MatFam}^*(\mathcal{I})))^*\\ & \subseteq & (\mathbb{IPM}^{-1}(\mathrm{MatFam}(\mathcal{I})))^*\\ & & \text{(Lemmas 1781 and 1782)}\\ & \subseteq & (\mathrm{MatFam}(\mathcal{I}))^*\\ & & \text{(Proposition 1783)}\\ & = & \mathrm{MatFam}^*(\mathcal{I}).\end{array}$$

■

Proposition 1795, together with Proposition 1783, give the following

Corollary 1796 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then*

$$\mathbb{M}\overleftarrow{\mathbb{IP}}^*(\mathrm{MatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I}).$$

Proof: We have, using Propositions 1783 and 1795,

$$\begin{array}{rcl}\mathbb{M}\overleftarrow{\mathbb{IP}}^*(\mathrm{MatFam}^*(\mathcal{I})) & \subseteq & \mathbb{M}(\mathrm{MatFam}^*(\mathcal{I}))\\ & \subseteq & \mathrm{MatFam}^*(\mathcal{I}).\end{array}$$

■

In order to establish our final result, we must show that, given a class M of reduced $\mathbf{F}$-matrix families, all reduced Lindenbaum matrix families of the π-institution $\mathcal{I}^{\mathsf{M}}$, i.e., all matrix families of the form $\langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle$, where $T \in \mathrm{ThFam}(\mathcal{I}^{\mathsf{M}})$, can be obtained by applying the operator $\overleftarrow{\mathbb{IP}}^*$ on the class M.

Lemma 1797 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of reduced* $\mathbf{F}$*-matrix families. Then*

$$\mathrm{LMatFam}^*(\mathcal{I}^{\mathsf{M}}) \subseteq \overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}).$$

Proof: we have

$$\begin{array}{rcl}\mathrm{LMatFam}^*(\mathcal{I}^{\mathsf{M}}) & = & (\mathrm{LMatFam}(\mathcal{I}^{\mathsf{M}}))^* \quad \text{(Definition)}\\ & \subseteq & (\mathbb{\Pi}\mathbb{M}^{-1}(M))^* \quad \text{(Lemma 1786)}\\ & = & \overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}). \quad \text{(Definition)}\end{array}$$

■

Now we provide the promised characterization of $\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})$ in terms of the class M of reduced $\mathbf{F}$-matrix families and the class operators $\mathbb{M}$ and $\overleftarrow{\mathbb{\Pi}}^*$.

Theorem 1798 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of reduced* $\mathbf{F}$*-matrix families. Then*

$$\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) = \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}).$$

Proof: First, since $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})$, we have, using Corollary 1796,

$$\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}) \subseteq \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})) \subseteq \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}).$$

Conversely, let $\mathfrak{A} \in \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})$. Then, by Proposition 1790 and Lemma 1797,

$$\mathfrak{A} \in \mathbb{M}(\mathrm{LMatFam}^*(\mathcal{I}^{\mathsf{M}})) \subseteq \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}).$$

Therefore, $\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) \subseteq \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})$, and equality follows. ■

As a consequence of this characterization, we can also show that the operator $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*$ is a closure operator on classes of reduced $\mathbf{F}$-matrix families and, moreover, given any such class M, applying the operator to the class results in the smallest class of reduced $\mathbf{F}$-matrix systems that contains M and is closed under the operations $\mathbb{M}$, $\overleftarrow{\mathbb{\Pi}}^*$.

Theorem 1799 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* M *a collection of reduced* $\mathbf{F}$*-matrix families.*

(a) $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^* : \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}^*(\mathbf{F}))$ *is a closure operator;*

(b) $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})$ *is the smallest class of* $\mathbf{F}$*-matrix families containing* M *and closed under the operators* $\mathbb{M}$ *and* $\overleftarrow{\mathbb{\Pi}}^*$*.*

Proof:

(a) Inflationarity and monotonicity follow from the corresponding properties of the operators $\mathbb{M}$ and $\mathbb{\Pi}$, which were established in Lemmas 1781 and 1782. For idempotency, we have

$$\begin{array}{rcl}\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})) & = & \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})) \\ & & \text{(by Theorem 1798)} \\ & \subseteq & \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) \\ & & \text{(by Corollary 1796)} \\ & = & \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}). \\ & & \text{(again by Theorem 1798)}\end{array}$$

(b) By Part (a), $\mathsf{M} \subseteq \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})$. Moreover, if $\mathbb{O} \in \{\mathbb{M}, \overleftarrow{\mathbb{\Pi}}^*\}$, then

$$\begin{array}{rcl}\mathbb{O}(\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})) & = & \mathbb{O}(\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})) \quad \text{(by Theorem 1798)} \\ & \subseteq & \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) \quad \text{(by Corollary 1796)} \\ & = & \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}). \quad \text{(by Theorem 1798)}\end{array}$$

Hence, $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})$ is closed under both operators. If N is a class of reduced **F**-matrix families such that $\mathsf{M} \subseteq \mathsf{N}$ and N closed under both operators, then, clearly, $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M}) \subseteq \mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{N}) = \mathsf{N}$. Therefore, $\mathbb{M}\overleftarrow{\mathbb{\Pi}}^*(\mathsf{M})$ is the smallest class satisfying these properties.

■

24.4 Protoclasses of Matrix Families

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A class of **F**-matrix families M is called a **protoclass** if it is the class of all reduced $\mathcal{I}$-matrix families for a protoalgebraic π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on **F**.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i \rangle \rangle$, $i \in I$, a collection of **F**-algebraic systems and $\mathfrak{A}^i = \langle \mathcal{A}^i, T^i \rangle$ a collection of **F**-matrix families. We say that an **F**-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, is a **subdirect intersection** of the collection $\mathfrak{A}^i$, $i \in I$, if there exist surjective morphisms

$$\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}^i, \quad i \in I,$$

such that:

- $T = \bigcap_{i \in I} (\gamma^i)^{-1}(T^i)$;
- $\bigcap_{i \in I} \mathrm{Ker}(\langle H^i, \gamma^i \rangle) = \Delta^{\mathcal{A}}$.

Let M be a class of $\mathbf{F}$-matrix families. Given an $\mathbf{F}$-matrix family $\mathfrak{A}$, we write $\mathfrak{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{M})$ to denote the fact that $\mathfrak{A}$ is a subdirect intersection of members of M.

It is not difficult to see that $\overset{\triangleleft}{\mathbb{I}\mathrm{I}}$ is a closure operator on classes of $\mathbf{F}$-matrix families.

Lemma 1800 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then*

$$\overset{\triangleleft}{\mathbb{I}\mathrm{I}} : \mathcal{P}(\mathrm{MatFam}(\mathbf{F})) \to \mathcal{P}(\mathrm{MatFam}(\mathbf{F}))$$

is a closure operator on $\mathrm{MatFam}(\mathbf{F})$.

Proof: Assume, first, that $\mathsf{M} \subseteq \mathrm{MatFam}(\mathbf{F})$ and $\mathfrak{A} \in \mathsf{M}$. Then $\langle I, \iota \rangle : \mathfrak{A} \to \mathfrak{A}$ is a subdirect intersection morphism and, therefore, since $\mathfrak{A} \in \mathsf{M}$, we get $\mathfrak{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{M})$. Therefore $\overset{\triangleleft}{\mathbb{I}\mathrm{I}}$ is inflationary.

Suppose, next, that $\mathsf{M} \subseteq \mathsf{N} \subseteq \mathrm{MatFam}(\mathbf{F})$. Let $\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}'^i$, $i \in I$, be a collection of subdirect intersection morphisms, with $\mathfrak{A}'^i \in \mathsf{M}$, for all $i \in I$. Since, then, $\mathfrak{A}'^i \in \mathsf{N}$, for all $i \in I$, the same collection of morphisms witnesses that $\mathfrak{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{N})$. Therefore, $\overset{\triangleleft}{\mathbb{I}\mathrm{I}}$ is also monotone.

Finally, assume that $\mathfrak{A} \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{M}))$, where $\mathsf{M} \subseteq \mathrm{MatFam}(\mathbf{F})$. Thus, there exists a collection of subdirect intersection morphisms

$$\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}^i, \quad i \in I,$$

where $\mathfrak{A}^i \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{M})$, for all $i \in I$. It now follows that, for each $i \in I$, there exists a collection of subdirect intersection morphisms

$$\langle H^{ij}, \gamma^{ij} \rangle : \mathfrak{A}^i \to \mathfrak{A}^{ij}, \quad j \in J_i,$$

where $\mathfrak{A}^{ij} \in \mathsf{M}$, for all $i \in I$ and all $j \in J_i$. We look at the collection

$$\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}^{ij}, \quad i \in I, j \in J_i,$$

with $\mathfrak{A}^{ij} \in \mathsf{M}$, for all $i \in I, j \in J_i$. We have

- For filter family intersections,

$$\begin{array}{rcl} \bigcap_{i \in I} \bigcap_{j \in J_i} (\gamma^i)^{-1}((\gamma^{ij})^{-1}(T^{ij})) & = & \bigcap_{i \in I} (\gamma^i)^{-1}(\bigcap_{j \in J_i} (\gamma^{ij})^{-1}(T^{ij})) \\ & = & \bigcap_{i \in I} (\gamma^i)^{-1}(T^i) \\ & = & T. \end{array}$$

- Similarly, for kernels,

$$\begin{array}{l} \bigcap_{i \in I} \bigcap_{j \in J_i} \mathrm{Ker}(\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle) \\ \quad = \bigcap_{i \in I} \bigcap_{j \in J_i} (\gamma^i)^{-1}((\gamma^{ij})^{-1}(\Delta^{\mathcal{A}^{ij}})) \\ \quad = \bigcap_{i \in I} (\gamma^i)^{-1}(\bigcap_{j \in J_i} \mathrm{Ker}(\langle H^{ij}, \gamma^{ij} \rangle)) \\ \quad = \bigcap_{i \in I} (\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\ \quad = \bigcap_{i \in I} \mathrm{Ker}(\langle H^i, \gamma^i \rangle) \\ \quad = \Delta^{\mathcal{A}}. \end{array}$$

Therefore, $\langle H^{ij},\gamma^{ij}\rangle\circ\langle H^i,\gamma^i\rangle$, $i\in I$, $j\in J_i$, is also a collection of subdirect intersection morphisms, and, hence $\mathfrak{A}\in\overset{\triangleleft}{\mathbb{IP}}(\mathsf{M})$. We conclude that $\overset{\triangleleft}{\mathbb{IP}}$ is also idempotent. ■

In general, given a class M of reduced $\mathbf{F}$-matrix families, its closures under both operators $\mathbb{IP}$ and $\mathbb{M}^{-1*}$ are included in its closure under $\overset{\triangleleft}{\mathbb{IP}}$.

Proposition 1801 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* M *a class of reduced* $\mathbf{F}$*-matrix families. Then*

$$\mathbb{IP}(\mathsf{M})\subseteq\overset{\triangleleft}{\mathbb{IP}}(\mathsf{M})\quad\textit{and}\quad\mathbb{M}^{-1*}(\mathsf{M})\subseteq\overset{\triangleleft}{\mathbb{IP}}(\mathsf{M}).$$

Proof: Assume, first, that $\mathfrak{A}=\langle\mathcal{A},T\rangle\in\mathbb{IP}(\mathsf{M})$. Thus, there exists a collection $\mathfrak{A}^i=\langle\mathcal{A},T^i\rangle\in\mathsf{M}$, such that

$$T=\bigcap_{i\in I}T^i.$$

Consider the family of surjective morphisms

$$\langle I,\iota\rangle:\langle\mathcal{A},T\rangle\to\langle\mathcal{A},T^i\rangle,\quad i\in I.$$

We have

- $T=\bigcap_{i\in I}T^i=\bigcap_{i\in I}\iota^{-1}(T^i)$, by hypothesis;
- $\bigcap_{i\in I}\mathrm{Ker}(\langle I,\iota\rangle)=\bigcap_{i\in I}\Delta^{\mathcal{A}}=\Delta^{\mathcal{A}}$.

Therefore, since $\mathfrak{A}^i\in\mathsf{M}$, for all $i\in I$, $\mathfrak{A}\in\overset{\triangleleft}{\mathbb{IP}}(\mathsf{M})$.

Assume, next, that $\mathfrak{A}^*=\langle\mathcal{A}/\Omega^{\mathcal{A}}(T),T/\Omega^{\mathcal{A}}(T)\rangle\in\mathbb{M}^{-1*}(\mathsf{M})$, where $\langle H,\gamma\rangle:\mathfrak{A}\to\mathfrak{A}'$ is a strict surjective morphism, with $\mathfrak{A}'=\langle\mathcal{A}',T'\rangle\in\mathsf{M}$. Since $\mathsf{M}\subseteq\mathrm{MatFam}^*(\mathbf{F})$, there exists a factorization

$$\begin{array}{ccc}\mathfrak{A} & \xrightarrow{\langle H,\gamma\rangle} & \mathfrak{A}'\\ {\scriptstyle\langle I,\pi\rangle}\searrow & & \swarrow{\scriptstyle\langle H,\gamma^*\rangle}\\ & \mathfrak{A}^* & \end{array}$$

Moreover, we have

- $\pi^{-1}(\gamma^{*-1}(T'))=\gamma^{-1}(T')=T$, whence $\gamma^{*-1}(T')=T/\Omega^{\mathcal{A}}(T)$;
- $\mathrm{Ker}(\langle H,\gamma^*\rangle)=\Delta^{\mathcal{A}^*}$ holds, since, for all $\Sigma\in|\mathbf{Sign}|$ and all $\phi,\psi\in\mathrm{SEN}(\Sigma)$,

$$\begin{array}{rll}\langle\phi,\psi\rangle\in\mathrm{Ker}_\Sigma(\langle H,\gamma^*\rangle) & \text{iff} & \gamma^*_\Sigma(\phi/\Omega^{\mathcal{A}}_\Sigma(T))=\gamma^*_\Sigma(\psi/\Omega^{\mathcal{A}}_\Sigma(T))\\ & \text{iff} & \gamma_\Sigma(\phi)=\gamma_\Sigma(\psi)\\ & \text{iff} & \langle\phi,\psi\rangle\in\gamma^{-1}_\Sigma(\Omega^{\mathcal{A}'}_{H(\Sigma)}(T'))\\ & \text{iff} & \langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}_\Sigma(\gamma^{-1}(T'))\\ & \text{iff} & \langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}_\Sigma(T).\end{array}$$

Therefore, $\mathfrak{A}^* \in \overset{\triangleleft}{\mathbb{P}}(\mathsf{M})$. ∎

Another useful feature of the operator $\overset{\triangleleft}{\mathbb{P}}$ is that among model classes of matrix families, it characterizes those that are protoclasses.

Theorem 1802 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathsf{M} = \mathrm{MatFam}^*(\mathcal{I})$ *a class of reduced* $\mathbf{F}$*-matrix families. Then* M *is a protoclass if and only if* $\overset{\triangleleft}{\mathbb{P}}(\mathsf{M}) \subseteq \mathsf{M}$.

Proof: Suppose, first, that $\mathsf{M} = \mathrm{MatFam}^*(\mathcal{I})$, with $\mathcal{I}$ protoalgebraic and let $\langle H^i, \gamma^i\rangle : \mathfrak{A} \to \mathfrak{A}'^i$, $i \in I$, be a collection of subdirect intersection morphisms. Then, clearly,

$$\begin{array}{rcll}\mathfrak{A} & \in & \mathbb{P}\mathbb{M}^{-1}(\mathsf{M}) & (\text{Definition of } \overset{\triangleleft}{\mathbb{P}})\\ & \subseteq & \mathbb{P}\mathbb{M}^{-1}(\mathrm{MatFam}^*(\mathcal{I})) & (\text{Lemmas 1781 and 1782})\\ & \subseteq & \mathrm{MatFam}(\mathcal{I}). & (\text{Proposition 1783})\end{array}$$

It suffices now to show that $\mathcal{A}$ is reduced. We have

$$\begin{array}{rcll}\Omega^{\mathcal{A}}(T) & = & \Omega^{\mathcal{A}}(\bigcap_{i\in I}(\gamma^i)^{-1}(T'^i)) & (\text{Subdirect Intersection})\\ & = & \bigcap_{i\in I}\Omega^{\mathcal{A}}((\gamma^i)^{-1}(T'^i)) & (\mathcal{I}\text{ protoalgebraic})\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Omega^{\mathcal{A}'^i}(T'^i)) & (\langle H^i,\gamma^i\rangle\text{ surjective})\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Delta^{\mathcal{A}'^i}) & (\mathfrak{A}'^i\text{ reduced})\\ & = & \bigcap_{i\in I}\mathrm{Ker}(\langle H^i,\gamma^i\rangle) & \\ & = & \Delta^{\mathcal{A}}. & (\text{Subdirect Intersection})\end{array}$$

Since $\mathfrak{A} \in \mathrm{MatFam}(\mathcal{I})$ and $\mathfrak{A}$ is reduced, we conclude that $\mathfrak{A} \in \mathrm{MatFam}^*(\mathcal{I})$. So $\overset{\triangleleft}{\mathbb{P}}(\mathrm{MatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I})$.

Suppose, conversely, that $\overset{\triangleleft}{\mathbb{P}}(\mathrm{MatFam}^*(\mathcal{I})) \subseteq \mathrm{MatFam}^*(\mathcal{I})$ and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, with $T \leq T'$. We set

$$\mathfrak{F} \coloneqq \langle \mathcal{F}/(\Omega(T) \cap \Omega(T')), (T \cap T')/(\Omega(T) \cap \Omega(T'))\rangle$$

and consider the surjective natural projection morphisms

$$\begin{array}{rl}\langle I, \pi\rangle : & \mathfrak{F} \to \langle \mathcal{F}/\Omega(T), T/\Omega(T)\rangle\\ \langle I, \pi'\rangle : & \mathfrak{F} \to \langle \mathcal{F}/\Omega(T'), T'/\Omega(T')\rangle.\end{array}$$

We observe that

- As far as filter families, we have

$$\begin{array}{l}(T \cap T')/(\Omega(T) \cap \Omega(T'))\\ = T/(\Omega(T) \cap \Omega(T')) \cap T'/(\Omega(T) \cap \Omega(T'))\\ = \pi^{-1}(T/\Omega(T')) \cap \pi'^{-1}(T'/\Omega(T'));\end{array}$$

- As far as kernels, we get

$$\begin{aligned}&\mathrm{Ker}(\langle I,\pi\rangle)\cap\mathrm{Ker}(\langle I,\pi'\rangle)\\&=\Omega(T)/(\Omega(T)\cap\Omega(T'))\cap\Omega(T')/(\Omega(T)\cap\Omega(T'))\\&=(\Omega(T)\cap\Omega(T'))/(\Omega(T)\cap\Omega(T'))=\Delta^{\mathfrak{F}}.\end{aligned}$$

Therefore,

$$\mathfrak{F}\in\overset{\triangleleft}{\mathbb{P}}(\mathrm{MatFam}^*(\mathcal{I}))\subseteq\mathrm{MatFam}^*(\mathcal{I}).$$

Hence $\Omega(T)=\Omega(T\cap T')=\Omega(T)\cap\Omega(T')$, which implies that $\Omega(T)\leq\Omega(T')$. Thus, Ω is monotone on theory families and, hence, $\mathcal{I}$ is protoalgebraic. ■

Finally, we work to obtain expressions for the protoclass $\mathrm{MatFam}^*(\mathcal{I})$ based on a reduced class M of generating $\mathbf{F}$-matrix families for $\mathcal{I}$.

We show, first, that if M is a class of reduced models of a protoalgebraic π-institution, then its closure under $\overset{\triangleleft}{\mathbb{P}}$ is included in its closure under $\overset{\leftarrow}{\mathbb{P}}^*$.

Proposition 1803 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a protoalgebraic π-institution based on* $\mathbf{F}$ *and* $\mathsf{M}\subseteq\mathrm{MatFam}^*(\mathcal{I})$ *a class of reduced $\mathcal{I}$-matrix families. Then*

$$\overset{\triangleleft}{\mathbb{P}}(\mathsf{M})\subseteq\overset{\leftarrow}{\mathbb{P}}^*(\mathsf{M}).$$

Proof: Let $\mathfrak{A}=\langle\mathcal{A},T\rangle\in\overset{\triangleleft}{\mathbb{P}}(\mathsf{M})$. Then, there exists a collection of subdirect intersection morphisms

$$\langle H^i,\gamma^i\rangle:\langle\mathcal{A},T\rangle\to\langle\mathcal{A}'^i,T'^i\rangle,\quad i\in I,$$

where $\mathfrak{A}'^i=\langle\mathcal{A}'^i,T'^i\rangle\in\mathsf{M}$, for all $i\in I$. By using the same morphisms,

$$\langle H^i,\gamma^i\rangle:\langle\mathcal{A},(\gamma^i)^{-1}(T'^i)\rangle\to\mathfrak{A}'^i,\quad i\in I,$$

which have now become strict and surjective, we get that, for all $i\in I$, $\langle\mathcal{A},(\gamma^i)^{-1}(T'^i)\rangle\in\mathbb{M}^{-1}(\mathsf{M})$. Moreover, since, by the definition of a subdirect intersection, $\mathfrak{A}=\langle\mathcal{A},T\rangle=\langle\mathcal{A},\bigcap_{i\in I}(\gamma^i)^{-1}(T'^i)\rangle$, we get that $\mathfrak{A}\in\mathbb{P}\mathbb{M}^{-1}(\mathsf{M})$. Now, by Theorem 1802, $\mathfrak{A}$ is reduced, whence $\mathfrak{A}\in(\mathbb{P}\mathbb{M}^{-1}(\mathsf{M}))^*=\overset{\leftarrow}{\mathbb{P}}^*(\mathsf{M})$. ■

Next, it is shown that, if M is a class of reduced models of a protoalgebraic π-institution, then its closure under $\overset{\leftarrow}{\mathbb{P}}^*$ is included in its closure under the operator $\overset{\triangleleft}{\mathbb{P}}\mathbb{M}^{-1*}$.

Proposition 1804 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a protoalgebraic π-institution based on* $\mathbf{F}$ *and* $\mathsf{M}\subseteq\mathrm{MatFam}^*(\mathcal{I})$ *a class of reduced $\mathcal{I}$-matrix families. Then*

$$\overset{\leftarrow}{\mathbb{P}}^*(\mathsf{M})\subseteq\overset{\triangleleft}{\mathbb{P}}\mathbb{M}^{-1*}(\mathsf{M}).$$

Proof: Suppose that $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I})$, for a protoalgebraic π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and let $\mathfrak{A}^* = \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle \in \overleftarrow{\mathbb{P}}^*(\mathsf{M})$, where $\mathfrak{A} = \langle \mathcal{A}, T\rangle = \langle \mathcal{A}, \bigcap_{i\in I} T^i\rangle$ is such that there exist strict surjective morphisms

$$\langle H^i, \gamma^i\rangle : \langle \mathcal{A}, T^i\rangle \to \langle \mathcal{A}'^i, T'^i\rangle, \quad i \in I,$$

with $\mathfrak{A}'^i = \langle \mathcal{A}'^i, T'^i\rangle \in \mathsf{M}$, for all $i \in I$. The key now is to look at the collection of the projection morphisms

$$\langle I, \pi^i\rangle : \mathfrak{A}^* \to \langle \mathcal{A}/\Omega^{\mathcal{A}}(T^i), T^i/\Omega^{\mathcal{A}}(T^i)\rangle, \quad i \in I,$$

where, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\pi^i_\Sigma(\phi/\Omega^{\mathcal{A}}_\Sigma(\bigcap_{i\in I} T^i)) = \phi/\Omega^{\mathcal{A}}_\Sigma(T^i).$$

Since $\langle H^i, \gamma^i\rangle$ is strict and surjective, we have that $\langle \mathcal{A}, T^i\rangle \in \mathbb{M}^{-1}(\mathsf{M})$, for all $i \in I$. Thus, $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T^i), T^i/\Omega^{\mathcal{A}}(T^i)\rangle \in \mathbb{M}^{-1*}(\mathsf{M})$. Therefore, to complete the proof, it suffices to show that the collection $\langle I, \pi^i\rangle$, $i \in I$, constitutes a collection of subdirect intersection morphisms. This is not difficult to verify. We have

- $\bigcap_{i\in I}(\pi^i)^{-1}(T^i/\Omega^{\mathcal{A}}(T^i)) = \bigcap_{i\in I} T^i/\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i) = (\bigcap_{i\in I} T^i)/\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i)$;
- For kernels,

$$\begin{array}{lcll}\bigcap_{i\in I}\mathrm{Ker}(\langle I, \pi^i\rangle) & = & \bigcap_{i\in I}\Omega^{\mathcal{A}}(T^i)/\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i) & \\ & = & \Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i)/\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i) & (\mathcal{I} \text{ protoalgebraic}) \\ & = & \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(\bigcap_{i\in I} T^i)}. & \end{array}$$

Now we have $\mathfrak{A}^* \in \overset{\triangleleft}{\mathbb{P}}\mathbb{M}^{-1}(\mathsf{M})$. ■

We are now able to obtain, under protoalgebraicity, some equivalent expressions for the operator $\overleftarrow{\mathbb{P}}^*$, which, based on Theorem 1798, will allow us to provide characterizations for the class $\mathrm{MatFam}^*(\mathcal{I})$, in case $\mathcal{I}$ is protoalgebraic.

Theorem 1805 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I})$*, for a protoalgebraic* π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *based on* $\mathbf{F}$*. Then*

$$\overset{\triangleleft}{\mathbb{P}}(\mathsf{M}) = \overleftarrow{\mathbb{P}}^*(\mathsf{M}) = \overset{\triangleleft}{\mathbb{P}}\mathbb{M}^{-1*}(\mathsf{M}).$$

Proof: Suppose $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I})$, for a protoalgebraic π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$. Then, we have

$$\begin{array}{lcll}\overset{\triangleleft}{\mathbb{P}}(\mathsf{M}) & \subseteq & \overleftarrow{\mathbb{P}}^*(\mathsf{M}) & (\text{Proposition 1803}) \\ & \subseteq & \overset{\triangleleft}{\mathbb{P}}\mathbb{M}^{-1*}(\mathsf{M}) & (\text{Proposition 1804}) \\ & \subseteq & \overset{\triangleleft}{\mathbb{P}}(\overset{\triangleleft}{\mathbb{P}}(\mathsf{M})) & (\text{Proposition 1801}) \\ & = & \overset{\triangleleft}{\mathbb{P}}(\mathsf{M}). & (\text{Lemma 1800})\end{array}$$

The conclusion follows. ∎

Finally, we get the following characterization of $\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}})$ in terms of closure operators on M, under the hypothesis that M is a subclass of a protoclass of $\mathbf{F}$-matrix families.

Theorem 1806 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I})$*, for a protoalgebraic* π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *based on* $\mathbf{F}$*. Then*

$$\mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) = \mathbb{M}\overset{\triangleleft}{\mathbb{III}}(\mathsf{M}).$$

Proof: Suppose $\mathsf{M} \subseteq \mathrm{MatFam}^*(\mathcal{I})$, for a protoalgebraic π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$. Then,

$$\begin{array}{rcll} \mathrm{MatFam}^*(\mathcal{I}^{\mathsf{M}}) & = & \mathbb{M}\overset{\leftarrow}{\mathbb{III}}^*(\mathsf{M}) & \text{(Theorem 1798)} \\ & = & \mathbb{M}\overset{\triangleleft}{\mathbb{III}}(\mathsf{M}). & \text{(Theorem 1805)} \end{array}$$

∎

24.5 Irreducibility

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, an $\mathbf{F}$-algebraic system and $\mathfrak{A} = \langle \mathcal{A}, X \rangle \in \mathrm{MatFam}(\mathcal{I})$.

An $\mathcal{I}$-filter family $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ is **completely meet irreducible in** $\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ if, for all $\{T^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$,

$$T = \bigcap_{i \in I} T^i \quad \text{implies} \quad T = T^i, \text{ for some } i \in I.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i \rangle \rangle$, $i \in I$, a collection of $\mathbf{F}$-algebraic systems and $\mathfrak{A}^i = \langle \mathcal{A}^i, T^i \rangle$ a collection of $\mathbf{F}$-matrix families. Recall that an $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, is a **subdirect intersection** of the collection $\mathfrak{A}^i$, $i \in I$, if there exist surjective morphisms

$$\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}^i, \quad i \in I,$$

such that $T = \bigcap_{i \in I} (\gamma^i)^{-1}(T^i)$ and $\bigcap_{i \in I} \mathrm{Ker}(\langle H^i, \gamma^i \rangle) = \Delta^{\mathcal{A}}$. This subdirect intersection is called a **special subdirect intersection** if $H^i : \mathbf{Sign} \to \mathbf{Sign}^i$ is an isomorphism, for all $i \in I$.

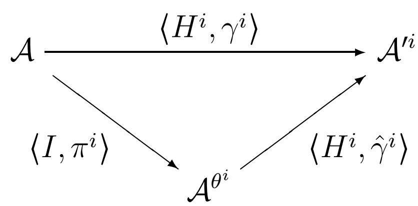
It turns out that $\mathbf{F}$-matrix families are representable as subdirect intersections if and only they are representable as special subdirect intersections.

Proposition 1807 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system and* $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ *an* $\mathbf{F}$*-matrix family. Then* $\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}'^i$*,* $i \in I$*, is a collection of subdirect intersection morphisms if and only if*

$$\langle I, \pi^i \rangle : \mathfrak{A} \to \langle \mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle), (\gamma^i)^{-1}(T'^i)/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) \rangle, \quad i \in I,$$

is a collection of special subdirect intersection morphisms.

Proof: Suppose, first, that $\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathcal{A}'^i$, $i \in I$, is a sibdirect intersection representation of $\mathfrak{A}$. For convenience, denote $\theta^i = \mathrm{Ker}(\langle H^i, \gamma^i \rangle)$, $i \in I$. Note that there exist algebraic system morphisms $\langle H^i, \hat{\gamma}^i \rangle : \mathcal{A}^{\theta^i} \to \mathcal{A}'^i$, such that



$$\langle H^i, \gamma^i \rangle = \langle H^i, \hat{\gamma}^i \rangle \circ \langle I, \pi^i \rangle,$$

where $\langle I, \pi^i \rangle : \mathcal{A} \to \mathcal{A}^{\theta^i}$, $i \in I$, are the quotient morphisms. Moreover, these morphisms are well-defined $\mathbf{F}$-matrix family morphisms, since, for all $i \in I$, we have, on the one hand, $T \le (\gamma^i)^{-1}(T'^i) = (\pi^i)^{-1}((\gamma^i)^{-1}(T'^i)/\theta^i)$, and, on the other, $(\pi^i)^{-1}((\gamma^i)^{-1}(T'^i)/\theta^i) = (\gamma^i)^{-1}(T'^i) = (\pi^i)^{-1}((\hat{\gamma}^i)^{-1}(T'^i))$ and, hence, by the surjectivity of $\langle I, \pi^i \rangle$, $(\gamma^i)^{-1}(T'^i)/\theta^i = (\hat{\gamma}^i)^{-1}(T'^i)$. Now we compute:

- For the filter families:

$$\begin{array}{l} \bigcap_{i \in I} (\pi^i)^{-1}((\gamma^i)^{-1}(T'^i)/\theta^i) \\ \quad = \bigcap_{i \in I} (\pi^i)^{-1}(\pi^i((\gamma^i)^{-1}(T'^i))) \\ \quad = \bigcap_{i \in I} (\gamma^i)^{-1}(T'^i) \\ \quad\quad (\theta^i \text{ compatible with } (\gamma^i)^{-1}(T'^i)) \\ \quad = T. \quad \text{(by hypothesis)} \end{array}$$

- For the kernels

$$\begin{array}{rcl} \bigcap_{i \in I} \mathrm{Ker}(\langle I, \pi^i \rangle) & = & \bigcap_{i \in I} \theta^i \\ & = & \Delta^{\mathcal{A}}. \quad \text{(by hypothesis)} \end{array}$$

Therefore,

$$\langle I, \pi^i \rangle : \mathfrak{A} \to \langle \mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle), (\gamma^i)^{-1}(T'^i)/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) \rangle, \quad i \in I,$$

is a collection of special subdirect intersection morphisms. ■

Special subdirect intersections of reduced matrix families have a characterization similar to the one applicable for subdirect products of reduced matriced.

Proposition 1808 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle$ *be an* $\mathbf{F}$*-algebraic system and* $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ *an* $\mathbf{F}$*-matrix family.* $\mathfrak{A}$ *is a special subdirect intersection of the system* $\{\mathfrak{A}'^i = \langle \mathcal{A}'^i, T'^i \rangle : i \in I\}$ *of reduced* $\mathbf{F}$*-matrix families if and only if, there exists a corresponding system of sentence families* $\{T^i : i \in I\} \subseteq \mathrm{SenFam}(\mathcal{A})$*, such that:*

(i) $\bigcap_{i \in I} T^i = T$*;*

(ii) $\mathfrak{A}/T^i \cong \mathfrak{A}'^i$*, for all* $i \in I$*.*

Proof: Suppose, first, that $\langle H^i, \gamma^i \rangle : \mathfrak{A} \to \mathfrak{A}'^i$, $i \in I$, is a collection of special subdirect intersection morphisms. Define $T^i = (\gamma^i)^{-1}(T'^i)$, $i \in I$. Then, we have

- $\bigcap_{i \in I} T^i = \bigcap_{i \in I} (\gamma^i)^{-1}(T'^i) = T$;
- Noting that

$$\begin{array}{rcl}\Omega^{\mathcal{A}}(T^i) & = & \Omega^{\mathcal{A}}((\gamma^i)^{-1}(T'^i)) \quad (\text{definition of } T^i)\\ & = & (\gamma^i)^{-1}(\Omega^{\mathcal{A}'^i}(T'^i)) \quad (\text{Proposition 24})\\ & = & (\gamma^i)^{-1}(\Delta^{\mathcal{A}'^i}) \quad (\mathfrak{A}'^i \text{ reduced})\\ & = & \mathrm{Ker}(\langle H^i, \gamma^i \rangle), \quad (\text{set theory})\end{array}$$

  we obtain

$$\begin{array}{rcl}\mathfrak{A}/T^i & = & \langle \mathcal{A}/\Omega^{\mathcal{A}}(T^i), T^i/\Omega^{\mathcal{A}}(T^i) \rangle\\ & = & \langle \mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle), (\gamma^i)^{-1}(T'^i)/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) \rangle\\ & \cong & \mathfrak{A}'^i,\end{array}$$

  where the last isomorphism is established by the morphism $\langle H^i, \hat{\gamma}^i \rangle : \mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) \to \mathcal{A}'^i$, given in Proposition 1807.

Thus, (i) and (ii) of the statement hold.

Assume, conversely, that there exists a system $\{T^i : i \in I\} \subseteq \mathrm{SenFam}(\mathcal{A})$ satisfying (i) and (ii). Consider $\langle I, \pi^i \rangle : \mathcal{A} \to \mathcal{A}/\Omega^{\mathcal{A}}(T^i)$, $i \in I$. This forms a well-defined system of $\mathbf{F}$-matrix family morphisms

$$\langle I, \pi^i \rangle : \mathfrak{A} \to \mathfrak{A}/T^i, \quad i \in I.$$

Since, by hypothesis, $\mathfrak{A}/T^i \cong \mathfrak{A}'^i$, for all $i \in I$, it suffices to show that the above system of morphisms constitutes a subdirect intersection. We indeed have

- $\bigcap_{i \in I} (\pi^i)^{-1}(T^i/\Omega^{\mathcal{A}}(T^i)) = \bigcap_{i \in I} T^i = T$;
- $\bigcap_{i \in I} \mathrm{Ker}(\langle I, \pi^i \rangle) = \bigcap_{i \in I} \Omega^{\mathcal{A}}(T^i) \leq \Omega^{\mathcal{A}}(\bigcap_{i \in I} T^i) = \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$.

So $\{\langle I,\pi^i\rangle : \mathfrak{A} \to \mathfrak{A}/T^i : i \in I\}$ is a system of special subdirect intersection morphisms. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, M a class of reduced $\mathbf{F}$-matrix families and $\mathfrak{A} = \langle \mathcal{A}, T\rangle \in \mathsf{M}$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$.

The $\mathbf{F}$-matrix family $\mathfrak{A} \in \mathsf{M}$ is called **subdirectly irreducible relative to** M if, for every subdirect intersection

$$\langle H^i, \gamma^i\rangle : \mathfrak{A} \to \mathfrak{A}'^i, \quad i \in I,$$

with $\mathfrak{A}'^i \in \mathsf{M}$, for all $i \in I$, there exists $i \in I$, such that

(i) $T = (\gamma^i)^{-1}(T'^i)$ and

(ii) $\mathrm{Ker}(\langle H^i, \gamma^i\rangle) = \Delta^{\mathcal{A}}$.

We write $\mathsf{M}^\S$ for the class of all relatively subdirectly irreducible members of M.

If $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is a π-institution based on $\mathbf{F}$ and $\mathsf{M} = \mathrm{MatFam}^*(\mathcal{I})$ is the class of all reduced $\mathcal{I}$-matrix families, then a subdirectly irreducible $\mathfrak{A}$ relative to M is also called **subdirectly irreducible relative to** $\mathcal{I}$.

It turns out that relative subdirect irreducibility and complete meet irreducibility have a close relationship. To detail the relationship, we need an additional operator on classes of $\mathbf{F}$-matrix families.

Proposition 1809 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, \mathbb{N}^\flat\rangle$ *be an algebraic system and* M *a class of reduced* $\mathbf{F}$*-matrix families closed under reduced inverse morphic images, i.e., such that* $\mathbb{M}^{-1*}(\mathsf{M}) \subseteq \mathsf{M}$*. Then an* $\mathbf{F}$*-matrix family* $\mathfrak{A} = \langle \mathcal{A}, T\rangle \in \mathsf{M}$ *is subdirectly irreducible relative to* M *if and only if* T *is completely meet irreducible in* $\mathcal{X} = \{X \in \mathrm{SenFam}(\mathcal{A}) : \mathfrak{A}/X \in \mathsf{M}\}$.

Proof: Suppose, first, that $\mathfrak{A} = \langle \mathcal{A}, T\rangle \in \mathsf{M}^\S$ and let $\{X^i : i \in I\} \subseteq \mathcal{X}$, such that $T = \bigcap_{i\in I} X^i$. Then, by Proposition 1807,

$$\langle I, \pi^i\rangle : \mathfrak{A} \to \mathfrak{A}/X^i, \quad i \in I,$$

constitutes a special subdirect intersection. Moreover, since $X^i \in \mathcal{X}$, for all $i \in I$, we have that $\mathfrak{A}/X^i \in \mathsf{M}$, for all $i \in I$. By hypothesis, there exists an $i \in I$, such that $T = (\pi^i)^{-1}(X^i/\Omega^{\mathcal{A}}(X^i)) = X^i$. We conclude that T is completely meet irreducible in $\mathcal{X}$.

Assume, conversely, that T is completely meet irreducible in $\mathcal{X}$ and let

$$\langle H^i, \gamma^i\rangle : \mathfrak{A} \to \mathfrak{A}'^i, \quad i \in I,$$

be a system of subdirect intersection morphisms, with $\mathfrak{A}'^i \in \mathsf{M}$, for all $i \in I$. By Proposition 1807,

$$\langle I, \pi^i\rangle : \mathfrak{A} \to \mathfrak{A}/(\gamma^i)^{-1}(T'^i), \quad i \in I,$$

is a collection of special subdirect intersection morphisms. Moreover, $\langle H^i, \hat{\gamma}^i\rangle : \mathfrak{A}/(\gamma^i)^{-1}(T'^i) \to \mathfrak{A}'^i$, $i \in I$, are strict surjective morphisms and $\mathfrak{A}/(\gamma^i)^{-1}(T'^i)$ is reduced. Thus, since $\mathfrak{A}'^i \in \mathsf{M}$, for all $i \in I$ and $\mathbb{M}^{-1*}(\mathsf{M}) \subseteq \mathsf{M}$, we get that $\mathfrak{A}/(\gamma^i)^{-1}(T'^i) \in \mathsf{M}$, for all $i \in I$. This shows that $(\gamma^i)^{-1}(T'^i) \in \mathcal{X}$, for all $i \in I$. But, by the subdirect intersection property, $T = \bigcap_{i\in I}(\gamma^i)^{-1}(T'^i)$, whence, by hypothesis, there exists $i \in I$, such that $T = (\gamma^i)^{-1}(T'^i)$. Moreover, $\mathrm{Ker}(\langle H^i, \gamma^i\rangle) = (\gamma^i)^{-1}(\Delta^{\mathcal{A}'^i}) = (\gamma^i)^{-1}(\Omega^{\mathcal{A}'^i}(T'^i)) = \Omega^{\mathcal{A}}((\gamma^i)^{-1}(T'^i)) = \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Therefore, $\mathfrak{A}$ is subdirectly irreducible relative to M. ∎

Chapter 25

Order Algebraizability

25.1 Algebraic PoSystems

Let **Sign** be a category and $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ be a sentence functor. A **qofamily** $\leq = \{\leq_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ on SEN is a relation family on SEN, such that, for all $\Sigma \in |\mathbf{Sign}|$, $\leq_\Sigma \subseteq \mathrm{SEN}(\Sigma)^2$ is a quasi-order on $\mathrm{SEN}(\Sigma)$. A **pofamily** $\leq = \{\leq_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ on SEN is a relation family on SEN, such that, for all $\Sigma \in |\mathbf{Sign}|$, $\leq_\Sigma \subseteq \mathrm{SEN}(\Sigma)^2$ is a partial order on $\mathrm{SEN}(\Sigma)$. A **qosystem** $\leq$ on SEN is a qofamily that is also a relation system. i.e., invariant under **Sign**-morphisms, that is, such that, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\leq_\Sigma) \subseteq \leq_{\Sigma'}.$$

Similarly, a **posystem** $\leq$ on SEN is a pofamily that is also a relation system.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system. A **qosystem** (**posystem**) on $\mathbf{A}$ is a qosystem (posystem, respectively) on SEN. The pair $\langle \mathbf{A}, \leq \rangle$ is then called an **algebraic qosystem** (**algebraic posystem**, respectively).

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. A **qosystem** (**posystem**) on $\mathcal{A}$ is a qosystem (posystem, respectively) on $\mathbf{A}$. We then term the pair $\langle \mathcal{A}, \leq \rangle$ an **F-algebraic qosystem** (**F-algebraic posystem**, respectively).

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system.

- The family of **F-inequations** $\mathrm{In}(\mathbf{F}) = \{\mathrm{In}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{In}_\Sigma(\mathbf{F}) = \{\phi \preccurlyeq \psi : \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\};$$

- The family of **F-quasi inequations** $\mathrm{QIn}(\mathbf{F}) = \{\mathrm{QIn}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{In}_\Sigma(\mathbf{F}) = \{\langle \{\phi_i \preccurlyeq \psi_i : i < k\}, \phi \preccurlyeq \psi \rangle : \vec{\phi}, \vec{\psi}, \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\};$$

- The family of **F-guasi inequations** $\mathrm{GIn}(\mathbf{F}) = \{\mathrm{GIn}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{In}_\Sigma(\mathbf{F}) = \{\langle \{\phi_i \preccurlyeq \psi_i : i \in I\}, \phi \preccurlyeq \psi \rangle : \vec{\phi}, \vec{\psi}, \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\}.$$

As done previously, we sometimes abbreviate a guasi inequation $\langle \{\phi_i \preccurlyeq \psi_i : i \in I\}, \phi \preccurlyeq \psi \rangle$ by writing $\langle \vec{\phi} \preccurlyeq \vec{\psi}, \phi \preccurlyeq \psi \rangle$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic posystems. We define the family $C^{\mathsf{K},\leq} : \mathcal{P}\mathrm{In}(\mathbf{F}) \to \mathcal{P}\mathrm{In}(\mathbf{F})$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$,

$$\begin{array}{l} \phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(I) \text{ iff, for all } \langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}, \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \\ \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(I)) \subseteq \leq^{\mathcal{A}}_{F(\Sigma')} \\ \qquad\qquad \text{implies } \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq^{\mathcal{A}}_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)). \end{array}$$

It is not difficult to see that $C^{\mathsf{K},\leq}$ is a closure system on $\mathrm{In}(\mathbf{F})$.

Lemma 1810 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems. Then* $C^{\mathsf{K},\leq} : \mathcal{P}\mathrm{In}(\mathbf{F}) \to \mathcal{P}\mathrm{In}(\mathbf{F})$ *is a closure system on* $\mathrm{In}(\mathbf{F})$*.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$. It is straightforward from the definition of $C^{\mathsf{K},\leq}$ that $C^{\mathsf{K},\leq}_\Sigma$ is inflationary and monotone. We show that it is also idempotent. To this end, let $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$, be such that $\phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(C^{\mathsf{K},\leq}_\Sigma(I))$. Then, for all$\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, we have $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(I)) \subseteq \leq^{\mathcal{A}}_{F(\Sigma')}$ implies, by definition,

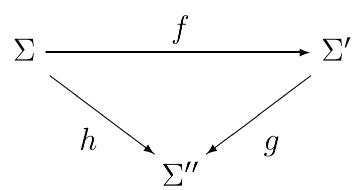
$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(C^{\mathsf{K},\leq}_\Sigma(I))) \subseteq \leq^{\mathcal{A}}_{F(\Sigma')},$$

whence, by the hypothesis and the definition,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq^{\mathcal{A}}_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).$$

We now get $\phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(I)$. Therefore, $C^{\mathsf{K},\leq}_\Sigma$ is also idempotent.

Finally, it only remains to show structurality. To this end, let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$, such that $\phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(I)$. Then, by definition, for every $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $h \in \mathbf{Sign}^\flat(\Sigma, \Sigma'')$, $\alpha_{\Sigma''}(\mathrm{SEN}^\flat(h)(I)) \subseteq \leq^{\mathcal{A}}_{F(\Sigma'')}$ implies $\alpha_{\Sigma''}(\mathrm{SEN}^\flat(h)(\phi)) \leq^{\mathcal{A}}_{F(\Sigma'')} \alpha_{\Sigma''}(\mathrm{SEN}^\flat(h)(\psi))$.



In particular, for all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$,

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(I))) \subseteq \leq^{\mathcal{A}}_{F(\Sigma'')}$$

implies

$$\alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\phi))) \leq^{\mathcal{A}}_{F(\Sigma'')} \alpha_{\Sigma''}(\mathrm{SEN}^\flat(g)(\mathrm{SEN}^\flat(f)(\psi))).$$

Therefore, $\mathrm{SEN}^\flat(f)(\phi) \preccurlyeq \mathrm{SEN}^\flat(f)(\psi) \in C^{\mathsf{K},\leq}_{\Sigma'}(\mathrm{SEN}^\flat(f)(I))$. We conclude that $C^{\mathsf{K},\leq}$ is also structural and, hence, a closure system on $\mathrm{In}(\mathbf{F})$. ∎

As a result of Lemma 1810, it makes sense to define the **inequational** π**-institution** $\mathcal{I}^{\mathsf{K},\leq} = \langle \mathbf{F}, C^{\mathsf{K},\leq} \rangle$ **associated with** a class K of $\mathbf{F}$-algebraic posystems.

We can show that the π-institution $\mathcal{I}^{\mathsf{K},\leq}$ associated with the class K satisfies a reflexivity and transitivity property. On the other hand, antisymmetry is not expressible in the language under consideration, since it is a language without equality.

Lemma 1811 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$*,*

(a) $\phi \preccurlyeq \phi \in C_\Sigma^{\mathsf{K},\leq}(\varnothing)$*;*

(b) $\phi \preccurlyeq \chi \in C_\Sigma^{\mathsf{K},\leq}(\phi \preccurlyeq \psi, \psi \preccurlyeq \chi)$*.*

Proof: Clearly, for all $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, we get, by the reflexivity of $\leq^{\mathcal{A}}$, that

$$\mathrm{SEN}^\flat(f)(\phi) \leq^{\mathcal{A}}_{F(\Sigma')} \mathrm{SEN}^\flat(f)(\phi).$$

Thus, by definition, $\phi \preccurlyeq \phi \in C_\Sigma^{\mathsf{K},\leq}(\varnothing)$.

Similarly, for all $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, by the transitivity of $\leq^{\mathcal{A}}$, we get that

$$\mathrm{SEN}^\flat(f)(\phi) \leq^{\mathcal{A}}_{F(\Sigma')} \mathrm{SEN}^\flat(f)(\psi) \text{ and } \mathrm{SEN}^\flat(f)(\psi) \leq^{\mathcal{A}}_{F(\Sigma')} \mathrm{SEN}^\flat(f)(\chi)$$

imply $\mathrm{SEN}^\flat(f)(\phi) \leq^{\mathcal{A}}_{F(\Sigma')} \mathrm{SEN}^\flat(f)(\chi)$. Therefore, by definition $\phi \preccurlyeq \chi \in C_\Sigma^{\mathsf{K},\leq}(\phi \preccurlyeq \psi, \psi \preccurlyeq \chi)$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle$ an $\mathbf{F}$-algebraic posystem and $g = \langle \vec{\phi} \preccurlyeq \vec{\psi}, \phi \preccurlyeq \psi \rangle \in \mathrm{GIn}_\Sigma(\mathbf{F})$. We say $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle$ **satisfies** g or that g **holds** or **is valid in** $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle$, written

$$\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \vDash_\Sigma g,$$

if, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_i)) \leq^{\mathcal{A}}_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi_i)), \text{ for all } i \in I,$$

imply $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq^{\mathcal{A}}_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))$. Equivalently, $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle$ satisfies g if $\phi \preccurlyeq \psi \in C_\Sigma^{\{\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle\},\leq}(\vec{\phi} \preccurlyeq \vec{\psi})$.

Given a class K of $\mathbf{F}$-algebraic posystems and a class G of $\mathbf{F}$-guasi inequations, we write $\mathrm{GIn}(\mathsf{K})$ for the class of all $\mathbf{F}$-guasi inequations satisfied by every $\mathbf{F}$-algebraic posystem in K and $\mathrm{PAlgSys}(G)$ for the class of all $\mathbf{F}$-algebraic posystems that satisfy all $\mathbf{F}$-guasi inequations in G.

We now turn to examining some operations on classes of $\mathbf{F}$-algebraic posystems. We first show that the inverse image of a posystem under an $\mathbf{F}$-algebraic system morphism is also a posystem.

Lemma 1812 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ *be two* $\mathbf{F}$*-algebraic systems and* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism.*

(a) If $\leq^{\mathcal{B}}$ *is a posystem on* $\mathcal{B}$*, then* $\gamma^{-1}(\leq^{\mathcal{B}})$ *is a qosystem on* $\mathcal{A}$*;*

(b) If $\leq^{\mathcal{B}}$ is a posystem on $\mathcal{B}$ and $\mathrm{Ker}(\langle H,\gamma\rangle) = \Delta^{\mathcal{A}}$*, then* $\gamma^{-1}(\leq^{\mathcal{B}})$ *is a posystem on* $\mathcal{A}$.

Proof: Let $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi,\chi \in \mathrm{SEN}(\Sigma)$.

By the reflexivity of $\leq^{\mathcal{B}}$, we have $\gamma_\Sigma(\phi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\phi)$. Thus, $\phi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\phi$ and, hence $\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})$ is reflexive.

Suppose, next, that $\phi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\psi$ and $\psi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\chi$. Then, $\gamma_\Sigma(\phi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\psi)$ and $\gamma_\Sigma(\psi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\chi)$. Thus, by the transitivity of $\leq^{\mathcal{B}}$, we get $\gamma_\Sigma(\phi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\chi)$. Therefore, $\phi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\chi$ and $\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})$ is also transitive.

If $\phi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\psi$, $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma,\Sigma')$, then we get $\gamma_\Sigma(\phi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\psi)$, whence $\mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)) \leq^{\mathcal{B}}_{H(\Sigma')} \mathrm{SEN}'(H(f))(\gamma_\Sigma(\psi))$. Thus,

$$\gamma_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \leq^{\mathcal{B}}_{H(\Sigma')} \gamma_{\Sigma'}(\mathrm{SEN}(f)(\psi)).$$

So we obtain $\mathrm{SEN}(f)(\phi)\gamma_{\Sigma'}^{-1}(\leq^{\mathcal{B}})\mathrm{SEN}(f)(\psi)$. This shows that $\gamma^{-1}(\leq^{\mathcal{B}})$ is a qosystem on $\mathcal{A}$.

Suppose, finally, for the sake of proving Part (b), that $\phi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\psi$ and $\psi\gamma_\Sigma^{-1}(\leq^{\mathcal{B}})\phi$. Then, $\gamma_\Sigma(\phi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\psi)$ and $\gamma_\Sigma(\psi) \leq^{\mathcal{B}}_{H(\Sigma)} \gamma_\Sigma(\phi)$. Thus, by the antisymmetry of $\leq^{\mathcal{B}}$, we get $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$. Since, by hypothesis, $\mathrm{Ker}(\langle H,\gamma\rangle) = \Delta^{\mathcal{A}}$, we get $\phi = \psi$ and, hence, $\gamma^{-1}(\leq^{\mathcal{B}})$ is a posystem on $\mathcal{A}$ in this case. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, K a class of $\mathbf{F}$-algebraic posystems and $\langle \mathcal{A}, \leq^{\mathcal{A}}\rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, an $\mathbf{F}$-algebraic posystem.

- Given $\Sigma \in |\mathbf{Sign}^\flat|$, we say that $\langle \mathcal{A}, \leq\rangle$ is Σ-K-**order certified** if there exists $\langle \mathcal{A}^\Sigma, \leq^\Sigma\rangle \in \mathsf{K}$, such that $\mathrm{In}_\Sigma(\langle \mathcal{A}, \leq\rangle) = \mathrm{In}_\Sigma(\langle \mathcal{A}^\Sigma, \leq^\Sigma\rangle)$. In this case $\langle \mathcal{A}^\Sigma, \leq^\Sigma\rangle$ will be referred to as the Σ-K-**order certificate** of $\langle \mathcal{A}, \leq\rangle$.

- We say that $\langle \mathcal{A}, \leq\rangle$ is K-**order certified** if it is Σ-K-order certified, for all $\Sigma \in |\mathbf{Sign}^\flat|$. This, of course, means that

$$(\forall \Sigma \in |\mathbf{Sign}^\flat|)(\exists \langle \mathcal{A}^\Sigma, \leq^\Sigma\rangle \in \mathsf{K})(\mathrm{In}_\Sigma(\langle \mathcal{A}, \leq\rangle) = \mathrm{In}_\Sigma(\langle \mathcal{A}^\Sigma, \leq^\Sigma\rangle)).$$

We write $\mathbb{C}(\mathsf{K})$ for the class of all $\mathbf{F}$-algebraic posystems that are K-order certified. We say that K is an **abstract order class** whenever every K-order certified $\mathbf{F}$-algebraic posystem belongs to K, i.e., when $\mathbb{C}(\mathsf{K}) = \mathsf{K}$.

It is not difficult to show that $\mathbb{C}$ is a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 1813 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system. Then the operator* $\mathbb{C}$ *on classes of* $\mathbf{F}$*-algebraic posystems is a closure operator.*

Proof: Suppose K is a class of $\mathbf{F}$-algebraic posystems.

- Let $\langle\mathcal{A},\leq\rangle\in\mathsf{K}$. Then, since for all $\Sigma\in|\mathbf{Sign}^\flat|$, $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle=\langle\mathcal{A},\leq\rangle\in\mathsf{K}$ is a Σ-K-order certificate for $\langle\mathcal{A},\leq\rangle$, we get that $\langle\mathcal{A},\leq\rangle\in\mathbb{C}(\mathsf{K})$. Thus, $\mathsf{K}\subseteq\mathbb{C}(\mathsf{K})$ and $\mathbb{C}$ is inflationary.

- If $\mathsf{K}\subseteq\mathsf{K}'$ and $\langle\mathcal{A},\leq\rangle\in\mathbb{C}(\mathsf{K})$, then, by definition, for every $\Sigma\in|\mathbf{Sign}^\flat|$, there exists a Σ-K-order certificate $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle$. Since $\mathsf{K}\subseteq\mathsf{K}'$, $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle\in\mathsf{K}'$ is also a Σ-K'-order certificate. Thus, $\langle\mathcal{A},\leq\rangle\in\mathbb{C}(\mathsf{K}')$ and $\mathbb{C}$ is also monotone.

- Finally, suppose that $\langle\mathcal{A},\leq\rangle\in\mathbb{C}(\mathbb{C}(\mathsf{K}))$. Then, there exists, for all $\Sigma\in|\mathbf{Sign}^\flat|$, a Σ-$\mathbb{C}(\mathsf{K})$-order certificate $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle$ for $\mathcal{A}$. Therefore, for every $\Sigma'\in|\mathbf{Sign}^\flat|$, there exists a Σ'-K-order certificate $\langle\mathcal{A}^{\langle\Sigma,\Sigma'\rangle},\leq^{\langle\Sigma,\Sigma'\rangle}\rangle$ for $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle$. Thus, for every $\Sigma\in|\mathbf{Sign}^\flat|$, there exists a Σ-K-order certificate $\langle\mathcal{A}^{\langle\Sigma,\Sigma\rangle},\leq^{\langle\Sigma,\Sigma\rangle}\rangle$ for $\langle\mathcal{A},\leq\rangle$, since, by hypothesis,
$$\mathrm{In}_\Sigma(\langle\mathcal{A},\leq\rangle)=\mathrm{In}_\Sigma(\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle)=\mathrm{In}_\Sigma(\langle\mathcal{A}^{\langle\Sigma,\Sigma\rangle},\leq^{\langle\Sigma,\Sigma\rangle}\rangle).$$

Thus $\mathbb{C}$ is a closure operator on classes of $\mathbf{F}$-algebraic posystems. ∎

The importance of abstract classes of $\mathbf{F}$-algebraic posystems rests on the fact that the validity of an $\mathbf{F}$-guasi inequation transfers from K-order certificates to an $\mathbf{F}$-algebraic posystem itself.

Lemma 1814 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* K *a class of* $\mathbf{F}$*-algebraic posystems and* $\langle\mathcal{A},\leq\rangle$, $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$*, an* $\mathbf{F}$*-algebraic posystem. If* $\mathcal{A}\in\mathbb{C}(\mathsf{K})$*, then* $\mathrm{GIn}(\mathsf{K})\leq\mathrm{GIn}(\mathcal{A})$.

Proof: Suppose $\langle\mathcal{A},\leq\rangle\in\mathbb{C}(\mathsf{K})$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\langle\vec{\phi}\preccurlyeq\vec{\psi},\phi\preccurlyeq\psi\rangle\in\mathrm{GIn}_\Sigma(\mathsf{K})$, such that $\vec{\phi}\preccurlyeq\vec{\psi}\subseteq\mathrm{In}_\Sigma(\langle\mathcal{A},\leq\rangle)$. Let $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle\in\mathsf{K}$ be a Σ-K-order certificate for $\mathcal{A}$. Then, by definition $\vec{\phi}\preccurlyeq\vec{\psi}\subseteq\mathrm{In}_\Sigma(\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle)$. Since $\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle\in\mathsf{K}$ and $\langle\vec{\phi}\preccurlyeq\vec{\psi},\phi\preccurlyeq\psi\rangle\in\mathrm{GIn}_\Sigma(\mathsf{K})$, we get $\phi\preccurlyeq\psi\in\mathrm{In}_\Sigma(\langle\mathcal{A}^\Sigma,\leq^\Sigma\rangle)=\mathrm{In}_\Sigma(\langle\mathcal{A},\leq\rangle)$. Therefore, $\langle\vec{\phi}\preccurlyeq\vec{\psi},\phi\preccurlyeq\psi\rangle\in\mathrm{GIn}_\Sigma(\langle\mathcal{A},\leq\rangle)$. We conclude that $\mathrm{GIn}(\mathsf{K})\leq\mathrm{GIn}(\langle\mathcal{A},\leq\rangle)$. ∎

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic posystems.

- K is called an **inequational class** if there exists $I\leq\mathrm{In}(\mathbf{F})$, such that $\mathsf{K}=\mathrm{PAlgSys}(I)$;

- K is called a **quasi inequational class** if there exists $Q\leq\mathrm{QIn}(\mathbf{F})$, such that $\mathsf{K}=\mathrm{PAlgSys}(Q)$;

- K is called a **guasi inequational class** if there exists $G\leq\mathrm{GIn}(\mathbf{F})$, such that $\mathsf{K}=\mathrm{PAlgSys}(G)$.

Clearly, by definition, if K is an inequational class, then it is a quasi inequational class and, if it is a quasi inequational class, then it is a guasi inequational class.

Directly by these definitions and Lemma 1814, we get

Corollary 1815 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems. If* K *is a guasi inequational class (and, hence, a fortiori, if it is a quasi inequational class or an inequational class), then it is abstract.*

Proof: Suppose K is a guasi inequational class defined by the $\mathbf{F}$-guasi inequations $G \leq \mathrm{GIn}(\mathbf{F})$ and let $\langle \mathcal{A}, \leq \rangle \in \mathbb{C}(\mathsf{K})$. Then, by Lemma 1814, $\mathrm{GIn}(\mathsf{K}) \leq \mathrm{GIn}(\langle \mathcal{A}, \leq \rangle)$, whence

$$\begin{array}{rcl} \langle \mathcal{A}, \leq \rangle & \in & \mathrm{PAlgSys}(\mathrm{GIn}(\mathcal{A})) \\ & \subseteq & \mathrm{PAlgSys}(\mathrm{GIn}(\mathsf{K})) \\ & = & \mathrm{PAlgSys}(\mathrm{GIn}(\mathrm{PAlgSys}(G))) \\ & = & \mathrm{PAlgSys}(G) \\ & = & \mathsf{K}. \end{array}$$

Thus, K is an abstract class. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic posystems. We define:

- The **semantic order variety generated by** K
$$\mathbb{VO}^{\mathsf{Sem}}(\mathsf{K}) = \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : \mathrm{In}(\mathsf{K}) \leq \mathrm{In}(\langle \mathcal{A}), \leq \rangle\};$$
- The **semantic order quasivariety generated by** K
$$\mathbb{QO}^{\mathsf{Sem}}(\mathsf{K}) = \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : \mathrm{QIn}(\mathsf{K}) \leq \mathrm{QIn}(\langle \mathcal{A}, \leq \rangle)\};$$
- The **semantic order guasivariety generated by** K
$$\mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) = \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : \mathrm{GIn}(\mathsf{K}) \leq \mathrm{GIn}(\langle \mathcal{A}, \leq \rangle)\}.$$

We have the following obvious relations between these classes.

Lemma 1816 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems. Then*

$$\mathsf{K} \subseteq \mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{QO}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{VO}^{\mathsf{Sem}}(\mathsf{K}).$$

Proof: The essential observation is that

$$\mathrm{In}(\mathsf{K}) \leq \mathrm{QIn}(\mathsf{K}) \leq \mathrm{GIn}(\mathsf{K}).$$

Thus, we get

$$\begin{array}{l} \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : (\forall g \in \mathrm{GIn}(\mathsf{K}))(\langle \mathcal{A}, \leq \rangle \vDash g)\} \\ \quad \subseteq \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : (\forall q \in \mathrm{QIn}(\mathsf{K}))(\langle \mathcal{A}, \leq \rangle \vDash q)\} \\ \quad \subseteq \{\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F}) : (\forall e \in \mathrm{In}(\mathsf{K}))(\langle \mathcal{A}, \leq \rangle \vDash e)\}. \end{array}$$

In other words, $\mathsf{K} \subseteq \mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{QO}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{VO}^{\mathsf{Sem}}(\mathsf{K})$. ■

Given a class K of $\mathbf{F}$-algebraic posystems

- K is a **semantic order variety** if $\mathbb{VO}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$;
- K is a **semantic order quasivariety** if $\mathbb{QO}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$;
- K is a **semantic order guasivariety** if $\mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$.

We have the following result identifying inequational classes with semantic order varieties, quasi inequational classes with semantic order quasivarieties and guasi inequational classes with semantic order guasivarieties.

Proposition 1817 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems.*

(a) K *is an inequational class iff it is a semantic order variety;*

(b) K *is a quasi inequational class iff it is a semantic order quasivariety;*

(c) K *is a guasi inequational class iff it is a semantic order guasivariety.*

Proof:

(a) Suppose, first, that K is an inequational class. Then, there exists $I \leq \mathrm{In}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{PAlgSys}(I)$. Let $\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F})$, such that $\mathrm{In}(\mathsf{K}) \leq \mathrm{In}(\langle \mathcal{A}, \leq \rangle)$. Then we have $\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathrm{In}(\langle \mathcal{A}, \leq \rangle)) \subseteq \mathrm{PAlgSys}(\mathrm{In}(\mathsf{K})) = \mathrm{PAlgSys}(\mathrm{In}(\mathrm{PAlgSys}(I))) = \mathrm{PAlgSys}(I) = \mathsf{K}$. Therefore, K is a semantic order variety.

Suppose, conversely, that K is a semantic order variety. Set $I = \mathrm{In}(\mathsf{K})$. Then $\mathsf{K} \subseteq \mathrm{PAlgSys}(\mathrm{In}(\mathsf{K})) = \mathrm{PAlgSys}(I)$. On the other hand, if $\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(I)$, then

$$\mathrm{In}(\mathsf{K}) = \mathrm{In}(\mathrm{PAlgSys}(\mathrm{In}(\mathsf{K}))) = \mathrm{In}(\mathrm{PAlgSys}(I)) \leq \mathrm{In}(\langle \mathcal{A}, \leq \rangle),$$

whence, by hypothesis, $\langle \mathcal{A}, \leq \rangle \in \mathsf{K}$. Therefore, $\mathsf{K} = \mathrm{PAlgSys}(I)$ and K is an inequational class.

(b) Suppose, first, that K is a quasi inequational class. Then, there exists $Q \leq \mathrm{QIn}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{PAlgSys}(Q)$. Let $\langle \mathcal{A}, \leq \rangle \in \mathrm{PAlgSys}(\mathbf{F})$, such that $\mathrm{QIn}(\mathsf{K}) \leq \mathrm{QIn}(\langle \mathcal{A}, \leq \rangle)$. Then we have

$$\begin{array}{rcl}\langle \mathcal{A}, \leq \rangle & \in & \mathrm{PAlgSys}(\mathrm{QIn}(\langle \mathcal{A}, \leq \rangle)) \\ & \subseteq & \mathrm{PAlgSys}(\mathrm{QIn}(\mathsf{K})) \\ & = & \mathrm{PAlgSys}(\mathrm{QIn}(\mathrm{PAlgSys}(Q))) \\ & = & \mathrm{PAlgSys}(Q) \\ & = & \mathsf{K}.\end{array}$$

Therefore, K is a semantic order quasivariety.

Suppose, conversely, that K is a semantic order quasivariety. Set $Q = \mathrm{QIn}(\mathsf{K})$. Then $\mathsf{K} \subseteq \mathrm{PAlgSys}(\mathrm{QIn}(\mathsf{K})) = \mathrm{PAlgSys}(Q)$. On the other hand, if $\langle \mathcal{A}, \leq\rangle \in \mathrm{PAlgSys}(Q)$, then

$$\mathrm{QIn}(\mathsf{K}) = \mathrm{QIn}(\mathrm{PAlgSys}(\mathrm{QIn}(\mathsf{K}))) = \mathrm{QIn}(\mathrm{PAlgSys}(Q)) \leq \mathrm{QIn}(\langle \mathcal{A}, \leq\rangle),$$

whence, by hypothesis, $\langle \mathcal{A}, \leq\rangle \in \mathsf{K}$. Therefore, $\mathsf{K} = \mathrm{PAlgSys}(Q)$ and K is a quasi inequational class.

(c) Very similar to Part (b).

■

We introduce, next, some operators on classes of **F**-algebraic posystems, paralleling those introduced previously for classes of **F**-algebraic systems, that will serve to provide different characterizations to the inequational, quasi inequational and guasi inequational classes of **F**-algebraic posystems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\langle \mathcal{A}, \leq\rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\langle \mathcal{A}^i, \leq^i\rangle$, with $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i\rangle\rangle$, $i \in I$, **F**-algebraic posystems and $\langle H^i, \gamma^i\rangle : \langle \mathcal{A}, \leq\rangle \to \langle \mathcal{A}^i, \leq^i\rangle$, $i \in I$, surjective morphisms. We say the collection

$$\langle H^i, \gamma^i\rangle : \langle \mathcal{A}, \leq\rangle \to \langle \mathcal{A}^i, \leq^i\rangle, \quad i \in I,$$

is a **subdirect intersection** if

$$\bigcap_{i\in I} (\gamma^i)^{-1}(\leq^i) = \leq.$$

Note that this implies that

$$\bigcap_{i\in I} \mathrm{Ker}(\langle H^i, \gamma^i\rangle) = \Delta^{\mathcal{A}}.$$

Indeed, we have

$$\begin{array}{rcl}\bigcap_{i\in I}\mathrm{Ker}(\langle H^i,\gamma^i\rangle) & = & \bigcap_{i\in I}((\gamma^i)^{-1}(\leq^i) \cap (\gamma^i)^{-1}(\leq^i)^{-1})\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\leq^i) \cap \bigcap_{i\in I}(\gamma^i)^{-1}(\leq^i)^{-1}\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\leq^i) \cap (\bigcap_{i\in I}(\gamma^i)^{-1}(\leq^i))^{-1}\\ & = & \leq \cap (\leq)^{-1}\\ & = & \Delta^{\mathcal{A}}.\end{array}$$

Given a class K of **F**-algebraic posystems, we write $\langle \mathcal{A}, \leq\rangle \in \overset{\triangleleft}{\mathbb{II}}(\mathsf{K})$ in case there exists a subdirect intersection $\{\langle H^i, \gamma^i\rangle : \langle \mathcal{A}, \leq\rangle \to \langle \mathcal{A}^i, \leq^i\rangle, i \in I\}$, with $\langle \mathcal{A}^i, \leq^i\rangle \in \mathsf{K}$, for all $i \in I$. If $\overset{\triangleleft}{\mathbb{II}}(\mathsf{K}) = \mathsf{K}$, we say that K is **closed under subdirect intersections**.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ an **F**-algebraic system and $\leq$ a posystem on $\mathcal{A}$. A congruence system $\theta \in$

$\mathrm{ConSys}(\mathcal{A})$ is said to be **compatible with** $\le$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc} \phi & \overset{\le_\Sigma}{\rule{2cm}{0.4pt}} & \psi \\ \theta_\Sigma \Big| & & \Big| \theta_\Sigma \\ \phi' & \underset{\le_\Sigma}{\rule{2cm}{0.4pt}} & \psi' \end{array}$$

$$\phi \le_\Sigma \psi, \quad \phi \mathrel{\theta_\Sigma} \phi' \quad \text{and} \quad \psi \mathrel{\theta_\Sigma} \psi' \quad \text{imply} \quad \phi' \le_\Sigma \psi'.$$

A congruence system $\theta \in \mathrm{ConSys}(\mathcal{A})$ is said to be a **congruence system on the F**-algebraic posystem $\langle \mathcal{A}, \le^{\mathcal{A}} \rangle$ if it is compatible with $\le^{\mathcal{A}}$. We write $\mathrm{ConSys}(\langle \mathcal{A}, \le^{\mathcal{A}} \rangle)$ for the collection of all congruence systems on $\langle \mathcal{A}, \le^{\mathcal{A}} \rangle$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\langle \mathcal{A}, \le \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, an $\mathbf{F}$-algebraic posystem and $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}(\langle \mathcal{A}, \le \rangle)$ a (upward) directed collection of congruence systems on $\langle \mathcal{A}, \le \rangle$. It is not difficult to show that $\bigcup_{i \in I} \theta^i \in \mathrm{ConSys}(\langle \mathcal{A}, \le \rangle)$.

Lemma 1818 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\langle \mathcal{A}, \le \rangle$ *an* $\mathbf{F}$*-algebraic posystem and* $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}(\langle \mathcal{A}, \le \rangle)$ *a directed collection of congruence systems on* $\langle \mathcal{A}, \le \rangle$*. Then* $\bigcup_{i \in I} \theta^i$ *is a congruence system on* $\langle \mathcal{A}, \le \rangle$*.*

Proof: We know, by Lemma **??** that $\bigcup_{i \in I} \theta^i_\Sigma$ is a congruence system on $\mathcal{A}$. Thus, it suffices to show that it is compatible with $\le$. To this end, suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \phi', \psi, \psi' \in \mathrm{SEN}(\Sigma)$, such that $\phi \le_\Sigma \psi$, $\phi \mathrel{\bigcup_{i \in I} \theta^i_\Sigma} \phi'$ and $\psi \mathrel{\bigcup_{i \in I} \theta^i_\Sigma} \psi'$. Thus, there exist $j \in I$ and $j' \in I$, such that $\phi \mathrel{\theta^j_\Sigma} \phi'$ and $\psi \mathrel{\theta^{j'}_\Sigma} \psi'$. But $\{\theta^i\}_{i \in I}$ is directed, whence, there exists $k \in I$, such that $\phi \mathrel{\theta^k_\Sigma} \phi'$ and $\psi \mathrel{\theta^k_\Sigma} \psi'$. Therefore, since $\theta^k \in \mathrm{ConSys}(\langle \mathcal{A}, \le \rangle)$, we get $\phi' \le_\Sigma \psi'$. We conclude that $\bigcup_{i \in I} \theta^i \in \mathrm{ConSys}(\langle \mathcal{A}, \le \rangle)$. ∎

Due to Lemma 1818, it makes sense to consider the quotient $\langle \mathcal{A}, \le \rangle / \bigcup_{i \in I} \theta^i$. This $\mathbf{F}$-algebraic posystem is called the **directed union** of the collection $\langle \mathcal{A}, \le \rangle / \theta^i$. Given a class K of $\mathbf{F}$-algebraic posystems, we write $\langle \mathcal{A}, \le \rangle / \bigcup_{i \in I} \theta^i \in \mathbb{U}(\mathsf{K})$ in case $\langle \mathcal{A}, \le \rangle / \theta^i \in \mathsf{K}$, for all $i \in I$. If $\mathbb{U}(\mathsf{K}) = \mathsf{K}$, we say that K is **closed under directed unions**.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\langle \mathcal{A}, \le^{\mathcal{A}} \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathcal{B}, \le^{\mathcal{B}} \rangle$, with $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, $\mathbf{F}$-algebraic posystems and

$$\langle H, \gamma \rangle : \langle \mathcal{A}, \le^{\mathcal{A}} \rangle \to \langle \mathcal{B}, \le^{\mathcal{B}} \rangle$$

a surjective morphism. In this case we say $\langle \mathcal{B}, \le^{\mathcal{B}} \rangle$ is an **morphic image** of $\langle \mathcal{A}, \le^{\mathcal{A}} \rangle$. Given a class K of $\mathbf{F}$-algebraic posystems, we write $\langle \mathcal{B}, \le^{\mathcal{B}} \rangle \in \mathbb{H}(\mathsf{K})$ in case there exists a surjective morphism

$$\langle H, \gamma \rangle : \langle \mathcal{A}, \le^{\mathcal{A}} \rangle \to \langle \mathcal{B}, \le^{\mathcal{B}} \rangle,$$

with $\langle \mathcal{A}, \leq^{\mathcal{A}} \rangle \in \mathsf{K}$. If $\mathbb{H}(\mathsf{K}) = \mathsf{K}$, we say that K is **closed under morphic images**.

It is not difficult to verify that all three operators are closure operators on classes of **F**-algebraic posystems.

Proposition 1819 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then the operators* $\overset{\triangleleft}{\mathbb{P}}$*,* $\mathbb{U}$ *and* $\mathbb{H}$ *on classes of* **F***-algebraic posystems are closure operators.*

Proof: We first look at $\overset{\triangleleft}{\mathbb{P}}$. Suppose K is a class of **F**-algebraic posystems.

- If $\langle \mathcal{A}, \leq \rangle \in \mathsf{K}$, then $\{\langle I, \iota \rangle : \langle \mathcal{A}, \leq \rangle \to \langle \mathcal{A}, \leq \rangle\}$, where $\langle I, \iota \rangle : \mathcal{A} \to \mathcal{A}$ is the identity morphism, is a subdirect intersection family. Thus, we get that $\langle \mathcal{A}, \leq \rangle \in \overset{\triangleleft}{\mathbb{P}}(\mathsf{K})$. Hence $\mathsf{K} \subseteq \overset{\triangleleft}{\mathbb{P}}(\mathsf{K})$ and $\overset{\triangleleft}{\mathbb{P}}$ is inflationary;
- It is obvious that $\overset{\triangleleft}{\mathbb{P}}$ is monotonic;
- Suppose that $\langle \mathcal{A}, \leq \rangle \in \overset{\triangleleft}{\mathbb{P}}(\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}))$. Then, there exists a subdirect intersection family

  $$\{\langle H^i, \gamma^i \rangle : \langle \mathcal{A}, \leq \rangle \to \langle \mathcal{A}^i, \leq^i \rangle, \ i \in I\},$$

  with $\langle \mathcal{A}^i, \leq^i \rangle \in \overset{\triangleleft}{\mathbb{P}}(\mathsf{K})$, for all $i \in I$. Therefore, for each $i \in I$, there exists a sibdirect intersection family

  $$\{\langle H^{ij}, \gamma^{ij} \rangle : \langle \mathcal{A}^i, \leq^i \rangle \to \langle \mathcal{A}^{ij}, \leq^{ij} \rangle, \ j \in J_i\},$$

  with $\langle \mathcal{A}^{ij}, \leq^{ij} \rangle \in \mathsf{K}$, for all $i \in I$ and all $j \in J_i$. Consider

  $$\{\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle : \langle \mathcal{A}, \leq \rangle \to \langle \mathcal{A}^{ij}, \leq^{ij} \rangle, \ i \in I, j \in J_i\}.$$

  It is a subdirect intersection family, since

  $$\begin{array}{rcl} \bigcap_{i \in I, j \in J_i} (\gamma^{ij} \circ \gamma^i)^{-1}(\leq^{ij}) & = & \bigcap_{i \in I, j \in J_i} (\gamma^i)^{-1}((\gamma^{ij})^{-1}(\leq^{ij})) \\ & = & \bigcap_{i \in I} (\gamma^i)^{-1}(\bigcap_{j \in J_i} (\gamma^{ij})^{-1}(\leq^{ij})) \\ & = & \bigcap_{i \in I} (\gamma^i)^{-1}(\leq^i) \\ & = & \leq. \end{array}$$

  Since $\langle \mathcal{A}^{ij}, \leq^{ij} \rangle \in \mathsf{K}$, for all $i \in I$, $j \in J_i$, we get that $\overset{\triangleleft}{\mathbb{P}}(\overset{\triangleleft}{\mathbb{P}}(\mathsf{K})) \subseteq \overset{\triangleleft}{\mathbb{P}}(\mathsf{K})$ and $\overset{\triangleleft}{\mathbb{P}}$ is idempotent.

Thus, $\overset{\triangleleft}{\mathbb{P}}$ is a closure operator.

Now we turn to $\mathbb{U}$. Suppose, again, that K is a class of **F**-algebraic posystems.

- If $\langle \mathcal{A}, \leq \rangle \in \mathsf{K}$, we look at the singleton family $\{\Delta^{\mathcal{A}}\}$, consisting of the identity congruence system on $\langle \mathcal{A}, \leq \rangle$. Clearly, it is directed and its union is $\Delta^{\mathcal{A}}$. Therefore, $\langle \mathcal{A}, \leq \rangle \cong \langle \mathcal{A}, \leq \rangle / \Delta^{\mathcal{A}} \in \mathbb{U}(\mathsf{K})$;

- Monotonicity is obvious in this case as well;

- Suppose that $\langle \mathcal{A}, \leq \rangle / \theta \in \mathbb{U}(\mathbb{U}(\mathsf{K}))$. Then $\theta = \bigcup_{i \in I} \theta^i$ for a directed family $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}(\langle \mathcal{A}, \leq \rangle)$, such that $\langle \mathcal{A}, \leq \rangle / \theta^i \in \mathbb{U}(\mathsf{K})$, for all $i \in I$. Thus, for all $i \in I$, $\theta^i = \bigcup_{j \in J_i} \theta^{ij}$ for a directed family $\{\theta^{ij} : j \in J_i\} \subseteq \mathrm{ConSys}(\langle \mathcal{A}, \leq \rangle)$, such that $\langle \mathcal{A}, \leq \rangle / \theta^{ij} \in \mathsf{K}$, for all $j \in J_i$. Now, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta^{ij_i}_\Sigma \cup \theta^{i'j_{i'}}_\Sigma$. By hypothesis, $\langle \phi, \psi \rangle \in \theta^i_\Sigma \cup \theta^{i'}_\Sigma$. Hence, since $\{\theta^i : i \in I\}$ is directed, there exists $k \in I$, such that $\langle \phi, \psi \rangle \in \theta^k_\Sigma$. Thus, again, by the hypothesis, there exists, $j_k \in J_k$, such that $\langle \phi, \psi \rangle \in \theta^{kj_k}$. We conclude that the collection $\{\theta^{ij} : j \in J_i, i \in I\}$ is directed, such that $\langle \mathcal{A}, \leq \rangle / \theta^{ij} \in \mathsf{K}$, for all $i \in I, j \in J_i$, and, moreover, $\theta = \bigcup_{i \in I} \theta^i = \bigcup_{i \in I} \bigcup_{j \in J_i} \theta^{ij} = \bigcup_{\substack{j \in J_i \\ i \in I}} \theta^{ij}$. Thus, $\langle \mathcal{A}, \leq \rangle / \theta \in \mathbb{U}(\mathsf{K})$ and $\mathbb{U}$ is also idempotent.

Therefore, $\mathbb{U}$ is also a closure operator.

Finally, we deal with $\mathbb{H}$, which is the easiest case. Let K be a class of $\mathbf{F}$-algebraic posystems. If $\langle \mathcal{A}, \leq \rangle \in \mathsf{K}$, then, using again the identity $\langle I, \iota \rangle : \langle \mathcal{A}, \leq \rangle \to \langle \mathcal{A}, \leq \rangle$, we see that $\langle \mathcal{A}, \leq \rangle \in \mathbb{H}(\mathsf{K})$, and, hence, $\mathbb{H}$ is inflationary. It is again obvious that it is monotonic. Finally, if $\mathcal{A} \in \mathbb{H}(\mathbb{H}(\mathsf{K}))$, then, there exists a surjective morphism $\langle G, \beta \rangle : \langle \mathcal{A}', \leq' \rangle \to \langle \mathcal{A}, \leq \rangle$, with $\langle \mathcal{A}', \leq' \rangle \in \mathbb{H}(\mathsf{K})$, whence, there also exists a surjective morphism $\langle H, \gamma \rangle : \langle \mathcal{A}'', \leq'' \rangle \to \langle \mathcal{A}', \leq' \rangle$, with $\langle \mathcal{A}'', \leq'' \rangle \in \mathsf{K}$. Now the surjective morphism

$$\langle G, \beta \rangle \circ \langle H, \gamma \rangle : \langle \mathcal{A}'', \leq'' \rangle \to \langle \mathcal{A}, \leq \rangle$$

witnesses the fact that $\langle \mathcal{A}, \leq \rangle \in \mathbb{H}(\mathsf{K})$. Therefore, $\mathbb{H}(\mathbb{H}(\mathsf{K})) \subseteq \mathbb{H}(\mathsf{K})$, and $\mathbb{H}$ is idempotent. Thus, $\mathbb{H}$ is a closure operator. ■

We show next that, if a class K of $\mathbf{F}$-algebraic posystems is closed under morphic images, then it is also closed under directed unions.

Proposition 1820 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *be a class of* $\mathbf{F}$*-algebraic posystems. If* K *is closed under morphic images, then it is closed under directed unions.*

Proof: Suppose K is closed under $\overset{\triangleleft}{\mathbb{P}}$ and $\mathbb{H}$ and let $\langle \mathcal{A}. \leq \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, be an $\mathbf{F}$-algebraic posystem and $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}(\langle \mathcal{A}, \leq \rangle)$, a directed family of congruence systems, such that $\langle \mathcal{A}, \leq \rangle / \theta^i \in \mathsf{K}$. Consider a morphism

$$\langle I, \pi^i \rangle : \langle \mathcal{A}, \leq \rangle / \theta^i \to \langle \mathcal{A}, \leq \rangle / \bigcup_{i \in I} \theta^i,$$

given, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\pi^i_\Sigma(\phi/\theta^i_\Sigma) = \phi/\bigcup_{i\in I}\theta^i_\Sigma.$$

It is well defined, since, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$, if $\langle\phi,\psi\rangle \in \theta^i_\Sigma$, then, automatically, $\langle\phi,\psi\rangle \in \bigcup_{i\in I}\theta^i_\Sigma$. Therefore, since $\langle\mathcal{A},\leq\rangle/\theta^i \in \mathsf{K}$, we get, by hypothesis, $\langle\mathcal{A},\leq\rangle/\bigcup_{i\in I}\theta^i \in \mathbb{H}(\mathsf{K}) = \mathsf{K}$. We conclude that $\mathbb{U}(\mathsf{K}) \subseteq \mathsf{K}$ and, hence, K is closed under directed unions. ■

We are now ready to provide alternative characterizations of inequational, quasi inequational and guasi inequational classes of **F**-algebraic posystems. Namely, we show that an abstract class of **F**-algebraic posystems is a guasi inequational class if and only if it is closed under subdirect intersections, that it is a quasi inequational class if and only if it is closed under subdirect intersections and directed unions and that it is an inequational class if and only if it is closed under subdirect intersections and morphic images.

Theorem 1821 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* K *an abstract class of* **F***-algebraic posystems.* K *is a guasi inequational class if and only if it is closed under subdirect intersections.*

Proof: Suppose, first, that K is a guasi inequational class and consider a subdirect intersection

$$\{\langle H^i,\gamma^i\rangle : \langle\mathcal{A},\leq\rangle \to \langle\mathcal{A}^i,\leq^i\rangle,\ i\in I\},$$

with $\langle\mathcal{A}^i,\leq^i\rangle \in \mathsf{K}$. Let G be the set of guasi inequations defining K and $\Sigma \in |\mathbf{Sign}^\flat|$, $\langle\vec{\phi} \preccurlyeq \vec{\psi},\phi \preccurlyeq \psi\rangle \in G_\Sigma$, such that, for some $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_j)) \leq_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi_j)),\ \text{for all } j \in J.$$

Then we get $\gamma^i_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_j))) \leq^i_{H^i(F(\Sigma'))} \gamma^i_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi_j)))$, for all $i \in I$, $j \in J$. This gives $\alpha^i_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi_j)) \leq^i_{F^i(\Sigma')} \alpha^i_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi_j))$, for all $i \in I$, $j \in J$. Since $\langle\mathcal{A}^i,\leq^i\rangle \in \mathsf{K}$, for all $i \in I$, and $\langle\vec{\phi} \preccurlyeq \vec{\psi},\phi \preccurlyeq \psi\rangle \in G_\Sigma$, we get that $\alpha^i_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq^i_{F^i(\Sigma')} \alpha^i_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))$, for all $i \in I$. Equivalently, $\gamma^i_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))) \leq^i_{H^i(F(\Sigma'))} \gamma^i_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)))$, for all $i \in I$, i.e.,

$$\langle\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)),\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))\rangle \in \bigcap_{i\in I}(\gamma^i_{F(\Sigma')})^{-1}(\leq^i).$$

Since $\{\langle H^i,\gamma^i\rangle : i \in I\}$ is a subdirect intersection, we get

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).$$

We conclude that $\langle\mathcal{A},\le\rangle\in\mathrm{PAlgSys}(G)=\mathsf{K}$. Hence, K is closed under subdirect intersections.

Assume, conversely, that K is closed under subdirect intersections and set $G=\mathrm{GIn}(\mathsf{K})$. Let $\langle\mathcal{A},\le\rangle\in\mathrm{PAlgSys}(\mathbf{F})$, such that $G\le\mathrm{GIn}(\langle\mathcal{A},\le\rangle)$. Let $\Sigma\in|\mathbf{Sign}^\flat|$, such that $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$, i.e., for some $\Sigma'\in|\mathbf{Sign}^\flat|$ and some $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))\not\le_{F(\Sigma')}\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))$. Thus, by definition, the guasi inequation $\langle\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle),\phi\preccurlyeq\psi\rangle\notin\mathrm{GIn}_\Sigma(\langle\mathcal{A},\le\rangle)$. Therefore, since $G\le\mathrm{GIn}(\langle\mathcal{A},\le\rangle)$, $\langle\mathrm{In}_\Sigma(\mathcal{A}),\phi\preccurlyeq\psi\rangle\notin\mathrm{GIn}_\Sigma(\mathsf{K})$. Hence, for every $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$, there exists $\langle\mathcal{K}^{\langle\Sigma,\phi,\psi\rangle},\le^{\langle\Sigma,\phi,\psi\rangle}\rangle\in\mathsf{K}$, such that

$$\begin{gathered}\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\subseteq\mathrm{In}_\Sigma(\langle\mathcal{K}^{\langle\Sigma,\phi,\psi\rangle},\le^{\langle\Sigma,\phi,\psi\rangle}\rangle),\\ \phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{K}^{\langle\Sigma,\phi,\psi\rangle},\le^{\langle\Sigma,\phi,\psi\rangle}\rangle).\end{gathered}$$

We conclude that

$$\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)=\bigcap\{\mathrm{In}_\Sigma(\langle\mathcal{K}^{\langle\Sigma,\phi,\psi\rangle},\le^{\langle\Sigma,\phi,\psi\rangle}\rangle):\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\}.$$

Denote, for all $\Sigma\in|\mathbf{Sign}^\flat|$, $\mathsf{K}^\Sigma=\{\langle\mathcal{K}^{\langle\Sigma,\phi,\psi\rangle},\le^{\langle\Sigma,\phi,\psi\rangle}\rangle:\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\}$, for brevity.

- Since K is closed under subdirect intersections, and

  $$\{\langle F^{\mathcal{K}},\alpha^{\mathcal{K}}\rangle:\langle\mathcal{F},\bigcap_{\langle\mathcal{K},\le^{\mathcal{K}}\rangle\in\mathsf{K}^\Sigma}(\alpha^{\mathcal{K}})^{-1}(\le^{\mathcal{K}})\rangle/\mathrm{Eq}(\mathsf{K}^\Sigma)\to\langle\mathcal{K},\le^{\mathcal{K}}\rangle,\langle\mathcal{K},\le^{\mathcal{K}}\rangle\in\mathsf{K}^\Sigma\}$$

  is a subdirect intersection, we get that

  $$\langle\mathcal{F},\bigcap_{\langle\mathcal{K},\le^{\mathcal{K}}\rangle\in\mathsf{K}^\Sigma}(\alpha^{\mathcal{K}})^{-1}(\le^{\mathcal{K}})\rangle/\mathrm{Eq}(\mathsf{K}^\Sigma)\in\mathsf{K}.$$

- Since, for all $\Sigma\in|\mathbf{Sign}^\flat|$,

  $$\begin{array}{rcl}\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)&=&\mathrm{In}_\Sigma(\mathsf{K}^\Sigma)\\ &=&\mathrm{In}_\Sigma(\langle\mathcal{F},\bigcap_{\langle\mathcal{K},\le^{\mathcal{K}}\rangle\in\mathsf{K}^\Sigma}(\alpha^{\mathcal{K}})^{-1}(\le^{\mathcal{K}})\rangle/\mathrm{Eq}(\mathsf{K}^\Sigma))\end{array}$$

  and $\langle\mathcal{F},\bigcap_{\langle\mathcal{K},\le^{\mathcal{K}}\rangle\in\mathsf{K}^\Sigma}(\alpha^{\mathcal{K}})^{-1}(\le^{\mathcal{K}})\rangle/\mathrm{Eq}(\mathsf{K}^\Sigma)\in\mathsf{K}$, $\langle\mathcal{A},\le\rangle\in\mathbb{C}(\mathsf{K})$. Since K is abstract, we conclude that $\langle\mathcal{A},\le\rangle\in\mathsf{K}$.

Hence, K is indeed a guasi inequational class of $\mathbf{F}$-algebraic posystems. ■

Theorem 1822 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* K *an abstract class of* $\mathbf{F}$*-algebraic posystems.* K *is a quasi inequational class if and only if it is closed under subdirect intersections and directed unions.*

Proof: Suppose, first, that K is a quasi inequational class, defined by a collection Q of $\mathbf{F}$-quasi inequations. Then it is a guasi inequational class and, therefore, by Theorem 1821, closed under subdirect intersections. Let

$\langle\mathcal{A},\le\rangle$ be an $\mathbf{F}$-algebraic posystem and $\{\theta^i : i\in I\}\subseteq \mathrm{ConSys}(\langle\mathcal{A},\le\rangle)$ a directed union of congruence systems on $\langle\mathcal{A},\le\rangle$, such that $\langle\mathcal{A},\le\rangle/\theta^i\in\mathsf{K}$, for all $i\in I$. Let $\Sigma\in|\mathbf{Sign}^\flat|$, $\langle\vec{\psi}\preccurlyeq\vec{\psi},\phi\preccurlyeq\psi\rangle\in Q_\Sigma$, such that, for some $\Sigma'\in|\mathbf{Sign}^\flat|$ and $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$\alpha_{\Sigma'}^{\bigcup_{i\in I}\theta^i}(\mathrm{SEN}^\flat(f)(\phi_j))\le_{F(\Sigma')}^{\bigcup_{i\in I}\theta^i}\alpha_{\Sigma'}^{\bigcup_{i\in I}\theta^i}(\mathrm{SEN}^\flat(f)(\psi_j)),\quad j<n.$$

Thus, for every $j<n$, there exists $k_j\in I$, such that

$$\alpha_{\Sigma'}^{\theta^{k_j}}(\mathrm{SEN}^\flat(f)(\phi_j))\le_{F(\Sigma')}^{\theta^{k_j}}\alpha_{\Sigma'}^{\theta^{k_j}}(\mathrm{SEN}^\flat(f)(\psi_j)).$$

Since $\{\theta^i : i\in I\}$ is directed, there exists $k\in I$, such that

$$\alpha_{\Sigma'}^{\theta^k}(\mathrm{SEN}^\flat(f)(\phi_j))\le_{F(\Sigma')}^{\theta^k}\alpha_{\Sigma'}^{\theta^k}(\mathrm{SEN}^\flat(f)(\psi_j)),\quad j<n.$$

Since $\langle\mathcal{A},\le\rangle/\theta^k\in\mathsf{K}$ and $\langle\vec{\psi}\preccurlyeq\vec{\psi},\phi\preccurlyeq\psi\rangle\in Q_\Sigma$, we get that

$$\alpha_{\Sigma'}^{\bigcup_{i\in I}\theta^i}(\mathrm{SEN}^\flat(f)(\phi))\le_{F(\Sigma')}^{\bigcup_{i\in I}\theta^i}\alpha_{\Sigma'}^{\bigcup_{i\in I}\theta^i}(\mathrm{SEN}^\flat(f)(\psi)).$$

Therefore, $\langle\mathcal{A},\le\rangle/\bigcup_{i\in I}\theta^i\in\mathrm{PAlgSys}(Q)=\mathsf{K}$ and K is closed under directed unions.

Suppose, conversely, that K is an abstract class of $\mathbf{F}$-algebraic posystems closed under subdirect intersections and directed unions. Set $Q=\mathrm{QIn}(\mathsf{K})$ and let $\langle\mathcal{A},\le\rangle\in\mathrm{PAlgSys}(\mathbf{F})$, such that $Q\le\mathrm{QIn}(\mathcal{A})$. Let $\Sigma\in|\mathbf{Sign}^\flat|$, such that $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$, i.e., for some $\Sigma'\in|\mathbf{Sign}^\flat|$ and some $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi))\nleq_{F(\Sigma')}\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))$. Thus, by definition, for every finite $I\le\mathrm{In}_\Sigma(\mathcal{A})$ the quasi inequation $\langle I,\phi\preccurlyeq\psi\rangle\notin\mathrm{QIn}_\Sigma(\langle\mathcal{A},\le\rangle)$. Therefore, since $Q\le\mathrm{QIn}(\langle\mathcal{A},\le\rangle)$, $\langle I,\phi\preccurlyeq\psi\rangle\notin\mathrm{QIn}_\Sigma(\mathsf{K})$. Hence, for every $\Sigma\in|\mathbf{Sign}^\flat|$, all $I\subseteq_f\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$ and all $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$, there exists

$$\langle\mathcal{K}^{\langle\Sigma,I,\phi,\psi\rangle},\le^{\langle\Sigma,I,\phi,\psi\rangle}\rangle\in\mathsf{K},$$

such that

- $I\subseteq\mathrm{In}_\Sigma(\langle\mathcal{K}^{\langle\Sigma,I,\phi,\psi\rangle},\le^{\langle\Sigma,I,\phi,\psi\rangle}\rangle)$;
- $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{K}^{\langle\Sigma,I,\phi,\psi\rangle},\le^{\langle\Sigma,I,\phi,\psi\rangle}\rangle)$.

We conclude that, for all $\Sigma\in|\mathbf{Sign}^\flat|$,

$$\begin{aligned}\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)=\bigcap\{\bigcup\{&\mathrm{In}_\Sigma(\mathcal{K}^{\langle\Sigma,I,\phi,\psi\rangle},\le^{\langle\Sigma,I,\phi,\psi\rangle}\rangle):\\ &I\subseteq_f\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\}:\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\}.\end{aligned}$$

Denote, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)$,

$$\mathsf{K}^{\langle\Sigma,\phi,\psi\rangle}=\{\langle\mathcal{F},(\alpha^{\langle\Sigma,I,\phi,\psi\rangle})^{-1}(\le^{\langle\Sigma,I,\phi,\psi\rangle})\rangle/\mathrm{Eq}(\mathcal{K}^{\langle\Sigma,I,\phi,\psi\rangle}):I\subseteq_f\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\},$$

and, for all $\Sigma\in|\mathbf{Sign}^\flat|$,

$$\begin{aligned}\mathsf{K}^\Sigma=\{\langle\mathcal{F},\textstyle\bigcup_{\mathcal{K}\in\mathsf{K}^{\langle\Sigma,\phi,\psi\rangle}}(\alpha^{\mathcal{K}})^{-1}(\le^{\mathcal{K}})\rangle/\textstyle\bigcup_{\mathcal{K}\in\mathsf{K}^{\langle\Sigma,\phi,\psi\rangle}}\mathrm{Eq}(\mathcal{K}):&\\ \phi\preccurlyeq\psi\notin\mathrm{In}_\Sigma(\langle\mathcal{A},\le\rangle)\},&\end{aligned}$$

for brevity.

- Since K is closed under directed unions, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \leqslant \psi \notin \mathrm{In}_\Sigma(\mathcal{A})$, we have $\langle \mathcal{F}, \bigcup_{\mathcal{K} \in \mathsf{K}\langle\Sigma,\phi,\psi\rangle} (\alpha^{\mathcal{K}})^{-1}(\leq^{\mathcal{K}})\rangle / \bigcup_{\mathcal{K} \in \mathsf{K}\langle\Sigma,\phi,\psi\rangle} \mathrm{Eq}(\mathcal{K}) \in \mathsf{K}$.
- Since K is closed under subdirect intersections,
$$\langle \mathcal{F}, \bigcap_{\mathcal{K} \in \mathsf{K}^\Sigma} (\alpha^{\mathcal{K}})^{-1}(\leq^{\mathcal{K}})\rangle / \mathrm{Eq}(\mathsf{K}^\Sigma) \in \mathsf{K},$$
for all $\Sigma \in |\mathbf{Sign}^\flat|$.
- Finally, noting that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\langle \mathcal{F}, \bigcap_{\mathcal{K} \in \mathsf{K}^\Sigma} (\alpha^{\mathcal{K}})^{-1}(\leq^{\mathcal{K}})\rangle / \mathrm{Eq}(\mathsf{K}^\Sigma)$ is a Σ-K-certificate for $\mathcal{A}$, and, taking into account that K is abstract, we conclude that $\mathcal{A} \in \mathsf{K}$.

Therefore K is indeed a quasiequational class of $\mathbf{F}$-algebraic systems. ■

25.2 Syntactic Order Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and K a class of $\mathbf{F}$-algebraic posystems. If $\mathcal{I}$ is equivalent to $\mathcal{I}^{\mathsf{K},\leq}$ via a conjugate pair $(\alpha, \beta) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\leq}$, we say that the class K **β-order algebraizes** the π-institution $\mathcal{I}$. Recall, in more detail, that this means that there exist a collection $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument and a collection $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$ and $I \subseteq \mathrm{In}_\Sigma(\mathbf{F})$,

1. $\phi \in C_\Sigma(\Phi)$ if and only if $\alpha_\Sigma[\phi] \leq C_\Sigma^{\mathsf{K},\leq}(\alpha_\Sigma[\Phi])$;
2. $\phi \leqslant \psi \in C_\Sigma^{\mathsf{K},\leq}(I)$ if and only if $\beta_\Sigma[\phi, \psi] \leq C(\beta_\Sigma[I])$;
3. $C^{\mathsf{K},\leq}(\phi \leqslant \psi) = C^{\mathsf{K},\leq}(\alpha[\beta_\Sigma[\phi, \psi]])$;
4. $C(\phi) = C(\beta[\alpha_\Sigma[\phi]])$.

Moreover, we say that $\mathcal{I}$ is **β-order algebraizable** if there exists a class K of $\mathbf{F}$-algebraic posystems, such that K β-order algebraizes $\mathcal{I}$. In this case, we call the least order guasivariety including K the **β-ordered class of $\mathcal{I}$** and denote it by $\mathrm{PAlgSys}(\mathcal{I})$.

Lemma 1823 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ having two distinguished arguments, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and K, K' two classes of $\mathbf{F}$-algebraic posystems. If both K and K' β-order algebraize $\mathcal{I}$, then $\mathcal{I}^{\mathsf{K},\leq} = \mathcal{I}^{\mathsf{K}',\leq}$. Therefore, $\mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}')$.*

Proof: Suppose both K and K' β-order algebraize $\mathcal{I}$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $I \cup \{\phi \preccurlyeq \psi\} \in \mathrm{In}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll}\phi \preccurlyeq \psi \in C_\Sigma^{\mathsf{K},\leq}(I) & \text{iff} & \beta_\Sigma[\phi,\psi] \leq C(\beta_\Sigma[I]) \\ & \text{iff} & \phi \preccurlyeq \psi \in C_\Sigma^{\mathsf{K}',\leq}(I).\end{array}$$

We conclude that $\mathcal{I}^{\mathsf{K},\leq} = \mathcal{I}^{\mathsf{K}',\leq}$, whence the semantic order guasivarieties generated by K and K' coincide. ■

We call the unique semantic order guasivariety that β-order algebraizes $\mathcal{I}$ the β-**order class of** $\mathcal{I}$ and denote it by $\mathrm{PAlgSys}^\beta(\mathcal{I})$.

Next we show that if two families $\beta, \beta' : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ are deductively equivalent, in the sense that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\beta_\Sigma[\phi,\psi]$ and $\beta'_\Sigma[\phi,\psi]$ are interderivable, then $\mathcal{I}$ is β-order algebraizable if and only if it is β'-order algebraizable and, in fact, in that case, the corresponding order classes of $\mathcal{I}$ coincide.

Lemma 1824 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta, \beta' : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. If, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\beta_\Sigma[\phi,\psi]) = C(\beta'_\Sigma[\phi,\psi])$, then $\mathcal{I}$ is β-order algebraizable if and only if $\mathcal{I}$ is β'-order algebraizable. In that case, the β- and β'-order classes of $\mathcal{I}$ coincide, i.e.,* $\mathrm{PAlgSys}^\beta(\mathcal{I}) = \mathrm{PAlgSys}^{\beta'}(\mathcal{I})$.

Proof: Suppose that $\mathcal{I}$ is β-order algebraizable. Then, there exists a conjugate pair $(\alpha,\beta) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\leq}$. We show that $\mathcal{I}$ is also β'-order algebraizable via the conjugate pair $(\alpha,\beta') : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\leq}$.

- We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll}\phi \preccurlyeq \psi \in C_\Sigma^{\mathsf{K},\leq}(I) & \text{iff} & \beta_\Sigma[\phi,\psi] \leq C(\beta_\Sigma[I]) \\ & \text{iff} & \beta'_\Sigma[\phi,\psi] \leq C(\beta'_\Sigma[I]).\end{array}$$

- $C(\phi) = C(\beta[\alpha_\Sigma[\phi]]) = C(\beta'[\alpha_\Sigma[\phi]])$.

Thus, by Proposition 898, $\mathcal{I}$ and $\mathcal{I}^{\mathsf{K},\leq}$ are equivalent via (α,β'). By symmetry, we infer the first statement of the lemma. The second conclusion now follows directly from Lemma 1823, since the same class K both β- and β'-order algebraizes $\mathcal{I}$. ■

Moreover, we can show that the conjugate transformation α in a β-order algebraization is essentially unique, in the sense that any two of them are deductively equivalent modulo inequational derivability.

Lemma 1825 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ having two distinguished arguments, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$ and K a class of $\mathbf{F}$-algebraic posystems. If K β-order* *algebraizes* $\mathcal{I}$ *via a conjugate pair* $(\alpha,\beta):\mathcal{I}\rightleftarrows\mathcal{I}^{\mathsf{K},\le}$ *and via a conjugate pair* $(\alpha',\beta):\mathcal{I}\rightleftarrows\mathcal{I}^{\mathsf{K},\le}$*, then, for all* $\Sigma\in|\mathbf{Sign}^\flat|$ *and all* $\phi\in\mathrm{SEN}^\flat(\Sigma)$*,*

$$C^{\mathsf{K},\le}(\alpha_\Sigma[\phi])=C^{\mathsf{K},\le}(\alpha'_\Sigma[\phi]).$$

Proof: We have, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\phi\in\mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\alpha_\Sigma[\phi]\le C^{\mathsf{K},\le}(\alpha'_\Sigma[\phi]) & \text{iff} & \beta[\alpha_\Sigma[\phi]]\le C(\beta[\alpha'_\Sigma[\phi]])\\ & \text{iff} & \phi\in C_\Sigma(\phi).\end{array}$$

Therefore, $\alpha_\Sigma[\phi]\le C^{\mathsf{K},\le}(\alpha'_\Sigma[\phi])$ and, hence, by symmetry, $C^{\mathsf{K},\le}(\alpha_\Sigma[\phi])=C^{\mathsf{K},\le}(\alpha'_\Sigma[\phi])$. ■

We give next some conditions that are equivalent to $\overset{\leftrightarrow}{\beta}$ defining Leibniz congruence systems of theory families of $\mathcal{I}$. Recall that this is tantamount to $\mathcal{I}$ being syntactically protoalgebraic.

Theorem 1826 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system, with* $\beta:(\mathrm{SEN}^\flat)^\omega\to\mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) *For all* $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$*,* $\beta^{\mathcal{A}}(T)$ *is reflexive and antisymmetric;*

(ii) *For all* $\sigma^\flat$ *in* $N^\flat$*, all* $\Sigma\in|\mathbf{Sign}^\flat|$ *and all* $\phi,\psi,\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$*,*

- $\beta_\Sigma[\phi,\phi]\le\mathrm{Thm}(\mathcal{I})$;
- $\sigma^\flat_\Sigma(\psi,\vec{\chi})\in C_\Sigma(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\phi],\sigma^\flat_\Sigma(\phi,\vec{\chi}))$;

(iii) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ *and every* $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T)=\overset{\leftrightarrow}{\beta}{}^{\mathcal{A}}(T)$*.*

Proof:

(i)⇒(ii) Suppose that, for all $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{A}}(T)$ is reflexive and antisymmetric and let $\sigma^\flat\in N^\flat$, $\Sigma\in|\mathbf{Sign}^\flat|$, and $\phi,\psi,\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$. Consider $\langle\mathcal{F}/\Omega(\mathrm{Thm}(\mathcal{I})),\mathrm{Thm}(\mathcal{I})/\Omega(\mathrm{Thm}(\mathcal{I}))\rangle\in\mathrm{MatFam}^*(\mathcal{I})$. Then, by hypothesis, $\langle\phi,\psi\rangle\in\beta_\Sigma^{\mathcal{F}/\Omega(\mathrm{Thm}(\mathcal{I}))}(\mathrm{Thm}(\mathcal{I}))$, i.e.,

$$\beta_\Sigma^{\mathcal{F}/\Omega(\mathrm{Thm}(\mathcal{I}))}[\phi/\Omega_\Sigma(\mathrm{Thm}(\mathcal{I})),\phi/\Omega_\Sigma(\mathrm{Thm}(\mathcal{I}))]\le\mathrm{Thm}(\mathcal{I})/\Omega(\mathrm{Thm}(\mathcal{I})).$$

This is equivalent to $\beta_\Sigma[\phi,\phi]\le\mathrm{Thm}(\mathcal{I})$.

Assume, next, that for some $T\in\mathrm{ThFam}(\mathcal{I})$, $\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\phi]\le T$ and $\sigma^\flat_\Sigma(\phi,\vec{\chi})\in T_\Sigma$. Then, we get

$$\begin{array}{l}\beta_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T),\psi/\Omega_\Sigma(T)]\le T/\Omega(T),\\ \beta_\Sigma^{\mathcal{F}/\Omega(T)}[\psi/\Omega_\Sigma(T),\phi/\Omega_\Sigma(T)]\le T/\Omega(T),\end{array}$$

i.e.,

$$\langle\phi/\Omega_\Sigma(T),\psi/\Omega_\Sigma(T)\rangle\in\beta_\Sigma^{\mathcal{F}/\Omega(T)}(T/\Omega(T)),$$
$$\langle\psi/\Omega_\Sigma(T),\phi/\Omega_\Sigma(T)\rangle\in\beta_\Sigma^{\mathcal{F}/\Omega(T)}(T/\Omega(T)).$$

But on $\langle\mathcal{F}/\Omega(T),T/\Omega(T)\rangle\in\mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{F}/\Omega(T)}(T/\Omega(T))$ is, by hypothesis, antisymmetric, whence we get $\langle\phi,\psi\rangle\in\Omega_\Sigma(T)$. Therefore, since $\sigma_\Sigma^\flat(\phi,\vec{\chi})\in T_\Sigma$, we have, by compatibility, that $\sigma_\Sigma^\flat(\psi,\vec{\chi})\in T_\Sigma$.

(ii)⇒(iii) Suppose that Condition (ii) holds and let $\mathcal{A}$ be an **F**-algebraic system and $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\Sigma\in|\mathbf{Sign}|$ and $\phi,\psi\in\mathrm{SEN}(\Sigma)$.

- If $\langle\phi,\psi\rangle\in\Omega_\Sigma^{\mathcal{A}}(T)$, then, for all $\sigma^\flat\in\beta$ and all $\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$, $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\begin{aligned}&\langle\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi),\vec{\chi}),\\ &\qquad\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\phi),\vec{\chi})\rangle\in\Omega_{\Sigma'}^{\mathcal{A}}(T),\\ &\langle\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi),\mathrm{SEN}(f)(\phi),\vec{\chi}),\\ &\qquad\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\phi),\vec{\chi})\rangle\in\Omega_{\Sigma'}^{\mathcal{A}}(T).\end{aligned}$$

  Thus, by compatibility, $\beta_\Sigma^{\mathcal{A}}[\phi,\psi]\le T$ and $\beta_\Sigma^{\mathcal{A}}[\psi,\phi]\le T$, i.e., $\overset{\leftrightarrow\mathcal{A}}{\beta}_\Sigma[\phi,\psi]\le T$. Thus, $\langle\phi,\psi\rangle\in\overset{\leftrightarrow}{\beta}_\Sigma(T)$.

- Suppose, conversely, that $\langle\phi,\psi\rangle\in\overset{\leftrightarrow\mathcal{A}}{\beta}_\Sigma(T)$, i.e., $\beta_\Sigma^{\mathcal{A}}[\phi,\psi]\le T$ and $\beta_\Sigma^{\mathcal{A}}[\psi,\phi]\le T$. Then, by hypothesis, we have, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma'\in|\mathbf{Sign}|$, all $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\sigma\mathcal{A}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})\in T_{\Sigma'}\quad\text{iff}\quad\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi),\vec{\chi})\in T_{\Sigma'}.$$

  Therefore, $\langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}(T)$.

we conclude that $\overset{\leftrightarrow\mathcal{A}}{\beta}(T)=\Omega^{\mathcal{A}}(T)$.

(iii)⇒(i) Finally, suppose that, for every **F**-algebraic system $\mathcal{A}$ and all $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\overset{\leftrightarrow\mathcal{A}}{\beta}(T)=\Omega^{\mathcal{A}}(T)$ and let $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$. Then we get that $\overset{\leftrightarrow\mathcal{A}}{\beta}(T)=\Omega^{\mathcal{A}}(T)=\Delta^{\mathcal{A}}$. Thus, clearly, $\beta^{\mathcal{A}}(T)$ is reflexive and antisymmetric. ■

We obtain as a corollary characterizing those collection of natural transformations with two distinguished arguments that define posystems on the class $\mathrm{AlgSys}^*(\mathcal{I})$, i.e., on the algebraic system reducts of the reduced matrix families of a π-institution $\mathcal{I}$.

Corollary 1827 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system, with* $\beta:(\mathrm{SEN}^\flat)^\omega\to\mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments, and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{A}}(T)$ *is a posystem on* $\mathcal{A}$ *if and only if the following conditions hold, for all* $\sigma^\flat$ *in* $N^\flat$, $\Sigma\in|\mathbf{Sign}^\flat|$, $\phi,\psi,\chi,\vec{\chi}\in\mathrm{SEN}^\flat(\Sigma)$*:*

1. $\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I})$;

2. $\beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\chi])$;

3. $\sigma^\flat_\Sigma(\psi,\vec{\chi}) \in C_\Sigma(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\sigma^\flat(\phi,\vec{\chi}))$.

Proof: Suppose that, for all $\langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{A}}(T)$ is a posystem on $\mathcal{A}$. Then, by Theorem 1826, Conditions 1 and 3 hold. By considering all reduced matrix families $\langle/\Omega(T),T/\Omega(T)\rangle$, with $t \in \mathrm{ThFam}(\mathcal{I})$, we get, by the transitivity of $\beta^{\mathcal{F}/\Omega(T)}(T/\Omega(T))$, $\beta^{\mathcal{F}/\Omega(T)}_\Sigma[\phi/\Omega_\Sigma(T),\psi/\Omega_\Sigma(T)] \leq T/\Omega(T)$ and $\beta^{\mathcal{F}/\Omega(T)}_\Sigma[\psi/\Omega_\Sigma(T),\chi/\Omega_\Sigma(T)] \leq T/\Omega(T)$ imply $\beta^{\mathcal{F}/\Omega(T)}_\Sigma[\phi/\Omega_\Sigma(T),\chi/\Omega_\Sigma(T)] \leq T/\Omega(T)$, i.e., $\beta_\Sigma[\phi,\psi] \leq T$ and $\beta_\Sigma[\psi,\chi] \leq T$ imply $\beta_\Sigma[\phi,\chi] \leq T$. This proves that $\beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\chi])$, i.e., that Condition 2 also holds.

Conversely, suppose Conditions 1-3 hold and let $\langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$. Then, by Theorem 1826, the relation system $\beta^{\mathcal{A}}(T)$ is reflexive and antisymmetric. But, by Condition 2 of the hypothesis, it is also transitive and, therefore, it is a posystem on $\mathcal{A}$. ∎

Given a π-institution $\mathcal{I} - \langle\mathbf{F},C\rangle$, we term any collection $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$, with two distinguished arguments, that satisfies 1-3 of Corollary 1827 a **semi-equivalence system for** $\mathcal{I}$.

Now we are in a position to provide a characterization of syntactic order algebraizability.

Theorem 1828 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$. The following conditions are equivalent:*

(i) $\mathcal{I}$ is syntactically order algebraizable;

(ii) There exists $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ having two distinguishes arguments and $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ with a single distinguished argument, such that, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi,\chi,\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

- $\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I})$;
- $\beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\chi])$;
- $\beta_\Sigma[\sigma^\flat_\Sigma(\psi,\vec{\chi}),\tau^\flat_\Sigma(\psi,\vec{\chi})] \leq C(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\beta_\Sigma[\sigma^\flat_\Sigma(\phi,\vec{\chi}),\tau^\flat_\Sigma(\phi,\vec{\chi})])$;
- $C(\phi) = C(\beta[\alpha_\Sigma[\phi]])$;

(iii) $\mathcal{I}$ has a semi-equivalence system β and there exists $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ with a single distinguished argument, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\phi) = C(\beta[\alpha_\Sigma[\phi]])$.

If any of Conditions (i)-(iii) holds, then $\mathcal{I}$ is β-order algebraizable, with β in $N^\flat$ any collection satisfying Condition (ii) or (iii).

Proof:

(i)⇒(ii) Suppose $\mathcal{I}$ is syntactically order algebraizable. Then, by definition, it is equivalent to the inequational π-institution $\mathcal{I}^{\mathsf{K},\leq} = \langle \mathbf{F}, C^{\mathsf{K},\leq}\rangle$ associated with some class K of $\mathbf{F}$-algebraic posystems, via a conjugate pair $(\alpha,\beta) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\leq}$. Let $\sigma^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi,\chi,\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$.

- We have, by Lemma 1811, $\phi \preccurlyeq \phi \in C_\Sigma^{\mathsf{K},\leq}(\varnothing)$. Thus, we get $\beta_\Sigma[\phi,\phi] \leq C(\varnothing)$.
- Similarly, by Lemma 1811, $\phi \preccurlyeq \chi \in C_\Sigma^{\mathsf{K},\leq}(\phi \preccurlyeq \psi, \psi \preccurlyeq \chi)$. Therefore, $\beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\chi])$.
- Since K is a class of $\mathbf{F}$-algebraic posystems, we have

  $$\sigma_\Sigma^\flat(\psi,\vec{\chi}) \preccurlyeq \tau_\Sigma^\flat(\psi,\vec{\chi}) \in C_\Sigma^{\mathsf{K},\leq}(\phi \preccurlyeq \psi, \psi \preccurlyeq \phi, \sigma_\Sigma^\flat(\phi,\vec{\chi}) \preccurlyeq \tau_\Sigma^\flat(\phi,\vec{\chi})).$$

  From this, we get

  $$\beta_\Sigma[\sigma_\Sigma^\flat(\psi,\vec{\chi}),\tau_\Sigma^\flat(\psi,\vec{\chi})] \leq C(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\beta_\Sigma[\sigma_\Sigma^\flat(\phi,\vec{\chi}),\tau_\Sigma^\flat(\phi,\vec{\chi})]).$$
- $C(\phi) = C(\beta[\alpha_\Sigma[\phi]])$ holds by the definition of equivalence.

(ii)⇒(iii) Assume that $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ with one distinguished argument and $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ with two distinguished arguments satisfy the Conditions in (ii). According to the definition of a semi-equivalence system, it suffices to show that, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi,\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma_\Sigma^\flat(\psi,\vec{\chi}) \in C_\Sigma(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\sigma_\Sigma^\flat(\phi,\vec{\chi})).$$

By the last condition in the hypothesis, we have

$$\beta[\alpha_\Sigma[\sigma_\Sigma^\flat(\phi,\vec{\chi})]] \leq C(\sigma_\Sigma^\flat(\phi,\vec{\chi})).$$

By the third condition in the hypothesis, we get

$$\beta[\alpha_\Sigma[\sigma_\Sigma^\flat(\psi,\vec{\chi})]] \leq C(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\beta[\alpha_\Sigma[\sigma_\Sigma^\flat(\phi,\vec{\chi})]]).$$

Again, using the last condition in the hypothesis, we get

$$\sigma_\Sigma^\flat(\psi,\vec{\chi}) \in C_\Sigma(\beta[\alpha_\Sigma[\sigma_\Sigma^\flat(\psi,\vec{\chi})]]).$$

Combining these, we get $\sigma_\Sigma^\flat(\psi,\vec{\chi}) \in C_\Sigma(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\sigma_\Sigma^\flat(\phi,\vec{\chi}))$.

(iii)⇒(i) Suppose $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, is a semi-equivalence system for $\mathcal{I}$ and $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ satisfies the condition in (iii). We have to construct a class of

$\mathbf{F}$-algebraic posystems that will serve as the basis for the syntactic order algebraization of $\mathcal{I}$. Consider $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$. Define on $\mathcal{A}$, $\leq^{\mathcal{A},T} = \{\leq^{\mathcal{A},T}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \leq^{\mathcal{A},T}_\Sigma \psi \quad \text{iff} \quad \beta^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T.$$

By Corollary 1827, $\leq^{\mathcal{A},T}$ is a posystem on $\mathcal{A}$. Set

$$\mathsf{K} = \{\langle \mathcal{A}, \leq^{\mathcal{A},T}\rangle : \langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})\}.$$

It now suffices to show that $\mathcal{I}$ is equivalent to $\mathcal{I}^{\mathsf{K},\leq}$ via the conjugate pair $(\alpha, \beta) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\leq}$. One of the two requirements demanded by Proposition 898 is fulfilled by the hypothesis. It suffices, therefore, to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$,

$$\phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(I) \quad \text{iff} \quad \beta_\Sigma[\phi, \psi] \leq C(\beta_\Sigma[I]).$$

We have $\phi \preccurlyeq \psi \in C^{\mathsf{K},\leq}_\Sigma(I)$ if and only if, for all $\langle \mathcal{A}, \leq^{\mathcal{A},T}\rangle \in \mathsf{K}$, $\Sigma' \in |\mathbf{Sign}^\flat|$ $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\begin{array}{l} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(I)) \subseteq \leq^{\mathcal{A},T}_{F(\Sigma')} \\ \qquad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq^{\mathcal{A},T}_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)) \end{array}$$

if and only if, for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\begin{array}{l} \beta[\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(I))] \leq T \\ \qquad \text{implies} \quad \beta[\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)), \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi))] \leq T \end{array}$$

if and only if, for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\begin{array}{l} \alpha(\beta_{\Sigma'}[\mathrm{SEN}^\flat(f)(I)]) \leq T \\ \qquad \text{implies} \quad \alpha(\beta_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)]) \leq T \end{array}$$

iff, by the completeness of $\mathcal{I}$ with respect to $\mathrm{MatFam}^*(\mathcal{I})$, $\beta_\Sigma[\phi, \psi] \leq C(\beta_\Sigma[I])$. ■

This characterization allows us to obtain several properties pertaining to syntactic order algebraizability.

Theorem 1829 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a β-order algebraizable π-institution based on $\mathbf{F}$.*

(a) For every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\Omega^{\mathcal{A}}(T) = \overset{\leftrightarrow}{\beta}{}^{\mathcal{A}}(T);$$

(b) *The β-order class of $\mathcal{I}$ is the semantic order guasivariety generated by* $\mathsf{K} = \{\langle\mathcal{A}, \leq^{\mathcal{A},T}\rangle : \langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$*, where, for all* $\langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$*,* $\Sigma \in |\mathbf{Sign}|$*,* $\phi,\psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi \leq_\Sigma^{\mathcal{A},T} \psi \quad \textit{iff} \quad \beta_\Sigma^{\mathcal{A}}[\phi,\psi] \leq T;$$

(c) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the mapping* $T \mapsto \beta^{\mathcal{A}}(T)$ *in injective on* $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

Proof:

(a) The conclusion follows from Theorems 1828 and 1826.

(b) This also follows from Theorem 1828.

(c) Suppose $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, having one distinguished argument, be as in Theorem 1828 and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & \beta^{\mathcal{A}}[\alpha_\Sigma^{\mathcal{A}}[\phi]] \leq T \\ & \text{iff} & \alpha_\Sigma^{\mathcal{A}}[\phi] \leq \beta^{\mathcal{A}}(T), \end{array}$$

and, similarly, $\phi \in T'_\Sigma$ if and only if $\alpha_\Sigma^{\mathcal{A}}[\phi] \leq \beta^{\mathcal{A}}(T')$. We conclude that, if $\beta^{\mathcal{A}}(T) = \beta^{\mathcal{A}}(T')$, then $T = T'$ and, hence, $T \mapsto \beta^{\mathcal{A}}(T)$ is injective.

■

We can now establish some connections between syntactic order algebraizability and syntactic protoalgebraicity.

Proposition 1830 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *has a semi-equivalence system if and only if it is syntactically protoalgebraic;*

(b) *If* $\mathcal{I}$ *is syntactically order algebraizable, then it is syntactically protoalgebraic;*

(c) *If* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, witnesses the syntactic protoalgebraicity of* $\mathcal{I}$ *and* $\mathcal{I}$ *is* β*-order algebraizable, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$C(\overset{\leftrightarrow}{I}{}^\flat_\Sigma[\phi,\psi]) = C(\overset{\leftrightarrow}{\beta}_\Sigma[\phi,\psi]).$$

Proof:

(a) $\mathcal{I}$ has a semi-equivalence system if and only if, by Corollary 1827, for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{A}}(T)$ is a posystem on $\mathcal{A}$, implies that, for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\beta^{\mathcal{A}}(T)$ is reflexive and antisymmetric, if and only if, by Theorem 1826, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \overrightarrow{\beta}^{\mathcal{A}}(T)$, if and only if $\mathcal{I}$ is syntactically protoalgebraic.

On the other hand, if $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$, having two distinguished arguments, then, for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\overleftrightarrow{I}^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$, whence for all $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, $\overleftrightarrow{I}^{\mathcal{A}}(T)$ is a posystem on $\mathcal{A}$ and, hence, by Corollary 1827, $\overleftrightarrow{I}^\flat$ is a semi-equivalence system for $\mathcal{I}$.

(b) By Part (a) of Theorem 1829.

(c) This follows from the fact that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\overleftrightarrow{I}^\flat_\Sigma[\phi, \psi] \le T$ if and only if $\langle \phi, \psi\rangle \in \Omega(T)$ if and only if $\overleftrightarrow{\beta}_\Sigma[\phi, \psi] \le T$.

■

Theorem 1830 reveals two important properties. First, that syntactic order algebraizability implies syntactic protoalgebraicity and, second, that the latter is equivalent to the existence of a semi-equivalence system for $\mathcal{I}$. Recall that syntactic protoalgebraicity is one component in syntactic WF algebraizability. We turn now to investigating how far syntactic WF algebraizability is from syntactic order algebraizability.

Theorem 1831 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a β-order algebraizable π-institution, based on $\mathbf{F}$, and K the β-order class of $\mathcal{I}$. Then, the following conditions are equivalent:*

(i) $\mathcal{I}$ is syntactically WF algebraizable;

(ii) There exists $\gamma : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with two distinguished arguments, such that, for all $\langle \mathcal{A}, \le^{\mathcal{A}}\rangle \in \mathsf{K}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \preccurlyeq^{\mathcal{A}}_\Sigma \psi \quad \text{iff} \quad \gamma^{\mathcal{A}}_\Sigma[\phi, \psi] \le \Delta^{\mathcal{A}};$$

(iii) There exists $\gamma : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with two distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\beta_\Sigma[\phi, \psi]) = C(\overleftrightarrow{\beta}[\gamma_\Sigma[\phi, \psi]]);$$

(iv) $\mathcal{I}$ is $S^{\mathcal{I}}$-fortified and for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is injective on $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$;

(v) $\mathcal{I}$ is $S^{\mathcal{I}}$-fortified and Ω is injective on ThFam($\mathcal{I}$).

Proof:

(iv)⇔(v) We know that injectivity of the Leibniz operator transfers from Theory families to all filter families over arbitrary algebraic systems.

(i)⇔(iv) If $\mathcal{I}$ is syntactically WF algebraizable, then it is $R^{\mathcal{I}}S^{\mathcal{I}}$-fortified, protoalgebraic and family injective. Suppose, conversely, that $\mathcal{I}$ is $S^{\mathcal{I}}$-fortified and family injective. This implies that $\mathcal{I}$ is family truth equational. Together with the syntactic protoalgebraicity following from the hypothesis and Proposition 1830, we get that $\mathcal{I}$ is syntactically WF algebraizable.

(ii)⇔(iii) Let $\gamma : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with two distinguished arguments. Suppose, first, that, for all $\langle\mathcal{A},\leq^{\mathcal{A}}\rangle \in \mathsf{K}$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, $\phi \leq^{\mathcal{A}}_\Sigma \psi$ iff $\gamma^{\mathcal{A}}_\Sigma[\phi,\psi] \leq \Delta^{\mathcal{A}}$. Then, we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\beta_\Sigma[\phi,\psi] \leq T \quad \text{iff} \quad \overleftrightarrow{\beta}[\gamma_\Sigma[\phi,\psi]] \leq T,$$

which yields the conclusion. Conversely, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\beta_\Sigma[\phi,\psi]) = C(\overleftrightarrow{\beta}[\gamma_\Sigma[\phi,\psi]])$, then, we get

$$C^{\mathsf{K},\leq}(\alpha[\beta_\Sigma[\phi,\psi]]) = C^{\mathsf{K},\leq}(\alpha[\overleftrightarrow{\beta}[\gamma_\Sigma[\phi,\psi]]]).$$

Thus, $C^{\mathsf{K},\leq}(\phi \preccurlyeq \psi) = C^{\mathsf{K},\leq}(\gamma_\Sigma[\phi,\psi] \cup \gamma_\Sigma[\phi,\psi]^{-1})$. This yields the conclusion if we take into account that K consists of $\mathbf{F}$-algebraic posystems.

(i)⇒(ii) Suppose that $\mathcal{I}$ is syntactically WF algebraizable via the conjugate pair $(\tau, I) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathrm{AlgSys}^*(\mathcal{I})}$. Then, by Proposition 1830, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\overleftrightarrow{I}^\flat_\Sigma[\phi,\psi]) = C(\overleftrightarrow{\beta}_\Sigma[\phi,\psi])$. Thus, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\phi) = C(\overleftrightarrow{I}^\flat[\tau^\flat_\Sigma[\phi]]) = C(\overleftrightarrow{\beta}[\tau^\flat_\Sigma[\phi]])$. Therefore, in particular, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\beta_\Sigma[\phi,\psi]) = C(\overleftrightarrow{\beta}[\tau^\flat[\beta_\Sigma[\phi,\psi]]]).$$

Now consider any $\langle\mathcal{A},\leq^{\mathcal{A},T}\rangle$, where $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Then, we get, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{aligned} \phi \leq^{\mathcal{A},T}_\Sigma \psi \quad &\text{iff} \quad \beta^{\mathcal{A}}_\Sigma[\phi,\psi] \leq T \\ &\text{iff} \quad \overleftrightarrow{\beta}^{\mathcal{A}}[\tau^{\mathcal{A}}[\beta^{\mathcal{A}}_\Sigma[\phi,\psi]]] \leq T \\ &\text{iff} \quad \tau^{\mathcal{A}}[\beta^{\mathcal{A}}_\Sigma[\phi,\psi]] \leq \Delta^{\mathcal{A}}. \end{aligned}$$

Thus, taking into account the fact that K is the semantic order guasivariety generated by the class $\{\langle\mathcal{A},\leq^{\mathcal{A},T}\rangle : \langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$, we conclude that $\gamma := \tau \circ \beta$ is witnessing the property asserted in Part (ii).

(iii)⇒(v) Finally, assume $(\alpha, \beta) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K},\le}$ witnesses the β-order algebraizability of $\mathcal{I}$ and that $\gamma : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, with two distinguished arguments satisfies the property in Condition (iii). Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have

$$\begin{array}{rll} \phi \in T_\Sigma & \text{iff} & \beta[\alpha_\Sigma[\phi]] \le T \\ & \text{iff} & \overleftrightarrow{\beta}[\gamma[\alpha_\Sigma[\phi]]] \le T \\ & \text{iff} & \gamma[\alpha_\Sigma[\phi]] \le \Omega^{\mathcal{A}}(T). \end{array}$$

This shows that $\mathcal{I}$ is truth equational, which implies that it is $S^{\mathcal{I}}$-fortified and family injective.

■

25.3 Polarities

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A **polarity for F** is a pair $M = (M^+, M^-)$, where M^+ and M^- are subsets of $N^\flat$.

The intuition behind the definition is that

- if $\sigma^\flat \in M^+$, then it is monotone in the first argument and
- if $\sigma^\flat \in M^-$, then it is antimonotone in the first argument.

Why only referring to the first argument? The reason is that it suffices to refer to the first argument to cover all arguments. Suppose, e.g., that $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ is in $N^\flat$. Then $\sigma^\flat \circ \langle p^{2,1}, p^{2,0} \rangle$ is also in $N^\flat$. If we denote $\sigma^\flat$ informally by $\sigma^\flat(x, y)$, then we may denote $\sigma^\flat \circ \langle p^{2,1}, p^{2,0} \rangle$ by $\sigma^\flat(y, x)$. Since both transformations are in $N^\flat$, if we wanted to declare that $\sigma^\flat$ is, say, antimonotone in the second argument, then we would assign $\sigma^\flat(y, x)$ in M^-, getting away with referring only to the first argument of some natural transformation in $N^\flat$. The same trick may be used for any argument position and, hence, the expression "$\sigma^\flat$ **has positive** (or **negative polarity**) **in the k-th argument**" should come as no surprise, even though the formal assignment is done only by classifying leading arguments.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Define the **polarity** $B = (B^+, B^-)$ **induced by** β (the letter B here is chosen to correspond to the transformation β) by setting, for all $\sigma^\flat$ in $N^\flat$:

(+) $\sigma^\flat \in B^+$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma^\flat_\Sigma(\psi, \vec{\chi}) \in C_\Sigma(\beta_\Sigma[\phi, \psi], \sigma^\flat_\Sigma(\phi, \vec{\chi}));$$

(−) $\sigma^\flat \in B^-$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma^\flat_\Sigma(\phi, \vec{\chi}) \in C_\Sigma(\beta_\Sigma[\phi, \psi], \sigma^\flat_\Sigma(\psi, \vec{\chi})).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system, $\le$ a relation system on $\mathcal{A}$ and $T \in \mathrm{SenFam}(\mathcal{A})$. We say that $\le$ is M-**compatible with** T if, for all $\sigma^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma)$,

- if $\sigma^\flat \in M^+$, $\phi \le_\Sigma \psi$, then $\sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \in T_\Sigma$ imply $\sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}) \in T_\Sigma$;
- if $\sigma^\flat \in M^-$, $\phi \le_\Sigma \psi$, then $\sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}) \in T_\Sigma$ imply $\sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \in T_\Sigma$.

Proposition 1832 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{SenFam}(\mathcal{A})$*, there exists a largest qosystem on* $\mathcal{A}$ *that is* M*-compatible with* T*.*

Proof: We consider the class $\mathrm{QoSys}^{\mathcal{A}}(T)$ of all qosystems on $\mathcal{A}$ that are M-compatible with T. We take the transitive closure of the union of all qosystems in $\mathrm{QoSys}^{\mathcal{A}}(T)$,

$$\mathrm{tc}(\bigcup \mathrm{QoSys}^{\mathcal{A}}(T)) = \{\mathrm{tc}_\Sigma(\bigcup \mathrm{QoSys}^{\mathcal{A}}(T))\}_{\Sigma \in |\mathbf{Sign}|}.$$

It suffices to show that this is also a qosystem on $\mathcal{A}$ M-compatible with T, i.e., it is itself a member of $\mathrm{QoSys}^{\mathcal{A}}(T)$. It will then follow that it is its largest member. It is clear by the definition that $\mathrm{tr}(\bigcup \mathrm{QoSys}^{\mathcal{A}}(T))$ is a qosystem on $\mathcal{A}$. So it suffices to show that it is M-compatible with T. Suppose $\sigma^\flat$ in M^+, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that $\phi \ \mathrm{tr}_\Sigma(\bigcup \mathrm{QoSys}^{\mathcal{A}}(T)) \ \psi$ and $\sigma^\flat_\Sigma(\phi, \vec{\chi}) \in T_\Sigma$. Then, there exist $q^0, \ldots, q^k \in \mathrm{QoSys}^{\mathcal{A}}(T)$ and $\xi_1, \ldots, \xi_k \in \mathrm{SEN}(\Sigma)$, such that

$$\phi \ q^0_\Sigma \ \xi_1 \ q^1_\Sigma \ \xi_2 \ q^2_\Sigma \ \cdots \ q^{k-1}_\Sigma \ \xi_k \ q^k_\Sigma \ \psi.$$

Since $\phi \ q^0_\Sigma \ \xi_1$ and $\sigma^\flat_\Sigma(\phi, \vec{\chi}) \in T_\Sigma$, we get $\sigma^\flat_\Sigma(\xi_1, \vec{\chi}) \in T_\Sigma$. Similarly, since $\xi_1 \ q^1_\Sigma \ \xi^2$ and $\sigma^\flat_\Sigma(\xi_1, \vec{\chi}) \in T_\Sigma$, we get $\sigma^\flat_\Sigma(\xi_2, \vec{\chi}) \in T_\Sigma$. We move one step to the right at a time in a similar fashion until we obtain $\sigma^\flat_\Sigma(\psi, \vec{\chi}) \in T_\Sigma$. A similar argument is used to handle the case of negative polarity for $\sigma^\flat$. This proves that $\mathrm{tr}(\bigcup \mathrm{QoSys}^{\mathcal{A}}(T)) \in \mathrm{QoSys}^{\mathcal{A}}(T)$ and, therefore, that it is its largest member. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{SenFam}(\mathcal{A})$. The M-**Leibniz order of** T **on** $\mathcal{A}$ is the largest qosystem $\preccurlyeq^{M,\mathcal{A}}(T)$ on $\mathcal{A}$ that is M-compatible with T.

The next theorem provides a characterization of the M-Leibniz order of a sentence family.

Theorem 1833 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *be a polarity for* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{SenFam}(\mathcal{A})$*. For all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,* $\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma(T) \ \psi$ *if and only if, for all* $\sigma^\flat$ *in* $N^\flat$*,* $\Sigma' \in |\mathbf{Sign}|$*,* $f \in \mathbf{Sign}(\Sigma, \Sigma')$*,* $\vec{\chi} \in \mathrm{SEN}(\Sigma')$*,*

- $\sigma^\flat \in M^+$ *and* $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$ *imply* $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in T_{\Sigma'}$*;*
- $\sigma^\flat \in M^-$ *and* $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in T_{\Sigma'}$ *imply* $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$*.*

Proof: We let $\preccurlyeq^{\mathcal{A}} = \{\preccurlyeq^{\mathcal{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ be defined by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\phi \preccurlyeq^{\mathcal{A}}_\Sigma \psi$ if and only if, for all $\sigma^\flat$ in $N^\flat$, $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

- $\sigma^\flat \in M^+$ and $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$ imply $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in T_{\Sigma'}$;
- $\sigma^\flat \in M^-$ and $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in T_{\Sigma'}$ imply $\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$.

Then it it clear that $\preccurlyeq^{\mathcal{A}}$ is a qosystem on $\mathcal{A}$. Moreover, by its definition, it is compatible with T. Hence, by the maximality of the M-Leibniz order of T on $\mathcal{A}$, $\preccurlyeq^{\mathcal{A}} \leq \preccurlyeq^{M,\mathcal{A}}(T)$. On the other hand, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma(T)\psi$, then, since $\preccurlyeq^{M,\mathcal{A}}(T)$ is a qosystem, we get for all $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathrm{SEN}^\flat(f)(\phi) \preccurlyeq^{M,\mathcal{A}}_{\Sigma'}(T)\mathrm{SEN}(f)(\psi)$. Thus, since $\preccurlyeq^{M,\mathcal{A}}(T)$ is M-compatible with T, we get $\phi \preccurlyeq^{\mathcal{A}}_\Sigma \psi$. Therefore, $\preccurlyeq^{M,\mathcal{A}}(T) \leq \preccurlyeq^{\mathcal{A}}$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The pair $\langle \mathcal{I}, M \rangle$ is called a **polar π-institution**.

Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, the qosystem $\preccurlyeq^{M,\mathcal{A}}(T)$ is called the **M-Leibniz order of T on $\mathcal{A}$**. The collection of maps

$$T \mapsto \preccurlyeq^{M,\mathcal{A}}(T), \quad T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}),$$

for all $\mathcal{A}$, constitute the **M-Leibniz order operator** $\preccurlyeq^M$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. We denote by $O = (O^+, O^-)$ the **total polarity for F**, i.e., the polarity consisting of

$$O^+ = O^- = N^\flat.$$

Corollary 1834 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $O = (O^+, O^-)$ *the total polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. The O-Leibniz order operator* $\preccurlyeq^O$ *of* $\mathcal{I}$ *coincides with the Leibniz operator* Ω *of* $\mathcal{I}$*.*

Proof: This follows directly from the definition of O, Theorem 1833 and Theorem 19. ■

Next we give two properties of the operator $\preccurlyeq^M$. The first is commutativity with inverse surjective morphisms and the second is a characterization of monotonicity. Both properties take after similar properties of the Leibniz operator that were established in previous chapters.

Lemma 1835 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. For all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$*, all surjective morphisms* $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{B})$*,*

$$\gamma^{-1}(\preccurlyeq^{M,\mathcal{B}}(T)) = \preccurlyeq^{M,\mathcal{A}}(\gamma^{-1}(T)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$. We have $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(\gamma^{-1}(T)\psi$ if and only if, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

- if $\sigma^\flat \in M^+$, then $\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in \gamma_{\Sigma'}^{-1}(T_{H(\Sigma')})$ implies $\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in \gamma_{\Sigma'}^{-1}(T_{H(\Sigma')})$;
- if $\sigma^\flat \in M^-$, then $\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in \gamma_{\Sigma'}^{-1}(T_{H(\Sigma')})$ implies $\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in \gamma_{\Sigma'}^{-1}(T_{H(\Sigma')})$;

if and only if for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

- if $\sigma^\flat \in M^+$, then $\gamma_{\Sigma'}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi), \vec{\chi})) \in T_{H(\Sigma')}$ implies $\gamma_{\Sigma'}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in T_{H(\Sigma')}$;
- if $\sigma^\flat \in M^-$, then $\gamma_{\Sigma'}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\psi), \vec{\chi})) \in T_{H(\Sigma')}$ implies $\gamma_{\Sigma'}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in T_{H(\Sigma')}$;

if and only if for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

- if $\sigma^\flat \in M^+$, then $\sigma_{H(\Sigma')}^{\mathcal{B}}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)), \gamma_{\Sigma'}(\vec{\chi})) \in T_{H(\Sigma')}$ implies $\sigma_{H(\Sigma')}^{\mathcal{B}}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\psi)), \gamma_{\Sigma'}(\vec{\chi})) \in T_{H(\Sigma')}$;
- if $\sigma^\flat \in M^-$, then $\sigma_{H(\Sigma')}^{\mathcal{B}}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\psi)), \gamma_{\Sigma'}(\vec{\chi})) \in T_{H(\Sigma')}$ implies $\sigma_{H(\Sigma')}^{\mathcal{B}}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)), \gamma_{\Sigma'}(\vec{\chi})) \in T_{H(\Sigma')}$;

if and only, by the surjectivity of $\langle H, \gamma\rangle$, $\gamma_\Sigma(\phi) \preccurlyeq_{H(\Sigma)}^{M,\mathcal{B}} \gamma_\Sigma(\psi)$ if and only if $\phi\gamma_\Sigma^{-1}(\preccurlyeq_{H(\Sigma)}^{M,\mathcal{B}}(T))\psi$. ■

Lemma 1836 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. For every $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\preccurlyeq^{M,\mathcal{A}}$ is monotone if and only if it commutes with arbitrary intersections.*

Proof: Suppose, first, that $\preccurlyeq^{M,\mathcal{A}}$ is monotone and let $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by monotonicity, $\preccurlyeq^{M,\mathcal{A}}(\bigcap_{T\in\mathcal{T}} T) \leq \bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{A}}(T)$. On the other hand, $\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{A}}(T)$ is a qosystem on $\mathcal{A}$, which can be easily seen to be M-compatible with $\bigcap\mathcal{T}$. Thus, by the maximality property of $\preccurlyeq^{M,\mathcal{A}}(\bigcap\mathcal{T})$, we get $\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{A}}(T) \leq \preccurlyeq^{M,\mathcal{A}}(\bigcap_{T\in\mathcal{T}} T)$. Therefore, the two qosystems are equal and $\preccurlyeq^{M,\mathcal{A}}$ commutes with arbitrary intersections.

Suppose, conversely, $\preccurlyeq^{M,\mathcal{A}}$ commutes with arbitrary intersections and let $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Then, we have

$$\preccurlyeq^{M,\mathcal{A}}(T) = \preccurlyeq^{M,\mathcal{A}}(T \cap T') = \preccurlyeq^{M,\mathcal{A}}(T) \cap \preccurlyeq^{M,\mathcal{A}}(T'),$$

whence, we get $\preccurlyeq^{M,\mathcal{A}}(T) \leq \preccurlyeq^{M,\mathcal{A}}(T')$ and, therefore, $\preccurlyeq^{M,\mathcal{A}}$ is monotone. ■

25.4 Directional Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The polar π-institution $\langle \mathcal{I}, M \rangle$ is called **directional** and the π-institution $\mathcal{I}$ is called M-**directional** if there exists $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, such that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi \quad \text{iff} \quad \beta_\Sigma^{\mathcal{A}}[\phi, \psi] \le T,$$

The collection β in $N^\flat$ will be called a family of **witnessing transformations for the M-directionality of $\mathcal{I}$**.

Here are a couple of direct consequences of the definition. The first asserts that any two set of witnessing transformations for the M-directionality of a given π-institution are deductively equivalent. The second asserts that M-directionality is preserved under extensions.

Lemma 1837 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\beta, \beta' : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-directional with witnessing transformations β and β', then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,*

$$C(\beta_\Sigma[\phi, \psi]) = C(\beta'_\Sigma[\phi, \psi]).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{rl} \beta_\Sigma[\phi, \psi] \le T & \text{iff} \quad \phi \preccurlyeq_\Sigma^{M,\mathcal{F}}(T)\ \psi \\ & \text{iff} \quad \beta'_\Sigma[\phi, \psi] \le T. \end{array}$$

Therefore, $C(\beta_\Sigma[\phi, \psi]) = C(\beta'_\Sigma[\phi, \psi])$. ■

Lemma 1838 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ two π-institutions based on $\mathbf{F}$. If $\mathcal{I}$ is M-directional with witnessing transformations β and $\mathcal{I} \le \mathcal{I}'$, then $\mathcal{I}'$ is also M-directional with witnessing transformations β.*

Proof: Suppose $\mathcal{I}$ is M-directional with witnessing transformations β and $\mathcal{I} \le \mathcal{I}'$. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$. Then, since every $\mathcal{I}'$-filter family of $\mathcal{A}$ is also an $\mathcal{I}$-filter family, we have, by hypothesis, $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$ iff $\beta_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$. We conclude that $\mathcal{I}'$ is also M-directional, with witnessing transformations β. ■

We give, next, sufficient conditions for the M-directionality of a given π-institution.

Theorem 1839 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments, and* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$*, satisfying the following conditions:*

1. $\beta_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I})$*, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*;*
2. $M \le B$*, where* $B = (B^+, B^-)$ *is the polarity induced by* β*;*
3. *For all* $\sigma^\flat \in \beta$*,* $\sigma^\flat(x, y, \vec{z}) \in M^-$ *or* $\sigma^\flat(y, x, \vec{z}) \in M^+$*.*

Then $\mathcal{I}$ *is* M*-directional, with witnessing transformations* β*.*

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$.

Suppose, first, that $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$ and $\sigma^\flat \in \beta$. Then, by Condition 3, either $\sigma^\flat$ is of negative M-polarity in the first argument or of positive M-polarity in the second argument.

- Assume $\sigma^\flat$ has negative polarity in the first argument. By Condition 1, we have $\sigma_\Sigma^{\mathcal{A}}[\psi, \psi] \le T$. Therefore, by Condition 2 and the hypothesis, we get $\sigma_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$.
- Assume $\sigma^\flat$ has positive polarity in the second argument. By Condition 1, we have $\sigma_\Sigma^{\mathcal{A}}[\phi, \phi] \le T$. Therefore, by Condition 2 and the hypothesis, we get $\sigma_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$.

In either case $\sigma_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$, whence, $\beta_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$.

Assume, conversely, that $\beta_\Sigma^{\mathcal{A}}[\phi, \psi] \le T$. Let $\sigma^\flat$ in $N^\flat$, viewed as having one distinguished argument.

- If $\sigma^\flat \in M^+$, then, by Condition 2, $\sigma^\flat \in B^+$. Hence, by definition of B and the hypothesis, $\sigma_\Sigma^{\mathcal{A}}[\phi] \le T$ implies $\sigma_\Sigma^{\mathcal{A}}[\psi] \le T$.
- If $\sigma^\flat \in M^-$, then, by Condition 2, $\sigma^\flat \in B^-$. Hence, by definition of B and the hypothesis, $\sigma_\Sigma^{\mathcal{A}}[\psi] \le T$ implies $\sigma_\Sigma^{\mathcal{A}}[\phi] \le T$.

Therefore, by Theorem 1833, we conclude that $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$. Hence, $\mathcal{I}$ is M-directional with witnessing transformations β. ■

Now we look at some properties of M-directional π-institutions.

Theorem 1840 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is* M*-directional, with witnessing transformations* β*, then the following properties hold:*

(a) *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\beta_\Sigma[\phi, \phi] \le \mathrm{Thm}(\mathcal{I}) \quad \textit{and} \quad \beta_\Sigma[\phi, \chi] \le C(\beta_\Sigma[\phi, \psi], \beta_\Sigma[\psi, \chi]);$$

(b) $M \leq B$, *where* B *is the polarity for* $\mathbf{F}$ *induced by* β*;*

(c) *For all* $\sigma^\flat \in \beta$,

$$\sigma^\flat(x,y,\vec{z}) \in B^- \quad \textit{and} \quad \sigma^\flat(y,x,\vec{z}) \in B^+;$$

(d) $\mathcal{I}$ *is* B*-directional, with witnessing transformations* β*;*

(e) *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$, $\preccurlyeq^{M,\mathcal{A}} = \preccurlyeq^{B,\mathcal{A}}$*;*

(f) B *is the largest polarity* M' *for* $\mathbf{F}$, *such that* $\preccurlyeq^{M'} = \preccurlyeq^M$.

Proof:

(a) Since $\preccurlyeq^M$ is a qosystem, it is reflexive and transitive. Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi,\chi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \preccurlyeq^{M,\mathcal{F}}_\Sigma (\mathrm{Thm}(\mathcal{I}))\ \phi,$$
$$\phi \preccurlyeq^{M,\mathcal{F}}_\Sigma (T)\ \psi \text{ and } \psi \preccurlyeq^{M,\mathcal{F}}_\Sigma (T)\ \chi \text{ imply } \phi \preccurlyeq^{M,\mathcal{F}}_\Sigma (T)\ \chi.$$

Hence, by M-directionality, we get $\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I})$ and

$$\beta_\Sigma[\phi,\psi] \leq T \text{ and } \beta_\Sigma[\psi,\chi] \leq T \text{ imply } \beta_\Sigma[\phi,\chi] \leq T.$$

The latter gives $\beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi],\beta_\Sigma[\psi,\chi])$.

(b) Suppose $\sigma^\flat \in M^+$ and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi,\vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that

$$\beta^{\mathcal{A}}_\Sigma[\phi,\psi] \leq T \quad \text{and} \quad \sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}) \in T_\Sigma.$$

By M-directionality, we get $\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma (T)\ \psi$ and $\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}) \in T_\Sigma$. Thus, since $\sigma^\flat \in M^+$, we get $\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi}) \in T_\Sigma$. We conclude that $\sigma^\flat \in B^+$ and, hence, $M^+ \subseteq B^+$. Similarly, we get that $M^- \subseteq B^-$ and, therefore, $M \leq B$.

(c) This follows directly by the second assertion of Part (a) and the definition of B.

(d) This follows from Parts (a), (c) and Theorem 1839.

(e) By the hypothesis and Part (d), we have, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{aligned}\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma (T)\ \psi \quad &\text{iff} \quad \beta^{\mathcal{A}}_\Sigma[\phi,\psi] \leq T\\ &\text{iff} \quad \phi \preccurlyeq^{B,\mathcal{A}}_\Sigma (T)\ \psi.\end{aligned}$$

Therefore, $\preccurlyeq^{M,\mathcal{A}} = \preccurlyeq^{B,\mathcal{A}}$.

(f) We have that $\preccurlyeq^{M'} = \preccurlyeq^M$ if and only β witnesses the M'-directionality of $\mathcal{I}$. This implies, by Part (b), that $M' \leq B$.

■

We now obtain the following characterization of the existence of a polarity M for which $\mathcal{I}$ is M-directional with a predetermined set $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$ as its witnessing set.

Corollary 1841 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) There exists a polarity $M = (M^+, M^-)$ *for* $\mathbf{F}$*, such that* $\mathcal{I}$ *is* M*-directional with witnessing transformations* β*;*

(ii) For all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I}) \quad \textit{and} \quad \beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi], \beta_\Sigma[\psi,\chi]);$$

(iii) $\mathcal{I}$ *is* B*-directional with witnessing transformations* β*.*

Proof: If Condition (i) holds, then Part (a) of Theorem 1840 ensures that Condition (ii) holds. If Condition (ii) holds, then, we get Part (c) of Theorem 1840 and, from Part (a) (our hypothesis) and Part (c) of Theorem 1840, we get, using Theorem 1839, Part (d) of Theorem 1840, which is Condition (iii). Finally, if (iii) holds, then B is a polarity on $\mathbf{F}$, such that $\mathcal{I}$ is B-directional, with witnessing transformations β and, thus, Condition (i) holds. ■

Our results allow us to show that families of collections of natural transformations in $N^\flat$ with two distinguished arguments, satisfying Condition (ii) of Corollary 1841 and polarities on $\mathbf{F}$ are in correspondence under appropriate identifications of deductively equivalent collections of transformations and of polarities giving rise to the same Leibniz order operators.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

- Let $\mathfrak{B}(\mathcal{I})$ be the collection of all families $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,

  $$\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I}) \quad \text{and} \quad \beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi], \beta_\Sigma[\psi,\chi]).$$

  Moreover, we declare two collections $\beta, \beta' \in \mathfrak{B}(\mathcal{I})$ to be equivalent, written $\beta \equiv^{\mathcal{I}} \beta'$ if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

  $$C(\beta_\Sigma[\phi,\psi]) = C(\beta'_\Sigma[\phi,\psi]).$$

- Let $\mathfrak{M}(\mathcal{I})$ be the collection of all polarities for $\mathbf{F}$, such that $\mathcal{I}$ is M-directional.

  Moreover, we declare two polarities M, M' in $\mathfrak{M}(\mathcal{I})$ to be equivalent, written $M \sim^{\mathcal{I}} M'$, if and only if $\preccurlyeq^M = \preccurlyeq^{M'}$.

Then we have the following correspondence.

Theorem 1842 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. There exists a bijection from* $\mathcal{B}(\mathcal{I})/{\equiv^{\mathcal{I}}}$ *onto* $\mathfrak{M}(\mathcal{I})/{\sim^{\mathcal{I}}}$*, such that*

$$\beta/{\equiv^{\mathcal{I}}} \mapsto B/{\sim^{\mathcal{I}}}, \quad \beta \in \mathfrak{B}(\mathcal{I}),$$

and such that every $\beta' \in \mathfrak{B}(\mathcal{I})$*, such that* $\beta' \equiv^{\mathcal{I}} \beta$*, witnesses the* M*-directionality of* $\mathcal{I}$*, for all* $M \in \mathfrak{M}(\mathcal{I})$*, such that* $M \sim^{\mathcal{I}} B$*.*

Proof: Let $\beta, \beta' \in \mathfrak{B}(\mathcal{I})$, such that $\beta \equiv^{\mathcal{I}} \beta'$. Then, for every $\mathbf{F}$-algebraic system, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rl}\phi \preccurlyeq^{B,\mathcal{A}}_\Sigma(T)\ \psi & \text{iff} \quad \beta_\Sigma[\phi,\psi] \leq T\\ & \text{iff} \quad \beta'_\Sigma[\phi,\psi] \leq T\\ & \text{iff} \quad \phi \preccurlyeq^{B',\mathcal{A}}_\Sigma\ \psi.\end{array}$$

Thus, $B \sim^{\mathcal{I}} B'$ and the mapping in the statement of the theorem is well-defined.

By definition of $\mathfrak{M}(\mathcal{I})$ and Theorem 1840, it is onto.

Finally, if $\beta, \beta' \in \mathfrak{B}(\mathcal{I})$, such that $B \sim^{\mathcal{I}} B'$, then, by definition, $\preccurlyeq^B = \preccurlyeq^{B'}$. Thus, for all $\langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})$, we get, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{rl}\beta_\Sigma[\phi,\psi] \leq T & \text{iff} \quad \phi \preccurlyeq^{B,\mathcal{A}}_\Sigma(T)\ \psi\\ & \text{iff} \quad \phi \preccurlyeq^{B',\mathcal{A}}_\Sigma(T)\ \psi\\ & \text{iff} \quad \beta'_\Sigma[\phi,\psi] \leq T.\end{array}$$

Therefore, by the completeness of $\mathcal{I}$ with respect to $\mathrm{MatFam}^*(\mathcal{I})$, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $C(\beta_\Sigma[\phi,\psi]) = C(\beta'_\Sigma[\phi,\psi])$, i.e., $\beta \equiv^{\mathcal{I}} \beta'$ and, therefore, the map in the statement of the theorem is also injective. ■

Corollary 1843 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* β *is a semi-equivalence system for* $\mathcal{I}$ *(in particular, if* $\mathcal{I}$ *is* β*-order algebraizable), then* $\mathcal{I}$ *is* B*-directional, with witnessing transformations* β*.*

Proof: By Theorem 1828 and Corollary 1841. ■

25.5 Monotonicity and Directionaility

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I}$ be a π-institution based on $\mathbf{F}$.

- We say that $\mathcal{I}$ is M-**order monotone** if the M-Leibniz order operator $\preccurlyeq^M$ is monotone.
- We say that $\mathcal{I}$ is M-**directional** if there exists $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, such that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,
$$\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma(T)\ \psi \quad \text{iff} \quad \beta^{\mathcal{A}}_\Sigma[\phi, \psi] \leq T.$$

Our goal is to connect these two notions.

We have the following obvious relationship.

Theorem 1844 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I}$ be a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-directional, then $\mathcal{I}$ is M-order monotone.*

Proof: Suppose $\mathcal{I}$ is M-directional, with witnessing transformations β. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Then, we get, by the M-directionality of $\mathcal{I}$, we get
$$\preccurlyeq^{M,\mathcal{A}}(T) = \beta(T) \leq \beta(T') = \preccurlyeq^{M,\mathcal{A}}(T').$$
Therefore, $\mathcal{I}$ is M-order monotone. ∎

We introduce a collection of natural transformations associated with $\mathcal{I}$ that play in the present context a role analog to the role that the reflexive core $R^{\mathcal{I}}$ played in the case of syntactic protoalgebraicity. In fact the collection we introduce is a subcollection of the reflexive core of a π-institution $\mathcal{I}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The M-**quasicore** $Q^{\mathcal{I},M}$ of $\mathcal{I}$ is the collection
$$\begin{array}{rcl} Q^{\mathcal{I},M} & = & \{\kappa^\flat \in N^\flat : \kappa^\flat(x, y, \vec{z}) \in M^- \text{ and } \kappa^\flat(y, x, \vec{z}) \in M^+ \text{ and} \\ & & (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))(\kappa^\flat_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I}))\}. \end{array}$$

It turns out that, if $\mathcal{I}$ is M-directional with witnessing transformations β, then $\beta \subseteq Q^{\mathcal{I},M}$.

Lemma 1845 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ having two distinguished arguments, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-directional, with witnessing transformations β, then $\beta \subseteq Q^{\mathcal{I},M}$.*

Proof: The conclusion follows directly from Parts (a) and (c) of Theorem 1840 and the definition of $Q^{\mathcal{I},M}$. ■

The M-directionality of a π-institution $\mathcal{I}$ guarantees that the M-quasicore of $\mathcal{I}$ has the global family modus ponens.

Theorem 1846 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is* M*-directional, then* $Q^{\mathcal{I},M}$ *has the global family modus ponens.*

Proof: Suppose $\mathcal{I}$ is M-directional with witnessing transformations β and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $Q^{\mathcal{I},M}_\Sigma[\phi,\psi] \le T$. Then, by Lemma 1845, $\phi \in T_\Sigma$ and $\beta_\Sigma[\phi,\psi] \le T$. By M-directionality, $\phi \in T_\Sigma$ and $\phi \preccurlyeq^{M,\mathcal{F}}_\Sigma (T)\ \psi$. Therefore, by the definition of $\preccurlyeq^{M,\mathcal{F}}(T)$, $\psi \in T_\Sigma$. We conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\psi \in C_\Sigma(Q^{\mathcal{I},M}_\Sigma[\phi,\psi], \phi),$$

i.e., $Q^{\mathcal{I},M}$ has the global family modus ponens in $\mathcal{I}$. ■

Conversely, it turns out that, if the M-quasicore $Q^{\mathcal{I},M}$ of $\mathcal{I}$ has the global family modus ponens, then $\mathcal{I}$ is M-directional, with $Q^{\mathcal{I},M}$ as its set of witnessing transformations.

Theorem 1847 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $Q^{\mathcal{I},M}$ *has the global family modus ponens in* $\mathcal{I}$*, then* $\mathcal{I}$ *is* M*-directional with witnessing transformations* $Q^{\mathcal{I},M}$*.*

Proof: We must show that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\preccurlyeq^{M,\mathcal{A}}(T) = Q^{\mathcal{I},M,\mathcal{A}}(T)$.

Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma (T)\ \psi$ and $\sigma \in Q^{\mathcal{I},M}$. Then, by the definition of the M-quasicore, $\sigma^{\mathcal{A}}_\Sigma[\psi,\psi] \le T$. Since $\phi \preccurlyeq^{M,\mathcal{A}}_\Sigma (T)\ \psi$ and $\sigma^\flat \in M^-$, we get that $\sigma^{\mathcal{A}}_\Sigma[\phi,\psi] \le T$. Therefore, $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi] \le T$, which gives $\langle \phi,\psi\rangle \in Q^{\mathcal{I},M,\mathcal{A}}_\Sigma(T)$. Thus, $\preccurlyeq^{M,\mathcal{A}}(T) \le Q^{\mathcal{I},M,\mathcal{A}}(T)$.

Conversely, to see that $Q^{\mathcal{I},M,\mathcal{A}}(T) \le \preccurlyeq^{M,\mathcal{A}}(T)$, it suffices to show that $Q^{\mathcal{I},M,\mathcal{A}}(T)$ is a qosystem on $\mathcal{A}$ that is M-compatible with T.

- By definition of the M-quasicore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\phi] \le T$, whence $Q^{\mathcal{I},M,\mathcal{A}}(T)$ is reflexive.
- Next let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi, \chi \in \mathrm{SEN}(\Sigma)$, such that $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi] \le T$ and $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\psi,\chi] \le T$. For $\sigma^\flat, \tau^\flat \in Q^{\mathcal{I},M}$, note that, by the definition of the M-quasicore, the transformation $\tau^\flat(\sigma^\flat(z,x,\vec{p}), \sigma^\flat(z,y,\vec{p}), \vec{q}) \in$

$Q^{\mathcal{I},M}$. Hence, using modus ponens, we get, for all $\sigma^\flat \in Q^{\mathcal{I},M}$ and all $\vec{\xi} \in \mathrm{SEN}(\Sigma')$,

$$\begin{array}{l}\sigma^{\mathcal{A}}_\Sigma(\phi,\chi,\vec{\xi})\\ \in C^{\mathcal{I},\mathcal{A}}_\Sigma(Q^{\mathcal{I},M,\mathcal{A}}_{\Sigma'}[\sigma^{\mathcal{A}}_\Sigma(\phi,\psi,\vec{\xi}),\sigma^{\mathcal{A}}_\Sigma(\phi,\chi,\vec{\xi})],\sigma^{\mathcal{A}}_\Sigma(\phi,\psi,\vec{\xi}))\\ \le C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(Q^{\mathcal{I},M,\mathcal{A}}_{\Sigma'}[\psi,\chi],\sigma^{\mathcal{A}}_\Sigma(\phi,\psi,\vec{\xi})).\end{array}$$

We conclude that $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\chi] \le C^{\mathcal{I},\mathcal{A}}(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi],Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\psi,\chi])$ and, therefore, $Q^{\mathcal{I},M,\mathcal{A}}(T)$ is also transitive.

- Suppose, next, that $\sigma^\flat \in M^+$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi,\vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in Q^{\mathcal{I},M,\mathcal{A}}_\Sigma(T)$ and $\sigma^\flat_\Sigma(\phi,\vec{\chi}) \in T_\Sigma$. Then $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi] \le T$ and $\sigma^{\mathcal{A}}(\phi,\vec{\chi}) \in T_\Sigma$. So we get

$$\begin{array}{rcl}\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi}) & \in & C^{\mathcal{I},\mathcal{A}}_\Sigma(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}),\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi})],\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}))\\ & \subseteq & C^{\mathcal{I},\mathcal{A}}(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi],\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}))\\ & \subseteq & T_\Sigma.\end{array}$$

  Similarly, consider $\sigma^\flat \in M^-$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi,\vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in Q^{\mathcal{I},M,\mathcal{A}}_\Sigma(T)$ and $\sigma^\flat_\Sigma(\psi,\vec{\chi}) \in T_\Sigma$. Then $Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi] \le T$ and $\sigma^{\mathcal{A}}(\psi,\vec{\chi}) \in T_\Sigma$. So we get

$$\begin{array}{rcl}\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi}) & \in & C^{\mathcal{I},\mathcal{A}}_\Sigma(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi}),\sigma^{\mathcal{A}}_\Sigma(\phi,\vec{\chi})],\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi}))\\ & \subseteq & C^{\mathcal{I},\mathcal{A}}(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi],\sigma^{\mathcal{A}}_\Sigma(\psi,\vec{\chi}))\\ & \subseteq & T_\Sigma.\end{array}$$

  Thus, $Q^{\mathcal{I},M,\mathcal{A}(T)}$ is M-compatible with T.

We conclude that $Q^{\mathcal{I},M,\mathcal{A}}(T)$ is a qosystem on $\mathcal{A}$ that is M-compatible with T, whence, by the maximality of $\preccurlyeq^{M,\mathcal{A}}(T)$, we get $Q^{\mathcal{I},M,\mathcal{A}}(T) \le \preccurlyeq^{M,\mathcal{A}}(T)$. ■

We now have a characterization of M-directionality in terms of the property of modus ponens of the M-quasicore $Q^{\mathcal{I},M}$ of the π-institution $\mathcal{I}$.

$$\mathcal{I} \text{ is } M\text{-directional} \longleftrightarrow Q^{\mathcal{I},M} \text{ has Global Family MP.}$$

Theorem 1848 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $M = (M^+,\ M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-directional if and only if* $Q^{\mathcal{I},M}$ *has the global family modus ponens in* $\mathcal{I}$*.*

Proof: Theorem 1846 gives the "only if" and the "if" is by Theorem 1847. ■

As a corollary, we obtain

Corollary 1849 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is* M*-directional with witnessing transformations* β*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$C(Q^{\mathcal{I},M}_\Sigma[\phi,\psi]) = C(\beta_{\Sigma|}[\phi,\psi]).$$

Proof: If $\mathcal{I}$ is M-directional, with witnessing transformations β, then, by Theorems 1846 and 1847, both β and $Q^{\mathcal{I},M}$ are families of witnessing transformations for the M-directionality of $\mathcal{I}$. Therefore, by Lemma 1837, we get the conclusion. ■

We get relatively easily another related characterization of M-directionality.

$$\mathcal{I} \text{ is } M\text{-directional} \longleftrightarrow Q^{\mathcal{I},M} \text{ Defines } M\text{-Leibniz QoSystems.}$$

Theorem 1850 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-directional if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\leqslant^{M,\mathcal{A}}(T) = Q^{\mathcal{I},M,\mathcal{A}}(T).$$

Proof: If $\mathcal{I}$ is M-directional, then, by Theorem 1846 and Theorem 1847, $Q^{\mathcal{I},M}$ constitutes a collection of witnessing transformations, whence, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ $\leqslant^{M,\mathcal{A}}(T) = Q^{\mathcal{I},M,\mathcal{A}}(T)$.

The converse follows by the definition of M-directionality, since, in that case, $Q^{\mathcal{I},M}$ forms a collection of witnessing transformations. ■

We finally show that the property that separates M-order monotonicity from M-directionality is the M-order compatibility property with respect to the theory family generated by the M-quasicore.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. In analogy with the property of the reflexive core being Leibniz, we say that the M-quasicore $Q^{\mathcal{I},M}$ is **order Leibniz** if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \leqslant^{M,\mathcal{A}}_\Sigma (C^{\mathcal{I},\mathcal{A}}(Q^{\mathcal{I},M,\mathcal{A}}_\Sigma[\phi,\psi]))\ \psi.$$

This property is weaker than $Q^{\mathcal{I},M}$ having the global family modus ponens, i.e., if $Q^{\mathcal{I},M}$ has the global family modus ponens, then it is order Leibniz.

Proposition 1851 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $Q^{\mathcal{I},M}$ *has the global family modus ponens, then it is order Leibniz.*

Proof: If $Q^{\mathcal{I},M}$ has the global family modus ponens, then, by Theorem 1847, we get, for every **F**-algebraic system $\mathcal{A}$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\preccurlyeq^{M,\mathcal{A}}(T) = Q^{\mathcal{I},M,\mathcal{A}}(T).$$

Therefore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, by considering, in particular, $T = C^{\mathcal{I},\mathcal{A}}(Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi])$, and taking into account that $Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi] \leq C^{\mathcal{I},\mathcal{A}}(Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi])$, we get that $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(C^{\mathcal{I},\mathcal{A}}(Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi]))\ \psi$. Thus, $Q^{\mathcal{I},M}$ is order Leibniz. ■

In the opposite direction, in an M-order monotone π-institution $\mathcal{I}$, if the M-quasicore is order Leibniz, then it has the global family modus ponens in $\mathcal{I}$.

Proposition 1852 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* **F** *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be an* M*-order monotone* π*-institution based on* **F**. *If* $Q^{\mathcal{I},M}$ *is order Leibniz, then it has the global family modus ponens in* $\mathcal{I}$.

Proof: Suppose that $\mathcal{I}$ is M-order monotone and that $Q^{\mathcal{I},M}$ is order Leibniz. Let $\mathcal{A}$ be an **F**-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in T_\Sigma$ and $Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi] \leq T$. Since $Q^{\mathcal{I},M}$ is order Leibniz, we have

$$\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(C(Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi]))\ \psi,$$

whence, since $\mathcal{I}$ is M-order monotone and $Q_\Sigma^{\mathcal{I},M,\mathcal{A}}[\phi,\psi] \leq T$,

$$\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi.$$

Therefore, since $\phi \in T_\Sigma$, we get, by M-compatibility of $\preccurlyeq^{M,\mathcal{A}}(T)$ with T, that $\psi \in T_\Sigma$. We conclude that $Q^{\mathcal{I},M}$ has the global family modus ponens in $\mathcal{I}$. ■

We now show that a π-institution is M-directional if and only if it is M-order monotone and it has an order Leibniz M-quasicore.

M-Directionality	=	$Q^{\mathcal{I},M}$ has Global Family MP
	=	$Q^{\mathcal{I},M}$ Defines Leibniz QoSystems
	=	M-Order Monotonicity + $Q^{\mathcal{I},M}$ Order Leibniz

Theorem 1853 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+,\ M^-)$ *be a polarity for* **F** *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* **F**. $\mathcal{I}$ *is* M*-directional if and only if it is* M*-order monotone and has an order Leibniz* M*-quasicore.*

Proof: Suppose, first, that $\mathcal{I}$ is M-directional. Then it is M-order monotone by Theorem 1844. Moreover, its M-quasicore has the global family modus ponens by Theorem 1846 and, hence, by Proposition 1851, its M-quasicore is order Leibniz.

Suppose, conversely, that $\mathcal{I}$ is M-order monotone with an order Leibniz M-quasicore. Then, by Proposition 1852, its M-quasicore has the global family modus ponens and, therefore, by Theorem 1848, $\mathcal{I}$ is M-directional. ∎

25.6 c-Reflectivity and Truth Inequationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The polar π-institution $\langle \mathcal{I}, M \rangle$ is called **truth inequational** and the π-institution $\mathcal{I}$ is called M-**truth inequational** if there exists a collection $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$, with a single distinguished argument, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T).$$

In this case $\tau^\flat$ is called a family of **witnessing transformations for the** M-**truth inequationality of** $\mathcal{I}$.

We can show, based on preceding work, that every β-order algebraizable π-institution $\mathcal{I}$ is B-truth inequational, where B is the polarity induced by β.

Proposition 1854 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, having two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is β-order algebraizable, then $\mathcal{I}$ is B-truth inequational.*

Proof: Suppose $\mathcal{I}$ is β-order algebraizable. Then, by Corollary 1843, it is B-directional, with witnessing transformations β. Thus, by Theorem 1828, there exists $\alpha : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, with a single distinguished argument, such that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{iff} & \beta^{\mathcal{A}}[\alpha^{\mathcal{A}}_\Sigma[\phi]] \leq T \\ & \text{iff} & \alpha^{\mathcal{A}}_\Sigma[\phi] \leq \preccurlyeq^{B,\mathcal{A}}(T). \end{array}$$

Thus, $\mathcal{I}$ is B-truth inequational, with witnessing transformations α. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ be a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We say that

$\preccurlyeq^M$ is **completely order reflecting** or **c-reflecting**, for short, if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T') \quad \text{implies} \quad \bigcap_{T\in\mathcal{T}} T \leq T'.$$

If this is the case, we call $\mathcal{I}$ M-**c-reflective**.

We formulate an equivalent condition to M-c-reflectivity.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Given an $\mathbf{F}$-algebraic system $\mathcal{A}$ and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we define the qosystem

$$\widetilde{\preccurlyeq}^{M,\mathcal{A}}(T) = \bigcap\{\preccurlyeq^{M,\mathcal{A}}(T') : T \leq T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\}.$$

By analogy with the Suszko congruence system, we call $\widetilde{\preccurlyeq}^{M,\mathcal{A}}(T)$ the M-**Suszko qosystem of** T.

Lemma 1855 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-c-reflective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\widetilde{\preccurlyeq}^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T') \quad \textit{implies} \quad T \leq T'.$$

Proof: Assume, first, that $\mathcal{I}$ is M-c-reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{\preccurlyeq}^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T')$. Then, we have

$$\bigcap\{\preccurlyeq^{M,\mathcal{F}}(T'') : T \leq T'' \in \mathrm{ThFam}(\mathcal{I})\} \leq \preccurlyeq^{M,\mathcal{F}}(T').$$

Therefore, by M-c-reflectivity, $\bigcap\{T'' : T \leq T'' \in \mathrm{ThFam}(\mathcal{I})\} \leq T'$, i.e., $T \leq T'$.

Suppose, conversely, that the displayed condition holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T')$. Then, we get

$$\begin{array}{rcl}\widetilde{\preccurlyeq}^{M,\mathcal{F}}(\bigcap\mathcal{T}) & = & \bigcap\{\preccurlyeq^{M,\mathcal{F}}(T) : \bigcap\mathcal{T} \leq T \in \mathrm{ThFam}(\mathcal{I})\} \\ & \leq & \bigcap\{\preccurlyeq^{M,\mathcal{F}}(T) : T \in \mathcal{T}\} \\ & \leq & \preccurlyeq^{M,\mathcal{F}}(T').\end{array}$$

Thus, by hypothesis, $\bigcap\mathcal{T} \leq T'$ and, therefore, $\mathcal{I}$ is M-c-reflective. ∎

Furthermore, under M-order monotonicity, it turns out that M-c-reflectivity is equivalent to the injectivity of the M-Leibniz order operator.

Lemma 1856 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is* M*-order monotone, then* $\mathcal{I}$ *is* M*-c-reflective if and only if* $\preccurlyeq^{M,\mathcal{F}}$ *is injective on theory families.*

Proof: Suppose that $\mathcal{I}$ is M-order monotone.

Assume, first, that $\mathcal{I}$ is M-c-reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\preccurlyeq^{M,\mathcal{F}}(T) = \preccurlyeq^{M,\mathcal{F}}(T')$. Then, we have

$$\preccurlyeq^{M,\mathcal{F}}(T) = \preccurlyeq^{M,\mathcal{F}}(T) \cap \preccurlyeq^{M,\mathcal{F}}(T') \leq \preccurlyeq^{M,\mathcal{F}}(T'),$$

whence, by M-c-reflectivity, $T \cap T' \leq T'$, i.e., $T \leq T'$. By symmetry, we get $T = T'$ and, therefore, $\preccurlyeq^{M,\mathcal{F}}$ is injective on theory families.

Assume, conversely, that $\preccurlyeq^{M,\mathcal{F}}$ is injective on theory families and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T')$. Then we get

$$\begin{array}{rcl}\preccurlyeq^{M,\mathcal{F}}(\bigcap_{T\in\mathcal{T}} T) & = & \bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \quad \text{(monotonicity)}\\ & = & \bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \cap \preccurlyeq^{M,\mathcal{F}}(T') \quad \text{(hypothesis)}\\ & = & \preccurlyeq^{M,\mathcal{F}}(\bigcap \mathcal{T} \cap T'). \quad \text{(monotonicity)}\end{array}$$

Thus, by injectivity, $\bigcap \mathcal{T} = \bigcap \mathcal{T} \cap T'$, whence $\bigcap \mathcal{T} \leq T'$ and, therefore, $\mathcal{I}$ is M-c-reflective. ∎

It is always the case that truth inequationality implies c-reflectivity.

Theorem 1857 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ be a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-truth inequational, then it is M-c-reflective.*

Proof: Suppose that $\mathcal{I}$ is M-truth inequational, with witnessing transformations $\tau^\flat$, and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T) \leq \preccurlyeq^{M,\mathcal{F}}(T')$. Then

$$\begin{array}{rcl}\bigcap_{T\in\mathcal{T}} T & = & \bigcap_{T\in\mathcal{T}} \tau^\flat(\preccurlyeq^{M,\mathcal{F}}(T)) \quad \text{(Truth Inequationality)}\\ & = & \tau^\flat(\bigcap_{T\in\mathcal{T}} \preccurlyeq^{M,\mathcal{F}}(T)) \quad \text{(Set Theory)}\\ & \leq & \tau^\flat(\preccurlyeq^{M,\mathcal{F}}(T')) \quad \text{(Hypothesis and Lemma 94)}\\ & = & T'. \quad \text{(Truth Inequationality)}\end{array}$$

Thus, $\mathcal{I}$ is M-c-reflective. ∎

Recall the characterization of truth equationality in terms of the solubility property of the Suszko core of the π-institution. We now work to establish an analog for truth inequationaility. More precisely, we provide a characterization of truth inequationality in terms of the order solubility property of the order core of a π-institution. Then, we provide an exact description of those M-c-reflective π-institutions which are M-truth inequational.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define the M-**order (Suszko) core** of $\mathcal{I}$ to be the collection

$$O^{\mathcal{I},M} = \{\sigma^\flat \in N^\flat : (\forall T \in \mathrm{ThFam}(\mathcal{I}))(\sigma^\flat[T] \leq \widetilde{\preccurlyeq}^{M,\mathcal{F}}(T))\}.$$

Lemma 1858 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For all* $\sigma^\flat$ *in* $N^\flat$*, the following conditions are equivalent:*

(i) For every $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\sigma^\flat[T] \le \precsim^{M,\mathcal{F}}(T)$*;*

(ii) For every $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma[\phi] \le \precsim^{M,\mathcal{F}}(C(\phi))$*.*

Proof: Suppose Condition (i) holds and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, setting $T = C(\phi)$ in (i), we obtain $\sigma^\flat[C(\phi)] \le \precsim^{M,\mathcal{F}}(C(\phi))$, whence, a fortiori, $\sigma^\flat_\Sigma[\phi] \le \precsim^{M,\mathcal{F}}(C(\phi))$. Assume, conversely, that Condition (ii) holds and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we get

$$\begin{array}{rcll}\sigma^\flat[T] & = & \bigcup\{\sigma^\flat_\Sigma[\phi] : \phi \in T_\Sigma, \Sigma \in |\mathbf{Sign}^\flat|\} & \text{(definition)}\\ & \le & \bigcup\{\precsim^{M,\mathcal{F}}(C(\phi)) : \phi \in T_\Sigma, \Sigma \in |\mathbf{Sign}^\flat|\} & \text{(Condition (ii))}\\ & \le & \bigcup\{\precsim^{M,\mathcal{F}}(T) : \phi \in T_\Sigma, \Sigma \in |\mathbf{Sign}^\flat|\} & (\text{monotonicity of } \precsim^{M,\mathcal{F}})\\ & = & \precsim^{M,\mathcal{F}}(T). & \end{array}$$

Thus shows that Condition (i) holds and, therefore, that the two conditions are equivalent. ■

By Lemma 1858, this definition is equivalent to setting

$$\begin{array}{c}O^{\mathcal{I},M} = \{\sigma^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat(\Sigma))\\ (\sigma^\flat_\Sigma[\phi] \le \precsim^{M,\mathcal{F}}(C(\phi)))\}.\end{array}$$

It is clear, by definition that the M-order core of a π-institution satisfies the following property:

Proposition 1859 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T \le O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T)).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\phi \in T_\Sigma & \text{implies} & O^{\mathcal{I},M}_\Sigma[\phi] \le \precsim^{M,\mathcal{F}}(T) \quad (\text{definition of } O^{\mathcal{I},M})\\ & \text{implies} & O^{\mathcal{I},M}_\Sigma[\phi] \le \preccurlyeq^{M,\mathcal{F}}(T). \quad (\precsim^{M,\mathcal{F}}(T) \le \preccurlyeq^{M,\mathcal{F}}(T))\end{array}$$

Thus, we get that $T \le O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T))$. ■

It is possible, but not necessary, that the M-order core of a π-institution satisfies the reverse inclusion. We call this property order solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We say that the M-order core of $\mathcal{I}$ is **order soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T)) \le T.$$

In other words $O^{\mathcal{I},M}$ is order soluble if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

It turns out that possession of the order solubility property by the M-order core intrinsically characterizes M-truth inequationality. We show, first, that the M-order core being order soluble is necessary for M-truth inequationality. To see this, observe that, in case a π-institution is M-truth inequational, the witnessing transformations form a subset of the M-order core.

Lemma 1860 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-truth inequational, with witnessing transformations $\tau^\flat \subseteq N^\flat$, then $\tau^\flat \subseteq O^{\mathcal{I},M}$.*

Proof: By truth inequationality, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T).$$

Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll}\phi \in T_\Sigma & \text{iff} & (\forall T \leq T' \in \mathrm{ThFam}(\mathcal{I}))(\phi \in T'_\Sigma)\\ & \text{iff} & (\forall T \leq T' \in \mathrm{ThFam}(\mathcal{I}))(\tau^\flat_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T'))\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \bigcap\{\preccurlyeq^{M,\mathcal{F}}(T') : T \leq T' \in \mathrm{ThFam}(\mathcal{I})\}\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \widetilde{\preccurlyeq}^{M,\mathcal{F}}(T).\end{array}$$

We conclude, by the definition of $O^{\mathcal{I},M}$, that $\tau^\flat \subseteq O^{\mathcal{I},M}$. ■

Now we prove the necessity of order solubility for truth inequationality.

Theorem 1861 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is M-truth inequational, then $O^{\mathcal{I},M}$ is order soluble.*

Proof: Suppose that $\mathcal{I}$ is M-truth equational, with witnessing equations $\tau^\flat$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{llll}O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) & \text{implies} & \tau^\flat_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) & \text{(Lemma 1860)}\\ & \text{iff} & \phi \in T_\Sigma. & \text{(truth inequationality)}\end{array}$$

Thus, $O^{\mathcal{I},M}$ is order soluble. ■

The reverse implication, which also holds and completes the promised characterization of M-truth inequationality in terms of the M-order core, is presented in the following result.

Theorem 1862 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. If $O^{\mathcal{I},M}$ is order soluble, then $\mathcal{I}$ is M-truth inequational, with witnessing equations $O^{\mathcal{I},M}$.*

Proof: It suffices to show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T).$$

The left-to-right implication is given in Proposition 1859, whereas the converse is ensured by the postulated order solubility of $O^{\mathcal{I},M}$. ∎

Theorems 1861 and 1862 provide the promised characterization of M-truth inequationality in terms of the order solubility of the M-order core.

$$\mathcal{I} \text{ is } M\text{-Truth Inequational} \longleftrightarrow O^{\mathcal{I},M} \text{ is Soluble.}$$

Theorem 1863 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-truth inequational if and only if* $O^{\mathcal{I},M}$ *is order soluble.*

Proof: Theorem 1861 gives the "only if" and the "if" is by Theorem 1862. ∎

If $\mathcal{I}$ is M-truth inequational, then the M-order core defines theory families in $\mathcal{I}$ in terms of their M-Leibniz qosystems.

Proposition 1864 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $O^{\mathcal{I},M}$ *is order soluble, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T)).$$

Proof: If $O^{\mathcal{I},M}$ is order soluble, then, by Theorem 1862, $O^{\mathcal{I},M}$ forms a set of witnessing transformations for the M-truth inequationality of $\mathcal{I}$. Therefore, by definition, we get that, for every $T \in \mathrm{ThFam}(\mathcal{I})$, $T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T))$. ∎

In fact, this property may also be restated as another characterization of truth inequationality. Let us say that $O^{\mathcal{I},M}$ **defines theory families** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T))$. Then we have:

$$\mathcal{I} \text{ is } M\text{-Truth Equational} \longleftrightarrow O^{\mathcal{I},M} \text{ Defines Theory Families.}$$

Theorem 1865 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-truth inequational if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T)).$$

Proof: If $\mathcal{I}$ is truth equational, then, by Theorem 1861, $O^{\mathcal{I},M}$ is order soluble. Thus, by Proposition 1864, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T))$.

Conversely, if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T = O^{\mathcal{I},M}(\preccurlyeq^{M,\mathcal{F}}(T))$, then, $O^{\mathcal{I},M}$ is order soluble. Thus, again by Theorem 1863, $O^{\mathcal{I},M}$ is a set of witnessing equations and $\mathcal{I}$ is M-truth inequational. ∎

We finally show that the property that separates M-complete reflectivity from M-truth inequationality is exactly the adequacy property of the M-order core. Roughly speaking, this property ensures that the M-order core is rich enough to define M-Suszko qosystems in terms of the M-Leibniz qosystems of theory families that it selects via inclusion.

We have the following relationship connecting the M-order core with both M-Leibniz quosystems and M-Suszko qosystems of enveloping theory families.

Proposition 1866 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) \} \leq \precapprox^{M,\mathcal{F}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{lll} \phi \in T_\Sigma & \text{implies} & O^{\mathcal{I},M}_\Sigma[\phi] \leq \precapprox^{M,\mathcal{F}}(T) \quad (M\text{-order core}) \\ & \text{implies} & O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T). \end{array}$$

Therefore, we have

$$\begin{array}{lll} \bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) \} & \leq & \bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \precapprox^{M,\mathcal{F}}(T) \} \\ & \leq & \bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : \phi \in T_\Sigma \} \\ & = & \precapprox^{M,\mathcal{F}}(C(\phi)). \end{array}$$

■

It is possible, but not necessary, that the M-order core of a π-institution satisfies, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, the reverse inclusion of that given in Proposition 1866:

$$\precapprox^{M,\mathcal{F}}(C(\phi)) \leq \bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) \}.$$

Intuitively speaking, this means that the M-order core $O^{\mathcal{I},M}$ is rich enough to allow, for every Σ-sentence ϕ, the determination of those theory families whose M-Leibniz qosystems form a covering of the M-Suszko qosystem of $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We say that the M-order core $O^{\mathcal{I},M}$ of $\mathcal{I}$ is **order adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\precapprox^{M,\mathcal{F}}(C(\phi)) = \bigcap \{ \preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T) \}.$$

It is not difficult to see that, if $O^{\mathcal{I},M}$ is order soluble, then it is order adequate.

Corollary 1867 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $O^{\mathcal{I},M}$ *is order soluble, then it is order adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{rcl}\widetilde{\preccurlyeq}^{M,\mathcal{F}}(C(\phi)) & = & \bigcap\{\preccurlyeq^{M,\mathcal{F}}(T) : \phi \in T_\Sigma\} \quad (\text{definition of } \widetilde{\preccurlyeq}^{M,\mathcal{F}}(C(\phi))) \\ & = & \bigcap\{\preccurlyeq^{M,\mathcal{F}}(T) : O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T)\}. \\ & & (\text{order solubility of } S^{\mathcal{I}} \text{ and Proposition 1864})\end{array}$$

We conclude that $O^{\mathcal{I},M}$ is order adequate. ■

In the opposite direction, in an M-c-reflective π-institution $\mathcal{I}$, if the M-order core is order adequate, then it is also order soluble.

Proposition 1868 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *an* M*-c-reflective* π*-institution based on* $\mathbf{F}$*. If* $O^{\mathcal{I},M}$ *is order adequate, then it is order soluble.*

Proof: Suppose that $\mathcal{I}$ is M-c-reflective and that $O^{\mathcal{I},M}$ is order adequate. We must show that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$

$$\phi \in T_\Sigma \quad \text{iff} \quad O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T).$$

The implication left-to-right is always satisfied by Proposition 1859. For the converse, assume that $O^{\mathcal{I},M}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}(T)$. Then, by the adequacy of $O^{\mathcal{I},M}$, we get that $\widetilde{\preccurlyeq}^{M,\mathcal{F}}(C(\phi)) \leq \preccurlyeq^{M,\mathcal{F}}(T)$. Thus, by M-c-reflectivity, we conclude that $C(\phi) \leq T$, which gives $\phi \in T_\Sigma$. ■

We finally show that a π-institution is M-truth inequational if and only if it is M-c-reflective and it has an order adequate M-order core.

$$\begin{array}{rcl}M\text{-Truth Inequationality} & = & O^{\mathcal{I},M} \text{ Order Soluble} \\ & = & O^{\mathcal{I},M} \text{ Defines Theory Families} \\ & = & M\text{-c-Reflectivity} + O^{\mathcal{I},M} \text{ Order Adequate}\end{array}$$

Theorem 1869 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-truth inequational if and only if it is* M*-c-reflective and has an order adequate* M*-order core.*

Proof: Suppose, first, that $\mathcal{I}$ is M-truth inequational. Then it is M-c-reflective by Theorem 1857. Moreover, its M-order core is order soluble by Theorem 1861 and, hence, by Corollary 1867, its M-order core is order adequate.

Suppose, conversely, that $\mathcal{I}$ is M-c-reflective with an order adequate M-order core. Then, by Proposition 1868, its M-order core is order soluble and, therefore, by Theorem 1863, $\mathcal{I}$ is M-truth inequational. ■

Taking into account Lemma 1856 we obtain the following

Corollary 1870 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *an* M*-order monotone* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-truth inequational if and only if it is* M*-order injective and has an order adequate* M*-order core.*

Proof: By Theorem 1869 and Lemma 1856. ■

Finally, it is not difficult to see that M-truth inequationality transfers from a π-institution to all $\mathcal{I}$-matrix families.

Theorem 1871 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $M = (M^+, M^-)$ *a polarity for* $\mathcal{I}$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is* M*-truth inequational, with witnessing transformations* $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*, if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T = \tau^{\mathcal{A}}(\preccurlyeq^{M,\mathcal{A}}(T))$*.*

Proof: Suppose $\mathcal{I}$ is truth equational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, whence, by hypothesis, $\alpha^{-1}(T) = \tau^\flat(\preccurlyeq^{M,\mathcal{F}}(\alpha^{-1}(T)))$. Hence, by Lemma 1835, $\alpha^{-1}(T) = \tau^\flat(\alpha^{-1}(\preccurlyeq^{M,\mathcal{A}}(T)))$. Therefore, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, we get

$$\begin{array}{lll}\alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})\\ & \text{iff} & \tau^\flat_\Sigma[\phi] \leq \alpha^{-1}(\preccurlyeq^{M,\mathcal{A}}(T))\\ & \text{iff} & \alpha(\tau^\flat_\Sigma[\phi]) \leq \preccurlyeq^{M,\mathcal{A}}(T)\\ & \text{iff} & \tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\phi)] \leq \preccurlyeq^{M,\mathcal{A}}(T). \quad (\langle F, \alpha\rangle \text{ surjective})\end{array}$$

Taking again into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau^{\mathcal{A}}_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{A}}(T)$, i.e., $T = \tau^{\mathcal{A}}(\preccurlyeq^{M,\mathcal{A}}(T))$. ■

25.7 Order Algebraizability

Theorem 1872 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *an* M*-directional* π*-institution based on* $\mathbf{F}$*, with witnessing transformations* β*, such that, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*, all* $\sigma^\flat, \tau^\flat$ *in* $N^\flat$*, and all* $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\beta_\Sigma[\sigma^\flat_\Sigma(\psi, \vec{\chi}), \tau^\flat_\Sigma(\psi, \vec{\chi})] \leq C(\overleftrightarrow{\beta}_\Sigma[\phi, \psi], \beta_\Sigma[\sigma^\flat_\Sigma(\phi, \vec{\chi}), \tau^\flat_\Sigma(\phi, \vec{\chi})]).$$

Then the following conditions are equivalent:

(i) $\mathcal{I}$ *is* β*-order algebraized by* $\{\langle \mathcal{A}, \leq^{\mathcal{A},T}(T)\rangle : \langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$*;*

(ii) $\mathcal{I}$ *is* β*-order algebraizable;*

(iii) $\mathcal{I}$ *is* M*-truth inequational;*

(iv) $\mathcal{I}$ *is* M*-order injective and has an order adequate* M*-order core.*

Proof:

(i)⇒(ii) This implication is trivial.

(ii)⇒(iii) By hypothesis, β witnesses the M-directionality of $\mathcal{I}$. Therefore, by Theorem 1840, $\preccurlyeq^M = \preccurlyeq^B$. Thus, since, by hypothesis, $\mathcal{I}$ is β-order algebraizable, by Proposition 1854, $\mathcal{I}$ is M-truth equational, with witnessing transformations β.

(iii)⇒(i) Suppose $\mathcal{I}$ is M-truth inequational, with witnessing transformations $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, having a single distinguished argument. Thus, we have, for every $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau^\flat_\Sigma[\phi] \leq \preccurlyeq^{M,\mathcal{F}}_\Sigma(T).$$

Thus, by M-directionality, $\phi \in T_\Sigma$ if and only if $\beta[\tau^\flat_\Sigma[\phi]] \leq T$. Thus, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$C(\phi) = C(\beta[\tau^\flat_\Sigma[\phi]]). \tag{25.1}$$

Since, by hypothesis, $\mathcal{I}$ is M-directional, we have, by Theorem 1840, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{l}\beta_\Sigma[\phi,\phi] \leq \mathrm{Thm}(\mathcal{I});\\ \beta_\Sigma[\phi,\chi] \leq C(\beta_\Sigma[\phi,\psi], \beta_\Sigma[\psi,\chi]).\end{array} \tag{25.2}$$

Given the hypothesis, Conditions (25.2) and Condition (25.1), we get, by Theorem 1828, that $\mathcal{I}$ is β-order algebraizable. Therefore, again by Theorem 1828, $\mathcal{I}$ is β-order algebraized by the class $\{\langle \mathcal{A}, \leq^{\mathcal{A},T}(T)\rangle : \langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$.

(iii)⇒(iv) Since $\mathcal{I}$ is M-truth inequational, by Theorem 1869, it is M-c-reflective and has an order adequate M-order core. Since $\mathcal{I}$ is M-directional, by Theorem 1853, it is M-order monotone. Hence, since it is M-c-reflective, by Lemma 1856, it is M-order injective, Thus, $\mathcal{I}$ is M-order injective and has an order adequate M-order core.

(iv)⇒(iii) Suppose $\mathcal{I}$ is M-order injective, with an order adequate M-order core. Since, by hypothesis, $\mathcal{I}$ is M-directional, it is, by Theorem 1853, M-order monotone. Thus, since it is, by hypothesis, M-order injective, it is by Lemma 1856, M-c-reflective. Being M-c-reflective with an M-order adequate M-order core, it is, by Theorem 1869, M-truth inequational.

■

Theorem 1873 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) There exists a polarity $M = (M^+, M^-)$ *for* $\mathbf{F}$*, such that* $\mathcal{I}$ *is* M*-order monotone,* M*-order injective,* $\preccurlyeq^M$ *is antisymmetric on* $\{T : \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$*, with an order Leibniz* M*-quasicore and an order adequate* M*-order core;*

(ii) $\mathcal{I}$ *is order algebraizable, i.e., it is* β*-order algebraizable, for some* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$ *having two distinguished arguments.*

If Condition (i) holds, then β *can be chosen so that* $\preccurlyeq^M = \preccurlyeq^B$ *and*

$$\{\langle \mathcal{A}, \leq^{\mathcal{A},T} \rangle : \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$$

generates the β*-order class of* $\mathcal{I}$*.*

If Condition (ii) holds, then Condition (i) holds with $M = B$*.*

Proof:

(i)⇒(ii) Suppose Condition (i) holds. Since, by hypothesis, $\mathcal{I}$ is M-order monotone and has an order Leibniz M-quasicore, we get, by Theorem 1853, that $\mathcal{I}$ is M-directional, with some family β of witnessing transformations. Thus, by Theorem 1840, $\preccurlyeq^M = \preccurlyeq^B$. By hypothesis and Theorem 1869, we get that $\mathcal{I}$ is M-truth inequational. Therefore, by hypothesis, Theorem 1826 and Theorem 1872, we get that $\mathcal{I}$ is β-order algebraizable and that its β-order class is generated by $\{\langle \mathcal{A}, \leq^{\mathcal{A},T} \rangle : \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$.

(ii)⇒(i) Suppose Condition (ii) holds. Then, by Corollary 1843, $\mathcal{I}$ is B-directional, with witnessing transformations β. Thus, by Theorem 1853, it is B-order monotone and has an order Leibniz B-quasicore. Moreover, by Proposition 1854, $\mathcal{I}$ is B-truth inequational and, therefore, by Theorem 1869, it is B-c-reflective and has on order adequate B-order core. Finally, taking into account Theorem 1828, we may apply Theorem 1872 to establish that $\preccurlyeq^B$ is antisymmetric on $\{T : \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}^*(\mathcal{I})\}$. ■

Corollary 1874 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, having two distinguished arguments,* $M = (M^+, M^-)$ *a polarity for* $\mathbf{F}$ *and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, such that, for all* $\sigma^\flat, \tau^\flat$ *in* $N^\flat$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$*:*

1. $\beta_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I})$*;*

2. $\sigma_\Sigma(\psi,\vec{\chi}) \in C_\Sigma(\beta_\Sigma[\phi,\psi],\sigma^\flat_\Sigma(\phi,\vec{\chi}))$, *if* $\sigma^\flat \in M^+$;

3. $\sigma_\Sigma(\phi,\vec{\chi}) \in C_\Sigma(\beta_\Sigma[\phi,\psi],\sigma^\flat_\Sigma(\psi,\vec{\chi}))$, *if* $\sigma^\flat \in M^-$;

4. $\beta_\Sigma[\sigma^\flat_\Sigma(\psi,\vec{\chi}),\tau^\flat_\Sigma(\psi,\vec{\chi})] \leq C(\overleftrightarrow{\beta}_\Sigma[\phi,\psi],\beta_\Sigma[\sigma^\flat_\Sigma(\phi,\vec{\chi}),\tau^\flat_\Sigma(\phi,\vec{\chi})])$.

If, for all $\sigma^\flat \in \beta$, $\sigma^\flat(x,y,\vec{z}) \in M^-$ *or* $\sigma^\flat(y,x,\vec{z}) \in M^+$, *then* $\mathcal{I}$ *is* β*-order algbebraizable if and only if it is* M*-order injective and has an order adequate* M*-order core.*

Proof: By Theorem 1872, it suffices to show that $\mathcal{I}$ is M-directional. But this follows from Theorem 1839. ■

25.8 Tonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $M = (M^+,M^-)$ a polarity for $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A},\langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system and $\leq^\mathcal{A}$ a qosystem on $\mathcal{A}$. $\leq^\mathcal{A}$ is called an M-**order** if, for all $\sigma^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi,\vec{\chi} \in \mathrm{SEN}(\Sigma)$,

- if $\sigma^\flat \in M^+$, then $\phi \leq^\mathcal{A}_\Sigma \psi$ implies $\sigma^\mathcal{A}_\Sigma(\phi,\vec{\chi}) \leq^\mathcal{A}_\Sigma \sigma^\mathcal{A}_\Sigma(\psi,\vec{\chi})$;
- if $\sigma^\flat \in M^-$, then $\phi \leq^\mathcal{A}_\Sigma \psi$ implies $\sigma^\mathcal{A}_\Sigma(\psi,\vec{\chi}) \leq^\mathcal{A}_\Sigma \sigma^\mathcal{A}_\Sigma(\phi,\vec{\chi})$.

In a way similar to the proof of the existence of $\preccurlyeq^{M,\mathcal{A}}(T)$ in Proposition 1832, we can also show that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A},\langle F,\alpha\rangle\rangle$ and all $T \in \mathrm{SenFam}(\mathcal{A})$, there always exists a largest M-order on $\mathcal{A}$, such that T is upward closed, i.e., for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{and} \quad \phi \leq^{M,\mathcal{A}}_\Sigma \psi \quad \text{imply} \quad \psi \in T_\Sigma.$$

Proposition 1875 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $M = (M^+,M^-)$ *a polarity for* $\mathbf{F}$. *For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A},\langle F,\alpha\rangle\rangle$ *and all* $T \in \mathrm{SenFam}(\mathcal{A})$*, there exists a largest* M*-order on* $\mathcal{A}$*, such that* T *is upward closed.*

Proof: We consider the class $\mathrm{MOrd}^\mathcal{A}(T)$ of all M-orders on $\mathcal{A}$ with respect to which T is upward closed. We take the transitive closure of the union of all qosystems in $\mathrm{MOrd}^\mathcal{A}(T)$,

$$\mathrm{tc}(\bigcup \mathrm{MOrd}^\mathcal{A}(T)) = \{\mathrm{tc}_\Sigma(\bigcup \mathrm{MOrd}^\mathcal{A}(T)\}_{\Sigma\in|\mathbf{Sign}|}.$$

It suffices to show that this is also an M-order on $\mathcal{A}$ with respect to which T is upward closed. i.e., it is itself a member of $\mathrm{MOrd}^\mathcal{A}(T)$. It will then follow that it is its largest member.

It is clear by the definition that $\mathrm{tr}(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T))$ is a qosystem on $\mathcal{A}$. So it suffices to show that it is an M-order with respect to which T is upward closed.

Suppose $\sigma^\flat$ in M^+, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma)$, such that

$$\phi \ \mathrm{tr}_\Sigma(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T)) \ \psi.$$

Then, there exist $q^0, \dots, q^k \in \mathrm{MOrd}^{\mathcal{A}}(T)$ and $\xi_1, \dots, \xi_k \in \mathrm{SEN}(\Sigma)$, such that

$$\phi \ q^0_\Sigma \ \xi_1 \ q^1_\Sigma \ \xi_2 \ q^2_\Sigma \cdots q^{k-1}_\Sigma \ \xi_k \ q^k_\Sigma \ \psi.$$

Since $\phi \ q^0_\Sigma \ \xi_1$ and $q^0 \in \mathrm{MOrd}^{\mathcal{A}}(T)$, we get $\sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \ q^0_\Sigma \ \sigma^{\mathcal{A}}_\Sigma(\xi_1, \vec{\chi})$. Since $\xi_1 \ q^1_\Sigma \ \xi_2$ and $q^1 \in \mathrm{MOrd}^{\mathcal{A}}(T)$, we get $\sigma^{\mathcal{A}}_\Sigma(\xi_1, \vec{\chi}) \ q^1_\Sigma \ \sigma^{\mathcal{A}}_\Sigma(\xi_2, \vec{\chi})$. We move one step to the right at a time in a similar fashion until we obtain $\sigma^{\mathcal{A}}_\Sigma(\xi_k, \vec{\chi}) \ q^k_\Sigma \ \sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi})$. Thus, we obtain

$$\sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \ \mathrm{tr}_\Sigma(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T)) \ \sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}).$$

A similar argument is used to handle the case of negative polarity for $\sigma^\flat$. This proves that $\mathrm{tr}(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T))$ is also an M-order on $\mathcal{A}$.

Finally, suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in T_\Sigma$ and

$$\phi \ \mathrm{tr}_\Sigma(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T)) \ \psi.$$

Then, there exist $q^0, \dots, q^k \in \mathrm{MOrd}^{\mathcal{A}}(T)$ and $\xi_1, \dots, \xi_k \in \mathrm{SEN}(\Sigma)$, such that

$$\phi \ q^0_\Sigma \ \xi_1 \ q^1_\Sigma \ \xi_2 \ q^2_\Sigma \cdots q^{k-1}_\Sigma \ \xi_k \ q^k_\Sigma \ \psi.$$

Since T is upward closed with respect to all elements in $\mathrm{MOrd}^{\mathcal{A}}(T)$ and $\phi \in T_\Sigma$, we get $\xi_1 \in T_\Sigma$, then $\xi_2 \in T_\Sigma$, then $\dots$, until, in the last step, $\xi_k \in T_\Sigma$ implies $\psi \in T_\Sigma$. Therefore, T is also upward closed with respect to $\mathrm{tr}_\Sigma(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T))$, showing that $\mathrm{tr}_\Sigma(\bigcup \mathrm{MOrd}^{\mathcal{A}}(T)) \in \mathrm{MOrd}^{\mathcal{A}}(T)$, whence it is its largest element. ■

Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $T \in \mathrm{SenFam}(\mathcal{A})$, the **Leibniz M-order $\leq^{M,\mathcal{A}}(T)$ of $\langle \mathcal{A}, T \rangle$** is the largest M-order on $\mathcal{A}$, such that T is upward closed, whose existence is assured by Proposition 1875.

It turns out that the Leibniz M-order $\leq^{M,\mathcal{A}}(T)$ is included in the M-Leibniz qosystem $\preccurlyeq^{M,\mathcal{A}}(T)$ of T on $\mathcal{A}$.

Proposition 1876 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \mathrm{SenFam}(\mathcal{A})$,*

$$\leq^{M,\mathcal{A}}(T) \leq \preccurlyeq^{M,\mathcal{A}}(T).$$

Proof: It suffices to show that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \mathrm{SenFam}(\mathcal{A})$, $\leq^{M,\mathcal{A}}(T)$ is M-compatible with T. To this end, let $\sigma^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma)$.

- Suppose $\sigma^\flat \in M^+$, $\phi \leq_\Sigma^{M,\mathcal{A}}(T)\psi$ and $\sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi}) \in T_\Sigma$. Since $\phi \leq_\Sigma^{M,\mathcal{A}}(T)\psi$ and $\leq^{M,\mathcal{A}}(T)$ is an M-order, we get $\sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi}) \leq \sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi})$. Hence, since $\sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi}) \in T_\Sigma$ and T is upward closed with respect to $\leq^{M,\mathcal{A}}(T)$, we get $\sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi}) \in T_\Sigma$.

- Suppose $\sigma^\flat \in M^-$, $\phi \leq_\Sigma^{M,\mathcal{A}}(T)\psi$ and $\sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi}) \in T_\Sigma$. Since $\phi \leq_\Sigma^{M,\mathcal{A}}(T)\psi$ and $\leq^{M,\mathcal{A}}(T)$ is an M-order, we get $\sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi}) \leq \sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi})$. Hence, since $\sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi}) \in T_\Sigma$ and T is upward closed with respect to $\leq^{M,\mathcal{A}}(T)$, we get $\sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi}) \in T_\Sigma$.

Thus, $\leq^{M,\mathcal{A}}(T)$ is M-compatible with T and, hence, by the maximality of $\preccurlyeq^{M,\mathcal{A}}(T)$, $\leq^{M,\mathcal{A}}(T) \leq \preccurlyeq^{M,\mathcal{A}}(T)$. ■

We finally provide sufficient conditions ensuring that the two orders on $\mathcal{A}$ associated with $\mathcal{I}$-filter families T of a π-institution $\mathcal{I}$, $\leq^{M,\mathcal{A}}(T)$ and $\preccurlyeq^{M,\mathcal{A}}(T)$, coincide.

Proposition 1877 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\beta : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$ having two distinguished arguments, $M = (M^+, M^-)$ a polarity for $\mathbf{F}$, such that $p^{1,0} \in M^+$, and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Suppose $\mathcal{I}$ is M-directional, with witnessing transformations β, and that, for all σ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi,\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,*

- *if $\sigma^\flat \in M^+$, $\beta_\Sigma[\sigma_\Sigma^\flat(\phi,\vec{\chi}), \sigma_\Sigma^\flat(\psi,\vec{\chi})] \leq C(\beta_\Sigma[\phi,\psi])$;*

- *if $\sigma^\flat \in M^-$, $\beta_\Sigma[\sigma_\Sigma^\flat(\psi,\vec{\chi}), \sigma_\Sigma^\flat(\phi,\vec{\chi})] \leq C(\beta_\Sigma[\phi,\psi])$.*

Then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\preccurlyeq^{M,\mathcal{A}}(T)$ is the largest M-order on $\mathcal{A}$ with respect to which T is upward closed, i.e., $\preccurlyeq^{M,\mathcal{A}}(T) = \leq^{M,\mathcal{A}}(T)$.

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We show that $\preccurlyeq^{M,\mathcal{A}}(T)$ is an M-order on $\mathcal{A}$, with respect to which T is upward closed. Then, it will follow, by the maximality property of $\leq^{M,\mathcal{A}}(T)$, that $\preccurlyeq^{M,\mathcal{A}}(T) \leq \leq^{M,\mathcal{A}}(T)$.

Let $\sigma^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi,\vec{\chi} \in \mathrm{SEN}(\Sigma)$.

- Suppose $\sigma^\flat \in M^+$ and $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$. Thus, by M-directionality of $\mathcal{I}$, $\beta_\Sigma^{\mathcal{A}}[\phi,\psi] \leq T$, whence, by hypothesis, $\beta_\Sigma^{\mathcal{A}}[\sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi}), \sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi})] \leq T$. Thus, again by M-directionaility, $\sigma^{\mathcal{A}}(\phi,\vec{\chi}) \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi})$.

- Suppose $\sigma^\flat \in M^-$ and $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$. Thus, by M-directionality of $\mathcal{I}$, $\beta_\Sigma^{\mathcal{A}}[\phi,\psi] \leq T$, whence, by hypothesis, $\beta_\Sigma^{\mathcal{A}}[\sigma_\Sigma^{\mathcal{A}}(\psi,\vec{\chi}), \sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi})] \leq T$. Thus, again by M-directionaility, $\sigma^{\mathcal{A}}(\psi,\vec{\chi}) \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \sigma_\Sigma^{\mathcal{A}}(\phi,\vec{\chi})$.

Thus, $\preccurlyeq^{M,\mathcal{A}}(T)$ is an M-order on $\mathcal{A}$.

Finally, suppose $\phi \preccurlyeq_\Sigma^{M,\mathcal{A}}(T)\ \psi$ and $\phi \in T_\Sigma$. Then, since, by hypothesis, $p^{1,0} \in M^+$ and $\preccurlyeq^{M,\mathcal{A}}(T)$ is M-compatible with T, we get $\psi \in T_\Sigma$. Therefore, $\preccurlyeq^{M,\mathcal{A}}(T)$ is an M-order with respect to which T is upward closed. It now follows by the maximality of $\leq^{M,\mathcal{A}}(T)$, that $\preccurlyeq^{M,\mathcal{A}}(T) \leq \leq^{M,\mathcal{A}}(T)$ and, hence, by Proposition 1876, that $\preccurlyeq^{M,\mathcal{A}}(T) = \leq^{M,\mathcal{A}}(T)$. ■

Chapter 26

Gentzen π-Institutions

26.1 Gentzen π-Institutions Revisited

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an $N^\flat$-algebraic system, $\Sigma \in |\mathbf{Sign}|$ and $m, n \in \omega$. An $\langle m,n \rangle$**-**Σ**-sequent of A** is an expression

$$\phi_0, \ldots, \phi_{m-1} \rhd_\Sigma \psi_0, \ldots, \psi_{n-1},$$

abbreviated $\vec{\phi} \rhd_\Sigma \vec{\psi}$, consisting of two finite (possibly empty) sequences $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$. A $\langle 0,n \rangle$-Σ-sequent $\varnothing \rhd_\Sigma \vec{\psi}$ is abbreviated $\rhd_\Sigma \vec{\psi}$.

Given $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and an $\langle m,n \rangle$-Σ-sequent $\vec{\phi} \rhd_\Sigma \vec{\psi}$, we write

$$\mathrm{SEN}(f)(\vec{\phi} \rhd_\Sigma \vec{\psi}) \coloneqq \mathrm{SEN}(f)(\vec{\phi}) \rhd_{\Sigma'} \mathrm{SEN}(f)(\vec{\psi}),$$

where, as usual,

$$\begin{array}{rcl}\mathrm{SEN}(f)(\vec{\phi}) & \coloneqq & \langle \mathrm{SEN}(f)(\phi_0), \ldots, \mathrm{SEN}(f)(\phi_{m-1}) \rangle, \\ \mathrm{SEN}(f)(\vec{\psi}) & \coloneqq & \langle \mathrm{SEN}(f)(\psi_0), \ldots, \mathrm{SEN}(f)(\psi_{n-1}) \rangle.\end{array}$$

Sometimes, we denote a Σ-sequent by $\boldsymbol{\phi} \coloneqq \vec{\phi}^0 \rhd_\Sigma \vec{\phi}^1$ and a set of Σ-sequents by $\mathbf{\Phi}$. The notation for images under morphisms is then extended to sets of Σ-sequents by writing

$$\mathrm{SEN}(f)(\mathbf{\Phi}) = \{\mathrm{SEN}(f)(\boldsymbol{\phi}) : \boldsymbol{\phi} \in \mathbf{\Phi}\}.$$

A **trace** tr is a nonempty subset of $\omega \times \omega$. An $\langle m,n \rangle$-Σ-sequent is a **tr-**Σ**-sequent** if $\langle m,n \rangle \in \mathrm{tr}$. The collection of all tr-Σ-sequents of $\mathbf{A}$ is denoted by $\mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{A})$ and we set

$$\mathrm{Seq}^{\mathrm{tr}}(\mathbf{A}) = \{\mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{A})\}_{\Sigma \in |\mathbf{Sign}|}.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and tr be a given trace. A **Gentzen** π**-institution** $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ **of trace** tr based on $\mathbf{F}$ consists of a closure system

$$G : \mathcal{P}\mathrm{Seq}^{\mathrm{tr}}(\mathbf{F}) \to \mathcal{P}\mathrm{Seq}^{\mathrm{tr}}(\mathbf{F}),$$

i.e., a collection of closure operators

$$G_\Sigma : \mathcal{P}\mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F}) \to \mathcal{P}\mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F}), \quad \Sigma \in |\mathbf{Sign}^\flat|,$$

that also satisfy structurality, that is, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, and all $\mathbf{\Phi} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\mathrm{SEN}(f)(G_\Sigma(\mathbf{\Phi})) \subseteq G_{\Sigma'}(\mathrm{SEN}(f)(\mathbf{\Phi})).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. If, for some $\Sigma \in |\mathbf{Sign}^\flat|$,

$\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi})$, we say that $\langle \mathbf{\Phi}, \boldsymbol{\phi}\rangle$ is a Σ-**rule of** $\mathfrak{G}$ or a Σ-**derivable rule of** $\mathfrak{G}$, sometimes denoted

$$\frac{\mathbf{\Phi}}{\boldsymbol{\phi}}.$$

A Σ-rule of form $\langle \varnothing, \boldsymbol{\phi}\rangle$ is called a Σ-**derivable sequent** or a Σ-**theorem of** $\mathfrak{G}$.

$\mathfrak{G}$ is **inconsistent** if all elements in $\mathrm{Seq}^{\mathrm{tr}}(\mathbf{F})$ are derivable sequents in $\mathfrak{G}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace and $\mathfrak{G}^i = \langle \mathbf{F}, G^i\rangle$, $i \in I$, a collection of Gentzen π-institutions, all of trace tr, based on $\mathbf{F}$. Then

$$\bigcap_{i\in I} \mathfrak{G}^i = \langle \mathbf{F}, \bigcap_{i\in I} G^i\rangle,$$

defined, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathbf{\Phi} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$(\bigcap_{i\in I} G^i)_\Sigma(\mathbf{\Phi}) = \bigcap_{i\in I} G^i_\Sigma(\mathbf{\Phi}),$$

is also a Gentzen π-institution.

Therefore, given a family $\mathfrak{X} = \{\mathfrak{X}_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ of rules, there is a smallest Gentzen π-institution $\mathfrak{G}^{\mathfrak{X}} = \langle \mathbf{F}, G^{\mathfrak{X}}\rangle$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\langle \mathbf{\Phi}, \boldsymbol{\phi}\rangle \in \mathfrak{X}_\Sigma$,

$$\boldsymbol{\phi} \in G^{\mathfrak{X}}_\Sigma(\mathbf{\Phi}).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution based on $\mathbf{F}$, with $\langle 0, 1\rangle \in \mathrm{tr}$. Consider

$$G^0 : \mathcal{P}\mathrm{SEN} \to \mathcal{P}\mathrm{SEN}$$

defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, by

$$\phi \in G^0_\Sigma(\Phi) \quad \text{iff} \quad \rhd_\Sigma \phi \in G_\Sigma(\{\rhd_\Sigma \psi : \psi \in \Phi\}).$$

Lemma 1878 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$*, with* $\langle 0, 1\rangle \in \mathrm{tr}$*.* $G^0 : \mathcal{P}\mathrm{SEN}^\flat \to \mathcal{P}\mathrm{SEN}^\flat$ *is a closure system on* $\mathbf{F}$*.*

Proof: Suppose, first, that $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \Phi$. Then, by the inflationarity of G, $\rhd_\Sigma \phi \in G_\Sigma(\{\rhd_\Sigma \psi : \psi \in \Phi\})$ and, hence, by definition of G^0, $\phi \in G^0_\Sigma(\Phi)$. Suppose, next, that $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\Phi \subseteq \Psi$. Then, by monotonicity of G, $G_\Sigma(\{\rhd_\Sigma \phi : \phi \in \Phi\}) \subseteq G_\Sigma(\{\rhd_\Sigma \psi : \psi \in \Psi\})$, whence, by the definition of G^0, $G^0_\Sigma(\Phi) \subseteq G^0_\Sigma(\Psi)$. Now assume that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in G^0_\Sigma(G^0_\Sigma(\Phi))$. Then, taking into account the idempotency of G, we get

$$\begin{array}{rcl}\rhd_\Sigma \phi & \in & G_\Sigma(\{\rhd_\Sigma \psi : \ \psi \in G^0_\Sigma(\Phi)\}) \\ & \subseteq & G_\Sigma(G_\Sigma(\{\rhd_\Sigma \phi : \phi \in \Phi\})) \\ & \subseteq & G_\Sigma(\{\rhd_\Sigma \phi : \phi \in \Phi\}),\end{array}$$

whence $\phi \in G^0_\Sigma(\Phi)$. Finally, the structurality property of G^0 follows directly by the structurality property of G. ■

According to Lemma 1878, the structure $\mathcal{G}^0 = \langle \mathbf{F}, G^0 \rangle$ is a π-institution, called the **π-institution reduct of** the Gentzen π-institution $\mathfrak{G}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic systems. Recall the closure system $C^\mathsf{K} : \mathcal{P}(\mathrm{SEN}^\flat)^2 \to \mathcal{P}(\mathrm{SEN}^\flat)^2$ defined, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)^2$,

$$\begin{array}{lll}\phi \approx \psi \in C^\mathsf{K}_\Sigma(E) & \text{iff} & \text{for all } \mathcal{A} \in \mathsf{K}, \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}(\Sigma, \Sigma'),\\ & & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(E)) \subseteq \Delta^\mathcal{A}_{F(\Sigma')}\\ & & \text{implies } \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) = \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).\end{array}$$

The π-institution $\mathcal{I}^\mathsf{K} = \langle \mathbf{F}, C^\mathsf{K} \rangle$ was called the **equational π-institution associated with** the class K. This π-institution may be recast as a Gentzen π-institution of trace $\{\langle 1, 1 \rangle\}$. More precisely, we define the Gentzen π-institution $\mathfrak{G}^\mathsf{K} = \langle \mathbf{F}, G^\mathsf{K} \rangle$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\{\phi_i, \psi_i : i \in I\} \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \rhd_\Sigma \psi \in G^\mathsf{K}_\Sigma(\{\phi_i \rhd_\Sigma \psi_i : i \in I\}) \quad \text{iff} \quad \phi \approx \psi \in C^\mathsf{K}_\Sigma(\{\phi_i \approx \psi_i : i \in I\}).$$

We call $\mathfrak{G}^\mathsf{K}$ the **Gentzen π-institution associated with** the class K.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ may also be recast as a Gentzen π-institution of trace $\{\langle 0, 1 \rangle\}$. More precisely, given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$, denote by

$$\rhd_\Sigma \Phi = \{\rhd_\Sigma \phi : \phi \in \Phi\}$$

and, similarly, given $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|} \in \mathrm{SenFam}(\mathbf{F})$, let

$$\rhd T = \{\rhd_\Sigma T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}.$$

We define $\mathfrak{G}^\mathcal{I} = \langle \mathbf{F}, G^\mathcal{I} \rangle$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\rhd_\Sigma \phi \in G^\mathcal{I}_\Sigma(\rhd_\Sigma \Phi) \quad \text{iff} \quad \phi \in C_\Sigma(\Phi).$$

We call $\mathfrak{G}^\mathcal{I}$ the **Hilbert π-institution associated with** $\mathcal{I}$. In this terminology, a Hilbert π-institution is a Gentzen π-institution of trace $\{\langle 0, 1 \rangle\}$.

Given a Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ of trace tr, such that $\langle 0, 1 \rangle \in \mathrm{tr}$, we call the Hilbert π-institution $\mathfrak{G}^{\mathcal{G}^0}$ associated with the π-institution reduct $\mathcal{G}^0$ of $\mathfrak{G}$ the **Hilbert π-institution reduct of** $\mathfrak{G}$ and we denote it by $\mathfrak{G}^0 = \langle \mathbf{F}, G^0 \rangle$ (note the overloading of notation for G^0, used both for the closure system of the π-institution $\mathcal{G}^0$ and for the closure system of $\mathfrak{G}^{\mathcal{G}^0}$; hopefully, this will not result into any confusion, since it should be resolvable based on context).

26.2 Equivalence of Gentzen π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{F}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be algebraic systems and tr, tr′ be traces. A tr-tr′-**translation** is a collection of functions

$$\alpha = \{\alpha^{m,n} : \langle m,n\rangle \in \mathrm{tr}\},$$

where, for all $\langle m,n\rangle \in \mathrm{tr}$,

$$\alpha^{m,n} = \{\alpha^{m,n}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$$

is such that, for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha^{m,n}_\Sigma : \mathrm{SEN}(\Sigma)^{m,n} \to \mathcal{P}(\mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F}'))$$

assigns to each $\langle m,n\rangle$-Σ-sequent $\vec{\phi} \rhd_\Sigma \vec{\psi}$ of $\mathbf{F}$ a set of tr′-Σ-sequents of $\mathbf{F}'$

$$\alpha^{m,n}_\Sigma[\vec{\phi};\vec{\psi}].$$

We extend the notation in a natural way in order to write expressions more concisely. Thus, given $\Sigma \in |\mathbf{Sign}|$ and $\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, we set

$$\alpha_\Sigma[\boldsymbol{\phi}] = \alpha_\Sigma[\vec{\phi};\vec{\psi}],$$

if $\boldsymbol{\phi} = \vec{\phi} \rhd_\Sigma \vec{\psi}$, and

$$\alpha_\Sigma[\mathbf{\Phi}] = \bigcup\{\alpha^{m,n}_\Sigma[\boldsymbol{\phi}] : \boldsymbol{\phi} \in \mathbf{\Phi}^{m,n},\ \langle m,n\rangle \in \mathrm{tr}\}.$$

Finally, if $\mathbf{\Phi} = \{\mathbf{\Phi}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|} \leq \mathrm{Seq}^{\mathrm{tr}}(\mathbf{F})$, we set

$$\alpha[\mathbf{\Phi}] = \bigcup\{\alpha_\Sigma[\mathbf{\Phi}_\Sigma] : \Sigma \in |\mathbf{Sign}|\}.$$

Even though we defined translations in a very general way, we will deal almost exclusively with a special kind of translation, called a transformation. To introduce those, we fix $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ and two traces tr and tr′. A tr-tr′-translation $\alpha = \{\alpha^{m,n} : \langle m,n\rangle \in \mathrm{tr}\}$ is called a tr-tr′-**transformation** if there exists a family

$$\tau = \{\tau^{m,n} : \langle m,n\rangle \in \mathrm{tr}\},$$

such that, for all $\langle m,n\rangle \in \mathrm{tr}$,

$$\tau^{m,n} : \mathrm{SEN}^\omega \to \bigcup\{\mathrm{SEN}^{k+\ell} : \langle k,\ell\rangle \in \mathrm{tr}'\}$$

is a collection of natural transformations in $N^\flat$, with $m+n$ distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \rhd_\Sigma \vec{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$,

$$\alpha^{m,n}_\Sigma[\vec{\phi};\vec{\psi}] = \tau^{m,n}_\Sigma[\vec{\phi};\vec{\psi}],$$

where, we let $\tau^{m,n}_\Sigma[\vec{\phi};\vec{\psi}]$ be defined, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, by

$$\tau^{m,n}_\Sigma[\vec{\phi};\vec{\psi}] \quad = \quad \bigcup\{\tau^{m,n}_\Sigma(\vec{\phi},\vec{\psi},\vec{\chi}) : \vec{\chi}' \in \mathrm{SEN}^\flat(\Sigma)\}.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr and tr′ two traces and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ and $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ two Gentzen π-institutions of traces tr and tr′, respectively, both based on $\mathbf{F}$. A tr-tr′-transformation τ is an **interpretation from $\mathfrak{G}$ to $\mathfrak{G}'$**, written $\tau : \mathfrak{G} \to \mathfrak{G}'$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi}) \quad \text{iff} \quad \tau_\Sigma[\boldsymbol{\phi}] \subseteq G'_\Sigma(\tau_\Sigma[\mathbf{\Phi}]).$$

The two π-institutions $\mathfrak{G}$ and $\mathfrak{G}'$ are **equivalent** if there exist a tr-tr′-transformation τ and a tr′-tr-transformation ρ, such that:

- $\tau : \mathfrak{G} \to \mathfrak{G}'$ is an interpretation;
- $\rho : \mathfrak{G}' \to \mathfrak{G}$ is an interpretation;
- for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,
$$G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]);$$
- for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F})$,
$$G'_\Sigma(\boldsymbol{\phi}') = G'_\Sigma(\tau_\Sigma[\rho_\Sigma[\boldsymbol{\phi}']]).$$

In this case the pair (τ,ρ) is called a **conjugate pair** of transformations and denoted by $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$.

As in Lemma 889, it suffices to check only the first and last conditions, or, equivalently, the middle two conditions to ensure that two Gentzen π-institutions are equivalent.

Lemma 1879 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr, tr′ *be traces,* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *two Gentzen π-institutions of traces* tr, tr′, *respectively, based on* $\mathbf{F}$, τ *a* tr-tr′*-transformation and* ρ *a* tr′-tr-*transformation. The following are equivalent:*

(i) $\tau : \mathfrak{G} \to \mathfrak{G}'$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F})$, $G'_\Sigma(\boldsymbol{\phi}') = G'_\Sigma(\tau_\Sigma[\rho_\Sigma[\boldsymbol{\phi}']])$;

(ii) $\rho : \mathfrak{G}' \to \mathfrak{G}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]])$.

Proof: Similar to the proof of Lemma 889. Suppose that the conditions in (i) hold. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\mathbf{\Phi}' \cup \{\boldsymbol{\phi}'\} \subseteq \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F})$, we have

$$\begin{array}{lll}\boldsymbol{\phi}' \in G'_\Sigma(\mathbf{\Phi}') & \text{iff} & \tau_\Sigma[\rho_\Sigma[\boldsymbol{\phi}']] \subseteq G'_\Sigma(\tau_\Sigma[\rho_\Sigma[\mathbf{\Phi}']]) \\ & \text{iff} & \rho_\Sigma[\boldsymbol{\phi}'] \subseteq G_\Sigma(\rho_\Sigma[\mathbf{\Phi}']).\end{array}$$

Hence, $\rho : \mathfrak{G}' \to \mathfrak{G}$ is also an interpretation. Finally, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, we get, for all $\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll}\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi}) & \text{iff} & \tau_\Sigma[\boldsymbol{\psi}] \subseteq G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]) \\ & \text{iff} & \tau_\Sigma[\boldsymbol{\psi}] \subseteq G_\Sigma(\tau_\Sigma[\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]]) \\ & \text{iff} & \boldsymbol{\psi} \in G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]).\end{array}$$

Thus, the second condition of (ii) is also satisfied. Thus (i) implies (ii) holds and, by symmetry, we conclude that (i) and (ii) are equivalent. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr, tr′ traces and τ a tr-tr′-transformation. Define

$$\tau^* : \mathrm{SenFam}(\mathrm{Seq}^{\mathrm{tr}'}(\mathbf{F})) \to \mathrm{SenFam}(\mathrm{Seq}^{\mathrm{tr}}(\mathbf{F}))$$

by setting, for all $\mathbf{\Phi}' \in \mathrm{SenFam}(\mathrm{Seq}^{\mathrm{tr}'}(\mathbf{F}))$,

$$\tau^*(\mathbf{\Phi}') = \{\tau^*_\Sigma(\mathbf{\Phi}')\}_{\Sigma \in |\mathbf{Sign}^\flat|}$$

be given, for all $\Sigma \in |\mathbf{Sign}^\flat|$, by

$$\tau^*_\Sigma(\mathbf{\Phi}') = \{\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F}) : \tau_\Sigma[\boldsymbol{\phi}] \subseteq \mathbf{\Phi}'_\Sigma\}.$$

Analogously to Theorem 893, we can show that, if $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent Gentzen π-institutions via a conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$, then $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}')$ and $\tau^* : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$ form a pair of mutually inverse order isomorphisms between the complete lattices of the corresponding theory families.

Theorem 1880 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr*,* tr′ *traces,* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen* π*-institutions of traces* tr*,* tr′*, respectively, and* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ *a conjugate pair of transformations. Then*

$$\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}') \quad \textit{and} \quad \tau^* : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$$

are mutually inverse order isomorphisms.

Proof: Similar to the proof of Theorem 893. Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, we get

$$\begin{array}{lll}\boldsymbol{\phi} \in \tau^*_\Sigma(\rho^*(\boldsymbol{T})) & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq \rho^*_\Sigma(\boldsymbol{T}) \\ & \text{iff} & \rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \boldsymbol{T}_\Sigma \\ & \text{iff} & \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma.\end{array}$$

Thus, $\tau^*(\rho^*(\boldsymbol{T})) = \boldsymbol{T}$. By symmetry, for all $\boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G}')$, $\rho^*(\tau^*(\boldsymbol{T}')) = \boldsymbol{T}'$. Thus, ρ^* and τ^* are mutually inverse bijections and, since they are both order preserving, they form a pair of mutually inverse order isomorphisms between $\mathbf{ThFam}(\mathfrak{G})$ and $\mathbf{ThFam}(\mathfrak{G}')$. ■

Conversely, it is true that, under ceratin hypotheses, given mutually inverse order isomorphisms between the complete lattices of two Gentzen π-institutions, one may define a conjugate pair between the two that establishes the order-isomorphism via the process that was described above.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr, tr′ be traces, and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ be Gentzen π-institutions of traces tr, tr′, respectively, based on $\mathbf{F}$. Consider an order isomorphism

$$h : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$$

between the corresponding complete lattices of theory families.

Define $\overrightarrow{h} = \{\overrightarrow{h}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\overrightarrow{h}_\Sigma : \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F}) \to \mathcal{P}(\mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F}))$$

be given, for all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, by

$$\overrightarrow{h}_\Sigma[\boldsymbol{\phi}] = h_\Sigma^{-1}(G(\boldsymbol{\phi})).$$

Further, define $\overleftarrow{h} = \{\overleftarrow{h}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\overleftarrow{h}_\Sigma : \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F}) \to \mathcal{P}(\mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F}))$$

be given, for all $\boldsymbol{\phi}' \in \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F})$, by

$$\overleftarrow{h}_\Sigma[\boldsymbol{\phi}'] = h_\Sigma(G'(\boldsymbol{\phi}')).$$

The order isomorphism $h : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$ is called **transformational** if there exist

- a tr-tr′-translation τ,
- a tr′-tr-translation ρ,

such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F})$,

$$\overrightarrow{h}_\Sigma[\boldsymbol{\phi}] = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]) \quad \text{and} \quad \overleftarrow{h}_\Sigma[\boldsymbol{\phi}'] = G_\Sigma(\rho_\Sigma[\boldsymbol{\phi}']),$$

i.e., by definition of $\overrightarrow{h}$ and $\overleftarrow{h}$, if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F})$,

$$h_\Sigma^{-1}(G(\boldsymbol{\phi})) = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]) \quad \text{and} \quad h_\Sigma(G'(\boldsymbol{\phi}')) = G_\Sigma(\rho_\Sigma[\boldsymbol{\phi}']).$$

Here $G(\phi)$ and $G'(\phi')$ denote the theory families of $\mathfrak{G}$ and $\mathfrak{G}$' generated by the Σ-sequents ϕ and ϕ', respectively. Since all components of these theory families other than the Σ-components consist of sets of theorems, we sometimes write by a slight abuse of notation

$$h_\Sigma^{-1}(G_\Sigma(\phi)) = G'_\Sigma(\tau_\Sigma[\phi]) \quad \text{and} \quad h_\Sigma(G'_\Sigma(\phi')) = G_\Sigma(\rho_\Sigma[\phi']).$$

In this case, we say that h is **induced by** the pair of translations (τ, ρ).

We can show that the properties defining transformationality of an order isomorphism extend to sets of Σ-sequents.

Lemma 1881 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *be traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $h : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$ *a transformational order isomorphism induced by the pair* (τ, ρ) *of translations, then, for all for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $\mathbf{\Phi} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ *and all* $\mathbf{\Phi}' \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathbf{F})$*,*

$$h_\Sigma^{-1}(G(\mathbf{\Phi})) = G'_\Sigma(\tau_\Sigma[\mathbf{\Phi}]) \quad \text{and} \quad h_\Sigma(G'(\mathbf{\Phi}')) = G_\Sigma(\rho_\Sigma[\mathbf{\Phi}']).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, and $\mathbf{\Phi} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$. Then, taking into account that both $\mathbf{ThFam}(\mathfrak{G})$ and $\mathbf{ThFam}(\mathfrak{G}')$ are ordered signature-wise, we have

$$\begin{array}{rcl} h_\Sigma^{-1}(G(\mathbf{\Phi})) & = & h_\Sigma^{-1}(\bigvee_{\phi \in \mathbf{\Phi}} G(\phi)) \\ & = & \bigvee_{\phi \in \mathbf{\Phi}} h_\Sigma^{-1}(G(\phi)) \\ & = & \bigvee_{\phi \in \mathbf{\Phi}} G'_\Sigma(\tau_\Sigma[\phi]) \\ & = & G'_\Sigma(\bigcup_{\phi \in \mathbf{\Phi}} \tau_\Sigma[\phi]) \\ & = & G'_\Sigma(\tau_\Sigma[\mathbf{\Phi}]). \end{array}$$

The second equality holds by symmetry. ∎

Then the following result forms an analog of Theorem 900.

Theorem 1882 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr*,* tr′ *be traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $h : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$ *a transformational order isomorphism induced by the pair* (τ, ρ) *of translations, then* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ *is a conjugate pair of transformations.*

Proof: Similar to the proof of Theorem 900. Suppose $h : \mathbf{ThFam}(\mathfrak{G}') \to \mathbf{ThFam}(\mathfrak{G})$ is an order isomorphism and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\mathbf{\Phi}' \cup \{\phi'\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}'}(\mathfrak{G}')$. Then we have

$$\begin{array}{rll} \phi' \in G'_\Sigma(\mathbf{\Phi}') & \text{iff} & G'_\Sigma(\phi') \subseteq G'_\Sigma(\mathbf{\Phi}') \\ & \text{iff} & h_\Sigma(G'(\phi')) \subseteq h_\Sigma(G'(\mathbf{\Phi}')) \\ & \text{iff} & G_\Sigma(\rho_\Sigma[\phi]) \subseteq G_\Sigma(\rho_\Sigma[\mathbf{\Phi}]) \\ & \text{iff} & \rho_\Sigma[\phi] \subseteq G_\Sigma(\rho_\Sigma[\mathbf{\Phi}]). \end{array}$$

Thus, $\rho : \mathfrak{G}' \to \mathfrak{G}$ is an interpretation. Furthermore, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, we have

$$\begin{array}{rcl} G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]) & = & h_\Sigma(G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}])) \\ & = & h_\Sigma(h_\Sigma^{-1}(G_\Sigma(\boldsymbol{\phi}))) \\ & = & G_\Sigma(\boldsymbol{\phi}). \end{array}$$

We conclude that $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ is a conjugate pair. ■

Finally, we show that interpretations compose and the same holds for equivalences of Gentzen π-institutions.

Lemma 1883 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr$'$, tr$''$ *be traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$, $\mathfrak{G}'' = \langle \mathbf{F}, G'' \rangle$ *be Gentzen π-institutions of traces* tr, tr$'$, tr$''$*, respectively, based on* $\mathbf{F}$.

(a) If $\tau : \mathfrak{G} \to \mathfrak{G}'$ and $\tau' : \mathfrak{G}' \to \mathfrak{G}''$ are interpretations, then $\tau' \circ \tau : \mathfrak{G} \to \mathfrak{G}''$ is also an interpretation;

(b) If $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and $(\tau', \rho') : \mathfrak{G}' \rightleftarrows \mathfrak{G}''$ are conjugate pairs, then $(\tau' \circ \tau, \rho \circ \rho') : \mathfrak{G} \rightleftarrows \mathfrak{G}''$ is also a conjugate pair.

Proof:

(a) Suppose $\tau : \mathfrak{G} \to \mathfrak{G}'$ and $\tau' : \mathfrak{G}' \to \mathfrak{G}''$ are interpretations. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, we get

$$\begin{array}{rll} \boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi}) & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq G'_\Sigma(\tau_\Sigma[\boldsymbol{\Phi}]) \\ & \text{iff} & \tau'_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq G''_\Sigma(\tau'_\Sigma[\tau_\Sigma[\Phi]]). \end{array}$$

hence, $\tau' \circ \tau : \mathfrak{G} \to \mathfrak{G}''$ is also an interpretation.

(b) Now suppose that $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and $(\tau', \rho') : \mathfrak{G}' \rightleftarrows \mathfrak{G}''$ are conjugate pairs. Then, by Part (a), $\tau' \circ \tau : \mathfrak{G} \to \mathfrak{G}''$ is an interpretation. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}'', \boldsymbol{\psi}'' \in \mathrm{Seq}_\Sigma^{\mathrm{tr}''}(\mathbf{F})$, we have $\boldsymbol{\psi}'' \in G''_\Sigma(\boldsymbol{\phi}'')$ if and only if

$$\rho'_\Sigma[\boldsymbol{\psi}''] \subseteq G'_\Sigma(\rho'_\Sigma[\boldsymbol{\phi}'']) = G'_\Sigma(\tau_\Sigma[\rho_\Sigma[\rho'_\Sigma[\boldsymbol{\phi}'']]]).$$

This holds if and only if

$$\tau'_\Sigma[\rho'_\Sigma[\boldsymbol{\psi}'']] \subseteq G''_\Sigma(\tau'_\Sigma[\tau_\Sigma[\rho_\Sigma[\rho'_\Sigma[\boldsymbol{\phi}'']]]]).$$

Equivalently,

$$\boldsymbol{\psi}'' \in G''_\Sigma(\tau'_\Sigma[\tau_\Sigma[\rho_\Sigma[\rho'_\Sigma[\boldsymbol{\phi}'']]]]).$$

We conclude that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}'' \in \mathrm{Seq}_\Sigma^{\mathrm{tr}''}(\mathbf{F})$,

$$G''_\Sigma(\boldsymbol{\phi}'') = G''_\Sigma(\tau'_\Sigma[\tau_\Sigma[\rho_\Sigma[\rho'_\Sigma[\boldsymbol{\phi}'']]]]).$$

Therefore, by Lemma 1879, $(\tau' \circ \tau, \rho \circ \rho') : \mathfrak{G} \rightleftarrows \mathfrak{G}''$ is also a conjugate pair.

■

26.3 Hilbertizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution based on $\mathbf{F}$. $\mathfrak{G}$ is **Hilbertizable** if it is equivalent to a Hilbert π-institution based on $\mathbf{F}$. In other words, $\mathfrak{G}$ is Hilbertizable if there exists a Hilbert π-institution $\mathfrak{H} = \langle \mathbf{F}, H \rangle$, based on $\mathbf{F}$, and a conjugate pair of transformations $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{H}$.

We have the following proposition that follows directly from the relevant definitions.

Proposition 1884 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system,* tr *a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace* tr *based on $\mathbf{F}$. $\mathfrak{G}$ is Hilbertizable if and only if there exist:*

(1) A Hilbert π-institution $\mathfrak{H} = \langle \mathbf{F}, H \rangle$;

(2) A collection $\rho : (\mathrm{SEN}^\flat)^\omega \to \bigcup_{\langle m,n \rangle \in \mathrm{tr}} \mathrm{SEN}^{m+m}$ in $N^\flat$ with a single distinguished argument;

(3) A family $\tau = \{\tau^{m,n} : \langle m, n \rangle \in \mathrm{tr}\}$, where, for all $\langle m, n \rangle \in \mathrm{tr}$, the collection $\tau^{m,n} : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}$ in $N^\flat$ has $m + n$ distinguished arguments;

such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

(a) $\boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi})$ iff $\tau_\Sigma[\boldsymbol{\phi}] \subseteq H_\Sigma(\tau_\Sigma[\mathbf{\Phi}])$;

(b) $H_\Sigma(\phi) = H_\Sigma(\tau_\Sigma[\rho_\Sigma[\phi]])$;

or, equivalently, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$ and all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$,

(c) $\rhd_\Sigma \phi \in H_\Sigma(\rhd_\Sigma \Phi)$ iff $\rho_\Sigma[\phi] \subseteq G_\Sigma(\rho_\Sigma[\Phi])$;

(d) $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]])$.

Proof: This is a rephrasing of the definition of Hilbertizability using the conditions establishing an equivalence between two Gentzen π-institutions and taking into account Lemma 1879. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution and $\mathfrak{H} = \langle \mathbf{F}, H \rangle$ a Hilbert π-institution both based on $\mathbf{F}$. Define the $\{\langle 0, 1 \rangle\}$-tr-transformation ρ^0 by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\rho_\Sigma^0[\phi] = \{\rhd_\Sigma \phi\}.$$

We say that $\mathfrak{G}$ and $\mathfrak{H}$ are **simply equivalent** if they are equivalent via a conjugate pair of the form $(\tau, \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{H}$. The Gentzen π-institution $\mathfrak{G}$ is **simply Hilbertizable** if it is simply equivalent to some Hilbert π-institution $\mathfrak{H} = \langle \mathbf{F}, H \rangle$.

If $\mathfrak{G}$ is simply Hilbertizable, it turns out that there is a unique Hilbert π-institution simply equivalent to $\mathfrak{G}$, namely, the Hilbert π-institution reduct $\mathfrak{G}^0$ of $\mathfrak{G}$.

Proposition 1885 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is simply Hilbertizable, then it is simply equivalent to a unique Hilbert* π*-institution, namely, the Hilbert* π*-institution reduct* $\mathfrak{G}^0 = \langle \mathbf{F}, G^0 \rangle$ *of* $\mathfrak{G}$*.*

Proof: Suppose that $\mathfrak{G}$ is simply Hilbertizable via the conjugate pair $(\tau, \rho^0) : \mathfrak{G} \to \mathfrak{H}$, with $\mathfrak{H} = \langle \mathbf{F}, H \rangle$. It suffices to show that $H = G^0$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll} \rhd_\Sigma \phi \in H_\Sigma(\rhd_\Sigma \Phi) & \text{iff} & \rho^0_\Sigma[\phi] \subseteq G_\Sigma(\rho^0_\Sigma[\Phi]) \quad \text{(by hypothesis)} \\ & \text{iff} & \rhd_\Sigma \phi \in G_\Sigma(\rhd_\Sigma \Phi) \quad \text{(definition of } \rho^0) \\ & \text{iff} & \rhd_\Sigma \phi \in G^0_\Sigma(\rhd_\Sigma \Phi). \quad \text{(definition of } G^0) \end{array}$$

Therefore $\mathfrak{H} = \mathfrak{G}^0$, whence it follows that $\mathfrak{G}$ is simply Hilbertizable via a simple equivalence involving the Hilbert π-institution reduct $\mathfrak{G}^0$ of $\mathfrak{G}$ ■

We have, further, the following simpler characterization of simple Hilbertizability, due to the fact that the interpretation in one of the two directions is required to be a fixed one.

Proposition 1886 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$*, be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is simply Hilbertizable if and only if there exists a* tr*-*$\{\langle 0,1 \rangle\}$*-transformation* $\tau = \{\tau^{m,n} : \langle m,n \rangle \in \mathrm{tr}\}$*, such that, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$*,*

$$G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rhd\, \tau_\Sigma[\boldsymbol{\phi}]).$$

Proof: If $\mathfrak{G}$ is simply Hilbertizable, then, by Proposition 1885, it is equivalent to the Hilbert π-institution reduct $\mathfrak{G}^0$ of $\mathfrak{G}$ via some conjugate pair $(\tau, \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^0$. Thus, by the definition of equivalence, we get, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll} G_\Sigma(\boldsymbol{\phi}) & = & G_\Sigma(\rho^0_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]) \\ & = & G_\Sigma(\rhd_\Sigma \tau_\Sigma[\boldsymbol{\phi}]). \end{array}$$

Assume, conversely, that there exists a tr-$\{\langle 0,1 \rangle\}$-transformation τ, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rhd\, \tau_\Sigma[\boldsymbol{\phi}])$. To show that $\mathfrak{G}$ is simply Hilbertizable, it suffices, by Proposition 1885 and Proposition 1884, to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\rhd_\Sigma \phi \in G^0_\Sigma(\rhd_\Sigma \Phi) \quad \text{iff} \quad \rhd_\Sigma \phi \in G_\Sigma(\rhd_\Sigma \Phi).$$

This equivalence, however, holds by the definition of G^0. ■

26.4 Syntactic WF Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. $\mathfrak{G}$ is (**syntactically WF**) **algebraizable** if it is equivalent to the Gentzen π-institution $\mathfrak{G}^{\mathsf{K}} = \langle \mathbf{F}, G^{\mathsf{K}} \rangle$ associated with some class K of $\mathbf{F}$-algebraic systems.

Explicitly, using the definition of equivalence, this means that there exists a class K of $\mathbf{F}$-algebraic systems, a tr-$\{\langle 1,1 \rangle\}$-transformation τ and a $\{\langle 1,1 \rangle\}$-tr-transformation ρ, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

(a) $\boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi})$ iff $\tau_\Sigma[\boldsymbol{\phi}] \subseteq G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\mathbf{\Phi}])$;

(b) $G^{\mathsf{K}}_\Sigma(\phi \rhd_\Sigma \psi) = G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[\phi;\psi]])$;

or, equivalently, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

(c) $\phi \rhd_\Sigma \psi \in G^{\mathsf{K}}_\Sigma(E)$ iff $\rho_\Sigma[\phi;\psi] \subseteq G_\Sigma(\rho_\Sigma[E])$;

(d) $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]])$.

Recall that, given a class K of $\mathbf{F}$-algebraic systems, we denote by $\mathbb{G}(\mathsf{K})$, the guasivariety of $\mathbf{F}$-algebraic systems generated by K, i.e., the collection of all $\mathbf{F}$-algebraic systems that satisfy the $\mathbf{F}$-guasiequations that are satisfied by all $\mathcal{A} \in \mathsf{K}$.

It turns out that, when a Gentzen π-institution $\mathfrak{G}$ is algebraizable via two different classes K and K' of $\mathbf{F}$-algebraic systems, then both classes K and K' generate the same guasivariety and, hence, that there exists a unique guasivariety of $\mathbf{F}$-algebraic systems that serves as the algebraizing class of $\mathfrak{G}$. This is proven in Proposition 1888, following a needed lemma.

Lemma 1887 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system,* tr *a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace* tr *based on $\mathbf{F}$. If $\mathfrak{G}$ is algebraizable via $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n \rangle \in \mathrm{tr}$,*

$$\boldsymbol{\psi} \in G_\Sigma(\{\boldsymbol{\phi}\} \cup \bigcup\{\rho_\Sigma[\boldsymbol{\phi}_i;\boldsymbol{\psi}_i] : i < m+n\}).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n \rangle \in \mathrm{tr}$. By the definition of an equational Gentzen π-institution, we get

$$\tau_\Sigma[\boldsymbol{\psi}] \subseteq G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\boldsymbol{\phi}] \cup \{\boldsymbol{\phi}_i \rhd_\Sigma \boldsymbol{\psi}_i : i < m+n\}).$$

Thus, since, by the definition of equivalence

$$G^{\mathsf{K}}_\Sigma(\boldsymbol{\phi}_i \rhd_\Sigma \boldsymbol{\psi}_i) = G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[\boldsymbol{\phi}_i;\boldsymbol{\psi}_i]]),$$

we get that

$$\tau_\Sigma[\boldsymbol{\psi}] \subseteq G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\boldsymbol{\phi}] \cup \bigcup\{\tau_\Sigma[\rho_\Sigma[\boldsymbol{\phi}_i;\boldsymbol{\psi}_i]] : i < m+n\}).$$

Therefore, since τ is an interpretation,

$$\boldsymbol{\psi} \in G_\Sigma(\{\boldsymbol{\phi}\} \cup \bigcup\{\rho_\Sigma[\boldsymbol{\phi}_i;\boldsymbol{\psi}_i] : i < m+n\}).$$

This establishes the conclusion. ∎

Proposition 1888 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *If* $\mathfrak{G}$ *is algebraizable via both the conjugate pair* $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$ *of transformations and the conjugate pair* $(\tau',\rho') : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$ *of transformations, then* $\mathbb{G}(\mathsf{K}) = \mathbb{G}(\mathsf{K}')$.

Proof: Suppose that $\mathfrak{G}$ is algebraizable via both the conjugate pair $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$ of transformations and the conjugate pair $(\tau',\rho') : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$ of transformations.

We show, first, that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$G_\Sigma(\rho_\Sigma[\phi;\psi]) = G_\Sigma(\rho'_\Sigma[\phi;\psi]).$$

Note that $\rho'_\Sigma[\phi;\phi] \subseteq G_\Sigma(\varnothing)$, since $\phi \rhd_\Sigma \phi \in G^{\mathsf{K}'}_\Sigma(\varnothing)$ and $\rho' : \mathfrak{G}^{\mathsf{K}'} \to \mathfrak{G}$ is an interpretation. Moreover, for all $\boldsymbol{\sigma} \in \rho'$ of trace $\langle m,n\rangle \in \mathrm{tr}$, all $i < m+n$,all $\Sigma \in |\mathbf{Sign}^\flat|$, and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\rho_\Sigma[\boldsymbol{\sigma}^i_\Sigma(\phi,\phi,\vec{\chi});\boldsymbol{\sigma}^i_\Sigma(\phi,\psi,\vec{\chi})] \subseteq G_\Sigma(\rho_\Sigma[\phi;\psi]).$$

Since, by Lemma 1887, ρ has the modus ponens in $\mathfrak{G}$, we get that $\rho'_\Sigma[\phi;\psi] \subseteq G_\Sigma(\rho_\Sigma[\phi;\psi])$. By symmetry, we conclude that $G_\Sigma(\rho_\Sigma[\phi;\psi]) = G_\Sigma(\rho'_\Sigma[\phi;\psi])$.

Finally, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \phi \rhd_\Sigma \psi \in G^{\mathsf{K}}_\Sigma(E) & \text{iff} & \rho_\Sigma[\phi;\psi] \subseteq G_\Sigma(\rho_\Sigma[E]) \\ & \text{iff} & \rho'_\Sigma[\phi;\psi] \subseteq G_\Sigma(\rho'_\Sigma[E]) \\ & \text{iff} & \phi \rhd_\Sigma \psi \in G^{\mathsf{K}'}_\Sigma(E). \end{array}$$

Thus, we get that $\mathbb{G}(\mathsf{K}) = \mathbb{G}(\mathsf{K}')$. ∎

Given an algebraizable Gentzen π-institution $\mathfrak{G}$, there exists, by Proposition 1888, a unique guasivariety K that serves as the algebraic counterpart of $\mathfrak{G}$. It is called the **equivalent algebraic semantics of** $\mathfrak{G}$.

The next result asserts that equivalent Gentzen systems have the same status vis-à-vis algebraizability and, in case they are algebraizable, they share a common algebraic semantics. Moreover, they share the same Hilbertizability status and, in case they are Hilbertizable, they share the same Hilbertizations (which, however, are not unique).

Proposition 1889 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G} = \langle \mathbf{F}, G' \rangle$ *two equivalent Gentzen* π*-institutions of traces* tr, tr′*, respectively, based on* $\mathbf{F}$.

(a) $\mathfrak{G}$ *is algebraizable if and only if* $\mathfrak{G}'$ *is algebraizable. If this is the case,* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *have the same algebraic semantics.*

(b) $\mathfrak{G}$ *is Hilbertizable if and only if* $\mathfrak{G}'$ *is Hilbertizable. If this is the case, every Hilbertization of* $\mathfrak{G}$ *is one of* $\mathfrak{G}'$ *also.*

Proof:

(a) Suppose $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and that $\mathfrak{G}'$ is algebraizable via $(\tau', \rho') : \mathfrak{G}' \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$, for some class K' of $\mathbf{F}$-algebraic systems. Then, by Lemma 1883,

$$\mathfrak{G} \underset{\rho}{\overset{\tau}{\rightleftarrows}} \mathfrak{G}' \underset{\rho'}{\overset{\tau'}{\rightleftarrows}} \mathfrak{G}^{\mathsf{K}'}$$

$(\tau' \circ \tau, \rho \circ \rho') : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$ is witnessing the algebraizability of $\mathfrak{G}$. By symmetry $\mathfrak{G}$ is algebraizable if and only if $\mathfrak{G}'$ is algebraizable. Since any algebraizing class K' for $\mathfrak{G}'$ is also an algebraizing class for $\mathfrak{G}$, and vice versa, we get that $\mathfrak{G}$ and $\mathfrak{G}'$ have the same equivalent algebraic semantics.

(b) Suppose $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and that $\mathfrak{G}'$ is Hilbertizable via $(\tau', \rho') : \mathfrak{G}' \rightleftarrows \mathfrak{H}'$, for some Hilbert π-institution $\mathfrak{H}'$. Then, again by Lemma 1883,

$$\mathfrak{G} \underset{\rho}{\overset{\tau}{\rightleftarrows}} \mathfrak{G}' \underset{\rho'}{\overset{\tau'}{\rightleftarrows}} \mathfrak{H}'$$

$(\tau' \circ \tau, \rho \circ \rho') : \mathfrak{G} \rightleftarrows \mathfrak{H}'$ is witnessing the Hilbertizability of $\mathfrak{G}$. By symmetry, $\mathfrak{G}$ is Hilbertizable if and only if $\mathfrak{G}'$ is. Moreover, any Hilbertization $\mathfrak{H}'$ for $\mathfrak{G}'$ serves also as one for $\mathfrak{G}$, and vice versa, i.e., $\mathfrak{G}$ and $\mathfrak{G}'$ share the same Hilbertizations.

■

Suppose that a Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ of trace tr, together with a trace tr′, are given. We give, next, a characterization of the existence of an equivalence $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ of $\mathfrak{G}$ with some Gentzen π-institution $\mathfrak{G}'$, having the given trace tr′.

Theorem 1890 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *be traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is equivalent to a Gentzen* π*-institution* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *of trace* tr′ *based on* $\mathbf{F}$ *if and only if there exist a* tr-tr′*-transformation* τ *and a* tr′-tr*-transformation* ρ*, such that:*

(1) $\rho^* : \mathrm{ThFam}(\mathfrak{G}) \to \mathrm{SenFam}(\mathrm{Seq}^{\mathrm{tr}'}(\mathbf{F}))$ *is injective on* $\mathrm{ThFam}(\mathfrak{G})$*;*

(2) For all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$*,* $\rho^*_\Sigma(G(\boldsymbol{\phi})) = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}])$*, where* G' *is the closure system induced by* $\rho^*(\mathrm{ThFam}(\mathfrak{G}))$*.*

Proof: Suppose, first, that there exists an equivalence $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$, where $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ is a Gentzen π-institution of trace tr′ based on $\mathbf{F}$. By Theorem 1880, we know that $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}')$ is an order isomorphism, whence, in particular, it is injective on $\mathrm{ThFam}(\mathfrak{G})$. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, we have

$$\begin{array}{lll}\boldsymbol{\psi} \in \rho^*_\Sigma(G(\boldsymbol{\phi})) & \text{iff} & \rho_\Sigma[\boldsymbol{\psi}] \subseteq G_\Sigma(\boldsymbol{\phi}) \\ & \text{iff} & \tau_\Sigma[\rho_\Sigma[\boldsymbol{\psi}]] \subseteq G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]) \\ & \text{iff} & \boldsymbol{\psi} \in G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]).\end{array}$$

Therefore, $\rho^*_\Sigma(G(\boldsymbol{\phi})) = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}])$.

Suppose, conversely, that there exist a tr-tr′-transformation τ and a tr′-tr-transformation ρ, such that Conditions (1) and (2) of the statement hold. Since $\rho^*(\mathrm{ThFam}(\mathfrak{G}))$ is closed under intersection, it defines a closure system on $\mathrm{Seq}^{\mathrm{tr}'}(\mathbf{F})$, which we denote by G', writing $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ for the corresponding Gentzen π-institution of trace tr′. It suffices now, by Theorem 1882, to show that $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}')$ is a transformational order isomorphism induced by (τ,ρ). We know, by hypothesis, that ρ^* is injective. By definition of $\mathfrak{G}'$, it is surjective. By definition of ρ^*, it is order preserving. Finally, it is order reflecting, since, for all $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$,

$$\begin{array}{lll}\rho^*(\boldsymbol{T}) \le \rho^*(\boldsymbol{T}') & \text{iff} & \rho^*(\boldsymbol{T}) \cap \rho^*(\boldsymbol{T}') = \rho^*(\boldsymbol{T}) \\ & \text{iff} & \rho^*(\boldsymbol{T} \cap \boldsymbol{T}') = \rho^*(\boldsymbol{T}) \\ & \text{iff} & \boldsymbol{T} \cap \boldsymbol{T}' = \boldsymbol{T} \\ & \text{iff} & \boldsymbol{T} \le \boldsymbol{T}'.\end{array}$$

Therefore, $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}')$ is, indeed, an order isomorphism. To show that $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{G}')$ is transformational, it suffices to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F})$,

$$\rho^*_\Sigma(G(\boldsymbol{\phi})) = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]) \quad \text{and} \quad (\rho^*)^{-1}_\Sigma(G'(\boldsymbol{\phi}')) = G_\Sigma(\rho_\Sigma[\boldsymbol{\phi}']).$$

The first holds by hypothesis and the second holds by the definition of G', since $\rho^*_\Sigma(G(\rho_\Sigma[\boldsymbol{\phi}']))$ is the least theory family of $\mathfrak{G}'$ containing $\boldsymbol{\phi}'$. ∎

26.5 Matrix Families and Algebraic Semantics

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, an $\mathbf{F}$-algebraic system. A tr-**filter family**

of $\mathcal{A}$ is a family $\boldsymbol{T} \le \mathrm{Seq}^{\mathrm{tr}}(\mathcal{A})$. The pair $\mathfrak{A} = \langle \mathcal{A}, \boldsymbol{T}\rangle$ is called a tr-**matrix family**. It defines a closure family $G^{\mathfrak{A}}$ of trace tr on $\mathbf{F}$ as follows: For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\boldsymbol{\phi} \in G^{\mathfrak{A}}_\Sigma(\boldsymbol{\Phi}) \quad \text{iff} \quad \text{for all } \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),$$
$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\Phi})) \subseteq \boldsymbol{T}_{F(\Sigma')} \text{ implies } \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\phi})) \in \boldsymbol{T}_{F(\Sigma')}.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system and $\boldsymbol{T}$ a tr-filter family of $\mathcal{A}$. $\boldsymbol{T}$ is called a $\mathfrak{G}$-**filter family of** $\mathcal{A}$ if $G \le G^{\mathfrak{A}}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi}) \quad \text{implies} \quad \boldsymbol{\phi} \in G^{\mathfrak{A}}_\Sigma(\boldsymbol{\Phi}).$$

Note that, as was pointed out previously, because of the structurality of G, it suffices to check that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$, we have

$$\alpha_\Sigma(\boldsymbol{\Phi}) \subseteq \boldsymbol{T}_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{F(\Sigma)}.$$

If $\boldsymbol{T}$ is a $\mathfrak{G}$-filter family of $\mathcal{A}$, then the pair $\mathfrak{A} = \langle \mathcal{A}, \boldsymbol{T}\rangle$ is called a $\mathfrak{G}$-**matrix family of** $\mathcal{A}$. We denote by $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ the collection of all $\mathfrak{G}$-filter families of $\mathcal{A}$ and by $\mathrm{MatFam}(\mathfrak{G})$ the collection of all $\mathfrak{G}$-matrix families.

Many facts, introduced previously in this work, that hold for $\mathcal{I}$-filter families and $\mathcal{I}$-matrix families, for a π-institution $\mathcal{I}$, have analogs for $\mathfrak{G}$-filter and $\mathfrak{G}$-matrix families, respectively. We list some of those that will be needed in the sequel.

Lemma 1891 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace,* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$ $\mathbf{F}$*-algebraic systems.*

(a) The collection $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ *forms a complete lattice*

$$\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) = \langle \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}), \le\rangle$$

under signature-wise inclusion $\le$*;*

(b) $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F}) = \mathrm{ThFam}(\mathfrak{G})$*;*

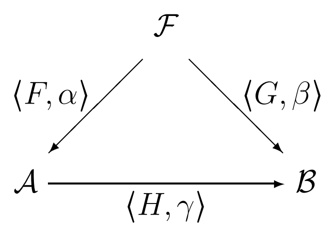
(c) If $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$ *are* $\mathbf{F}$*-algebraic systems and* $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ *a surjective morphism, then* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{B})$ *if and only if* $\gamma^{-1}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*.*

Proof:

(a) Let $\{\boldsymbol{T}^i : i \in I\} \subseteq \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, such that $\boldsymbol{\phi} \subseteq G_\Sigma(\boldsymbol{\Phi})$. Then, if $\alpha_\Sigma(\boldsymbol{\Phi}) \subseteq \bigcap_{i\in I} \boldsymbol{T}^i_{F(\Sigma)}$, we get $\alpha_\Sigma(\boldsymbol{\Phi}) \subseteq \boldsymbol{T}^i_{F(\Sigma)}$, for all $i \in I$, whence, since $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, $\alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}^i_{F(\Sigma)}$, for all $i \in I$, i.e., $\alpha_\Sigma(\boldsymbol{\phi}) \in \bigcap_{i\in I} \boldsymbol{T}^i_{F(\Sigma)}$. We conclude that $\bigcap_{i\in I} \boldsymbol{T}^i \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$.

(b) For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, such that $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$, we get that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\boldsymbol{\Phi} \subseteq \boldsymbol{T}_\Sigma$ implies $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Therefore, $\mathrm{ThFam}(\mathfrak{G}) \subseteq \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F})$. On the other hand, if $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F})$, then, if $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{T}_\Sigma)$, then $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$, i.e., $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$. Therefore, $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F}) = \mathrm{ThFam}(\mathfrak{G})$.

(c) Assume, first, that $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{B})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, such that $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$ and $\alpha_\Sigma(\boldsymbol{\Phi}) \subseteq \gamma^{-1}_{F(\Sigma)}(\boldsymbol{T}_{H(F(\Sigma))})$. Then



$\gamma_{F(\Sigma)}(\alpha_\Sigma(\boldsymbol{\Phi})) \subseteq \boldsymbol{T}_{H(F(\Sigma))}$, i.e., $\beta_\Sigma(\boldsymbol{\Phi}) \subseteq \boldsymbol{T}_{G(\Sigma)}$. Since $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{B})$, we now get $\beta_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{G(\Sigma)}$. Reversing the steps above, we conclude that $\alpha_\Sigma(\boldsymbol{\phi}) \in \gamma^{-1}_{F(\Sigma)}(\boldsymbol{T}_{H(F(\Sigma))})$. Therefore, $\gamma^{-1}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$.

Assume, conversely, that $\gamma^{-1}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, such that $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$ and $\beta_\Sigma(\boldsymbol{\Phi}) \subseteq \boldsymbol{T}_{G(\Sigma)}$. Then $\gamma_{F(\Sigma)}(\alpha_\Sigma(\boldsymbol{\Phi})) \subseteq \boldsymbol{T}_{H(F(\Sigma))}$, whence $\alpha_\Sigma(\boldsymbol{\Phi}) \subseteq \gamma^{-1}_{F(\Sigma)}(\boldsymbol{T}_{H(F(\Sigma))})$. Since $\gamma^{-1}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, we get $\alpha_\Sigma(\boldsymbol{\phi}) \in \gamma^{-1}_{F(\Sigma)}(\boldsymbol{T}_{H(F(\Sigma))})$. Reversing, once more, the preceding steps, we get that $\beta_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{G(\Sigma)}$. Therefore, $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{B})$. ■

The isomorphism between the complete lattices of theory families induced by an equivalence extends to corresponding order isomorphisms between the complete lattices of filter families of the equivalent Gentzen π-institutions on the same algebraic system.

Proposition 1892 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr, tr′ *be traces, and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *two Gentzen π-institutions of traces* tr, tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent via the conjugate pair* $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$*, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$*, the mappings*

$$T \longmapsto \rho^{\mathcal{A}*}(T), \quad T \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}),$$

$$\tau^{\mathcal{A}*}(T') \longleftarrow T', \quad T' \in \mathrm{FiFam}^{\mathfrak{G}'}(\mathcal{A}),$$

are mutually inverse isomorphisms from $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$ *onto* $\mathbf{FiFam}^{\mathfrak{G}'}(\mathcal{A})$*.*

Proof: We show, first, that, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathcal{G}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\rho^{\mathcal{A}}_{F(\Sigma)}[\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\boldsymbol{\phi})]] \subseteq \boldsymbol{T}_{F(\Sigma)} \quad \text{iff} \quad \alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{F(\Sigma)}.$$

Indeed, taking into account the surjectivity of $\langle F, \alpha\rangle$, we obtain

$$\begin{array}{lll}\rho^{\mathcal{A}}_{F(\Sigma)}[\tau^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\boldsymbol{\phi})]] \subseteq \boldsymbol{T}_{F(\Sigma)} & \text{iff} & \rho^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\tau_\Sigma[\boldsymbol{\phi}])] \subseteq \boldsymbol{T}_{F(\Sigma)}\\ & \text{iff} & \alpha_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]]) \subseteq \boldsymbol{T}_{F(\Sigma)}\\ & \text{iff} & \rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \alpha^{-1}_\Sigma(\boldsymbol{T}_{F(\Sigma)})\\ & \text{iff} & \boldsymbol{\phi} \in \alpha^{-1}_\Sigma(\boldsymbol{T}_{F(\Sigma)})\\ & \text{iff} & \alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{F(\Sigma)}.\end{array}$$

By symmetry, we also have, for all $\boldsymbol{T}' \in \mathrm{FiFam}^{\mathcal{G}'}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathbf{F})$,

$$\tau^{\mathcal{A}}_{F(\Sigma)}[\rho^{\mathcal{A}}_{F(\Sigma)}[\alpha_\Sigma(\boldsymbol{\phi}')]] \subseteq \boldsymbol{T}'_{F(\Sigma)} \quad \text{iff} \quad \alpha_\Sigma(\boldsymbol{\phi}') \in \boldsymbol{T}'_{F(\Sigma)}.$$

Using the first of these equivalences and, once again, taking into account the surjectivity of $\langle F, \alpha\rangle$, we get, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\boldsymbol{\phi} \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{lll}\boldsymbol{\phi} \in \tau^{\mathcal{A}*}_\Sigma(\rho^{\mathcal{A}*}(\boldsymbol{T})) & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}] \subseteq \rho^{\mathcal{A}*}_\Sigma(\boldsymbol{T})\\ & \text{iff} & \rho^{\mathcal{A}}_\Sigma[\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]] \subseteq \boldsymbol{T}_\Sigma\\ & \text{iff} & \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma.\end{array}$$

Thus, $\tau^{\mathcal{A}*}(\rho^{\mathcal{A}*}(\boldsymbol{T})) = \boldsymbol{T}$, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ and, by symmetry, we also have $\rho^{\mathcal{A}*}(\tau^{\mathcal{A}*}(\boldsymbol{T}')) = \boldsymbol{T}'$, for all $\boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}'}(\mathcal{A})$. Therefore, $\rho^{\mathcal{A}*}$ and $\tau^{\mathcal{A}*}$ are mutually inverse bijections and reflect component-wise inclusion, since they are obviously order preserving undel $\leq$. We conclude that

$$\rho^{\mathcal{A}*} : \mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) \rightleftarrows \mathbf{FiFam}^{\mathfrak{G}'}(\mathcal{A}) : \tau^{\mathcal{A}*}$$

are mutually inverse order isomorphisms. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ an $N^\flat$-algebraic system and $\theta \in \mathrm{ConSys}(\mathbf{A})$.

Given $\boldsymbol{\phi} = \vec{\phi} \rhd_\Sigma \vec{\psi}$, $\boldsymbol{\phi}' = \vec{\phi}' \rhd_\Sigma \vec{\psi}' \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{A})$ of the same trace $\langle m, n\rangle$, we say that $\boldsymbol{\phi}$ is **θ-equivalent to $\boldsymbol{\phi}'$**, denoted $\boldsymbol{\phi}\ \theta_\Sigma\ \boldsymbol{\phi}'$, if, for all $i < m$ and all $j < n$,

$$\phi_i\ \theta_\Sigma\ \phi'_i \quad \text{and} \quad \psi_j\ \theta_\Sigma\ \psi'_j.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ an $N^\flat$-algebraic system, $\boldsymbol{T} \leq \mathrm{Seq}^{\mathrm{tr}}(\mathbf{A})$ and $\theta \in \mathrm{ConSys}(\mathbf{A})$.

We say that θ is **compatible with $\boldsymbol{T}$** if, for all $\Sigma \in |\mathbf{Sign}|$, and all $\boldsymbol{\phi}, \boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{A})$ (of the same trace),

$$\boldsymbol{\phi}\ \theta_\Sigma\ \boldsymbol{\phi}' \quad \text{and} \quad \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \text{imply} \quad \boldsymbol{\phi}' \in \boldsymbol{T}_\Sigma.$$

An alternative characterization of compatibility is given in the following lemma.

Lemma 1893 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system,* $\boldsymbol{T} \le \mathrm{Seq}^{\mathrm{tr}}(\mathcal{A})$ *and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*.* θ *is compatible with* $\boldsymbol{T}$ *if and only if the quotient morphism* $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}^\theta$ *induces a strict matrix family morphism*

$$\langle I, \pi^\theta \rangle : \langle \mathcal{A}, \boldsymbol{T} \rangle \to \langle \mathcal{A}^\theta, \pi^\theta(\boldsymbol{T}) \rangle,$$

i.e., if and only if $(\pi^\theta)^{-1}(\pi^\theta(\boldsymbol{T})) = \boldsymbol{T}$*.*

Proof: Suppose, first, that θ is compatible with $\boldsymbol{T}$ and let $\Sigma \in |\mathbf{Sign}|$, $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$, such that $\boldsymbol{\phi} \in (\pi^\theta_\Sigma)^{-1}(\pi^\theta_\Sigma(\boldsymbol{T}_\Sigma))$. Then, we get $\pi^\theta_\Sigma(\boldsymbol{\phi}) \in \pi^\theta_\Sigma(\boldsymbol{T}_\Sigma)$. Hence, there exists $\boldsymbol{\phi}' \in \boldsymbol{T}_\Sigma$, such that $\boldsymbol{\phi} \; \theta_\Sigma \; \boldsymbol{\phi}'$. Therefore, by the compatibility of θ with $\boldsymbol{T}$, we get that $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Thus, $(\pi^\theta)^{-1}(\pi^\theta(\boldsymbol{T})) \le \boldsymbol{T}$ and, since the reverse inclusion always holds, we conclude that $(\pi^\theta)^{-1}(\pi^\theta(\boldsymbol{T})) = \boldsymbol{T}$.

Conversely, assume that $(\pi^\theta)^{-1}(\pi^\theta(\boldsymbol{T})) = \boldsymbol{T}$. Let $\Sigma \in |\mathbf{Sign}|$, $\boldsymbol{\phi}, \boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$, such that $\boldsymbol{\phi} \; \theta_\Sigma \; \boldsymbol{\phi}'$ and $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Then $\boldsymbol{\phi}' \in (\pi^\theta_\Sigma)^{-1}(\pi^\theta_\Sigma(\boldsymbol{T}_\Sigma)) = \boldsymbol{T}_\Sigma$ and, hence, θ is compatible with $\boldsymbol{T}$. ■

Given a Gentzen π-institution, taking the quotient of any filter family by a compatible congruence system results in a filter family on the quotient algebraic system.

Lemma 1894 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace,* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*,* $\langle \mathcal{A}, \boldsymbol{T} \rangle$ *an* $\mathbf{F}$*-matrix family and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*. If* θ *is compatible with* $\boldsymbol{T}$*, then*

$$\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}) \quad \textit{iff} \quad \boldsymbol{T}/\theta \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}^\theta).$$

Proof: Suppose that θ is compatible with $\boldsymbol{T}$. Then, using Lemmas 1891 and 1893, we have the following equivalences:

$$\begin{array}{lll} \boldsymbol{T}/\theta \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}/\theta) & \text{iff} & (\pi^\theta \circ \alpha)^{-1}(\boldsymbol{T}/\theta) \in \mathrm{ThFam}(\mathfrak{G}) \\ & \text{iff} & \alpha^{-1}((\pi^\theta)^{-1}(\boldsymbol{T}/\theta)) \in \mathrm{ThFam}(\mathfrak{G}) \\ & \text{iff} & \alpha^{-1}(\boldsymbol{T}) \in \mathrm{ThFam}(\mathfrak{G}) \\ & \text{iff} & \boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}). \end{array}$$

Hence $\boldsymbol{T}/\theta$ is a $\mathfrak{G}$-filter family of $\mathcal{A}^\theta$ iff $\boldsymbol{T}$ is a $\mathfrak{G}$-filter family of $\mathcal{A}$. ■

The following lemma forms an analog of the characterization of the Leibniz congruence system of a filter family on a given $\mathbf{F}$-algebraic system. It will also give rise to a corresponding operator, also termed the Leibniz operator, for theory families of Gentzen π-institutions.

Lemma 1895 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *an* $N^\flat$*-algebraic system,* $\boldsymbol{T} \le \mathrm{Seq}^{\mathrm{tr}}(\mathbf{A})$ *and* $\theta \in \mathrm{ConSys}(\mathbf{A})$*.* θ *is compatible with* $\boldsymbol{T}$ *if and only if, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$\langle\phi,\psi\rangle\in\theta_\Sigma$ *implies, for all* $\langle m,n\rangle\in\mathrm{tr}$*, all* $\vec{\sigma}=\langle\sigma^0,\dots,\sigma^{m-1}\rangle$*, and all* $\vec{\tau}=\langle\tau^0,\dots,\tau^{n-1}\rangle$ *in* $N^\flat$*, all* $\Sigma'\in|\mathbf{Sign}|$*, all* $f\in\mathbf{Sign}(\Sigma,\Sigma')$ *and all* $\vec{\chi}\in\mathrm{SEN}(\Sigma')$*,*

$$\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})\rhd_{\Sigma'}\vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})\in\boldsymbol{T}_{\Sigma'}$$
$$\textit{iff}\quad\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\rhd_{\Sigma'}\vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\in\boldsymbol{T}_{\Sigma'}.$$

Proof: Suppose that $\Sigma\in|\mathbf{Sign}|$ and $\langle\phi,\psi\rangle\in\mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle\in\theta_\Sigma$. Since θ is a congruence *system*, for all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$ $\langle\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi)\rangle\in\theta_{\Sigma'}$. Since θ is a *congruence* system, we get, for all $i<m$, all $j<n$ and all $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\langle\sigma^i_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}),\sigma^i_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\rangle\in\theta_{\Sigma'}$$
$$\text{and}\quad\langle\tau^j_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}),\tau^j_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\rangle\in\theta_{\Sigma'}.$$

The conclusion follows immediately by the assumption of compatibility of θ with $\boldsymbol{T}$. ■

Lemma 1895 serves to show that, given an algebraic system $\mathbf{A}$ and $\boldsymbol{T}\le\mathrm{Seq}^{\mathrm{tr}}(\mathbf{A})$, there exists a largest congruence system on $\mathbf{A}$ that is compatible with $\boldsymbol{T}$.

Corollary 1896 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* tr *a trace,* $\mathbf{A}=\langle\mathbf{Sign},\mathrm{SEN},N\rangle$ *an* $N^\flat$*-algebraic system and* $\boldsymbol{T}\le\mathrm{Seq}^{\mathrm{tr}}(\mathbf{A})$*. There exists a largest congruence system on* $\mathbf{A}$ *compatible with* $\boldsymbol{T}$*.*

Proof: Define $\theta=\{\theta_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ as follows: For all $\Sigma\in|\mathbf{Sign}|$ and all $\phi,\psi\in\mathrm{SEN}(\Sigma)$, $\langle\phi,\psi\rangle\in\theta_\Sigma$ iff, for all $\langle m,n\rangle\in\mathrm{tr}$, all $\vec{\sigma}=\langle\sigma^0,\dots,\sigma^{m-1}\rangle$, and all $\vec{\tau}=\langle\tau^0,\dots,\tau^{n-1}\rangle$ in $N^\flat$, all $\Sigma'\in|\mathbf{Sign}|$, all $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})\rhd_{\Sigma'}\vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})\in\boldsymbol{T}_{\Sigma'}$$
$$\text{iff}\quad\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\rhd_{\Sigma'}\vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\in\boldsymbol{T}_{\Sigma'}.$$

It is easy to see that θ, thus defined, is a congruence system on $\mathbf{A}$ compatible with $\boldsymbol{T}$. By Lemma 1895, it is the largest one compatible with $\boldsymbol{T}$. ■

The largest congruence system on $\mathbf{A}$ compatible with $\boldsymbol{T}$ is denoted by $\Omega^{\mathbf{A}}(\boldsymbol{T})$ and called the **Leibniz congruence system of $\boldsymbol{T}$ on $\mathbf{A}$**.

As a consequence of the definition of the Leibniz congruence system, given $\boldsymbol{T}\in\mathrm{Seq}^{\mathrm{tr}}(\mathbf{A})$ and $\theta\in\mathrm{ConSys}(\mathbf{A})$,

$$\theta\text{ is compatible with }\boldsymbol{T}\text{ if and only if }\theta\le\Omega^{\mathbf{A}}(\boldsymbol{T}).$$

Given an algebraic system $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$, a trace tr, a Gentzen π-institution $\mathfrak{G}=\langle\mathbf{F},G\rangle$ of trace tr based on $\mathbf{F}$ and an $\mathbf{F}$-algebraic system $\mathcal{A}$, the operator

$$\Omega^{\mathbf{A}}:\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\to\mathrm{ConSys}(\mathcal{A})$$

is called the **Leibniz operator of $\mathfrak{G}$ on $\mathcal{A}$**.

Recall from Proposition 1892 that, given two equivalent Gentzen π-institutions, the conjugate transformations establishing the equivalence induce an order isomorphism between the corresponding filter families of the gentzen π-institutions involved on arbitrary algebraic systems. It turns out that, under this isomorphism, corresponding filter families have identical Leibniz congruence systems.

Proposition 1897 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr, tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent via a conjugate pair* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ *of transformations, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,*

$$\Omega^{\mathcal{A}}(\boldsymbol{T}) = \Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}|$, $\boldsymbol{\phi}, \boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$, such that $\boldsymbol{\phi} \ \Omega^{\mathcal{A}}_\Sigma(\boldsymbol{T}) \ \boldsymbol{\phi}'$ and suppose that $\boldsymbol{\phi} \in \rho^{\mathcal{A}*}_\Sigma(\boldsymbol{T})$. Then, we obtain $\rho^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}] \subseteq \boldsymbol{T}_\Sigma$. Thus, since, by definition, $\Omega^{\mathcal{A}}(\boldsymbol{T})$ is a congruence system compatible with $\boldsymbol{T}$, we get that $\rho^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}'] \subseteq \boldsymbol{T}_\Sigma$ and, therefore, $\boldsymbol{\phi}' \in \rho^{\mathcal{A}*}_\Sigma(\boldsymbol{T})$. Hence $\Omega^{\mathcal{A}}(\boldsymbol{T})$ is compatible with $\rho^{\mathcal{A}*}(\boldsymbol{T})$, showing that $\Omega^{\mathcal{A}}(\boldsymbol{T}) \leq \Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T}))$.

Assume, conversely, that $\Sigma \in |\mathbf{Sign}|$, $\boldsymbol{\phi}, \boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathcal{A})$, such that

$$\boldsymbol{\phi} \ \Omega^{\mathcal{A}}_\Sigma(\rho^{\mathcal{A}*}(\boldsymbol{T})) \ \boldsymbol{\phi}'$$

and suppose that $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Then, we obtain $\rho^{\mathcal{A}}_\Sigma[\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]] \subseteq \boldsymbol{T}_\Sigma$, i.e., $\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}] \subseteq \rho^{\mathcal{A}*}_\Sigma(\boldsymbol{T})$. Thus, since, by definition, $\Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T}))$ is a congruence system compatible with $\rho^{\mathcal{A}*}(\boldsymbol{T})$, we get that $\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}'] \subseteq \rho^{\mathcal{A}*}(\boldsymbol{T})$. Therefore, $\rho^{\mathcal{A}}_\Sigma[\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}']] \subseteq \boldsymbol{T}_\Sigma$. So $\boldsymbol{\phi}' \in \boldsymbol{T}_\Sigma$ and, hence, $\Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T}))$ is compatible with $\boldsymbol{T}$, showing that $\Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T})) \leq \Omega^{\mathcal{A}}(\boldsymbol{T})$. ∎

As was the case with ordinary π-institutions, the Suszko operator is a very useful tool in the study of the algebraization of Gentzen π-institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. The **Suszko operator** $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ **of** $\mathfrak{G}$ **on** $\mathcal{A}$ is the operator

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}} : \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$$

defined, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, by

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \bigcap \{\Omega^{\mathcal{A}}(\boldsymbol{T}') : \boldsymbol{T} \leq \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\}.$$

Since, obviously, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$,

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) \leq \Omega^{\mathcal{A}}(\boldsymbol{T}),$$

$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ is also a congruence system on $\mathcal{A}$ compatible with $\boldsymbol{T}$. Moreover, the operator $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ is monotone on $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

Using the definition of the Suszko congruence system and Corollary 1896, it is not difficult to see that the following characterization of the Suszko congruence system of a filter family holds:

Proposition 1898 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace,* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*. For all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,* $\langle \phi, \psi\rangle \in \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}_\Sigma(\boldsymbol{T})$ *if and only if, for all* $\langle m, n\rangle \in \mathrm{tr}$*, all* $\sigma^0, \dots, \sigma^{m-1}$*,* $\tau^0, \dots, \tau^{n-1}$ *in* $N^\flat$*, all* $\Sigma' \in |\mathbf{Sign}|$*, all* $f \in \mathbf{Sign}(\Sigma, \Sigma')$ *and all* $\vec{\chi} \in \mathrm{SEN}(\Sigma')$*,*

$$\begin{aligned} &G^{\mathfrak{G},\mathcal{A}}_{\Sigma'}(\boldsymbol{T}_{\Sigma'}, \vec{\sigma}^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}))\\ &\quad = G^{\mathfrak{G},\mathcal{A}}_{\Sigma'}(\boldsymbol{T}_{\Sigma'}, \vec{\sigma}^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})).\end{aligned}$$

Proof: The statement follows directly by combining the definition of the Suszko congruence system of $\boldsymbol{T}$ on $\mathcal{A}$ with the characterization of the Leibniz operator of each $\boldsymbol{T}'$, with $\boldsymbol{T} \le \boldsymbol{T}'$, given in the proof of Corollary 1896. ■

Moreover, as is clear from the definition, we have

Lemma 1899 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *be a trace,* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system. The Suszko and the Leibniz operators on* $\mathcal{A}$ *coincide, i.e.,* $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}} = \Omega^{\mathcal{A}}$*, if and only if* $\Omega^{\mathcal{A}}$ *is monotone on* $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$*.*

Proof: Since $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ is monotone on $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$, if the two operators coincide, $\Omega^{\mathcal{A}}$ is also monotone on $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$.

On the other hand, if $\Omega^{\mathcal{A}}$ is monotone on $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$, then, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, we get

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{T}') : \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\}\\ & = & \Omega^{\mathcal{A}}(\boldsymbol{T}).\end{array}$$

Therefore, $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}} = \Omega^{\mathcal{A}}$. ■

An analog of Proposition 1897 holds also for the Suszko operator. That is, under the isomorphism between the corresponding filter families of two gentzen π-institutions that are equivalent, corresponding filter families have identical Suszko congruence systems.

Proposition 1900 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr*,* tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *Gentzen π-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent via the conjugate pair* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$*, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,*

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \widetilde{\Omega}^{\mathfrak{G}',\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T})).$$

Proof: Since $\rho^{\mathcal{A}*} : \mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathbf{FiFam}^{\mathfrak{G}'}(\mathcal{A})$ is an order isomorphism, and taking into account Proposition 1897, we obtain, for all $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$,

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{T}') : \boldsymbol{T} \leq \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \\ & = & \bigcap\{\Omega^{\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T}')) : \rho^{\mathcal{A}*}(\boldsymbol{T}) \leq \rho^{\mathcal{A}*}(\boldsymbol{T}') \in \mathrm{FiFam}^{\mathfrak{G}'}(\mathcal{A})\} \\ & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{T}'') : \rho^{\mathcal{A}*}(\boldsymbol{T}) \leq \boldsymbol{T}'' \in \mathrm{FiFam}^{\mathfrak{G}'}(\mathcal{A})\} \\ & = & \widetilde{\Omega}^{\mathfrak{G}',\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T})).\end{array}$$

Thus, the conclusion holds. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. A $\mathfrak{G}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, \boldsymbol{T} \rangle$ is called **Suszko reduced** if

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \Delta^{\mathcal{A}}.$$

We denote by $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$ the class of all Suszko reduced $\mathfrak{G}$-matrix families.

Foe every $\mathfrak{G}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, \boldsymbol{T} \rangle$, the quotient structure

$$\langle \mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}), \boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) \rangle$$

is also a $\mathfrak{G}$-matrix family and it is Suszko reduced. Moreover, if a $\mathfrak{G}$-matrix family $\langle \mathcal{A}, \boldsymbol{T} \rangle$ is Suszko reduced, it is obviously isomorphic to a $\mathfrak{G}$-matrix family of this form.

Among other things, Suszko reduced $\mathfrak{G}$-matrix families are important because they form a class of structures with respect to which $\mathfrak{G}$ enjoys a completeness property.

Theorem 1901 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *be a trace, and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$ *if and only if, for all* $\langle \mathcal{A}, \boldsymbol{T} \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$, *all* $\Sigma' \in |\mathbf{Sign}^\flat|$ *and all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\Phi})) \subseteq \boldsymbol{T}_{F(\Sigma')} \quad \textit{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\phi})) \in \boldsymbol{T}_{F(\Sigma')}.$$

Proof: Suppose $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\Phi})$ and let $\langle \mathcal{A}, \boldsymbol{T} \rangle$ be a Suszko reduced $\mathfrak{G}$-matrix family. Then $\langle \mathcal{A}, \boldsymbol{T} \rangle$ is, in particular, a $\mathfrak{G}$-matrix family, whence the conclusion holds by applying the definition of a $\mathfrak{G}$-filter family to the $\mathfrak{G}$-filter family $\boldsymbol{T}$. Suppose, conversely, that, for all $\langle \mathcal{A}, \boldsymbol{T} \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\Phi})) \subseteq \boldsymbol{T}_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\boldsymbol{\phi})) \in \boldsymbol{T}_{F(\Sigma')}.$$

Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$ and consider the Suszko reduced $\mathfrak{G}$-matrix family

$$\langle \mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}), \boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \rangle.$$

Then, we have, by hypothesis, taking $\Sigma' = \Sigma$ and $f = i_\Sigma$,

$$\mathbf{\Phi}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T}) \subseteq \boldsymbol{T}_\Sigma/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T}) \quad \text{implies} \quad \boldsymbol{\phi}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T}) \in \boldsymbol{T}_\Sigma/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T}),$$

i.e., using the compatibility of $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ with $\boldsymbol{T}$, $\mathbf{\Phi} \subseteq \boldsymbol{T}_\Sigma$ implies $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Equivalently, since $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$ was arbitrary, $\boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi})$. ∎

If two Gentzen π-institutions are equivalent, then the classes of algebraic system reducts of their Suszko reduced matrix families coincide.

Theorem 1902 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr*,* tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *Gentzen* π*-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent via the conjugate pair* $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$*, then* $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$ *and* $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}')$ *have the same class of* $\mathbf{F}$*-algebraic system reducts.*

Proof: Suppose that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ is the $\mathbf{F}$-algebraic system reduct of $\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. Then, by definition, we have $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \Delta^{\mathcal{A}}$. Therefore, by Proposition 1900, we obtain $\widetilde{\Omega}^{\mathfrak{G}',\mathcal{A}}(\rho^{\mathcal{A}*}(\boldsymbol{T})) = \Delta^{\mathcal{A}}$. Since, $\rho^{\mathcal{A}*}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, we conclude that $\langle \mathcal{A}, \rho^{\mathcal{A}*}(\boldsymbol{T})\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}')$ and, hence, $\mathcal{A}$ is also the $\mathbf{F}$-algebraic system reduct of a Suszko reduced $\mathfrak{G}'$-matrix family. By symmetry of equivalence, every $\mathbf{F}$-algebraic system reduct of a Suszko reduced $\mathfrak{G}'$-matrix family is also one of a Suszko reduced $\mathfrak{G}$-matrix family. Therefore, the two classes of $\mathbf{F}$-algebraic system reducts coincide. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr be a trace, and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. The class of all $\mathbf{F}$-algebraic system reducts of Suszko reduced $\mathfrak{G}$-matrix families is denoted by $\mathrm{AlgSys}(\mathfrak{G})$, i.e., we have, by definition,

$$\begin{array}{rcl}\mathrm{AlgSys}(\mathfrak{G}) & = & \{\mathcal{A} : (\exists \boldsymbol{T} \leq \mathrm{Seq}^{\mathrm{tr}}(\mathcal{A}))(\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}))\} \\ & = & \{\mathcal{A} : (\exists \boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}))(\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \Delta^{\mathcal{A}})\}.\end{array}$$

It is not difficult to show that the class $\mathrm{AlgSys}(\mathfrak{G})$ is closed under $\overset{\triangleleft}{\mathbb{I}\mathbb{P}}$ and, thence, conclude that the class of all $\mathrm{AlgSys}(\mathfrak{G})$-congruence systems on every $\mathbf{F}$-algebraic system $\mathcal{A}$ forms a complete lattice under signature-wise inclusion.

Proposition 1903 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. Then* $\mathrm{AlgSys}(\mathfrak{G})$ *is closed under subdirect intersections, i.e.,*

$$\overset{\triangleleft}{\mathbb{I}\mathbb{P}}(\mathrm{AlgSys}(\mathfrak{G})) \subseteq \mathrm{AlgSys}(\mathfrak{G}).$$

Proof: Suppose that $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i\rangle\rangle \in \mathrm{AlgSys}(\mathfrak{G})$, for all $i \in I$, and let

$$\langle H^i, \gamma^i\rangle : \mathfrak{A} \to \mathcal{A}^i, \quad i \in I,$$

be a subdirect intersection, i.e., such that $\bigcap_{i\in I} \mathrm{Ker}(\langle H^i, \gamma^i\rangle) = \Delta^{\mathcal{A}}$. Then, for all $i \in I$, there exists $\boldsymbol{T}^i \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}^i)$, such that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}^i}(\boldsymbol{T}^i) = \Delta^{\mathcal{A}^i}$. We consider the least $\mathfrak{G}$-filter family on $\mathcal{A}$, namely $\bigcap \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$. We have

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\bigcap \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})) & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{X}) : \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\}\\ & \le & \bigcap_{i\in I}\bigcap_{\boldsymbol{X}^i\in\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}^i)}(\gamma^i)^{-1}(\Omega^{\mathcal{A}^i}(\boldsymbol{X}^i))\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\bigcap_{\boldsymbol{X}^i\in\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}^i)}\Omega^{\mathcal{A}^i}(\boldsymbol{X}^i))\\ & \le & \bigcap_{i\in I}(\gamma^i)^{-1}(\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}^i}(\boldsymbol{T}^i))\\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Delta^{\mathcal{A}^i})\\ & = & \Delta^{\mathcal{A}}.\end{array}$$

Hence, we get that $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$. Therefore, $\mathrm{AlgSys}(\mathfrak{G})$ is indeed closed under subdirect intersections. ∎

26.6 Equivalence and Algebraic Counterpart

In Theorem 1890, given a π-institution $\mathfrak{G}$ and a trace tr', we gave a characterization of the existence of an equivalence $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ of $\mathfrak{G}$ with some Gentzen π-institution $\mathfrak{G}'$, having the given trace tr'. We strengthen this result here, by considering only $\mathfrak{G}$-filter families on algebraic systems belonging to $\mathrm{AlgSys}(\mathfrak{G})$.

Theorem 1904 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr*,* tr' *be traces and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is equivalent to a Gentzen* π*-institution* $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ *of trace* tr' *based on* $\mathbf{F}$ *if and only if there exist a* tr-tr'*-transformation* τ *and a* tr'-tr*-transformation* ρ*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$*:*

(1) $\rho^{\mathcal{A}*} : \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathrm{SenFam}(\mathrm{Seq}^{\mathrm{tr}'}(\mathcal{A}))$ *is injective on* $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*;*

(2) For all $\Sigma \in |\mathbf{Sign}|$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$*,* $\rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) = G'_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}])$*, where* G' *is the closure system on* $\mathcal{A}$ *induced by* $\rho^{\mathcal{A}*}(\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}))$*.*

Proof: Suppose, first, that there exists an equivalence $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$, where $\mathfrak{G}' = \langle \mathbf{F}, G'\rangle$ is a Gentzen π-institution of trace tr' based on $\mathbf{F}$. By Proposition 1892, we know that $\rho^{\mathcal{A}*} : \mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathbf{FiFam}^{\mathfrak{G}'}(\mathcal{A})$ is an order isomorphism, whence, in particular, it is injective on $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$. Moreover, for all $\Sigma \in |\mathbf{Sign}|$ and all $\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$, we have

$$\begin{array}{rll}\boldsymbol{\psi} \in \rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) & \text{iff} & \rho^{\mathcal{A}}_\Sigma[\boldsymbol{\psi}] \subseteq G^{\mathfrak{G},\mathcal{A}}_\Sigma(\boldsymbol{\phi})\\ & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\rho^{\mathcal{A}}_\Sigma[\boldsymbol{\psi}]] \subseteq G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}])\\ & \text{iff} & \boldsymbol{\psi} \in G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]).\end{array}$$

Therefore, $\rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) = G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}])$ and, again by Proposition 1892, $G^{\mathfrak{G}',\mathcal{A}}$ is the closure system on $\mathcal{A}$ induced by $\rho^{\mathcal{A}*}(\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}))$.

Suppose, conversely, that there exist a tr-tr′-transformation τ and a tr′-tr-transformation ρ, such that Conditions (1) and (2) of the statement hold. The function $\rho^{\mathcal{A}*}$ commutes with intersections of $\mathfrak{G}$-filter families on $\mathcal{A}$. As a consequence, we obtain, on the one hand, that $\rho^{\mathcal{A}*}$ is order reflecting on $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ and, on the other, that $\rho^{\mathcal{A}*}(\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}))$ is closed under intersection, and, hence, defines a closure system on $\mathrm{Seq}^{\mathrm{tr}'}(\mathcal{A})$, which we denote by G'. It suffices now, to prove the two conditions of Theorem 1890.

Assume, first, that $\boldsymbol{T},\boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$, such that $\rho^*(\boldsymbol{T}) \le \rho^*(\boldsymbol{T}')$. Let $\boldsymbol{X} = G(\rho[\rho^*(\boldsymbol{T})])$ and $\mathcal{A} = \mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$. Since $\boldsymbol{X}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, we get that $\langle \mathcal{A}, \boldsymbol{X}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. Therefore, $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$. Further, $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$ and $\rho[\rho^*(\boldsymbol{T})] \le \boldsymbol{T}$, which give $\boldsymbol{X} \le \boldsymbol{T}$. Moreover, $\rho[\rho^*(\boldsymbol{T})] \le \rho[\rho^*(\boldsymbol{T}')] \le \boldsymbol{T}'$. Hence, $\boldsymbol{X} \le \boldsymbol{T}'$. Thus, by the monotonicity of the Suszko operator, $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X}) \le \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ and $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X}) \le \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}')$. These imply that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$ is compatible with both $\boldsymbol{T}$ and $\boldsymbol{T}'$. This, in turn, gives that both $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$ and $\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$ are $\mathfrak{G}$-filter families on $\mathcal{A}$ and, furthermore, that

$$\rho^{\mathcal{A}*}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})) = \rho^*(\boldsymbol{T})/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$$

and, similarly, $\rho^{\mathcal{A}*}(\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})) = \rho^*(\boldsymbol{T}')/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$. Since, by hypothesis, $\rho^*(\boldsymbol{T}) \le \rho^*(\boldsymbol{T}')$, we get

$$\rho^{\mathcal{A}*}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})) \le \rho^{\mathcal{A}*}(\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})).$$

Thus, by Condition (1) in the hypothesis, we get $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X}) \le \boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$, whence, using again the compatibility of $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{X})$ with both $\boldsymbol{T}$ and $\boldsymbol{T}'$, we obtain $\boldsymbol{T} \le \boldsymbol{T}'$. We conclude that ρ^* is order reflecting and, therefore, a fortiori, injective on $\mathrm{ThFam}(\mathfrak{G})$.

Finally, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ and consider $\theta = \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\mathrm{Thm}(\mathfrak{G}))$. Then $\mathcal{F}/\theta \in \mathrm{AlgSys}(\mathfrak{G})$, whence, by hypothesis,

$$\rho^{(\mathcal{F}/\theta)*}(G^{\mathfrak{G},\mathcal{F}/\theta}(\boldsymbol{\phi}/\theta_\Sigma)) = G'_\Sigma(\tau^{\mathcal{F}/\theta}_\Sigma[\boldsymbol{\phi}/\theta_\Sigma]),$$

where G' is the closure system on $\mathcal{F}/\theta$ generated by

$$\begin{array}{rcl}\rho^{(\mathcal{F}/\theta)*}(\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F}/\theta)) & = & \rho^{(\mathcal{F}/\theta)*}(\mathrm{ThFam}(\mathfrak{G})/\theta)\\ & = & \rho^*(\mathrm{ThFam}(\mathfrak{G}))/\theta.\end{array}$$

Thus, we get $\rho^*_\Sigma(G(\boldsymbol{\phi}))/\theta = G'_\Sigma(\tau_\Sigma[\boldsymbol{\phi}]/\theta_\Sigma)$, whence

$$\begin{array}{rcl}\rho^{(\mathcal{F}/\theta)*}_\Sigma(G(\boldsymbol{\phi})/\theta) & = & \bigcap\{\rho^*(\boldsymbol{X})/\theta : \tau_\Sigma[\boldsymbol{\phi}]/\theta \subseteq \rho^*(\boldsymbol{X})/\theta\}\\ & = & \bigcap\{\rho^*(\boldsymbol{X}) : \tau_\Sigma[\boldsymbol{\phi}] \subseteq \rho^*(\boldsymbol{X})\}/\theta.\end{array}$$

Therefore, $\rho^*_\Sigma(G(\boldsymbol{\phi})) = \bigcap\{\rho^*(\boldsymbol{X}) : \tau_\Sigma[\boldsymbol{\phi}] \subseteq \rho^*_\Sigma(\boldsymbol{X})\} = G''(\tau_\Sigma[\boldsymbol{\phi}])$, where G'' is the closure system on $\mathcal{F}$ generated by $\rho^*(\mathrm{ThFam}(\mathfrak{G}))$. ■

Theorem 1904 may be used to provide a characterization of equivalence based on the coincidence of the algebraic counterparts of two Gentzen π-institutions.

Theorem 1905 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*.* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent if and only if*

- $\mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathfrak{G}')$ *and*
- *there exist a* tr-tr′*-transformation* τ *and a* tr′-tr*-transformation* ρ*, such that, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$*,*
  - $\rho^{\mathcal{A}*} : \mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathbf{FiFam}^{\mathfrak{G}'}(\mathcal{A})$ *is an order isomorphism and*
  - *for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}(\mathcal{A})$*,*
$$\rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) = G'^{\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]),$$
where $G'^{\mathcal{A}}$ *is the closure system on* $\mathcal{A}$ *induced by* $\rho^{\mathcal{A}*}(\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}))$*.*

Proof: Suppose that $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via the conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$. Then, by Theorem 1902, $\mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathfrak{G}')$. By Proposition 1892, $\rho^{\mathcal{A}*}$ is an order isomorphism and, finally, for all $\Sigma \in |\mathbf{Sign}|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathcal{A})$ and all $\boldsymbol{\phi}' \in \mathrm{Seq}^{\mathrm{tr}'}_\Sigma(\mathcal{A})$,

$$\begin{array}{rll} \boldsymbol{\phi}' \in \rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) & \text{iff} & \rho^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}'] \subseteq G^{\mathfrak{G},\mathcal{A}}_\Sigma(\boldsymbol{\phi}) \\ & \text{iff} & \tau^{\mathcal{A}}_\Sigma[\rho^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}']] \subseteq G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]) \\ & \text{iff} & \boldsymbol{\phi}' \in G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]), \end{array}$$

i.e., for all $\Sigma \in |\mathbf{Sign}|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}(\mathcal{A})$, $\rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) = G^{\mathfrak{G}',\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}])$.

Conversely, assume that the conditions in the claimed characterization of equivalence hold. Then, by Theorem 1904, there exists a Gentzen π-institution $\mathfrak{X}'$ of trace tr′ to which $\mathfrak{G}$ is equivalent, such that $\rho^* : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ThFam}(\mathfrak{X})$ is an order isomorphism. Thus, ρ^* is both order preserving and order reflecting and, hence, injective, on $\mathrm{ThFam}(\mathfrak{G})$. Thus, it suffices to show that it is onto $\mathrm{ThFam}(\mathfrak{G}')$.

Suppose $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$. Set $\mathcal{A} = \mathcal{F}/\Omega(\boldsymbol{T})$ and let $\langle I, \pi \rangle : \mathcal{F} \to \mathcal{A}$ be the quotient morphism. Then, since $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T})$, we get, by the definition of $\mathrm{AlgSys}(\mathfrak{G})$ and the hypothesis, $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G}) = \mathrm{AlgSys}(\mathfrak{G}')$. By the compatibility of $\Omega(\boldsymbol{T})$ with $\boldsymbol{T}$, we get that $\boldsymbol{T}/\Omega(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ and $\pi^{-1}(\boldsymbol{T}/\Omega(\boldsymbol{T})) = \boldsymbol{T}$. By hypothesis, $\rho^{\mathcal{A}*}(\boldsymbol{T}/\Omega(\boldsymbol{T})) \in \mathrm{FiFam}^{\mathfrak{G}'}(\mathcal{A})$, whence $\pi^{-1}(\rho^{\mathcal{A}*}(\boldsymbol{T}/\Omega(\boldsymbol{T}))) \in \mathrm{ThFam}(\mathfrak{G}')$. On the other hand, we have

$$\rho^*(\boldsymbol{T}) = \rho^*(\pi^{-1}(\boldsymbol{T}/\Omega(\boldsymbol{T}))) = \pi^{-1}(\rho^{\mathcal{A}*}(\boldsymbol{T}/\Omega(\boldsymbol{T}))).$$

Hence, we obtain $\rho^*(\boldsymbol{T}) \in \mathrm{ThFam}(\mathfrak{G}')$.

Finally, consider $\boldsymbol{T}' \in \text{ThFam}(\mathfrak{G}')$. Set $\mathfrak{B} = \mathcal{F}/\Omega(\boldsymbol{T}') \in \text{AlgSys}(\mathfrak{G}') = \text{AlgSys}(\mathfrak{G})$ and let $\langle I, \pi' \rangle : \mathcal{F} \to \mathcal{B}$ be the quotient morphism. Then we have $\boldsymbol{T}'/\Omega(\boldsymbol{T}') \in \text{FiFam}^{\mathfrak{G}'}(\mathcal{B})$ and, by compatibility, $\pi'^{-1}(\boldsymbol{T}'/\Omega(\boldsymbol{T}')) = \boldsymbol{T}'$. By hypothesis, there exists $\boldsymbol{T} \in \text{FiFam}^{\mathfrak{G}}(\mathcal{B})$, such that $\boldsymbol{T}'/\Omega(\boldsymbol{T}') = \rho^{\mathcal{B}*}(\boldsymbol{T})$. On the other hand, $\pi'^{-1}(\boldsymbol{T}) \in \text{ThFam}(\mathfrak{G})$ and

$$\rho^*(\pi'^{-1}(\boldsymbol{T})) = \pi'^{-1}(\rho^{\mathcal{B}*}(\boldsymbol{T})) = \pi'^{-1}(\boldsymbol{T}'/\Omega(\boldsymbol{T}')) = \boldsymbol{T}'.$$

thus, ρ^* maps $\text{ThFam}(\mathfrak{G})$ onto $\text{ThFam}(\mathfrak{G}')$ and, hence, it is an order isomorphism from $\mathbf{ThFam}(\mathfrak{G})$ onto $\mathbf{ThFam}(\mathfrak{G}')$. Therefore, $\mathfrak{G}' = \mathfrak{X}$ and $\mathfrak{G}'$ is equivalent to $\mathfrak{G}$. ■

Directly from Theorem 1904, we get the following

Corollary 1906 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is Hilbertizable if and only if there exist a* tr-$\{\langle 0,1 \rangle\}$*-transformation* τ *and a* $\{\langle 0,1 \rangle\}$-tr*-transformation* ρ*, such that, for all* $\mathcal{A} \in \text{AlgSys}(\mathfrak{G})$*:*

(1) $\rho^{\mathcal{A}*} : \text{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \text{SenFam}(\mathcal{A})$ *is injective on* $\text{FiFam}^{\mathfrak{G}}(\mathcal{A})$*;*

(2) For all $\Sigma \in |\mathbf{Sign}|$ *and all* $\boldsymbol{\phi} \in \text{Seq}^{\text{tr}}_\Sigma(\mathcal{A})$*,*

$$\rho^{\mathcal{A}*}_\Sigma(G^{\mathfrak{G},\mathcal{A}}(\boldsymbol{\phi})) = G'^{\mathcal{A}}_\Sigma(\tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}]),$$

where $G'^{\mathcal{A}}$ *is the closure system on* $\mathcal{A}$ *induced by* $\rho^{\mathcal{A}*}(\text{FiFam}^{\mathfrak{G}}(\mathcal{A}))$.

Proof: This is a special case of Theorem 1904. ■

Specializing further, we get the following result characterizing simple Hilbertizability.

Corollary 1907 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is simply Hilbertizable if and only if there exists a* tr-$\{\langle 0,1 \rangle\}$*-transformation* τ*, such that:*

(1) For all $\mathcal{A} \in \text{AlgSys}(\mathfrak{G})$ *and all* $\boldsymbol{T}, \boldsymbol{T}' \in \text{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,*

$$\boldsymbol{T} \cap \triangleright \mathcal{A} = \boldsymbol{T}' \cap \triangleright \mathcal{A} \quad \textit{implies} \quad \boldsymbol{T} = \boldsymbol{T}';$$

(2) For all $\Sigma \in |\mathbf{Sign}|$ *and all* $\boldsymbol{\phi} \in \text{Seq}^{\text{tr}}_\Sigma(\mathcal{A})$*,*

$$G^{\mathfrak{G},\mathcal{A}}_\Sigma(\boldsymbol{\phi}) \cap \triangleright \mathcal{A} = \bigcap \{\triangleright \boldsymbol{T}_\Sigma : \tau^{\mathcal{A}}_\Sigma[\boldsymbol{\phi}] \subseteq \boldsymbol{T}_\Sigma, \boldsymbol{T} \in \text{FiFam}^{\mathfrak{G}}(\mathcal{A})\}.$$

Proof: It suffices to see that Conditions (1) and (2) in the statement reflect exactly Conditions (1) and (2) in the statement of Corollary 1906, where the role of ρ is assumed by the special $\{\langle 0,1 \rangle\}$-tr-transformation ρ^0. ■

Finally, we obtain a characterization of those algebraic Gentzen π-institutions, i.e., Gentzen π-institutions associated with guasivarieties of algebraic systems, which are equivalent to some Hilbert π-institution.

Corollary 1908 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a quasivariety of* $\mathbf{F}$*-algebraic systems.* $\mathfrak{G}^\mathsf{K} = \langle \mathbf{F}, G^\mathsf{K} \rangle$ *is Hilbertizable if and only if there exists a* $\{\langle 1,1\rangle\}$-$\{\langle 0,1\rangle\}$*-transformation* τ *and a* $\{\langle 0,1\rangle\}$-$\{\langle 1,1\rangle\}$*-transformation* ρ*, such that, for all* $\mathcal{A} \in \mathsf{K}$*:*

(1) $\rho^{\mathcal{A}*} : \mathrm{ConSys}^\mathsf{K}(\mathcal{A}) \to \mathrm{SenFam}(\underset{\sim}{\mathcal{A}})$ *is injective on* $\mathrm{ConSys}^\mathsf{K}(\mathcal{A})$*;*

(2) For all $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\rho_\Sigma^{\mathcal{A}*}(\Theta^{\mathsf{K},\mathcal{A}}(\phi \approx \psi)) = G'^{\mathcal{A}}(\tau_\Sigma^{\mathcal{A}}[\phi;\psi]),$$

where $G'^{\mathcal{A}}$ *is the closure system on* $\mathcal{A}$ *induced by* $\rho^{\mathcal{A}*}(\mathrm{ConSys}^\mathsf{K}(\mathcal{A}))$*.*

Proof: This is again a specialization of Theorem 1904 for $\mathfrak{G} = \mathfrak{G}^\mathsf{K}$, where we take into account the facts $\mathrm{FiFam}^{\mathfrak{G}^\mathsf{K}}(\mathcal{A}) = \mathrm{ConSys}^\mathsf{K}(\mathcal{A})$, $\mathrm{AlgSys}(\mathfrak{G}^\mathsf{K}) = \mathsf{K}$ and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, we have, under appropriate identifications, $G^{\mathfrak{G}^\mathsf{K},\mathcal{A}}(\phi \rhd_\Sigma \psi) = \Theta^{\mathsf{K},\mathcal{A}}(\phi \approx \psi)$. ■

26.7 Protoalgebraicity

We now start a relatively brief tour of analogs of some of the classes in the algebraic hierarchy of π-institutions that were introduced in the earlier chapters of this work, as adapted and generalized for Gentzen π-institutions. Even though we revisit and recast only very few of the classes considered previously for π-institutions, the observant reader would realize that all other classes have similarly adapted analogs that have analogous properties.

In this section, we define protoalgebraic and syntactically protoalgebraic Gentzen π-institutions and study some of their properties. In the following section, we shall take a look at order algebraizable Gentzen π-institutions, which parallel the order algebraizable π-institutions of Chapter 25. In the last section, we look at completely reflective and truth equational Gentzen π-institutions.

We look, first, at some properties of the Leibniz operator, whose analogs for π-institutions have been established in Chapter 2.

Lemma 1909 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{B} = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems and* $\langle H, \gamma \rangle : \mathbf{A} \to \mathbf{B}$ *a morphism. For every trace* tr *and all* $\boldsymbol{T} \leq \mathrm{Seq}^{\mathrm{tr}}(\mathbf{B})$*,*

(a) $\gamma^{-1}(\Omega^\mathbf{B}(\boldsymbol{T})) \leq \Omega^\mathbf{A}(\gamma^{-1}(\boldsymbol{T}))$*;*

(b) $\gamma^{-1}(\Omega^\mathbf{B}(\boldsymbol{T})) = \Omega^\mathbf{A}(\gamma^{-1}(\boldsymbol{T}))$*, if* $\langle H, \gamma \rangle$ *is surjective.*

Proof:

(a) It is straightforward to check that $\gamma^{-1}(\Omega^{\mathbf{B}}(\boldsymbol{T}))$ is a congruence system on $\mathbf{A}$ compatible with $\gamma^{-1}(\boldsymbol{T})$. Hence, by the maximality property of $\Omega^{\mathbf{A}}(\gamma^{-1}(\boldsymbol{T}))$, we get that $\gamma^{-1}(\Omega^{\mathbf{B}}(\boldsymbol{T})) \leq \Omega^{\mathbf{A}}(\gamma^{-1}(\boldsymbol{T}))$.

(b) Suppose, now, that $\langle H,\gamma\rangle$ is surjective and let $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \Omega^{\mathbf{A}}_\Sigma(\gamma^{-1}(\boldsymbol{T}))$. Then, by Lemma 1895, we get that, for all $\langle m,n\rangle \in \mathrm{tr}$, all $\vec{\sigma} = \langle\sigma^0,\dots,\sigma^{m-1}\rangle$, and all $\vec{\tau} = \langle\tau^0,\dots,\tau^{n-1}\rangle$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\begin{array}{l}\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \in \gamma^{-1}_{\Sigma'}(\boldsymbol{T}_{H(\Sigma')})\\ \quad\text{iff}\quad \vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \in \gamma^{-1}_{\Sigma'}(\boldsymbol{T}_{H(\Sigma')}).\end{array}$$

Equivalently,

$$\begin{array}{l}\gamma_{\Sigma'}(\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}\\ \quad\text{iff}\quad \gamma_{\Sigma'}(\vec{\sigma}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \rhd_{\Sigma'} \vec{\tau}^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}.\end{array}$$

This holds if and only if, by the morphism property,

$$\begin{array}{l}\vec{\sigma}^{\mathbf{B}}_{H(\Sigma')}(\gamma_{\Sigma'}(\mathrm{SEN}(f)(\phi)),\gamma_{\Sigma'}(\vec{\chi}))\\ \qquad \rhd_{H(\Sigma')} \vec{\tau}^{\mathbf{B}}_{H(\Sigma')}(\gamma_{\Sigma'}(\mathrm{SEN}(f)(\phi)),\gamma_{\Sigma'}(\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}\\ \quad\text{iff}\quad \vec{\sigma}^{\mathbf{B}}_{H(\Sigma')}(\gamma_{\Sigma'}(\mathrm{SEN}(f)(\psi)),\gamma_{\Sigma'}(\vec{\chi}))\\ \qquad \rhd_{H(\Sigma')} \vec{\tau}^{\mathbf{B}}_{H(\Sigma')}(\gamma_{\Sigma'}(\mathrm{SEN}(f)(\psi)),\gamma_{\Sigma'}(\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}.\end{array}$$

Equivalently, by the naturality of γ,

$$\begin{array}{l}\vec{\sigma}^{\mathbf{B}}_{H(\Sigma')}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)),\gamma_{\Sigma'}(\vec{\chi}))\\ \qquad \rhd_{H(\Sigma')} \vec{\tau}^{\mathbf{B}}_{H(\Sigma')}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\phi)),\gamma_{\Sigma'}(\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}\\ \quad\text{iff}\quad \vec{\sigma}^{\mathbf{B}}_{H(\Sigma')}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\psi)),\gamma_{\Sigma'}(\vec{\chi}))\\ \qquad \rhd_{H(\Sigma')} \vec{\tau}^{\mathbf{B}}_{H(\Sigma')}(\mathrm{SEN}'(H(f))(\gamma_\Sigma(\psi)),\gamma_{\Sigma'}(\vec{\chi})) \in \boldsymbol{T}_{H(\Sigma')}.\end{array}$$

Hence, taking into account the surjectivity of $\langle H,\gamma\rangle$, by Lemma 1895, we get $\langle\gamma_\Sigma(\phi),\gamma_\Sigma(\psi)\rangle \in \Omega^{\mathbf{B}}_{H(\Sigma)}(\boldsymbol{T})$, i.e., $\gamma_\Sigma(\Omega^{\mathbf{A}}_\Sigma(\gamma^{-1}(\boldsymbol{T}))) \subseteq \Omega^{\mathbf{B}}_{H(\Sigma)}(\boldsymbol{T})$. We conclude that $\Omega^{\mathbf{A}}(\gamma^{-1}(\boldsymbol{T})) \leq \gamma^{-1}(\Omega^{\mathbf{B}}(\boldsymbol{T}))$.

■

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle\mathbf{F},G\rangle$ a Gentzen π-institution based on $\mathbf{F}$.

- We say $\mathfrak{G}$ is **protoalgebraic** if the Leibniz operator $\Omega : \mathrm{ThFam}(\mathfrak{G}) \to \mathrm{ConSys}(\mathcal{F})$ is monotone on $\mathrm{ThFam}(\mathfrak{G})$;
- We say $\mathfrak{G}$ is **syntactically protoalgebraic** if, for all $\langle m,n\rangle \in \mathrm{tr}$, there exists $I^{\langle m,n\rangle} : (\mathrm{SEN}^\flat)^\omega \to \bigcup_{\langle k,\ell\rangle\in\mathrm{tr}}(\mathrm{SEN}^\flat)^{k+\ell}$ in $N^\flat$ with $(m+n)+(m+n)$ distinguished arguments, such that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi},\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n\rangle$,

$$\langle\boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T}) \quad\text{iff}\quad I^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma.$$

In this case the collection $I = \{I^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$ is called a collection of **witnessing transformations** of the syntactic protoalgebraicity of $\mathfrak{G}$.

We give an alternative characterization of syntactic protoalgebraicity that comes handy in what follows.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and tr a trace. Given $\langle m,n\rangle \in \mathrm{tr}$, we say that a collection $I : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^k$ of natural transformations in $N^\flat$, with $(m+n)+(m+n)$ distinguished variables is **(pairwise) permutable** if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$ and all $\{i_1,\dots,i_{m+n}\} = \{0,\dots,m+n-1\}$,

$$I_\Sigma[\phi_{i_1},\dots,\phi_{i_{m+n}},\psi_{i_1},\dots,\psi_{i_{m+n}}] = I_\Sigma[\phi_0,\dots,\phi_{(m+n)-1},\psi_0,\dots,\psi_{(n+m)-1}].$$

When we want to refer to an arbitrary pairwise permutation of two sequences $\vec{\phi}, \vec{\psi}$ of the same length as above, we write $\vec{\phi}^\pi, \vec{\psi}^\pi$, the meaning being that $\vec{\phi}, \vec{\psi}$ have the same length and that in $\vec{\phi}^\pi, \vec{\psi}^\pi$, their elements have been permuted both by applying the same arbitrary permutation π.

Theorem 1910 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution based on* $\mathbf{F}$. $\mathfrak{G}$ *is syntactically protoalgebraic if and only if, for all* $\langle m,n\rangle \in \mathrm{tr}$, *there exists* $\hat{I}^{\langle m,n\rangle} : (\mathrm{SEN}^\flat)^\omega \to \bigcup_{\langle k,\ell\rangle \in \mathrm{tr}} (\mathrm{SEN}^\flat)^{k+\ell}$ *in* $N^\flat$, *with* $(m+n)+(m+n)$ *distinguished arguments, which is permutable, such that, for all* $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, *all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi,\psi\rangle \in \Omega_\Sigma(\boldsymbol{T}) \quad \textit{iff} \quad \hat{I}^{\langle m,n\rangle}_\Sigma[\langle \phi,\vec{\chi}\rangle, \langle \psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma.$$

Proof: Suppose, first, that $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations $I = \{I^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$. For all $\langle m,n\rangle \in \mathrm{tr}$, we symmetrize $I^{\langle m,n\rangle}$ by defining $\hat{I}^{\langle m,n\rangle}$ in $N^\flat$, with $(m+n)+(m+n)$ distinguished arguments, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$,

$$\hat{I}^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] = \bigcup\{I^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi}^\pi,\boldsymbol{\psi}^\pi] : \pi \text{ a permutation}\}.$$

Then, we have, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of the same trace $\langle m,n\rangle$,

$$\begin{array}{rll} I^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma & \text{iff} & \langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T}) \\ & \text{iff} & \langle \boldsymbol{\phi}^\pi,\boldsymbol{\psi}^\pi\rangle \in \Omega_\Sigma(\boldsymbol{T}), \text{ for all } \pi, \\ & \text{iff} & \hat{I}^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq_\Sigma \boldsymbol{T}_\Sigma. \end{array}$$

Therefore, we obtain, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll} \langle \phi,\psi\rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & I^{\langle m,n\rangle}_\Sigma[\langle \phi,\vec{\chi}\rangle, \langle \psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma \\ & \text{iff} & \hat{I}^{\langle m,n\rangle}_\Sigma[\langle \phi,\vec{\chi}\rangle, \langle \psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma. \end{array}$$

Suppose, conversely, that there exists a permutable $I = \{I^{\langle m,n\rangle} : \langle m,n\rangle \in \text{tr}\}$ that satisfies the condition in the statement of the theorem. Define a collection $\check{I} = \{\check{I}^{\langle m,n\rangle} : \langle m,n\rangle \in \text{tr}\}$ in $N^\flat$ having $(m+n)+(m+n)$ distinguished arguments by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi},\boldsymbol{\psi} \in \text{Seq}^{\text{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$,

$$\check{I}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] = \bigcup\{I^{\langle m,n\rangle}_\Sigma[(\boldsymbol{\phi}\boldsymbol{\psi})^{i+1},(\boldsymbol{\phi}\boldsymbol{\psi})^i] : i < m+n-1\},$$

where

$$(\boldsymbol{\phi}\boldsymbol{\psi})^i \coloneqq \langle \phi_0,\dots,\phi_{i-1},\psi_i,\dots,\psi_{m+n-1}\rangle.$$

Then we have, for all $\boldsymbol{T} \in \text{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi},\boldsymbol{\psi} \in \text{Seq}^{\text{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$,

$$\begin{array}{lll}\langle\boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & \langle\phi_i,\psi_i\rangle \in \Omega_\Sigma(\boldsymbol{T}),\ i < m+n-1,\\ & \text{iff} & I^{\langle m,n\rangle}[(\boldsymbol{\phi}\boldsymbol{\psi})^{i+1},(\boldsymbol{\phi}\boldsymbol{\psi})^i] \subseteq \boldsymbol{T}_\Sigma,\ i < m+n-1,\\ & \text{iff} & \check{I}^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma.\end{array}$$

Therefore, $\mathfrak{G}$ is syntactically protoalgebraic with witnessing transformations $\check{I}$. ∎

Before embarking on a characterization of the exact relationship between syntactic protoalgebraicity and protoalgebraicity, we look at some properties related to notions that have been studied in this chapter, namely, the algebraic counterpart of a Gentzen π-institution and equivalence between Gentzen π-institutions.

The first property states that it suffices to check monotonicity of the Leibniz operator only on the filter families of algebraic systems belonging to the algebraic counterpart.

Lemma 1911 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *If, for all* $\mathcal{A} = \langle \mathbf{A},\langle F,\alpha\rangle\rangle \in \text{AlgSys}(\mathfrak{G})$, $\Omega^{\mathcal{A}}$ *is monotone, then* $\mathfrak{G}$ *is protoalgebraic.*

Proof: Suppose that $\Omega^{\mathcal{A}}$ is monotone, for all $\mathcal{A} \in \text{AlgSys}(\mathfrak{G})$ and let $\boldsymbol{T},\boldsymbol{T}' \in \text{ThFam}(\mathfrak{G})$, such that $\boldsymbol{T} \le \boldsymbol{T}'$. Then, by the monotonicity of the Suszko operator, $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \le \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}')$. Thus, the congruence system $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ is compatible with both $\boldsymbol{T}$ and $\boldsymbol{T}'$. Hence, both $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ and $\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ are $\mathfrak{G}$-filter families of $\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$, such that $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \le \boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$. By hypothesis, since $\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \in \text{AlgSys}(\mathfrak{G})$,

$$\Omega^{\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})) \le \Omega^{\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})}(\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})).$$

Thus, applying the inverse of the quotient morphism $\langle I,\pi\rangle : \mathcal{F} \to \mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$, we get that

$$\pi^{-1}(\Omega^{\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}))) \le \pi^{-1}(\Omega^{\mathcal{F}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})}(\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}))),$$

whence, by Lemma 1909,

$$\Omega(\pi^{-1}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}))) \leq \Omega(\pi^{-1}(\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}))).$$

Thus, since $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T})$ is compatible with both $\boldsymbol{T}$ and $\boldsymbol{T}'$, we get that $\Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Therefore, $\mathfrak{G}$ is protoalgebraic. ■

Now we prove that protoalgebraicity is preserved under equivalence.

Theorem 1912 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr*,* tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen* π*-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent, then* $\mathfrak{G}$ *is protoalgebraic if and only if* $\mathfrak{G}'$ *is also.*

Proof: Suppose $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via the conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and that $\mathfrak{G}'$ is protoalgebraic. Let $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$, such that $\boldsymbol{T} \leq \boldsymbol{T}'$. Then, by Theorem 1880, $\rho^*(\boldsymbol{T}) \leq \rho^*(\boldsymbol{T}')$. Thus, by hypothesis, $\Omega(\rho^*(\boldsymbol{T})) \leq \Omega(\rho^*(\boldsymbol{T}'))$. Hence, by Proposition 1897, $\Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Therefore, $\mathfrak{G}$ is also protoalgebraic. The converse follows by the symmetry of equivalence. ■

Finally, it is shown that the same applies to syntactic protoalgebraicity, i.e., if two Gentzen π-institutions are equivalent, then one is syntactically protoalgebraic if and only if the other is also.

Theorem 1913 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr*,* tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$*,* $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen* π*-institutions of traces* tr*,* tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent, then* $\mathfrak{G}$ *is syntactically protoalgebraic if and only if* $\mathfrak{G}'$ *is also.*

Proof: Suppose that $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via a conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and that $\mathfrak{G}'$ is syntactically protoalgebraic, with witnessing transformations $I := \{I^{\langle m,m \rangle} : \langle m, n \rangle \in \mathrm{tr}'\}$. Then, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, we get, setting, according to Theorem 1880, $\boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G}')$ be such that $\boldsymbol{T} \underset{\tau^*}{\overset{\rho^*}{\rightleftarrows}} \boldsymbol{T}'$, and taking into account Theorem 1919,

$$\begin{array}{rll}\langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\rho^*(\boldsymbol{T})) \\ & \text{iff} & \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\boldsymbol{T}') \\ & \text{iff} & \hat{I}_\Sigma[\langle \phi_i, \vec{\chi} \rangle, \langle \psi_i, \vec{\chi} \rangle] \subseteq \boldsymbol{T}'_\Sigma, i < m + n, \\ & \text{iff} & \hat{I}_\Sigma[\langle \phi_i, \vec{\chi} \rangle, \langle \psi_i, \vec{\chi} \rangle] \subseteq \tau^*_\Sigma(\boldsymbol{T}), i < m + n, \\ & \text{iff} & \tau_\Sigma[\hat{I}_\Sigma[\langle \phi_i, \vec{\chi} \rangle, \langle \psi_i, \vec{\chi} \rangle]] \subseteq \boldsymbol{T}_\Sigma, i < m + n.\end{array}$$

Therefore, $(\tau \circ \hat{I})^\smile$ witnesses the syntactic protoalgebraicity of $\mathfrak{G}$. The converse follows by the symmetry of equivalence. ■

It is relatively easy to see that, if a Gentzen π-institution $\mathfrak{G}$ is syntactically protoalgebraic, then it is protoalgebraic.

Theorem 1914 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is syntactically protoalgebraic, then it is protoalgebraic.*

Proof: Suppose $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations $I = \{I^{\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\}$ in $N^\flat$, and let $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$, such that $\boldsymbol{T} \le \boldsymbol{T}'$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of the same trace $\langle m,n \rangle$, we have

$$\begin{array}{rcl} \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & I_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma \\ & \text{implies} & I_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}'_\Sigma \\ & \text{iff} & \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\boldsymbol{T}'). \end{array}$$

Hence $\Omega(\boldsymbol{T}) \le \Omega(\boldsymbol{T}')$ and $\mathfrak{G}$ is protoalgebraic. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. The **reflexive core** $R^{\mathfrak{G}}$ **of** $\mathfrak{G}$ is the collection

$$R^{\mathfrak{G}} = \{R^{\mathfrak{G},\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\},$$

where, for all $\langle m,n \rangle \in \mathrm{tr}$, $R^{\mathfrak{G},\langle m,n \rangle}$ consists of all natural transformations $\rho : (\mathrm{SEN}^\flat)^\omega \to \bigcup_{\langle k,\ell \rangle \in \mathrm{tr}} (\mathrm{SEN}^\flat)^{k+\ell}$ in $N^\flat$ with $(m+n)+(m+n)$ distinguished arguments that satisfy:

1. For all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$\rho_\Sigma[\langle \phi, \vec{\chi} \rangle, \langle \phi, \vec{\chi} \rangle] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G});$$
2. For all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle$,
$$\rho_{\Sigma'}[\mathrm{SEN}^\flat(f)(\boldsymbol{\phi}), \mathrm{SEN}^\flat(f)(\boldsymbol{\psi})] \subseteq G_{\Sigma'}(\rho_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}]).$$

Using the notation in the proof of Theorem 1919, we observe that, $\hat{R}^{\mathfrak{G}} \subseteq R^{\mathfrak{G}}$ and that $\check{R}^{\mathfrak{G}} \subseteq R^{\mathfrak{G}}$:

- If $\rho \in R^{\mathfrak{G}}$, then, for
$$\sigma_\Sigma(\boldsymbol{\phi}, \boldsymbol{\psi}, \vec{\chi}) \coloneqq \rho_\Sigma(\boldsymbol{\phi}^\pi, \boldsymbol{\psi}^\pi, \vec{\chi}),$$
we get $\sigma_\Sigma[\boldsymbol{\phi}, \boldsymbol{\phi}] = \rho_\Sigma[\boldsymbol{\phi}^\pi, \boldsymbol{\phi}^\pi] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G})$;
- If $\rho \in R^{\mathfrak{G}}$, then, for
$$\sigma_\Sigma(\boldsymbol{\phi}, \boldsymbol{\psi}, \vec{\chi}) \coloneqq \rho_\Sigma((\boldsymbol{\phi}\boldsymbol{\psi})^{i+1}, (\boldsymbol{\phi}\boldsymbol{\psi})^i, \vec{\chi}),$$
we get $\sigma_\Sigma[\boldsymbol{\phi}, \boldsymbol{\phi}] = \rho_\Sigma[\boldsymbol{\phi}, \boldsymbol{\phi}] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G})$.

If a Gentzen π-institution $\mathfrak{G}$ of trace tr is syntactically protoalgebraic with witnessing transformations I, then $I^{\langle m,n\rangle} \subseteq R^{\mathfrak{G},\langle m,n\rangle}$, for all $\langle m,n\rangle \in \mathrm{tr}$.

Lemma 1915 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is syntactically protoalgebraic with witnessing transformations* $I = \{I^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$*, then* $I \subseteq R^{\mathfrak{G}}$*.*

Proof: Suppose that $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations I.

- Since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, $\langle \boldsymbol{\phi}, \boldsymbol{\phi}\rangle \in \Omega_\Sigma(\mathrm{Thm}(\mathfrak{G}))$, we get that $I_\Sigma[\boldsymbol{\phi}, \boldsymbol{\phi}] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G})$.
- If, for some $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, we have $I_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$, then we get $\langle \boldsymbol{\phi}, \boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T})$, whence, since $\Omega(\boldsymbol{T})$ is a congruence system on $\mathbf{F}$, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, we get $\langle \mathrm{SEN}^\flat(f)(\boldsymbol{\phi}), \mathrm{SEN}^\flat(f)(\boldsymbol{\psi})\rangle \in \Omega_{\Sigma'}(\boldsymbol{T})$, showing that
$$I_{\Sigma'}[\mathrm{SEN}^\flat(f)(\boldsymbol{\phi}), \mathrm{SEN}^\flat(f)(\boldsymbol{\psi})] \subseteq \boldsymbol{T}_{\Sigma'}.$$

Thus, by definition of $R^{\mathfrak{G}}$, we get that $I \subseteq R^{\mathfrak{G}}$. ■

Another important property of syntactic protoalgebraicity is that it guarantees that the reflexive core of $\mathfrak{G}$ possesses a modus ponens property in $\mathfrak{G}$.

Theorem 1916 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is syntactically protoalgebraic, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ *of the same trace,*
$$\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi}, R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}]).$$

Proof: Suppose $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations I and let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$, such that $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ and $R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$. Then, by Lemma 1915, we get $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ and $I_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$, that is, by syntactic protoalgebraicity, $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ and $\langle \boldsymbol{\phi}, \boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T})$. Therefore, by compatibility, we get $\boldsymbol{\psi} \in \boldsymbol{T}_\Sigma$, showing that $\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi}, R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi}, \boldsymbol{\psi}])$. ■

Conversely, if the reflexive core $R^{\mathfrak{G}}$ of a Gentzen π-institution $\mathfrak{G}$ has the modus ponens property in $\mathfrak{G}$, then $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations $R^{\mathfrak{G}}$. First, a lemma of a technical nature. For a Gentzen π-institution $\mathfrak{G}$ and $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, we set
$$R^{\mathfrak{G}}(\boldsymbol{T}) = \{R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})\}_{\Sigma \in |\mathbf{Sign}^\flat|},$$

where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$R^{\mathfrak{G}}_\Sigma(\boldsymbol{T}) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma) : (\forall\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma))(R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma)\}.$$

Of course, by the symmetry of the transformations in $N^\flat$, in this definition, ϕ and ψ may appear, equivalently, in any position of the sequents on the right, as long as they appear in the same position in both of the first sequent arguments of $R^{\mathfrak{G}}$.

Lemma 1917 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle\mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *If, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi},\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ *of the same trace,*

$$\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi}, R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}]),$$

the $R^{\mathfrak{G}}(\boldsymbol{T})$ *is a congruence family on* $\mathbf{F}$ *compatible with* $\boldsymbol{T}$.

Proof: We start by showing that $R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ is an equivalence family on $\mathbf{F}$.

- By the definition of $R^{\mathfrak{G}}$, we get, for all $\phi,\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

  $$R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\phi,\vec{\chi}\rangle] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G}) \subseteq \boldsymbol{T}_\Sigma.$$

  Thus, $\langle\phi,\phi\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ and $R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ is reflexive.

- Suppose $\langle\phi,\psi\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$. Then, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, we have

  $$R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma.$$

  But then, by the definition of $R^{\mathfrak{G}}$ and the symmetry of $N^\flat$, we get

  $$R^{\mathfrak{G}}_\Sigma[\langle\psi,\vec{\chi}\rangle,\langle\phi,\vec{\chi}\rangle] \subseteq R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma.$$

  Therefore, $\langle\psi,\phi\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ and $R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ is also symmetric.

- Suppose, now, that $\langle\phi,\psi\rangle,\langle\psi,\chi\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$. Thus, we get, for all $\vec{\chi} \in \mathrm{SEN}(\Sigma)$,

  $$R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma \text{ and } R^{\mathfrak{G}}_\Sigma[\langle\psi,\vec{\chi}\rangle,\langle\chi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma.$$

  By hypothesis, we have, for all $\rho \in R^{\mathfrak{G}}$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$,

  $$\begin{aligned}\rho_\Sigma(\langle\phi,\vec{\chi}\rangle,\langle\chi,\vec{\chi}\rangle,\vec{\xi}) \subseteq G_\Sigma(&\rho_\Sigma(\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle,\vec{\xi}),\\ &R^{\mathfrak{G}}_\Sigma[\rho_\Sigma(\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle,\vec{\xi}),\rho_\Sigma(\langle\phi,\vec{\chi}\rangle,\langle\chi,\vec{\chi}\rangle,\vec{\xi})])\\ \subseteq G_\Sigma(&R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\psi,\vec{\chi}\rangle],R^{\mathfrak{G}}_\Sigma[\langle\psi,\vec{\chi}\rangle,\langle\chi,\vec{\chi}\rangle])\\ \subseteq G_\Sigma(&\boldsymbol{T}_\Sigma) = \boldsymbol{T}_\Sigma.\end{aligned}$$

  Therefore, $R^{\mathfrak{G}}_\Sigma[\langle\phi,\vec{\chi}\rangle,\langle\chi,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma$, showing that $\langle\phi,\chi\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ and, hence, $R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ is also transitive.

We show, next, that $R^{\mathfrak{G}}(\boldsymbol{T})$ is a congruence family. Let σ be in $N^\flat$, $\vec{\phi},\vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, such that, for all $i < k$, $\langle \phi_i,\psi_i\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$. Then, for all $i < k$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $R^{\mathfrak{G}}_\Sigma[\langle \phi_i,\vec{\chi}\rangle,\langle \psi_i,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma$. But, then, for all $i < k$,

$$R^{\mathfrak{G}}_\Sigma[\langle \sigma_\Sigma((\vec{\phi}\vec{\psi})^{i+1}),\vec{\chi}\rangle,\langle \sigma_\Sigma((\vec{\phi}\vec{\psi})^{i}),\vec{\chi}\rangle] \subseteq R^{\mathfrak{G}}_\Sigma[\langle \phi_i,\vec{\chi}\rangle,\langle \psi_i,\vec{\chi}\rangle] \subseteq \boldsymbol{T}_\Sigma,$$

i.e., $\langle \sigma_\Sigma((\vec{\phi}\vec{\psi})^{i+1}),\sigma_\Sigma((\vec{\phi}\vec{\psi})^{i})\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$. Since this holds for all $i < k$, we get by the transitivity of $R^{\mathfrak{G}}(\boldsymbol{T})$ proven above, that $\langle \sigma_\Sigma(\vec{\phi}),\sigma_\Sigma(\vec{\psi})\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ and, therefore, $R^{\mathfrak{G}}(\boldsymbol{T})$ is also a congruence family.

Finally, $R^{\mathfrak{G}}(\boldsymbol{T})$ is a congruence system by the definition of $R^{\mathfrak{G}}$. Compatibility of $R^{\mathfrak{G}}(\boldsymbol{T})$ with $\boldsymbol{T}$ is also readily obtainable by the hypothesis, since $\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$ implies $R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$. Therefore, if $\boldsymbol{\phi} \in T_\Sigma$ and $\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in R^{\mathfrak{G}}_\Sigma(\boldsymbol{T})$, we get

$$\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi},R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}]) \subseteq G_\Sigma(\boldsymbol{T}_\Sigma) = \boldsymbol{T}_\Sigma.$$

Hence, $R^{\mathfrak{G}}(\boldsymbol{T})$ is a congruence system on $\mathbf{F}$ compatible with $\boldsymbol{T}$. ■

Now we are ready for the promised theorem.

Theorem 1918 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F},G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. *If, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi},\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ *of the same trace,*

$$\boldsymbol{\psi} \in G_\Sigma(\boldsymbol{\phi},R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}]),$$

then $\mathfrak{G}$ *is syntactically protoalgebraic, with witnessing transformations* $R^{\mathfrak{G}}$.

Proof: Suppose that $R^{\mathfrak{G}}$ satisfies the displayed condition. We must show that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi},\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$,

$$\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T}) \quad \text{iff} \quad R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma.$$

Suppose, first, that $\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T})$. Then,, since $\Omega(\boldsymbol{T})$ is a congruence system on $\mathbf{F}$, we get, for all $\rho \in R^{\mathfrak{G}}$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \rho_\Sigma(\boldsymbol{\phi},\boldsymbol{\phi},\vec{\chi}),\rho_\Sigma(\boldsymbol{\phi},\boldsymbol{\psi},\vec{\chi})\rangle \in \Omega_\Sigma(\boldsymbol{T}).$$

Moreover, $R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\phi}] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G}) \subseteq \boldsymbol{T}_\Sigma$, by the definition of the reflexive core. Therefore, by the compatibility of $\Omega(\boldsymbol{T})$, with $\boldsymbol{T}$, we get that, for all $\rho \in R^{\mathfrak{G}}$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $\rho_\Sigma(\boldsymbol{\phi},\boldsymbol{\psi},\vec{\chi}) \in \boldsymbol{T}_\Sigma$. We conclude that $R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$.

Assume, conversely, that $R^{\mathfrak{G}}_\Sigma[\boldsymbol{\phi},\boldsymbol{\psi}] \subseteq T_\Sigma$. Since, by Lemma 1917, $R^{\mathfrak{G}}(\boldsymbol{T})$ is a congruence system on $\mathbf{F}$ compatible with $\boldsymbol{T}$, we get, by the maximality of $\Omega(\boldsymbol{T})$, that $R^{\mathfrak{G}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T})$. But the hypothesis implies that $\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in R^{\mathfrak{G}}_\Sigma(T)$. Therefore, we conclude that $\langle \boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \Omega_\Sigma(\boldsymbol{T})$. ■

We now have a characterization of syntactic protoalgebraicity in terms of the property of modus ponens of the reflexive core $R^{\mathfrak{G}}$ of the Gentzen π-institution $\mathfrak{G}$.

$$\mathfrak{G} \text{ is syntactically protoalgebraic} \longleftrightarrow R^{\mathfrak{G}} \text{ has the MP}.$$

Theorem 1919 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is syntactically protoalgebraic if and only if* $R^{\mathfrak{G}}$ *has the modus ponens in* $\mathfrak{G}$*.*

Proof: Theorem 1916 gives the "only if" and the "if" is by Theorem 1918. ∎

As a corollary, we obtain

Corollary 1920 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is syntactically protoalgebraic with witnessing transformations* $I = \{I^{\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\}$*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ *of trace* $\langle m,n \rangle$*,*

$$G_\Sigma(R_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}]) = G_\Sigma(I_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}]).$$

Proof: If $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations I, then, by Theorems 1919 and 1918, both I and $R^{\mathfrak{G}}$ are families of witnessing transformations for the syntactic protoalgebraicity of $\mathfrak{G}$. Therefore, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle$,

$$\begin{array}{rll} R_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma & \text{iff} & \langle \boldsymbol{\phi}, \boldsymbol{\psi} \rangle \in \Omega_\Sigma(\boldsymbol{T}) \\ & \text{iff} & I_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma. \end{array}$$

Therefore, $G_\Sigma(R_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}]) = G_\Sigma(I_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}, \boldsymbol{\psi}])$. ∎

We get relatively easily another related characterization of syntactic protoalgberaicity.

$\mathfrak{G}$ is syntactically protoalgebraic
$\longleftrightarrow$ $R^{\mathfrak{G}}$ Defines Leibniz Congruence Systems.

Theorem 1921 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is syntactically protoalgebraic if and only if, for every* $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$*,*

$$\Omega(\boldsymbol{T}) = R^{\mathfrak{G}}(\boldsymbol{T}).$$

Proof: If $\mathfrak{G}$ is syntactically protoalgebraic, then, by Theorems 1919 and 1918, $R^{\mathfrak{G}}$ constitutes a collection of witnessing transformations, whence, for every $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$ $\Omega(\boldsymbol{T}) = \hat{R}^{\mathfrak{G}}(\boldsymbol{T}) = R^{\mathfrak{G}}(\boldsymbol{T})$.

The converse follows by the definition of syntactic protoalgberaicity, since, in that case, $\check{R}^{\mathfrak{G}} = R^{\mathfrak{G}}$ forms a collection of witnessing transformations. ∎

We finally show that the property that separates protoalgebraicity from syntactic protoalgebraicity is the compatibility property with respect to the theory family generated by the reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. We say that the reflexive core $R^{\mathfrak{G}}$ is **Leibniz** if, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$,

$$\boldsymbol{\phi} \; \Omega_\Sigma(G(R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}])) \; \boldsymbol{\psi}.$$

This property is weaker than $R^{\mathfrak{G}}$ having the modus ponens, i.e., if $R^{\mathfrak{G}}$ has the modus ponens, then it is Leibniz.

Proposition 1922 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system,* tr *a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace* tr *based on $\mathbf{F}$. If $R^{\mathfrak{G}}$ has the modus ponens, then it is Leibniz.*

Proof: If $R^{\mathfrak{G}}$ has the modus ponens, then, by Theorem 1919, we get, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m, n \rangle \in \mathrm{tr}$,

$$\boldsymbol{\phi} \; \Omega_\Sigma(\boldsymbol{T}) \; \boldsymbol{\psi} \quad \text{iff} \quad R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma.$$

Therefore, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$, by considering, in particular, $\boldsymbol{T} = G(R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}])$, and taking into account that

$$R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq G_\Sigma(R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}]),$$

we get that $\boldsymbol{\phi} \; \Omega_\Sigma(G(R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}])) \; \boldsymbol{\psi}$. Thus, $R^{\mathfrak{G}}$ is Leibniz. ∎

In the opposite direction, in a protoalgebraic Gentzen π-institution $\mathfrak{G}$, if the reflexive core $R^{\mathfrak{G}}$ is Leibniz, then it has the modus ponens in $\mathfrak{G}$.

Proposition 1923 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system,* tr *a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a protoalgebraic Gentzen π-institution of trace* tr *based on $\mathbf{F}$. If $R^{\mathfrak{G}}$ is Leibniz, then it has the modus ponens in $\mathfrak{G}$.*

Proof: Suppose that $\mathfrak{G}$ is protoalgebraic and that $R^{\mathfrak{G}}$ is Leibniz. Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi}, \boldsymbol{\psi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m, n \rangle \in \mathrm{tr}$, such that $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ and $R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$. Since $R^{\mathfrak{G}}$ is Leibniz, we have

$$\boldsymbol{\phi} \; \Omega_\Sigma(G(R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}])) \; \boldsymbol{\psi},$$

whence, since $\mathfrak{G}$ is protoalgebraic and $R_\Sigma^{\mathfrak{G}}[\boldsymbol{\phi}, \boldsymbol{\psi}] \subseteq \boldsymbol{T}_\Sigma$, we get $\boldsymbol{\phi} \; \Omega_\Sigma(\boldsymbol{T}) \; \boldsymbol{\psi}$. Therefore, since $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$, we get, by the compatibility of $\Omega(\boldsymbol{T})$ with $\boldsymbol{T}$, that $\boldsymbol{\psi} \in \boldsymbol{T}_\Sigma$. We conclude that $R^{\mathfrak{G}}$ has the modus ponens in $\mathfrak{G}$. ∎

We now show that a Gentzen π-institution is syntactically protoalgebraic if and only if it is protoalgebraic and it has a Leibniz reflexive core.

Syntactic Protoalgebraicity	=	$R^{\mathfrak{G}}$ has the Modus Ponens
	=	$R^{\mathfrak{G}}$ Defines Leibniz Congruence Systems
	=	Protoalgebraicity + $R^{\mathfrak{G}}$ Leibniz

Theorem 1924 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. $\mathcal{I}$ *is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core.*

Proof: Suppose, first, that $\mathfrak{G}$ is syntactically protoalgebraic. Then it is protoalgebraic by Theorem 1914. Moreover, its reflexive core has the modus ponens by Theorem 1916 and, hence, by Proposition 1922, its reflexive core is Leibniz.

Suppose, conversely, that $\mathfrak{G}$ is protoalgebraic with a Leibniz reflexive core. Then, by Proposition 1923, its reflexive core has the modus ponens and, therefore, by Theorem 1919, $\mathfrak{G}$ is syntactically protoalgebraic. ■

26.8 Order Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic posystems. Recall the inequational π-institution $\mathcal{I}^{\mathsf{K}} = \langle \mathbf{F}, C^{\mathsf{K}} \rangle$ associated with the class K, i.e., in which, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $I \cup \{\phi \preccurlyeq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll}\phi \preccurlyeq \psi \in C^{\mathsf{K}}_\Sigma(I) & \text{iff} & \text{for all } \langle \mathcal{A}, \leq \rangle \in \mathsf{K}, \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'),\\ & & \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(I)) \subseteq \leq_{F(\Sigma')} \text{ implies}\\ & & \qquad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \leq_{F(\Sigma')} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).\end{array}$$

To $\mathcal{I}^{\mathsf{K}}$ we associate the Gentzen π-institution $\mathfrak{G}^{\mathsf{K}} = \langle \mathbf{F}, G^{\mathsf{K}} \rangle$ of trace $\{\langle 1, 1 \rangle\}$ defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\{\phi_i, \psi_i : i \in I\} \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \rhd_\Sigma \psi \in G^{\mathsf{K}}_\Sigma(\{\phi_i \rhd_\Sigma \psi_i : i \in I\}) \quad \text{iff} \quad \phi \preccurlyeq \psi \in C^{\mathsf{K}}_\Sigma(\{\phi_i \preccurlyeq \psi_i : i \in I\}).$$

We call $\mathfrak{G}^{\mathsf{K}}$ the **inequational Gentzen π-institution associated with K**.

It turns out that, for every class K of $\mathbf{F}$-algebraic posystems, the associated inequational Gentzen π-institution $\mathfrak{G}^{\mathsf{K}}$ is syntactically protoalgebraic.

Theorem 1925 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic posystems. Then* $\mathfrak{G}^{\mathsf{K}} = \langle \mathbf{F}, G^{\mathsf{K}} \rangle$ *is syntactically protoalgebraic.*

Proof: Consider $I = \{I^{\langle 1,1 \rangle}\}$, where $I^{\langle 1,1 \rangle} : (\mathrm{SEN}^\flat)^4 \to (\mathrm{SEN}^\flat)^2$ is given, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \phi', \psi' \in \mathrm{SEN}^\flat(\Sigma)$, by

$$I^{\langle 1,1 \rangle}_\Sigma[\langle \phi, \psi \rangle, \langle \phi', \psi' \rangle] = \{\phi \rhd_\Sigma \phi',\ \phi' \rhd_\Sigma \phi\ \psi \rhd_\Sigma \psi',\ \psi' \rhd_\Sigma \psi\}.$$

Then, we have, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G}^{\mathsf{K}}$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \rhd_\Sigma \psi \in \mathrm{Seq}^{\{\langle 1,1 \rangle\}}_\Sigma(\mathbf{F})$,

$$\begin{array}{lll}\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & \{\phi \rhd_\Sigma \phi',\ \phi' \rhd_\Sigma \phi,\ \psi \rhd_\Sigma \psi',\ \psi' \rhd_\Sigma \psi\} \subseteq \boldsymbol{T}_\Sigma\\ & \text{iff} & I^{\langle 1,1 \rangle}_\Sigma[\phi \rhd_\Sigma \psi, \phi' \rhd_\Sigma \psi'] \subseteq \boldsymbol{T}_\Sigma.\end{array}$$

Therefore, $\mathfrak{G}^{\mathsf{K}}$ is syntactically protoalgebraic, with witnessing transformations I. ■

Note, also, how $I^{\langle 1,1\rangle}$ satisfies the modus ponens property in $\mathfrak{G}^{\mathsf{K}}$, i.e., for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \phi', \psi' \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi' \rhd_\Sigma \psi' \in G^{\mathsf{K}}_\Sigma(\phi \rhd_\Sigma \psi, I^{\langle 1,1\rangle}_\Sigma[\phi \rhd_\Sigma \psi, \phi' \rhd_\Sigma \psi']).$$

We now show that, if the class K happens to be an order guasivariety of $\mathbf{F}$-algebraic posystems, then the Leibniz reduced $\mathfrak{G}^{\mathsf{K}}$-matrix families coincide with the class K.

Proposition 1926 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *an ordered guasivariety of* $\mathbf{F}$*-algebraic posystems. Then* $\mathrm{MatFam}^*(\mathfrak{G}^{\mathsf{K}}) = \mathsf{K}$.

Proof: Suppose $\langle \mathcal{A}, \leq\rangle \in \mathsf{K}$ and let $\Sigma \in |\mathbf{Sign}|$ $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(\leq)$. Since $\phi \leq_\Sigma \phi$, we get, by compatibility of $\Omega^{\mathcal{A}}(\leq)$ with $\leq$, that $\phi \leq_\Sigma \psi$ and $\psi \leq_\Sigma \phi$. Thus, since $\leq$ is a posystem on $\mathcal{A}$ and, therefore, antisymmetric, we get that $\phi = \psi$. Hence, $\Omega^{\mathcal{A}}(\leq) = \Delta^{\mathcal{A}}$. We conclude that $\langle \mathcal{A}, \leq\rangle \in \mathrm{MatFam}^*(\mathfrak{G}^{\mathsf{K}})$. Thus, $\mathsf{K} \subseteq \mathrm{MatFam}^*(\mathfrak{G}^{\mathsf{K}})$.

Suppose, conversely, that $\langle \mathcal{A}, \leq\rangle \in \mathrm{MatFam}^*(\mathfrak{G}^{\mathsf{K}})$. Then $\Omega^{\mathcal{A}}(\leq) = \Delta^{\mathcal{A}}$. Since K is a class of $\mathbf{F}$-algebraic posystems, we get that, for all σ, τ in $N^\flat$, all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in |\mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\begin{aligned}&\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \leq_{\Sigma'} \tau^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})\\ &\in G^{\mathsf{K},\mathcal{A}}_\Sigma(\phi \leq_\Sigma \psi, \psi \leq_\Sigma \phi, \sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \leq_{\Sigma'} \tau^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi})).\end{aligned}$$

Therefore, if $\phi \leq_\Sigma \psi$ and $\psi \leq_\Sigma \phi$, then we get that $\langle \phi, \psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(\leq) = \Delta^{\mathcal{A}}_\Sigma$, i.e., that $\phi = \psi$. Therefore, $\leq$ is antisymmetric, i.e., $\langle \mathcal{A}, \leq\rangle \in \mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$. We conclude that $\mathrm{MatFam}^*(\mathfrak{G}^{\mathsf{K}}) \subseteq \mathsf{K}$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. $\mathfrak{G}$ is **order algebraizable** if it is equivalent to the inequational Gentzen π-institution $\mathfrak{G}^{\mathsf{K}}$ associated with some class K of $\mathbf{F}$-algebraic posystems.

Order algebraizability implies protoalgebraicity.

Proposition 1927 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is order algebraizable, then it is protoalgebraic.*

Proof: Suppose that $\mathfrak{G}$ is equivalent to $\mathfrak{G}^{\mathsf{K}}$, for some class K of $\mathbf{F}$-algebraic posystems. Then, since, by Theorem 1925, $\mathfrak{G}^{\mathsf{K}}$ is syntactically protoalgebraic, it is, by Theorem 1914, protoalgebraic. Therefore, by Theorem 1912, $\mathfrak{G}$ is protoalgebraic as well. ■

The following result provides a characterization of order algebraizability.

Theorem 1928 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is order algebraizable if and only if there exist a* tr-$\{\langle 1,1\rangle\}$*-transformation* τ *and an* $\{\langle 1,1\rangle\}$-tr*-transformation* ρ*, such that, for all* σ, σ' *in* $N^\flat$*, all* $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$*, all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$*, all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$*, all* $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$*, all* $\{\phi_i, \psi_i : i \in I\} \subseteq \mathrm{SEN}^\flat(\Sigma)$*, and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$*:*

(1) $\rho_\Sigma[\phi, \phi] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G})$*;*

(2) $\rho_\Sigma[\phi, \chi] \subseteq G_\Sigma(\rho_\Sigma[\phi, \psi], \rho_\Sigma[\psi, \chi])$*;*

(3) $\rho_\Sigma[\sigma_\Sigma(\psi, \vec{\chi}), \sigma'_\Sigma(\psi, \vec{\chi})]$
$\subseteq G_\Sigma(\rho_\Sigma[\phi, \psi], \rho_\Sigma[\psi, \phi], \rho_\Sigma[\sigma_\Sigma(\phi, \vec{\chi}), \sigma'_\Sigma(\phi, \vec{\chi})])$*;*

(4) $\rho_\Sigma[\phi, \psi] \subseteq G_\Sigma(\bigcup_{i \in I} \rho_\Sigma[\phi_i, \psi_i])$ *implies*

$$\rho_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(\psi)] \subseteq G_{\Sigma'}(\bigcup_{i \in I} \rho_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi_i), \mathrm{SEN}^\flat(f)(\psi_i)]);$$

(5) $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]])$.

Proof: Suppose, first, that $\mathfrak{G}$ is order algebraizable. Then there exist τ and ρ as postulated and a class K of $\mathbf{F}$-algebraic posystems, such that $\mathfrak{G}$ is equivalent to $\mathfrak{G}^{\mathsf{K}}$ via the conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$. Since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \rhd_\Sigma \phi \in \mathrm{Thm}_\Sigma(\mathfrak{G}^{\mathsf{K}})$, we get that $\rho_\Sigma[\phi, \phi] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{G})$. So Condition (1) holds. Since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi \rhd_\Sigma \chi \in G^{\mathsf{K}}_\Sigma(\phi \rhd \psi, \psi \rhd_\Sigma \chi)$, we get that

$$\rho_\Sigma[\phi, \chi] \subseteq G_\Sigma(\rho_\Sigma[\phi, \psi], \rho_\Sigma[\psi, \chi]).$$

Hence, Condition (2) is also satisfied. If, for some $\langle \mathcal{A}, \leq \rangle \in \mathsf{K}$, we have, for some $\Sigma \in |\mathbf{Sign}|$ and some $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\phi \leq_\Sigma \psi$ and $\psi \leq_\Sigma \phi$, then, since K is a class of $\mathbf{F}$-algebraic posystems, we get that $\phi = \psi$. Hence, it follows that, if, for σ, σ' in $N^\flat$, and $\vec{\chi} \in \mathrm{SEN}(\Sigma)$, $\sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \leq_\Sigma \sigma'^{\mathcal{A}}_\Sigma(\phi, \vec{\chi})$, then, we will also have $\sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}) \leq_\Sigma \sigma'^{\mathcal{A}}_\Sigma(\psi, \vec{\chi})$. In other words, we get that, for all σ, σ' in $N^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$, and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma_\Sigma(\psi, \vec{\chi}) \rhd_\Sigma \sigma'_\Sigma(\psi, \vec{\chi}) \in G^{\mathsf{K}}_\Sigma(\phi \rhd_\Sigma \psi, \psi \rhd_\Sigma \phi, \sigma_\Sigma(\phi, \vec{\chi}) \rhd_\Sigma \sigma'_\Sigma(\phi, \vec{\chi})).$$

Again, by applying ρ we get that Condition (3) holds. Suppose, now, that for some $\Sigma \in |\mathbf{Sign}^\flat|$ and $\{\phi_i, \psi_i : i \in I\} \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, $\rho_\Sigma[\phi, \psi] \subseteq G_\Sigma(\bigcup_{i \in I} \rho_\Sigma[\phi_i, \psi_i])$. Then, we get $\phi \rhd_\Sigma \psi \in G^{\mathsf{K}}_\Sigma(\{\phi_i \rhd_\Sigma \psi_i : i \in I\})$. Therefore, since $\mathfrak{G}^{\mathsf{K}}$ is structural, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\mathrm{SEN}^\flat(f)(\phi \rhd_\Sigma \psi) \in G^{\mathsf{K}}_{\Sigma'}(\{\mathrm{SEN}^\flat(f)(\phi_i \rhd_\Sigma \psi_i) : i \in I\}).$$

By applying ρ again, we get that Condition (4) holds. Finally, Condition (5) holds directly by the definition of equivalence.

Assume, conversely, that ρ and τ, as postulated in the statement, exist and that they satisfy Conditions (1)-(5). Define $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ of trace $\{\langle 1,1 \rangle\}$ by setting, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $\{\phi_i, \psi_i : i \in I\} \cup \{\phi, \psi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \rhd_\Sigma \psi \in G'_\Sigma(\{\phi_i \rhd_\Sigma \psi_i : i \in I\}) \quad \text{iff} \quad \rho_\Sigma[\phi, \psi] \subseteq G_\Sigma(\bigcup\{\rho_\Sigma[\phi_i, \psi_i] : i \in I\}).$$

Then, by the fact that $\mathfrak{G}$ is a Gentzen π-institution and Property (4), we get that $\mathfrak{G}'$ is also a Gentzen π-institution. Moreover, by its definition and Condition (5), taking into account Lemma 1879, $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ is an equivalence. Thus, it suffices to show that $\mathfrak{G}' = \mathfrak{G}^{\mathsf{K}}$, for some class K of $\mathbf{F}$-algebraic posystems. For this, in turn, it suffices, by Theorem 1901, to show that $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}')$ is a class of $\mathbf{F}$-algebraic posystems.

Note, first, that $I = \{I^{\langle 1,1 \rangle}\}$, defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \phi', \psi' \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^{\langle 1,1 \rangle}_\Sigma[\langle \phi, \psi \rangle, \langle \phi', \psi' \rangle] \coloneqq \{\phi \rhd_\Sigma \phi',\ \phi' \rhd_\Sigma \phi,\ \psi \rhd_\Sigma \psi',\ \psi' \rhd_\Sigma \psi\}$$

is a subset of $R^{\mathfrak{G}'}$, which, by Condition (2) and the definition of $\mathfrak{G}'$ satisfies the Modus Ponens in $\mathfrak{G}'$. Therefore, by Theorem 1918, $\mathfrak{G}'$ is syntactically protoalgebraic and, hence, by Theorem 1914, it is protoalgebraic. Thus, by Lemma 1899, the Leibniz and the Suszko operator coincide. Moreover, by Conditions (1) and (2) and the definition of $\mathfrak{G}'$, for all $\langle \mathcal{A}, \leq \rangle \in \mathrm{MatFam}(\mathfrak{G}')$, the relation family $\leq$ is reflexive and transitive. Also, by Condition (3) and the definition of $\mathfrak{G}'$, we get that, for all $\langle \mathcal{A}, \leq \rangle \in \mathrm{MatFam}(\mathfrak{G}')$, all σ, σ' in $N^\flat$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi, \vec{\chi} \in \mathrm{SEN}(\Sigma)$,

$$\phi \leq_\Sigma \psi,\ \psi \leq_\Sigma \phi,\ \sigma^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \leq_\Sigma \sigma'^{\mathcal{A}}_\Sigma(\phi, \vec{\chi}) \text{ imply } \sigma^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}) \leq_\Sigma \sigma'^{\mathcal{A}}_\Sigma(\psi, \vec{\chi}).$$

We finish the proof by showing that, for all $\langle \mathcal{A}, \leq \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}')$, $\leq$ is also antisymmetric. To this end, let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\phi \leq_\Sigma \psi$ and $\psi \leq_\Sigma \phi$. Then, by Property (4) and the definition of $\mathfrak{G}'$, we get that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\phi) \leq_{\Sigma'} \mathrm{SEN}(f)(\psi) \text{ and } \mathrm{SEN}(f)(\psi) \leq_{\Sigma'} \mathrm{SEN}(f)(\phi).$$

Then, by what was shown above, we have, for all σ, σ' in $N^\flat$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\begin{aligned} &\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \leq_{\Sigma'} \sigma'^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \\ &\qquad \text{iff} \quad \sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \leq_{\Sigma'} \sigma'^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}). \end{aligned}$$

Therefore, by Corollary 1896, we get $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(\leq) = \widetilde{\Omega}^{\mathfrak{G}', \mathcal{A}}_\Sigma(\leq) = \Delta^{\mathcal{A}}_\Sigma$. We conclude that $\langle \mathcal{A}, \leq \rangle$ is indeed an $\mathbf{F}$-algebraic posystem. Hence, $\mathfrak{G}'$ is an inequational Gentzen π-institution associated with the class $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}')$ of $\mathbf{F}$-algebraic posystems and, as a consequence, the Gentzen π-institution $\mathfrak{G}$ is indeed order algebraizable. ∎

Specializing Theorem 1928 to the case of Hilbert π-institutions, we get

Corollary 1929 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathfrak{H} = \langle \mathbf{F}, H \rangle$ *a Hilbert* π*-institution based on* $\mathbf{F}$*.* $\mathfrak{H}$ *is order algebraizable if and only if there exist a* $\{\langle 0,1\rangle\}$-$\{\langle 1,1\rangle\}$*-transformation* τ *and an* $\{\langle 1,1\rangle\}$-$\{\langle 0,1\rangle\}$*-transformation* ρ*, such that, for all* σ, σ' *in* $N^\flat$*, all* $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$*, all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$*, all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$ *all* $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$ *and all* $\{\phi_i, \psi_i : i \in I\} \subseteq \mathrm{SEN}^\flat(\Sigma)$*:*

(1) $\rho_\Sigma[\phi, \phi] \subseteq \mathrm{Thm}_\Sigma(\mathfrak{H})$*;*

(2) $\rho_\Sigma[\phi, \chi] \subseteq H_\Sigma(\rho_\Sigma[\phi, \psi], \rho_\Sigma[\psi, \chi])$*;*

(3) $$\rho_\Sigma[\sigma_\Sigma(\psi, \vec{\chi}), \sigma'_\Sigma(\psi, \vec{\chi})] \subseteq H_\Sigma(\rho_\Sigma[\phi, \psi], \rho_\Sigma[\psi, \phi], \rho_\Sigma[\sigma_\Sigma(\phi, \vec{\chi}), \sigma'_\Sigma(\phi, \vec{\chi})]);$$

(4) $\rho_\Sigma[\phi, \psi] \subseteq H_\Sigma(\bigcup_{i \in I} \rho_\Sigma[\phi_i, \psi_i])$ *implies*
$$\rho_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(\psi)] \subseteq H_{\Sigma'}(\bigcup_{i \in I} \rho_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi_i), \mathrm{SEN}^\flat(f)(\psi_i)]);$$

(5) $H_\Sigma(\triangleright_\Sigma \phi) = H_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]])$.

Proof: Directly from Theorem 1928. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. $\mathfrak{G}$ is **simply order algebraizable** if it is equivalent to the inequational Gentzen π-institution $\mathfrak{G}^{\mathsf{K}}$, associated with some class K of $\mathbf{F}$-algebraic posystems, via a conjugate pair $(\tau, \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$, where, as before, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\rho^0_\Sigma(\phi; \psi) = \phi \triangleright_\Sigma \psi.$$

We have the following analog of Lemma 1823.

Lemma 1930 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is simply order algebraizable via both* $(\tau, \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$ *and* $(\tau', \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$*, then* $\mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{GO}^{\mathsf{Sem}}(\mathsf{K}')$*.*

Proof: Suppose $\mathfrak{G}$ is simply order algebraizable via both $(\tau, \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$ and $(\tau', \rho^0) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}'}$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $I \cup \{\phi \leq \psi\} \subseteq \mathrm{In}_\Sigma(\mathbf{F})$, we have
$$\begin{array}{lll} \phi \leq \psi \in G^{\mathsf{K}}_\Sigma(I) & \text{iff} & \rho^0_\Sigma[\phi; \psi] \subseteq G_\Sigma(\rho^0_\Sigma[I]) \\ & \text{iff} & \phi \leq \psi \in G^{\mathsf{K}'}_\Sigma(I). \end{array}$$
Thus, K and K' satisfy exactly the same $\mathbf{F}$-guasiinequations. ■

The unique order guasivariety K that simply order algebraizes a simply order algebraizable Gentzen π-institution $\mathfrak{G}$ is called the **order class of** $\mathfrak{G}$.

Specializing Theorem 1928, we get

Corollary 1931 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace, with* $\langle 1,1 \rangle \in$ tr*, and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is simply order algebraizable if and only if there exists a* tr*-*$\{\langle 1,1 \rangle\}$*-transformation* τ*, such that, for all* σ, σ' *in* $N^\flat$*, all* $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$*, all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$*, all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$*, all* $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$*:*

(1) $\phi \rhd_\Sigma \phi \in \mathrm{Thm}_\Sigma(\mathfrak{G})$*;*

(2) $\phi \rhd_\Sigma \chi \in G_\Sigma(\phi \rhd_\Sigma \psi, \psi \rhd_\Sigma \chi)$*;*

(3) $\sigma_\Sigma(\psi, \vec{\chi}) \rhd_\Sigma \sigma'_\Sigma(\psi, \vec{\chi}) \in G_\Sigma(\phi \rhd_\Sigma \psi, \psi \rhd_\Sigma \phi, \sigma_\Sigma(\phi, \vec{\chi}) \rhd_\Sigma \sigma'_\Sigma(\phi, \vec{\chi}))$*;*

(4) $G_\Sigma(\boldsymbol{\phi}) = G_\Sigma(\rho^0_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]])$*.*

Proof: Directly by Theorem 1928. ■

26.9 Truth Equationality

By Theorem 1901, the closure system G of a Gentzen π-institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ can be recovered by the class $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$ of its Suszko reduced matrix families. A related issue is to investigate when G can be recovered just from the class of underlying $\mathbf{F}$-algebraic systems of the class $\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$, i.e., from the class $\mathrm{AlgSys}(\mathfrak{G})$. The algebraizability property of $\mathfrak{G}$ gives that

$$\mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G}) = \{\langle \mathcal{A}, \tau^{\mathcal{A}*}(\Delta^{\mathcal{A}}) : \mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})\},$$

where $\tau : \mathfrak{G} \to \mathfrak{G}^{\mathsf{K}}$ is the $\{\langle 1,1 \rangle\}$-tr-transformation witnessing the algebraizability. In this case, the $\mathbf{F}$-algebraic system $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$ is the $\mathbf{F}$-algebraic system reduct of a unique Suszko reduced $\mathfrak{G}$-matrix family, i.e., the $\mathfrak{G}$-filter family of every Suszko reduced $\mathfrak{G}$-matrix family is uniquely determined by the $\mathbf{F}$-algebraic system $\mathcal{A}$, since it is exactly $\tau^{\mathcal{A}*}(\Delta^{\mathcal{A}})$ and this expression does not depend on the choice of τ witnessing the algebraizability of $\mathfrak{G}$.

Even in the absence of algebraizability, however, if each $\mathbf{F}$-algebraic system in $\mathrm{AlgSys}(\mathfrak{G})$ is the $\mathbf{F}$-algebraic system reduct of e unique Suszko reduced $\mathfrak{G}$-matrix family, then, there exists, modulo a technical condition, analogous to the adequacy of the Suszko core introduced in a preceding chapter, a $\{\langle 1,1 \rangle\}$-tr-transformation τ that determines the unique $\mathfrak{G}$-matrix filter on the $\mathbf{F}$-algebraic system, as described previously.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution os trace tr based on $\mathbf{F}$.

- $\mathfrak{G}$ is **completely reflective**, or **c-reflective** for short, if, for all $\boldsymbol{\mathcal{T}} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{ThFam}(\mathfrak{G})$,

$$\bigcap_{\boldsymbol{T} \in \boldsymbol{\mathcal{T}}} \Omega^{\mathcal{A}}(\boldsymbol{T}) \leq \Omega^{\mathcal{A}}(\boldsymbol{T}') \quad \text{implies} \quad \bigcap \boldsymbol{\mathcal{T}} \leq \boldsymbol{T}';$$

- $\mathfrak{G}$ is **truth equational** if there exists $\tau = \{\tau^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$, where $\tau^{\langle m,n\rangle} : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$, with $m+n$ distinguished arguments, such that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$,
$$\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \text{iff} \quad \tau^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

First, we provide a characterization of c-reflectivity.

Theorem 1932 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution os trace* tr *based on* $\mathbf{F}$*. Then, the following statements are equivalent:*

(i) For every $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$*, there exists unique* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*, such that* $\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$*;*

(ii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, and all* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,* $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ *is the least $\mathfrak{G}$-filter family on* $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ *is injective on* $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*;*

(iv) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$ *and all* $\boldsymbol{\mathcal{T}} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,*
$$\bigcap_{\boldsymbol{T}\in\boldsymbol{\mathcal{T}}} \Omega^{\mathcal{A}}(\boldsymbol{T}) \le \Omega^{\mathcal{A}}(\boldsymbol{T}') \quad \textit{implies} \quad \bigcap \boldsymbol{\mathcal{T}} \le \boldsymbol{T}';$$

(v) For all $\boldsymbol{\mathcal{T}} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{ThFam}(\mathfrak{G})$*,* $\bigcap_{\boldsymbol{T}\in\boldsymbol{\mathcal{T}}} \Omega(\boldsymbol{T}) \le \Omega(\boldsymbol{T}')$ *implies* $\bigcap \boldsymbol{\mathcal{T}} \le \boldsymbol{T}'$*.*

Proof:

(i)⇒(ii) Suppose (i) holds and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$. Consider the algebraic system $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ and let $\boldsymbol{T}'$ be the least filter on $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$. Then, since $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}))$, we get that $\boldsymbol{T}' \le \boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$. Thus, by the monotonicity of the Suszko operator,
$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})}(\boldsymbol{T}') \le \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})}(\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})) = \Delta^{\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})}.$$
But, noting that $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) \in \mathrm{AlgSys}(\mathfrak{G})$, we get, by hypothesis, that $\boldsymbol{T}' = \boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$. Therefore, $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ is the least $\mathfrak{G}$-filter family on $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$.

(ii)⇒(iii) Suppose that (ii) holds and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}')$. Then $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ is compatible with both $\boldsymbol{T}$ and $\boldsymbol{T}'$ and, hence, $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ and $\boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ are both $\mathfrak{G}$-filter families on $\mathcal{A}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$. Thus, by hypothesis, $\boldsymbol{T}/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) \le \boldsymbol{T}'/\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$. Therefore, taking into account the compatibility of $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T})$ with both $\boldsymbol{T}$ and $\boldsymbol{T}'$, we get $\boldsymbol{T} \le \boldsymbol{T}'$. By symmetry, we also have $\boldsymbol{T}' \le \boldsymbol{T}$, whence $\boldsymbol{T} = \boldsymbol{T}'$. Thus, $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ is injective on $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$.

(iii)⇒(iv) Suppose (iii) holds and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, such that

$$\bigcap_{\boldsymbol{T} \in \mathcal{T}} \Omega^{\mathcal{A}}(\boldsymbol{T}) \leq \Omega^{\mathcal{A}}(\boldsymbol{T}').$$

Then, we have

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\bigcap \mathcal{T} \cap \boldsymbol{T}') & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{X}) : \mathcal{T} \cap \boldsymbol{T}' \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \\ & = & \bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{X}) : \bigcap \mathcal{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \\ & = & \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\bigcap \mathcal{T}).\end{array}$$

By hypothesis, we get $\bigcap \mathcal{T} \cap \boldsymbol{T}' = \bigcap \mathcal{T}$, whence $\bigcap \mathcal{T} \leq \boldsymbol{T}'$.

(iv)⇒(v) Condition (v) is a special case of Condition (iv).

(v)⇒(i) Assume that (v) holds and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathrm{AlgSys}(\mathfrak{G})$ and $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}') = \Delta^{\mathcal{A}}$. By Lemma 1891, $\alpha^{-1}(\boldsymbol{T})$ and $\alpha^{-1}(\boldsymbol{T}')$ are both theory families of $\mathfrak{G}$. Now we have, by hypothesis, $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}) = \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}(\boldsymbol{T}')$, whence, by the definition of the Suszko operator,

$$\bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{X}) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \leq \Omega^{\mathcal{A}}(\boldsymbol{T}').$$

Hence, applying α^{-1} to both sides,

$$\alpha^{-1}(\bigcap\{\Omega^{\mathcal{A}}(\boldsymbol{X}) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\}) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\boldsymbol{T}')).$$

Equivalently,

$$\bigcap\{\alpha^{-1}(\Omega^{\mathcal{A}}(\boldsymbol{X})) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\boldsymbol{T}')).$$

By Lemma 1909,

$$\bigcap\{\Omega(\alpha^{-1}(\boldsymbol{X})) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \leq \Omega(\alpha^{-1}(\boldsymbol{T}')).$$

By Condition (v),

$$\bigcap\{\alpha^{-1}(\boldsymbol{X}) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\} \leq \alpha^{-1}(\boldsymbol{T}').$$

Hence, $\alpha^{-1}(\boldsymbol{T}) \leq \alpha^{-1}(\boldsymbol{T}')$, which gives, by the surjectivity of $\langle F, \alpha \rangle$, $\boldsymbol{T} \leq \boldsymbol{T}'$. By symmetry, we get that $\boldsymbol{T} = \boldsymbol{T}'$ and, therefore, there exists only one $\mathfrak{G}$-filter family $\boldsymbol{T}$ on $\mathcal{A}$, such that $\langle \mathcal{A}, \boldsymbol{T} \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. ■

It also turns out that a sufficient condition for the c-reflectivity of a Gentzen π-institution $\mathfrak{G}$ is the injectivity of the Suszko operator on all $\mathbf{F}$-algebraic systems in $\mathrm{AlgSys}(\mathfrak{G})$.

Lemma 1933 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If, for all* $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$*,* $\widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}$ *is injective on* $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*, then* $\mathfrak{G}$ *is c-reflective.*

Proof: By the hypothesis, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathfrak{G})$, there exists a unique $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, such that $\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. Therefore, by Theorem 1932, $\mathfrak{G}$ is c-reflective. ∎

Next we provide an alternative characterization of truth equationality, forming an analog of Theorem 818.

Theorem 1934 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is truth equational if and only if, there exists* $\tau = \{\tau^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$*, where* $\tau^{\langle m,n\rangle} : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$*, with* $m+n$ *distinguished arguments, such that, for all* $\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$*,* $\boldsymbol{T} = \tau^{\mathcal{A}*}(\Delta^{\mathcal{A}})$*.*

Proof: Suppose $\mathfrak{G}$ is truth equational, with witnessing transformations $\tau = \{\tau^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$. Let $\langle \mathcal{A}, \boldsymbol{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$. Then we have

$$\begin{array}{lll}
\alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{F(\Sigma)} & \text{iff} & \alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}'_{F(\Sigma)}, \text{ all } \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\\
& \text{iff} & \boldsymbol{\phi} \in \alpha_\Sigma^{-1}(\boldsymbol{T}'_{F(\Sigma)}), \text{ all } \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\\
& \text{iff} & \tau_\Sigma^{\langle m,n\rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\alpha^{-1}(\boldsymbol{T}')), \text{ all } \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\\
& \text{iff} & \tau_\Sigma^{\langle m,n\rangle}[\boldsymbol{\phi}] \subseteq \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(\boldsymbol{T}')), \text{ all } \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\\
& \text{iff} & \alpha_\Sigma(\tau_\Sigma^{\langle m,n\rangle}[\boldsymbol{\phi}]) \subseteq \Omega^{\mathcal{A}}_{F(\Sigma)}(\boldsymbol{T}'), \text{ all } \boldsymbol{T} \le \boldsymbol{T}' \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})\\
& \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A},\langle m,n\rangle}[\alpha_\Sigma(\boldsymbol{\phi})] \subseteq \widetilde{\Omega}^{\mathfrak{G},\mathcal{A}}_{F(\Sigma)}(\boldsymbol{T})\\
& \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A},\langle m,n\rangle}[\alpha_\Sigma(\boldsymbol{\phi})] \subseteq \Delta^{\mathcal{A}}_{F(\Sigma)}.
\end{array}$$

The conclusion follows by taking into account the surjectivity of $\langle F, \alpha\rangle$.

Conversely, assume that the condition in the statement holds and let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$. Then, since

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}/\Omega(\boldsymbol{T})}(\boldsymbol{T}/\Omega(\boldsymbol{T})) \le \Omega^{\mathcal{F}/\Omega(\boldsymbol{T})}(\boldsymbol{T}/\Omega * \boldsymbol{T}) = \Delta^{\mathcal{F}/\Omega(\boldsymbol{T})},$$

we get that $\langle \mathcal{F}/\Omega(\boldsymbol{T}), \boldsymbol{T}/\Omega(\boldsymbol{T})\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. Therefore, by hypothesis,

$$\boldsymbol{\phi}/\Omega_\Sigma(\boldsymbol{T}) \in \boldsymbol{T}_\Sigma/\Omega_\Sigma(\boldsymbol{T}) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(\boldsymbol{T}),\langle m,n\rangle}[\boldsymbol{\phi}/\Omega_\Sigma(\boldsymbol{T})] \subseteq \Delta_\Sigma^{\mathcal{F}/\Omega(\boldsymbol{T})},$$

i.e.,

$$\boldsymbol{\phi}/\Omega_\Sigma(\boldsymbol{T}) \in \boldsymbol{T}_\Sigma/\Omega_\Sigma(\boldsymbol{T}) \quad \text{iff} \quad \tau_\Sigma^{\langle m,n\rangle}[\boldsymbol{\phi}]/\Omega_\Sigma(\boldsymbol{T}) \subseteq \Delta_\Sigma^{\mathcal{F}/\Omega(\boldsymbol{T})}.$$

By the compatibility of $\Omega(\boldsymbol{T})$ with $\boldsymbol{T}$, we now get

$$\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\langle m,n\rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

Therefore, $\mathfrak{G}$ is truth equational. ∎

Before turning into a characterization of the exact relationship between c-reflectivity and truth equationality, we prove that both c-reflectivity and truth equationality are preserved under equivalence of Gentzen π-institutions.

Theorem 1935 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr, tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent, then* $\mathfrak{G}$ *is c-reflective if and only if* $\mathfrak{G}'$ *is also.*

Proof: Suppose that $\mathfrak{G}'$ is c-reflective and let $\boldsymbol{\mathcal{T}} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{ThFam}(\mathfrak{G})$, such that $\bigcap_{\boldsymbol{T} \in \boldsymbol{\mathcal{T}}} \Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Then, by Proposition 1897, $\bigcap_{\boldsymbol{T} \in \boldsymbol{\mathcal{T}}} \Omega(\rho^*(\boldsymbol{T})) \leq \Omega(\rho^*(\boldsymbol{T}'))$. Thus, by Theorem 1880 and the hypothesis, we get $\bigcap_{\boldsymbol{T} \in \boldsymbol{\mathcal{T}}} \rho^*(\boldsymbol{T}) \leq \rho^*(\boldsymbol{T}')$ and, then, $\rho^*(\bigcap \boldsymbol{\mathcal{T}}) \leq \rho^*(\boldsymbol{T}')$. As ρ^* is order reflecting, we conclude that $\bigcap \boldsymbol{\mathcal{T}} \leq \boldsymbol{T}'$ and, therefore, $\mathfrak{G}$ is c-reflective. The converse follows by the symmetry of the notion of equivalence. ∎

Theorem 1936 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr, tr′ *traces and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ *Gentzen π-institutions of traces* tr, tr′*, respectively, based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *and* $\mathfrak{G}'$ *are equivalent, then* $\mathfrak{G}$ *is truth equational if and only if* $\mathfrak{G}'$ *is also.*

Proof: Suppose that $\mathfrak{G}$ and $\mathfrak{G}'$ are equivalent via a conjugate pair $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}'$ and that $\mathfrak{G}'$ is truth equational, with witnessing transformations $\sigma := \{\sigma^{\langle m,m \rangle} : \langle m, n \rangle \in \mathrm{tr}'\}$. Then, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m, n \rangle \in \mathrm{tr}$, we get, setting, according to Theorem 1880, $\boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G}')$ be such that $\boldsymbol{T} \underset{\tau^*}{\overset{\rho^*}{\rightleftarrows}} \boldsymbol{T}'$,

$$\begin{array}{rll}
\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma & \text{iff} & \boldsymbol{\phi} \in \tau^*_\Sigma(\boldsymbol{T}') \quad \text{(definition of } \boldsymbol{T}'\text{)} \\
& \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq \boldsymbol{T}'_\Sigma \quad \text{(definition of } \tau^*\text{)} \\
& \text{iff} & \sigma_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \Omega_\Sigma(\boldsymbol{T}') \quad \text{(hypothesis)} \\
& \text{iff} & \sigma_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \Omega_\Sigma(\rho^*(\boldsymbol{T})) \quad \text{(definition of } \boldsymbol{T}^*\text{)} \\
& \text{iff} & \sigma_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \Omega_\Sigma(\boldsymbol{T}). \quad \text{(Proposition 1897)}
\end{array}$$

Therefore, $\sigma \circ \tau$ witnesses the truth equationality of $\mathfrak{G}$. The converse follows by the symmetry of equivalence. ∎

We now turn to the investigation of the exact relationship between complete reflectivity and truth equationality. We will show that for a Gentzen π-institution to be truth equational, it must be c-reflective and, in addition satisfy a technical condition analogous to the adequacy of the Suszko core in the context of π-institutions, that ensures that there are enough natural transformations in its category of natural transformations to specify the Suszko operator in a precise sense.

We start by showing that truth equationality implies c-reflectivity.

Proposition 1937 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *if* $\mathfrak{G}$ *is truth equational, then it is c-reflective.*

Proof: Suppose $\mathfrak{G}$ is truth equational, with witnessing transformations $\tau = \{\tau^{\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$, and let $\mathcal{T} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{ThFam}(\mathfrak{G})$, such that $\bigcap_{\boldsymbol{T}\in\mathcal{T}} \Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$, we have

$$\begin{array}{rcl} \boldsymbol{\phi} \in \bigcap_{\boldsymbol{T}\in\mathcal{T}} \boldsymbol{T}_\Sigma & \text{iff} & \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma,\ \boldsymbol{T} \in \mathcal{T}, \\ & \text{iff} & \tau^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}),\ \boldsymbol{T} \in \mathcal{T}, \\ & \text{iff} & \tau^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \bigcap_{\boldsymbol{T}\in\mathcal{T}} \Omega_\Sigma(\boldsymbol{T}) \\ & \text{implies} & \tau^{\langle m,n\rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}') \\ & \text{iff} & \boldsymbol{\phi} \in \boldsymbol{T}'_\Sigma. \end{array}$$

Thus, $\bigcap \mathcal{T} \leq \boldsymbol{T}'$ and, hence, $\mathfrak{G}$ is c-reflective. ∎

The property of c-reflectivity also has a characterization involving both the Suszko and the Leibniz operator. Namely, we obtain

Lemma 1938 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is c-reflective if and only if, for all* $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$,

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}') \quad \textit{implies} \quad \boldsymbol{T} \leq \boldsymbol{T}'.$$

Proof: Suppose, first, that $\mathfrak{G}$ is c-reflective and let $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$, such that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Then, we get

$$\bigcap\{\Omega(\boldsymbol{X}) : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{ThFam}(\mathfrak{G})\} \leq \Omega(\boldsymbol{T}').$$

Hence, by hypothesis, $\bigcap\{\boldsymbol{X} : \boldsymbol{T} \leq \boldsymbol{X} \in \mathrm{ThFam}(\mathfrak{G})\} \leq \boldsymbol{T}'$, i.e., $\boldsymbol{T} \leq \boldsymbol{T}'$.

Assume, conversely, that the condition of the statement holds and let $\mathcal{T} \cup \{\boldsymbol{T}'\} \subseteq \mathrm{ThFam}(\mathfrak{G})$, such that $\bigcap_{\boldsymbol{T}\in\mathcal{T}} \Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$. Then we get

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\bigcap \mathcal{T}) \leq \bigcap\{\Omega(\boldsymbol{T}) : \boldsymbol{T} \in \mathcal{T}\} \leq \Omega(\boldsymbol{T}').$$

Thus, by hypothesis, $\bigcap \mathcal{T} \leq \boldsymbol{T}'$ and $\mathfrak{G}$ is c-reflective. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G\rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. Define the **Suszko core**

$$S^{\mathfrak{G}} = \{S^{\mathfrak{G},\langle m,n\rangle} : \langle m,n\rangle \in \mathrm{tr}\}$$

of $\mathfrak{G}$, by setting, for all $\langle m,n\rangle \in \mathrm{tr}$,

$$\begin{array}{rl} S^{\mathfrak{G},\langle m,n\rangle} = \{\sigma : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2 \in N^\flat : & \\ & (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \boldsymbol{\phi} \in \mathrm{Seq}^{\{\langle m,n\rangle\}}_\Sigma(\mathbf{F})) \\ & \qquad (\sigma_\Sigma[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(G(\boldsymbol{\phi})))\}. \end{array}$$

$S^{\mathfrak{G}}$ is a set of natural candidates from which to seek witnesses for the truth equationality of $\mathfrak{G}$, if such exist, since it satisfies the following property.

Lemma 1939 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is truth equational, with witnessing transformations* τ*, then* $\tau \subseteq S^{\mathfrak{G}}$*.*

Proof: Suppose $\mathfrak{G}$ is truth equational, with witnessing transformations $\tau = \{\tau^{\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\}$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle$, we have $\boldsymbol{\phi} \in G_\Sigma(\boldsymbol{\phi})$, whence, $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$, for all $G(\boldsymbol{\phi}) \leq \boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$. Thus, by truth equationality, $\tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})$ and, therefore, $\tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}_\Sigma^{\mathfrak{G},\mathcal{F}}(G(\boldsymbol{\phi}))$. We conclude that $\tau^{\langle m,n \rangle} \subseteq S^{\mathfrak{G},\langle m,n \rangle}$. ■

The Suszko core of $\mathfrak{G}$ always carries a theory family $\boldsymbol{T}$ of $\mathfrak{G}$ into the Leibniz congruence system $\Omega(\boldsymbol{T})$ of the theory family $\boldsymbol{T}$.

Proposition 1940 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. For all* $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ *of trace* $\langle m,n \rangle \in \mathrm{tr}$*,*

$$S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

Proof: Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$ of trace $\langle m,n \rangle \in \mathrm{tr}$. Then, by the definition of $S^{\mathfrak{G}}$, we get

$$S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}_\Sigma^{\mathfrak{G},\mathcal{F}}(G(\boldsymbol{\phi})) \subseteq \widetilde{\Omega}_\Sigma^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

This establishes the conclusion. ■

The converse property, which does not always hold, is called *solubility of the Suszko core.*

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. $S^{\mathfrak{G}}$ is **soluble** if, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle \in \mathrm{tr}$, we get

$$S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}) \quad \text{implies} \quad \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma.$$

Truth equationality of a Gentzen π-institution guarantees the solubility of its Suszko core.

Theorem 1941 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is truth equational, then the Suszko core* $S^{\mathfrak{G}}$ *is soluble.*

Proof: Suppose that $\mathfrak{G}$ is truth equational, with witnessing transformations τ, and let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle$, such that $S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})$. Then, by Lemma 1939, $\tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})$. By truth equationality, $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Therefore, $S^{\mathfrak{G}}$ is indeed soluble. ■

Conversely, if the Suszko core of a given Gentzen π-institution $\mathfrak{G}$ is soluble, then it acts as a set of witnessing transformations for the truth equationality of $\mathfrak{G}$.

Theorem 1942 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. *If* $S^{\mathfrak{G}}$ *is soluble, then* $\mathfrak{G}$ *is truth equational, with witnessing transformations* $S^{\mathfrak{G}}$.

Proof: We must show that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m, n \rangle$,

$$\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \text{iff} \quad S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

The left to right implication is by Proposition 1940, whereas the reverse is by the hypothesis of the solubility of the Suszko core. ∎

Theorems 1941 and 1942 allow two characterizations of truth equationality in terms of the solubility of the Suszko core and in terms of the definability of theory families by the Suszko core.

$$\mathfrak{G} \text{ is Truth Equational} \longleftrightarrow S^{\mathfrak{G}} \text{ is Soluble.}$$

Theorem 1943 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is truth equational if and only if its Suszko core* $S^{\mathfrak{G}}$ *is soluble.*

Proof: The "only if" by Theorem 1941. The "if" by Theorem 1942. ∎

We say that $S^{\mathfrak{G}}$ **defines theory families** if, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$,

$$\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \text{iff} \quad S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

Then we can show

$$\mathfrak{G} \text{ is Truth Equational} \longleftrightarrow S^{\mathfrak{G}} \text{ Defines Theory Families.}$$

Theorem 1944 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is truth equational if and only if* $S^{\mathfrak{G}}$ *defines theory families.*

Proof: If $\mathfrak{G}$ is truth equational, then, by Theorem 1943, $S^{\mathfrak{G}}$ is soluble, whence it defines theory families. On the other hand, if $S^{\mathfrak{G}}$ defines theory families, then it is soluble and, hence, by Theorem 1943, $\mathfrak{G}$ is truth equational. ∎

We now know that truth equationality of a Gentzen π-institution is equivalent to the solubility property of its Suszko core. The solubility property implies another property, which, in accordance with our previous work on π-institutions, we call adequacy. It says, roughly speaking, that in a Gentzen π-institution the category of natural transformations is rich enough to determine Suszko congruence systems in terms of the Leibniz congruence systems that it selects by inclusion. This property arises in a natural way by considering the following result relating the Suszko core with both Suszko and Leibniz congruence systems of theory families generated by single sequents.

Proposition 1945 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ *of trace* $\langle m, n \rangle$*,*

$$\bigcap \{\Omega(\boldsymbol{T}) : S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})\} \leq \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(G(\boldsymbol{\phi})).$$

Proof: Note that, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m, n \rangle$, we have

$$\begin{array}{lll} \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma & \Rightarrow & S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T}) \quad \text{(Suszko core)} \\ & \Rightarrow & S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}). \quad (\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T})) \end{array}$$

Therefore, we get

$$\begin{array}{lll} \bigcap\{\Omega(\boldsymbol{T}) : S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})\} & \leq & \bigcap\{\Omega(\boldsymbol{T}) : S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(\boldsymbol{T})\} \\ & \leq & \bigcap\{\Omega(\boldsymbol{T}) : \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma\} \\ & = & \widetilde{\Omega}(G(\boldsymbol{\phi})). \end{array}$$

Thus, the displayed inclusion always holds. ∎

The reverse inclusion is not always guaranteed, but, when it holds, we say that the Suszko core of $\mathfrak{G}$ is adequate. As the name suggests, the property somehow conveys the idea that $S^{\mathfrak{G}}[\boldsymbol{\phi}]$ suffices to determine the theory families whose Leibniz congruence systems form a covering of the Suszko congruence system corresponding to the theory family $G(\boldsymbol{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. The Suszko core $S^{\mathfrak{G}}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m, n \rangle$,

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}_\Sigma(G(\boldsymbol{\phi})) \leq \bigcap\{\Omega(\boldsymbol{T}) : S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})\}.$$

We can prove immediately that solubility implies adequacy.

Proposition 1946 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If the Suszko core* $S^{\mathfrak{G}}$ *is soluble, then it is adequate.*

Proof: Suppose $S^{\mathfrak{G}}$ is soluble. We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m, n \rangle$,

$$\begin{array}{lll} \widetilde{\Omega}^{\mathfrak{G},\mathcal{F}}(G(\boldsymbol{\phi})) & = & \bigcap\{\Omega(\boldsymbol{T}) : \boldsymbol{\phi} \in \boldsymbol{T}_\Sigma\} \\ & & \text{(Suszko congrunece system)} \\ & = & \bigcap\{\Omega(\boldsymbol{T}) : S^{\mathfrak{G},\langle m,n \rangle}_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})\}. \\ & & \text{(solubility of } S^{\mathfrak{G}}) \end{array}$$

Hence, the Suszko core of $\mathfrak{G}$ is adequate. ∎

Conversely, if a Gentzen π-institution is c-reflective, then the adequacy of its Suszko core is sufficient to give its solubility.

Proposition 1947 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is c-reflective and the Suszko core* $S^{\mathfrak{G}}$ *is adequate, then* $S^{\mathfrak{G}}$ *is soluble.*

Proof: Assume $\mathfrak{G}$ is c-reflective and $S^{\mathfrak{G}}$ is adequate. Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m, n \rangle$.

If $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$, then, by the definition of the Suszko core, we get

$$S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \widetilde{\Omega}_\Sigma^{\mathfrak{G},\mathcal{F}}(G(\boldsymbol{\phi})) \subseteq \widetilde{\Omega}_\Sigma^{\mathfrak{G},\mathcal{F}}(\boldsymbol{T}) \subseteq \Omega_\Sigma(\boldsymbol{T}).$$

Assume conversely, that $S_\Sigma^{\mathfrak{G},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})$. Then, by adequacy of the Suszko core, $\widetilde{\Omega}^{\mathfrak{G},\mathfrak{F}}(G(\boldsymbol{\phi})) \leq \Omega(\boldsymbol{T})$. Hence, by c-reflectivity and Lemma 1938, $G(\boldsymbol{\phi}) \leq \boldsymbol{T}$, i.e., $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. We conclude that $S^{\mathfrak{G}}$ is soluble. ■

We finally show that a Gentzen π-institution is truth equational if and only if it is c-reflective and has an adequate Suszko core.

Truth Equationality	=	$S^{\mathfrak{G}}$ Soluble
	=	$S^{\mathfrak{G}}$ Defines Theory Families
	=	c-Reflectivity + $S^{\mathfrak{G}}$ Adequate

Theorem 1948 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is truth equational if and only if it is c-reflective and has an adequate Suszko core.*

Proof: If $\mathfrak{G}$ is truth equational, then, by Proposition 1937, it is c-reflective, by Theorem 1941, its Suszko core is soluble and, by Proposition 1946, its Suszko core is adequate. On the other hand, if $\mathfrak{G}$ is c-reflective with an adequate Suszko core, then, by Proposition 1947, its Suszko core is soluble and, hence, by Theorem 1942, $\mathfrak{G}$ is truth equational. ■

We also obtain immediately

Corollary 1949 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a protoalgebraic Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*.* $\mathfrak{G}$ *is truth equational if and only if its Leibniz operator is injective on theory families and has an adequate Suszko core.*

Proof: If $\mathfrak{G}$ is truth equational, then, by Theorem 1948, it is c-reflective and has an adequate Suszko core, whence, it has, a fortiori, a Leibniz operator injective on theory families and an adequate Suszko core.

Conversely, by Theorem 1948, it suffices to show that monotonicity and injectivity of the Leibniz operator imply its c-reflectivity. In fact, given $\boldsymbol{T}, \boldsymbol{T}' \in \mathrm{ThFam}(\mathfrak{G})$, we have

$$\begin{array}{rcl}
\widetilde{\Omega}^{\mathfrak{G},\mathcal{G}}(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}') & \Rightarrow & \Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}') \quad \text{(Protoalgebraicity)} \\
& \Rightarrow & \Omega(\boldsymbol{T} \cap \boldsymbol{T}') = \Omega(\boldsymbol{T}) \cap \Omega(\boldsymbol{T}') = \Omega(\boldsymbol{T}) \\
& & \text{(Protoalgebraicity)} \\
& \Rightarrow & \boldsymbol{T} \cap \boldsymbol{T}' = \boldsymbol{T} \quad \text{(Injectivity)} \\
& \Rightarrow & \boldsymbol{T} \leq \boldsymbol{T}'.
\end{array}$$

Thus, $\mathfrak{G}$ is c-reflective, by Lemma 1938. ■

We close the section by a result asserting that truth equationality transfers from a Gentzen π-institution $\mathfrak{G}$ to all $\mathfrak{G}$-matrix families.

Theorem 1950 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is truth equational, with witnessing transformations* $\tau = \{\tau^{\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, and all* $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$*,* $\Sigma \in |\mathbf{Sign}|$ *and* $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathcal{A})$ *of trace* $\langle m,n \rangle$*,*

$$\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma \quad \textit{iff} \quad \tau_\Sigma^{\mathcal{A},\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma^{\mathcal{A}}(\boldsymbol{T}).$$

Proof: Suppose $\mathfrak{G}$ is truth equational, with witnessing transformations $\tau = \{\tau^{\langle m,n \rangle} : \langle m,n \rangle \in \mathrm{tr}\}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$ of trace $\langle m,n \rangle$. Then, we have

$$\begin{array}{rll} \alpha_\Sigma(\boldsymbol{\phi}) \in \boldsymbol{T}_{F(\Sigma)} & \text{iff} & \boldsymbol{\phi} \in \alpha_\Sigma^{-1}(\boldsymbol{T}_{F(\Sigma)}) \\ & \text{iff} & \tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\alpha^{-1}(\boldsymbol{T})) \\ & \text{iff} & \tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}] \subseteq \alpha_\Sigma^{-1}(\Omega_{F(\Sigma)}^{\mathcal{A}}(\boldsymbol{T})) \\ & \text{iff} & \alpha_\Sigma(\tau_\Sigma^{\langle m,n \rangle}[\boldsymbol{\phi}]) \subseteq \Omega_{F(\Sigma)}^{\mathcal{A}}(\boldsymbol{T}) \\ & \text{iff} & \tau_{F(\Sigma)}^{\mathcal{A},\langle m,n \rangle}[\alpha_\Sigma(\boldsymbol{\phi})] \subseteq \Omega_{F(\Sigma)}^{\mathcal{A}}(\boldsymbol{T}). \end{array}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we have the conclusion. ■

26.10 Weak Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, tr a trace and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π-institution of trace tr based on $\mathbf{F}$. $\mathfrak{G}$ is called **WF algebraizable** if it is protoalgebraic and c-reflective.

Proposition 1951 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen π-institution of trace* tr *based on* $\mathbf{F}$. $\mathfrak{G}$ *is WF algebraizable if and only if the Leibniz operator is monotone and injective on* $\mathrm{ThFam}(\mathfrak{G})$.

Proof: It suffices to show that, under monotonicity, c-reflectivity and injectivity are equivalent properties. Indeed, c-reflectivity always implies injectivity because it implies order reflectivity. On the other hand, suppose that the Leibniz operator is monotone and injective. Then, we have, by monotonicity, for all $\mathcal{T} \cup \{\boldsymbol{T}\} \subseteq \mathrm{ThFam}(\mathfrak{G})$, such that $\bigcap_{\boldsymbol{T} \in \mathcal{T}} \Omega(\boldsymbol{T}) \leq \Omega(\boldsymbol{T}')$,

$$\Omega(\bigcap \mathcal{T} \cap \boldsymbol{T}') = \bigcap_{\boldsymbol{T} \in \mathcal{T}} \Omega(\boldsymbol{T}) \cap \Omega(\boldsymbol{T}') = \bigcap_{\boldsymbol{T} \in \mathcal{T}} \Omega(\boldsymbol{T}) = \Omega(\bigcap \mathcal{T}).$$

Thus, by injectivity, $\bigcap \mathcal{T} \cap \boldsymbol{T}' = \bigcap \mathcal{T}$ and, hence, $\bigcap \mathcal{T} \leq \boldsymbol{T}'$. Therefore $\mathfrak{G}$ is also c-reflective. ■

The following theorem provides characterations of WF algebraizability.

Theorem 1952 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. Then the following statements are equivalent:*

(i) $\mathfrak{G}$ *is WF algebraizable;*

(ii) The Leibniz operator defines an order isomorphism from $\mathbf{ThFam}(\mathfrak{G})$ *onto the lattice of all* $\mathrm{AlgSys}(\mathfrak{G})$*-congruence families on* $\mathcal{F}$*;*

(iii) For every $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the Leibniz operator defines an order isomorphism from* $\mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A})$ *onto the lattice of all* $\mathrm{AlgSys}(\mathfrak{G})$*-congruence systems on* $\mathcal{A}$*;*

(iv) For every $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathrm{AlgSys}(\mathfrak{G})$*, the Leibniz operator defines an order isomorphism from* $\mathrm{FiFam}^{\mathfrak{G}}(\mathcal{A})$ *onto the lattice of all* $\mathrm{AlgSys}(\mathfrak{G})$*-congruence systems on* $\mathcal{A}$*.*

Proof:

(i)⇒(ii) Suppose $\mathfrak{G}$ is WF algebraizable. Denote $\mathrm{ConSys}(\mathfrak{G})$ the collection of all $\mathrm{AlgSys}(\mathfrak{G})$-congruences on $\mathcal{F}$. Then, since, for all $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$,

$$\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}/\Omega(\boldsymbol{T})}(\boldsymbol{T}/\Omega(\boldsymbol{T})) \le \Omega^{\mathcal{F}/\Omega(\boldsymbol{T})}(\boldsymbol{T}/\Omega(\boldsymbol{T})) = \Delta^{\mathcal{F}/\Omega(\boldsymbol{T})},$$

we get that $\langle \mathcal{F}/\Omega(\boldsymbol{T}), \boldsymbol{T}/\Omega(\boldsymbol{T}) \rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathfrak{G})$. Thus, $\mathcal{F}/\Omega(\boldsymbol{T}) \in \mathrm{AlgSys}(\mathfrak{G})$ and, therefore, $\Omega(\boldsymbol{T}) \in \mathrm{ConSys}(\mathfrak{G})$. This shows that $\Omega : \mathrm{ThFam}(\mathfrak{G}) \to \mathrm{ConSys}(\mathfrak{G})$ is well defined. By Proposition 1951, it is injective. To see that it is surjective, consider $\theta \in \mathrm{ConSys}(\mathfrak{G})$. Then, by definition, $\mathcal{F}/\theta \in \mathrm{AlgSys}(\mathfrak{G})$, i.e., there exists $\boldsymbol{T} \in \mathrm{FiFam}^{\mathfrak{G}}(\mathcal{F}/\theta)$, such that $\widetilde{\Omega}^{\mathfrak{G},\mathcal{F}/\theta}(\boldsymbol{T}) = \Delta^{\mathcal{F}/\theta}$. However, since the Leibniz operator is monotone, by hypothesis, we get that the Susko operator coincides with the Leibniz operator, whence $\Omega^{\mathcal{F}/\theta}(\boldsymbol{T}) = \Delta^{\mathcal{F}/\theta}$. Denoting by $\langle I, \pi \rangle : \mathcal{F} \to \mathcal{F}/\theta$ the quotient morphism, we now get

$$\Omega(\pi^{-1}(\boldsymbol{T})) = \pi^{-1}(\Omega^{\mathcal{F}/\theta}(\boldsymbol{T})) = \pi^{-1}(\Delta^{\mathcal{F}/\theta}) = \theta.$$

Thus, Ω is indeed surjective. It is monotone by hypothesis and it is order reflecting, since it is c-reflective. Thus, $\Omega : \mathbf{ThFam}(\mathfrak{G}) \to \mathbf{ConSys}(\mathfrak{G})$ is in fact an order isomorphism.

(ii)⇒(iii) It is not difficult to show that $\Omega^{\mathcal{A}}$ is also monotone and c-reflective. Therefore, one can work in the same way as in Part (ii) replacing the mapping Ω by $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathfrak{G}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathfrak{G}}(\mathcal{A})$, where $\mathrm{ConSys}^{\mathfrak{G}}(\mathcal{A})$ denotes the collection of $\mathrm{AlgSys}(\mathfrak{G})$-congruence systems on $\mathcal{A}$.

(iii)⇒(iv) Condition (iv) is a special case of Condition (iii).

(iv)⇒(i) If Condition (iv) holds, the $\mathfrak{G}$ is protoalgebraic, by Lemma 1911. Hence the Leibniz and Suszko operators coincide on the $\mathfrak{G}$-filter families of all $\mathbf{F}$-algebraic systems. Thus, by Theorem 1932, $\mathfrak{G}$ is also truth equational. Therefore, it is WF algebraizable.

■

Finally, based on results of preceding sections, we can also give a relation between algebraizability and WF algebraizability.

We show, first, that, if $\mathfrak{G}$ is algebraizable, then it is both syntactically protoalgebraic and truth equational.

We start by giving a modus ponens property in the case of algebraizability.

Lemma 1953 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. *If* $\mathfrak{G}$ *is algebraizable via the conjugate pair* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\boldsymbol{\phi}, \boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ *of trace* $\langle m, n \rangle$,

$$\boldsymbol{\psi} \in G_\Sigma(\{\boldsymbol{\phi}\} \cup \bigcup_{i < m+n} \rho_\Sigma[\phi_i, \psi_i]).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\boldsymbol{\phi}, \boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m, n \rangle$,

$$\tau_\Sigma[\boldsymbol{\psi}] \subseteq G^{\mathsf{K}}_\Sigma(\tau_\Sigma[\boldsymbol{\phi}] \cup \{\phi_i \rhd_\Sigma \psi_i : i < m+n\}).$$

Thus, we get

$$\rho_\Sigma[\tau_\Sigma[\boldsymbol{\psi}]] \subseteq G_\Sigma(\rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \cup \bigcup_{i < m+n} \rho_\Sigma[\phi_i, \psi_i]).$$

Therefore, $\boldsymbol{\psi} \in G_\Sigma(\{\boldsymbol{\phi}\} \cup \bigcup_{i<m+n} \rho_\Sigma[\phi_i, \psi_i])$. ■

Moreover, in case of algebraizability, the isomorphism ρ^* from the theory families of the Gentzen π-institution $\mathfrak{G}$ to the K-congruence systems on $\mathcal{F}$ coincides with the Leibniz operator Ω.

Proposition 1954 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$. *If* $\mathfrak{G}$ *is algebraizable via the conjugate pair* $(\tau, \rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$,

$$\rho^*(\boldsymbol{T}) = \Omega(\boldsymbol{T}).$$

Proof: Let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

If $\langle \phi, \psi \rangle \in \Omega_\Sigma(\boldsymbol{T})$, then, since $\Omega(\boldsymbol{T})$ is a congruence system, we get, for all $\sigma \in \rho$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \sigma_\Sigma(\phi, \phi, \vec{\chi}), \sigma_\Sigma(\phi, \psi, \vec{\chi}) \rangle \in \Omega_\Sigma(\boldsymbol{T}).$$

But $\sigma_\Sigma(\phi,\phi,\vec{\chi}) \in \mathrm{Thm}_\Sigma(\mathfrak{G}) \subseteq \boldsymbol{T}_\Sigma$. Therefore, by the compatibility of $\Omega(\boldsymbol{T})$ with $\boldsymbol{T}$, we get that $\sigma_\Sigma(\phi,\psi,\vec{\chi}) \in \boldsymbol{T}_\Sigma$. Therefore, $\rho_\Sigma[\phi,\psi] \subseteq \boldsymbol{T}_\Sigma$, which gives that $\langle\phi,\psi\rangle \in \rho^*_\Sigma(\boldsymbol{T})$.

Conversely, to see that $\rho^*(\boldsymbol{T}) \le \Omega(\boldsymbol{T})$ it suffices, by the maximality property of $\Omega(\boldsymbol{T})$, to show that $\rho^*(\boldsymbol{T})$ is compatible with $\boldsymbol{T}$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi},\boldsymbol{\psi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$, such that $\langle\boldsymbol{\phi},\boldsymbol{\psi}\rangle \in \rho^*_\Sigma(\boldsymbol{T})$ and $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$. Then, we have $\rho_\Sigma[\phi_i,\psi_i] \subseteq \boldsymbol{T}_\Sigma$, for all $i < m+n$, and $\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma$, whence, by Lemma 1953, $\boldsymbol{\psi} \in \boldsymbol{T}_\Sigma$. We conclude that $\rho^*(\boldsymbol{T})$ is compatible with $\boldsymbol{T}$, giving $\rho^*(\boldsymbol{T}) \le \Omega(\boldsymbol{T})$. ■

Now, we prove one of the main theorems of the section to the effect that algebraizability implies both syntactic protoalgebraicity and truth equationality.

Theorem 1955 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle\mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is algebraizable via the conjugate pair* $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then,* $\mathfrak{G}$ *is syntactically protoalgebraic and truth equational.*

Proof: Suppose $\mathfrak{G}$ is algebraizable via the conjugate pair $(\tau,\rho) : \mathfrak{G} \rightleftarrows \mathfrak{G}^{\mathsf{K}}$, for some class K of $\mathbf{F}$-algebraic systems.

Let, first, $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{llll}\langle\phi,\psi\rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & \langle\phi,\psi\rangle \in \rho^*_\Sigma(\boldsymbol{T}) & \text{(Proposition 1954)}\\ & \text{iff} & \rho_\Sigma[\phi,\psi] \subseteq \boldsymbol{T}_\Sigma. & \text{(definition of } \rho^*)\end{array}$$

Therefore, $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations ρ.

Finally, let $\boldsymbol{T} \in \mathrm{ThFam}(\mathfrak{G})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\boldsymbol{\phi} \in \mathrm{Seq}^{\mathrm{tr}}_\Sigma(\mathbf{F})$ of trace $\langle m,n\rangle$. Then, we have

$$\begin{array}{llll}\boldsymbol{\phi} \in \boldsymbol{T}_\Sigma & \text{iff} & \rho_\Sigma[\tau_\Sigma[\boldsymbol{\phi}]] \subseteq \boldsymbol{T}_\Sigma & ((\tau,\rho) \text{ conjugate pair})\\ & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq \rho^*_\Sigma(\boldsymbol{T}) & \text{(definition of } \rho^*)\\ & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq \Omega_\Sigma(\boldsymbol{T}). & \text{((Proposition 1954))}\end{array}$$

Therefore, $\mathfrak{G}$ is truth equational, with witnessing transformations τ. ■

We show, next, that, conversely, syntactic protoalgebraicity and truth equationality guarantee algebraizability.

Theorem 1956 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle\mathbf{F}, G\rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. If* $\mathfrak{G}$ *is syntactically protoalgebraic and truth equational, then it is algebraizable.*

Proof: Suppose that $\mathfrak{G}$ is syntactically protoalgebraic, with witnessing transformations ρ, and truth equational, with witnessing transformations τ. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\mathbf{\Phi} \cup \{\boldsymbol{\phi}\} \subseteq \mathrm{Seq}_\Sigma^{\mathrm{tr}}(\mathbf{F})$,

$$\begin{array}{lll} \boldsymbol{\phi} \in G_\Sigma(\mathbf{\Phi}) & \text{iff} & \boldsymbol{\phi} \in \bigcap\{\boldsymbol{T}_\Sigma : \mathbf{\Phi} \subseteq \boldsymbol{T}_\Sigma\} \\ & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq \bigcap\{\Omega_\Sigma(\boldsymbol{T}) : \tau_\Sigma[\mathbf{\Phi}] \subseteq \Omega_\Sigma(\boldsymbol{T})\} \\ & \text{iff} & \tau_\Sigma[\boldsymbol{\phi}] \subseteq G_\Sigma^{\mathsf{K}}(\tau_\Sigma[\mathbf{\Phi}]). \end{array}$$

Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{lll} \langle \phi, \psi \rangle \in \Omega_\Sigma(\boldsymbol{T}) & \text{iff} & \rho_\Sigma[\phi, \psi] \subseteq \boldsymbol{T}_\Sigma \\ & \text{iff} & \tau_\Sigma[\rho_\Sigma[\phi, \psi]] \subseteq \Omega_\Sigma(\boldsymbol{T}). \end{array}$$

Hence, we have that $G_\Sigma^{\mathsf{K}}(\phi \rhd_\Sigma \psi) = G_\Sigma^{\mathsf{K}}(\tau_\Sigma[\rho_\Sigma[\phi, \psi]])$.

We conclude, by Lemma 1879, that $\mathfrak{G}$ is equivalent to $\mathfrak{G}^{\mathsf{K}}$ and, therefore, $\mathfrak{G}$ is algebraizable. ■

Now we can formulate the main characterization theorem:

Theorem 1957 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* tr *a trace and* $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ *a Gentzen* π*-institution of trace* tr *based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathfrak{G}$ *is algebraizable;*

(ii) $\mathfrak{G}$ *is syntactically protoalgebraic and truth equational;*

(iii) $\mathfrak{G}$ *is WF algebraizable (i.e., protoalgebraic and c-reflective) and has both a Leibniz reflexive core and an adequate Suszko core.*

Proof: If $\mathfrak{G}$ is algebraizable, then, by Theorem 1955, it is syntactically protoalgebraic and truth equational. If $\mathfrak{G}$ is syntactically protoalgebraic and truth equational, then, by Theorems 1924 and 1948, it is protoalgebraic, c-reflective and has both a Leibniz reflexive core and an adequate Suszko core. Finally, if $\mathfrak{G}$ is WF algebraizable, with a Leibniz reflexive core and an adequate Suszko core, then, by Theorems 1924 and 1948, it is syntactically protoalgebraic and truth equational, whence, by Theorem 1956, it is algebraizable. ■

Chapter 27

Behavioral Algebraizability

27.1 Behavioral π-Institutions

Let **Sign** be an arbitrary category of **signatures**, S a nonempty set of **sorts** and, for each $s \in S$,

$$\mathrm{SEN}_s : \mathbf{Sign} \to \mathbf{Set}$$

a functor giving, for each signature Σ, a set of Σ-sentences **of sort** s. By a **multi-sorted sentence functor over set of sorts** S we understand the collection

$$\{\mathrm{SEN}_s : s \in S\},$$

where all sets $\mathrm{SEN}_s(\Sigma)$, $s \in S$, are assumed to be disjoint, i.e.,

$$\mathrm{SEN}_s(\Sigma) \cap \mathrm{SEN}_{s'}(\Sigma) = \varnothing, \text{ for all } s, s' \in S, s \neq s'.$$

Because of this condition, given $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\Phi \subseteq \bigcup_{s \in S} \mathrm{SEN}_s(\Sigma)$, we write

$$\mathrm{SEN}(f)(\Phi) = \bigcup_{s \in S} \{\mathrm{SEN}_s(f)(\phi) : \phi \in \Phi \text{ of sort } s\}.$$

A multi-sorted sentence functor over set of sorts S is called **behavioral** if a nonempty subset $V \subseteq S$ of **formula sorts** has been singled out and, moreover, there exists a companion subset $V^* = \{v^* : v \in V\}$ of **visible sorts**. In that case the (perhaps empty) set $H = S - (V \cup V^*)$ is called the set of **hidden sorts**. To denote a behavioral functor, making the set of visible and set of hidden sorts explicit, we write

$$\{\mathrm{SEN}_v, \mathrm{SEN}_{v^*}, \mathrm{SEN}_h : v \in V, h \in H\},$$

or sometimes, for the sake of succinctness,

$$\{\mathrm{SEN}_s\}_H^{V,V^*}.$$

Let **Sign** be a category and $\{\mathrm{SEN}_s\}_{s \in S}$ a multi-sorted sentence functor. The **clone of all natural transformations** on $\{\mathrm{SEN}_s\}_{s \in S}$ is the locally small category with:

- objects $\prod_{\kappa < \alpha} \mathrm{SEN}_{s_\kappa}$, with $s_\kappa \in S$, α an ordinal;
- morphisms $\tau : \prod_{\kappa < \alpha} \mathrm{SEN}_{s_\kappa} \to \prod_{\lambda < \beta} \mathrm{SEN}_{s'_\lambda}$ are β-sequences of natural transformations

$$\tau_\lambda : \prod_{\kappa < \alpha} \mathrm{SEN}_{s_\kappa} \to \mathrm{SEN}_{s'_\lambda}, \ \lambda < \beta.$$

Composition is defined as ordinary composition, i.e., by setting

$$\prod_{\kappa < \alpha} \mathrm{SEN}_{s_\kappa} \xrightarrow{\langle \tau_\lambda : \lambda < \beta \rangle} \prod_{\lambda < \beta} \mathrm{SEN}_{s'_\lambda} \xrightarrow{\langle \sigma_\mu : \mu < \gamma \rangle} \prod_{\mu < \gamma} \mathrm{SEN}_{s''_\mu}$$

$$\langle \sigma_\mu : \mu < \gamma \rangle \circ \langle \tau_\lambda : \lambda < \beta \rangle = \langle \sigma_\mu(\langle \tau_\lambda : \lambda < \beta \rangle) : \mu < \gamma \rangle.$$

A subcategory N of the clone of all natural transformations on $\{\mathrm{SEN}_s\}_{s\in S}$, with objects all objects of the form $\prod_{i=1}^k \mathrm{SEN}_{s_i}$, $k < \omega$, is called a **category of natural transformations on** $\{\mathrm{SEN}_s\}_{s\in S}$ if the following conditions hold:

- It contains all natural projections

$$p^{s_1\cdots s_k \to s_i} : \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_{s_i}, i < k, k < \omega.$$

- For every collection $\{\tau_i : \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_{s'_i} : i < \ell\}$ of ℓ natural transformations in N, the tuple

$$\langle \tau_i : i < \ell \rangle : \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \prod_{j=1}^\ell \mathrm{SEN}_{s'_j}$$

  is also a natural transformation in N.

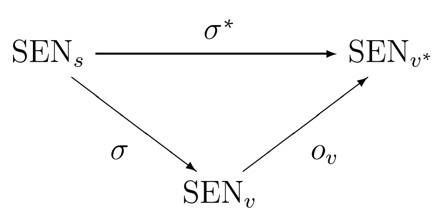
We refer to these conditions by saying that N "includes all projections" and is "closed under combinations" of natural transformations.

Let $\{\mathrm{SEN}_s\}_H^{V,V^*}$ be a behavioral sentence functor. A subcategory N of the clone of all natural transformations on $\{\mathrm{SEN}_s\}_{s\in S}$, with objects all objects of the form $\prod_{i=1}^k \mathrm{SEN}_{s_i}$, $k < \omega$, is called a **category of natural transformations on** $\{\mathrm{SEN}_s\}_H^{V,V^*}$ if, in addition to being a category of natural transformations on $\{\mathrm{SEN}_s\}_{s\in S}$, i.e., to including all projections and being closed under combinations, the following condition also holds:

- For all $v \in V$, there is no outgoing natural transformation from SEN_{v^*}, other than the identity, and there exists a unique surjective natural transformation

$$o_v : \mathrm{SEN}_v \to \mathrm{SEN}_{v^*},$$

  called the v-**observation natural transformation**, or, simply, **observation**, when the formula sort v to which it corresponds is clear from context, such that, every incoming natural transformation $\sigma^* : \mathrm{SEN}_s \to \mathrm{SEN}_{v^*}$ factors through o_v:



We express this condition by saying that N "has observations".

Given a natural transformation $\sigma : \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_s$ in N, we call $s_1 \cdots s_k \to s$ the **type of** σ and say that σ is **of sort** s (i.e., of the output sort).

A **multi-sorted algebraic system** $\mathbf{F} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle$ consists of a category of signatures, a multi-sorted sentence functor and a category N of natural transformations on $\{\mathrm{SEN}\}_{s\in S}$. It is called **behavioral** if $\{\mathrm{SEN}_s\}_H^{V,V^*}$ is a behavioral sentence functor and N is a category of natural transformations on $\{\mathrm{SEN}_s\}_H^{V,V^*}$ (i.e., has observations), and we then write

$$\mathbf{F} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_H^{V,V^*}, N\rangle.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_{s\in S}, N^\flat\rangle$ be a multi-sorted algebraic system. An $N^\flat$**-algebraic system** is a multi-sorted algebraic system

$$\mathbf{A} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle,$$

such that there exists a surjective functor $F : N^\flat \to N$ that preserves all natural projections (and, hence, the type of all natural transformations in $N^\flat$). We use $\sigma^{\mathbf{A}}$ to refer to the image of σ in $N^\flat$ under F.

Moreover, given two N-algebraic systems $\mathbf{A} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle$ and $\mathbf{B} = \langle \mathbf{Sign}', \{\mathrm{SEN}'_s\}_{s\in S}, N'\rangle$, a **morphism**

$$\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{B}$$

consists of a functor $F : \mathbf{Sign} \to \mathbf{Sign}'$ and a collection $\alpha = \{\alpha^s\}_{s\in S}$ of natural transformations $\alpha^s : \mathrm{SEN}_s \to \mathrm{SEN}'_s \circ F$, $s \in S$, such that, for every $\sigma : \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat \to \mathrm{SEN}_s^\flat$ in N, all $\Sigma \in |\mathbf{Sign}|$, and all $\phi_i \in \mathrm{SEN}_{s_i}(\Sigma)$, $i \le k$,

$$\alpha_\Sigma^s(\sigma_\Sigma^{\mathbf{A}}(\phi_1, \dots \phi_k)) = \sigma_{F(\Sigma)}^{\mathbf{B}}(\alpha_\Sigma^{s_1}(\phi_1), \dots, \alpha_\Sigma^{s_k}(\phi_k)).$$

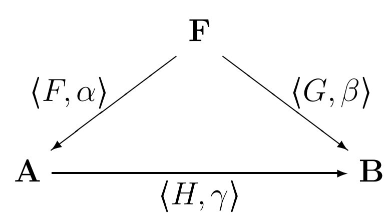
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_{s\in S}, N^\flat\rangle$ be a multi-sorted algebraic system. An $\mathbf{F}$**-algebraic system** $\mathcal{A}$ is a pair $\langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, where

- $\mathbf{A} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle$ is an $N^\flat$-algebraic system;
- $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{A}$ is a surjective morphism, i.e., such that $F : \mathbf{Sign} \to \mathbf{Sign}'$ is surjective and full and $\alpha_\Sigma^s : \mathrm{SEN}_s^\flat(\Sigma) \to \mathrm{SEN}_s(F(\Sigma))$ is surjective, for all $\Sigma \in |\mathbf{Sign}|$ and all $s \in S$.

Given two $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle$ and $\mathbf{B} = \langle \mathbf{Sign}', \{\mathrm{SEN}'_s\}_{s\in S}, N'\rangle$, a **morphism**

$$\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$$

is a morphism $\langle H, \gamma\rangle : \mathbf{A} \to \mathbf{B}$, such that



$$\langle H,\gamma\rangle\circ\langle F,\alpha\rangle=\langle G,\beta\rangle.$$

A **behavioral π-institution** is a pair $\mathcal{I}=\langle\mathbf{F},C\rangle$, where

- $\mathbf{F}=\langle\mathbf{Sign}^\flat,\{\mathrm{SEN}^\flat_s\}^{V,V^*}_H,N^\flat\rangle$ is a behavioral algebraic system;
- $C=\{C_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ is a **closure system on** $\{\mathrm{SEN}^\flat_v\}_{v\in V}$, i.e., for all $\Sigma\in|\mathbf{Sign}^\flat|$,
$$C_\Sigma:\mathcal{P}(\bigcup_{v\in V}\mathrm{SEN}^\flat_v(\Sigma))\to\mathcal{P}(\bigcup_{v\in V}\mathrm{SEN}^\flat_v(\Sigma))$$
is a closure operator and, for all $\Sigma,\Sigma'\in|\mathbf{Sign}^\flat|$, all $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\Phi\subseteq\cup_{v\in V}\mathrm{SEN}^\flat_v(\Sigma)$,
$$\mathrm{SEN}^\flat(f)(C_\Sigma(\Phi))\subseteq C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)).$$

Given a behavioral algebraic system $\mathbf{F}=\langle\mathbf{Sign}^\flat,\{\mathrm{SEN}^\flat_s\}^{V,V^*}_H,N^\flat\rangle$, a **behavioral sentence family $T=\{T_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ of F** consists of subsets

$$T_\Sigma\subseteq\bigcup_{v\in V}\mathrm{SEN}_v(\Sigma),\quad\Sigma\in|\mathbf{Sign}^\flat|.$$

Given a behavioral π-institution $\mathcal{I}=\langle\mathbf{F},C\rangle$, based on $\mathbf{F}$, a **behavioral theory family $T=\{T_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ of $\mathcal{I}$** is a behavioral sentence family of $\mathbf{F}$, such that, for all $\Sigma\in|\mathbf{Sign}^\flat|$,
$$C_\Sigma(T_\Sigma)=T_\Sigma.$$
We write $\mathrm{ThFam}(\mathcal{I})$ for the collection of all behavioral theory families of $\mathcal{I}$.

27.2 Behavioral Algebra

Let $\mathbf{F}=\langle\mathbf{Sign},\{\mathrm{SEN}_s\}_{s\in S},N\rangle$ be a multi-sorted algebraic system. An **equivalence family $\theta=\{\theta_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ on F** is a family, such that, for all $\Sigma\in|\mathbf{Sign}|$, $\theta_\Sigma=\{\theta^s_\Sigma\}_{s\in S}$ consists of equivalence relations $\theta^s_\Sigma\subseteq\mathrm{SEN}_s(\Sigma)^2$. It is called an **equivalence system on F** if it is invariant under **Sign**-morphisms, i.e., such that, for all $\Sigma,\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and $s\in S$,

$$\mathrm{SEN}_s(f)(\theta^s_\Sigma)\subseteq\theta^s_{\Sigma'}.$$

An equivalence family/system θ on $\mathbf{F}$ is called a **congruence family/system on F** if, for all $\sigma:\prod_{i=1}^k\mathrm{SEN}_{s_i}\to\mathrm{SEN}_s$ in N, all $\Sigma\in|\mathbf{Sign}|$ and all $\vec{\phi},\vec{\psi}\in\prod_{i=1}^k\mathrm{SEN}_{s_i}(\Sigma)$,

$$\vec{\phi}\ \prod_{i=1}^k\theta^{s_i}_\Sigma\ \vec{\psi}\quad\text{implies}\quad\sigma_\Sigma(\vec{\phi})\ \theta^s_\Sigma\ \sigma_\Sigma(\vec{\psi}).$$

The collection of all congruence systems on $\mathbf{F}$ is denoted by ConSys($\mathbf{F}$) and it forms a complete lattice under signature-wise and sort-wise inclusion $\le$:

$$\mathbf{ConSys}(\mathbf{F}) = \langle \mathrm{ConSys}(\mathbf{F}), \le \rangle.$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ a behavioral sentence family of $\mathbf{F}$. A congruence family $\theta = \{\theta_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ on $\mathbf{F}$ is **compatible with** T if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}_v(\Sigma)$,

$$\langle \phi, \psi \rangle \in \theta_\Sigma^v \quad \text{and} \quad \phi \in T_\Sigma \quad \text{imply} \quad \psi \in T_\Sigma.$$

A fundamental result, akin to that allowing us to define Leibniz congruence systems in the context of ordinary π-institutions, is asserting that, given a behavioral sentence family, there exists a largest congruence system on $\mathbf{F}$ compatible with the theory family.

Theorem 1958 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system,* $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ *a behavioral sentence family of* $\mathbf{F}$*. There exists a largest congruence system on* $\mathbf{F}$ *compatible with* T*.*

Proof: We define $\theta = \{\theta_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, where $\theta_\Sigma = \{\theta_\Sigma^s\}_{s \in S}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $s \in S$ and all $\phi, \psi \in \mathrm{SEN}_s^\flat(\Sigma)$, $\langle \phi, \psi \rangle \in \theta_\Sigma^s$ if and only if, for all $\sigma : \mathrm{SEN}_s^\flat \times \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat \to \mathrm{SEN}_v^\flat$ in $N^\flat$, with $v \in V$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat(\Sigma')$,

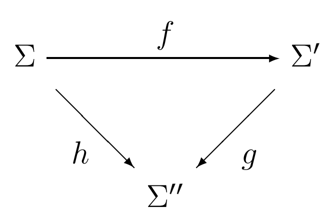
$$\sigma_{\Sigma'}(\mathrm{SEN}_s^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}(\mathrm{SEN}_s^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

We show that θ, thus defined, is a congruence system on $\mathbf{F}$ that is compatible with T.

First, it is straightforward by the definition that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $s \in S$, θ_Σ^s is reflexive, symmetric and transitive. So θ is an equivalence family on $\mathbf{F}$. To see that it is a system, let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $s \in S$ and $\phi, \psi \in \mathrm{SEN}_s^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma^s$. Then, for all $\sigma : \mathrm{SEN}_s^\flat \times \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat \to \mathrm{SEN}_v^\flat$ in $N^\flat$, with $v \in V$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$, all $h \in \mathbf{Sign}^\flat(\Sigma, \Sigma'')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat(\Sigma'')$,

$$\sigma_{\Sigma''}(\mathrm{SEN}_s^\flat(h)(\phi), \vec{\chi}) \in T_{\Sigma''} \quad \text{iff} \quad \sigma_{\Sigma''}(\mathrm{SEN}_s^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma''}.$$

Thus, as fortiori, for all $\sigma : \mathrm{SEN}_s^\flat \times \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat \to \mathrm{SEN}_v^\flat$ in $N^\flat$, with $v \in V$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$, all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}^\flat(\Sigma'')$,



$$\sigma_{\Sigma''}(\mathrm{SEN}^\flat_s(g)(\mathrm{SEN}^\flat_s(f)(\phi)),\vec{\chi}) \in T_{\Sigma''}$$
$$\text{iff}\quad \sigma_{\Sigma''}(\mathrm{SEN}^\flat_s(g)(\mathrm{SEN}^\flat_s(f)(\psi)),\vec{\chi}) \in T_{\Sigma''}.$$

This shows that $\langle \mathrm{SEN}^\flat_s(f)(\phi), \mathrm{SEN}^\flat_s(f)(\psi)\rangle \in \theta^s_{\Sigma'}$ and, hence, θ is an equivalence system.

To see that θ is a congruence system, let $\tau : \prod_{j=1}^\ell \mathrm{SEN}^\flat_{s'_j} \to \mathrm{SEN}^\flat_s$ be in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi},\vec{\psi} \in \prod_{j=1}^\ell \mathrm{SEN}^\flat_{s'_j}(\Sigma)$, such that $\vec{\phi} \prod_{j=1}^\ell \theta^{s'_j}_\Sigma \vec{\psi}$. Then, we have, for all $\sigma : \mathrm{SEN}^\flat_s \times \prod_{i=1}^k \to \mathrm{SEN}^\flat_v$ in $N^\flat$, with $v \in V$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\begin{array}{ll}
& \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\tau_\Sigma(\vec{\phi})),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff} & \sigma_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}^\flat_{s'_1}(f)(\phi_1), \mathrm{SEN}^\flat_{s'_2}(f)(\phi_2), \mathrm{SEN}^\flat_{s'_3}(f)(\phi_3),\ldots, \\
& \qquad \mathrm{SEN}^\flat_{s'_{\ell-1}}(f)(\phi_{\ell-1}), \mathrm{SEN}^\flat_{s'_\ell}(f)(\phi_\ell)),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff} & \sigma_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}^\flat_{s'_1}(f)(\psi_1), \mathrm{SEN}^\flat_{s'_2}(f)(\phi_2), \mathrm{SEN}^\flat_{s'_3}(f)(\phi_3),\ldots, \\
& \qquad \mathrm{SEN}^\flat_{s'_{\ell-1}}(f)(\phi_{\ell-1}), \mathrm{SEN}^\flat_{s'_\ell}(f)(\phi_\ell)),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff} & \sigma_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}^\flat_{s'_1}(f)(\psi_1), \mathrm{SEN}^\flat_{s'_2}(f)(\psi_2), \mathrm{SEN}^\flat_{s'_3}(f)(\phi_3),\ldots, \\
& \qquad \mathrm{SEN}^\flat_{s'_{\ell-1}}(f)(\phi_{\ell-1}), \mathrm{SEN}^\flat_{s'_\ell}(f)(\phi_\ell)),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff}\cdots & \\
\text{iff} & \sigma_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}^\flat_{s'_1}(f)(\psi_1), \mathrm{SEN}^\flat_{s'_2}(f)(\psi_2), \mathrm{SEN}^\flat_{s'_3}(f)(\psi_3),\ldots, \\
& \qquad \mathrm{SEN}^\flat_{s'_{\ell-1}}(f)(\psi_{\ell-1}), \mathrm{SEN}^\flat_{s'_\ell}(f)(\phi_\ell)),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff} & \sigma_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}_{s'_1}(f)(\psi_1), \mathrm{SEN}^\flat_{s'_2}(f)(\psi_2), \mathrm{SEN}^\flat_{s'_3}(f)(\psi_3),\ldots, \\
& \qquad \mathrm{SEN}^\flat_{s'_{\ell-1}}(f)(\psi_{\ell-1}), \mathrm{SEN}^\flat_{s'_\ell}(f)(\psi_\ell)),\vec{\chi}) \in T_{\Sigma'} \\
\text{iff} & \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\tau_\Sigma(\vec{\psi})),\vec{\chi}) \in T_{\Sigma'}.
\end{array}$$

Hence, $\langle \tau_\Sigma(\vec{\phi}), \tau_\Sigma(\vec{\psi})\rangle \in \theta^s_\Sigma$, showing that θ is a congruence system on $\mathbf{F}$.

θ is also compatible with T, since, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\psi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in T_\Sigma$ and $\langle \phi,\psi\rangle \in \theta^v_\Sigma$, we get, as a special instance in the definition by taking $\sigma = \iota : \mathrm{SEN}^\flat_v \to \mathrm{SEN}^\flat_v$ in $N^\flat$, $\Sigma' = \Sigma$ and $f = i_\Sigma$, $\phi \in T_\Sigma$ iff $\psi \in T_\Sigma$. Therefore, $\psi \in T_\Sigma$ and θ is, in fact, a congruence system on $\mathbf{F}$ compatible with T.

Finally, we show that, if θ' is a congruence system on $\mathbf{F}$ compatible with T, then $\theta' \le \theta$. Suppose, to this end, that θ' is a congruence system on $\mathbf{F}$ compatible with T and let $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi,\psi \in \mathrm{SEN}^\flat_s(\Sigma)$, such that $\langle \phi,\psi\rangle \in \theta'^s_\Sigma$. Then, since θ' is a congruence system, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\langle \mathrm{SEN}^\flat_s(f)(\phi), \mathrm{SEN}^\flat_s(f)(\psi)\rangle \in \theta'^s_{\Sigma'}$. Thus, since θ' is a congruence system, for all $\sigma : \mathrm{SEN}^\flat_s \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_v$ in $N^\flat$, with $v \in V$, and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\langle \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}), \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi),\vec{\chi})\rangle \in \theta'^v_{\Sigma'}.$$

Therefore, by the compatibility of θ' with T, we get

$$\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi),\vec{\chi}) \in T_{\Sigma'}.$$

This shows that $\langle\phi,\psi\rangle \in \theta^s_\Sigma$ and, hence, $\theta' \le \theta$. Thus, θ is indeed the largest congruence system on $\mathbf{F}$ compatible with T. ■

The largest congruence system on $\mathbf{F}$ compatible with T is called the **behavioral Leibniz congruence system of** T **on** $\mathbf{F}$ and is denoted by $\Upsilon(T)$. Moreover, given a behavioral π-institution $\mathcal{I} = \langle\mathbf{F}, C\rangle$, and a behavioral theory family $T \in \mathrm{ThFam}(\mathcal{I})$, we define the **behavioral Suszko congruence system of** T **on** $\mathbf{F}$ by

$$\widetilde{\Upsilon}^{\mathcal{I}}(T) = \bigcap\{\Upsilon(T') : T \le T' \in \mathrm{ThFam}(\mathcal{I})\}.$$

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat\rangle$ be a behavioral algebraic system and $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle\mathbf{Sign}, \{\mathrm{SEN}_s\}_{s\in S}, N\rangle$, an $\mathbf{F}$-algebraic system. We define $\equiv^{\mathcal{A}} = \{\equiv^{\mathcal{A}}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$, where, for all $\Sigma \in |\mathbf{Sign}|$, $\equiv^{\mathcal{A}}_\Sigma = \{\equiv^{\mathcal{A},s}_\Sigma\}_{s\in S}$ is given, for all $s \in S$, all $\phi,\psi \in \mathrm{SEN}_s(\Sigma)$, by $\phi \equiv^{\mathcal{A},s}_\Sigma \psi$ if and only if, for all $\sigma : \mathrm{SEN}_s \times \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_{v^*}$, with $v \in V$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}(\Sigma')$,

$$\sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}_s(f)(\phi),\vec{\chi}) = \sigma^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}_s(f)(\psi),\vec{\chi}).$$

We show that $\equiv^{\mathcal{A}}$ is a congruence system on $\mathcal{A}$.

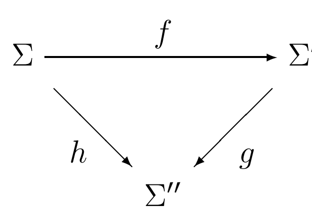
Proposition 1959 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$*, with* $\mathbf{A} = \langle\mathbf{Sign}, \{\mathrm{SEN}_s\}^{V,V^*}_H, N\rangle$*, an* $\mathbf{F}$*-algebraic system. The relation family* $\equiv^{\mathcal{A}}$ *is a congruence system on* $\mathcal{A}$*.*

Proof: By the definition, it is obvious that, for all $\Sigma \in |\mathbf{Sign}|$ and all $s \in S$, $\equiv^{\mathcal{A},s}_\Sigma$ is an equivalence family on $\mathrm{SEN}_s(\Sigma)$. We show that $\equiv^{\mathcal{A}}$ is a system and that it satisfies the congruence property.

Let $\Sigma,\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma,\Sigma')$, $s \in S$ and $\phi,\psi \in \mathrm{SEN}_s(\Sigma)$, such that $\phi \equiv^{\mathcal{A},s}_\Sigma \psi$. Then, for all $\sigma : \mathrm{SEN}_s \times \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_{v^*}$, with $v \in V$, all $\Sigma'' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma,\Sigma'')$ and $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}(\Sigma'')$,

$$\sigma^{\mathcal{A}}_{\Sigma''}(\mathrm{SEN}_s(h)(\phi),\vec{\chi}) = \sigma^{\mathcal{A}}_{\Sigma''}(\mathrm{SEN}_s(h)(\psi),\vec{\chi}).$$

In particular, for all $g \in \mathbf{Sign}(\Sigma',\Sigma'')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}(\Sigma'')$,



$$\sigma^{\mathcal{A}}_{\Sigma''}(\mathrm{SEN}_s(g)(\mathrm{SEN}_s(f)(\phi)),\vec{\chi}) = \sigma^{\mathcal{A}}_{\Sigma''}(\mathrm{SEN}_s(g)(\mathrm{SEN}_s(f)(\psi)),\vec{\chi}).$$

Thus, by definition, $\mathrm{SEN}_s(f)(\phi) \equiv^{\mathcal{A},s}_{\Sigma'} \mathrm{SEN}_s(f)(\psi)$ and, therefore, $\equiv^{\mathcal{A}}$ is an equivalence system.

Finally, let $\sigma : \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_s$ be in N, $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi},\vec{\psi} \in \prod_{i=1}^k \mathrm{SEN}_{s_i}(\Sigma)$, such that $\vec{\phi} \prod_{i=1}^k \equiv_\Sigma^{\mathcal{A},s_i} \vec{\psi}$. Then, we have, for all $\tau : \mathrm{SEN}_s \times \prod_{j=1}^\ell \mathrm{SEN}_{s'_j} \to \mathrm{SEN}_{v^*}$, with $v \in V$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma,\Sigma')$ and all $\vec{\chi} \in \prod_{j=1}^\ell \mathrm{SEN}_{s'_j}(\Sigma')$,

$$\begin{aligned}
&\tau_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_s(f)(\sigma_\Sigma^{\mathcal{A}}(\vec{\phi})),\vec{\chi})\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_{s_1}(f)(\phi_1),\mathrm{SEN}_{s_2}(f)(\phi_2),\mathrm{SEN}_{s_3}(f)(\phi_3),\dots,\\
&\qquad\qquad \mathrm{SEN}_{s_{k-1}}(f)(\phi_{k-1}),\mathrm{SEN}_{s_k}(f)(\phi_k)),\vec{\chi})\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_{s_1}(f)(\psi_1),\mathrm{SEN}_{s_2}(f)(\phi_2),\mathrm{SEN}_{s_3}(f)(\phi_3),\dots,\\
&\qquad\qquad \mathrm{SEN}_{s_{k-1}}(f)(\phi_{k-1}),\mathrm{SEN}_{s_k}(f)(\phi_k)),\vec{\chi})\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_{s_1}(f)(\psi_1),\mathrm{SEN}_{s_2}(f)(\psi_2),\mathrm{SEN}_{s_3}(f)(\phi_3),\dots,\\
&\qquad\qquad \mathrm{SEN}_{s_{k-1}}(f)(\phi_{k-1}),\mathrm{SEN}_{s_k}(f)(\phi_k)),\vec{\chi})\\
&= \cdots\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_{s_1}(f)(\psi_1),\mathrm{SEN}_{s_2}(f)(\psi_2),\mathrm{SEN}_{s_3}(f)(\psi_3),\dots,\\
&\qquad\qquad \mathrm{SEN}_{s_{k-1}}(f)(\psi_{k-1}),\mathrm{SEN}_{s_k}(f)(\phi_k)),\vec{\chi})\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\sigma_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_{s_1}(f)(\psi_1),\mathrm{SEN}_{s_2}(f)(\psi_2),\mathrm{SEN}_{s_3}(f)(\psi_3),\dots,\\
&\qquad\qquad \mathrm{SEN}_{s_{k-1}}(f)(\psi_{k-1}),\mathrm{SEN}_{s_k}(f)(\psi_k)),\vec{\chi})\\
&= \tau_{\Sigma'}^{\mathcal{A}}(\mathrm{SEN}_s(f)(\sigma_\Sigma^{\mathcal{A}}(\vec{\psi})),\vec{\chi})
\end{aligned}$$

Hence, $\sigma_\Sigma^{\mathcal{A}}(\vec{\phi}) \equiv_\Sigma^{\mathcal{A},s} \sigma_\Sigma^{\mathcal{A}}(\vec{\phi})$ and $\equiv^{\mathcal{A}}$ is a congruence system on $\{\mathrm{SEN}_s\}_H^{V,V^*}$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat\rangle$ be a behavioral algebraic system and K a class of $\mathbf{F}$-algebraic systems. We define the closure system $C^{\mathsf{K}} = \{C_\Sigma^{\mathsf{K}}\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$C_\Sigma^{\mathsf{K}} : \mathcal{P}(\bigcup_{v\in V} \mathrm{SEN}_v^\flat(\Sigma)^2) \to \mathcal{P}(\bigcup_{v\in V} \mathrm{SEN}_v^\flat(\Sigma)^2)$$

be given, for all $E \cup \{\phi \approx \psi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}_v(\Sigma)^2$,

$$\begin{aligned}
\phi \approx \psi \in C_\Sigma^{\mathsf{K}}(E) \quad \text{iff} \quad & \text{for all } \mathcal{A} \in \mathsf{K}, \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma,\Sigma'),\\
& \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(E)) \subseteq \equiv_{F(\Sigma')}^{\mathcal{A}} \text{ implies}\\
& \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)) \equiv_{F(\Sigma')}^{\mathcal{A}} \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).
\end{aligned}$$

Proposition 1960 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. Then* C^{K} *is a closure system on* $\bigcup_{v\in V}(\mathrm{SEN}_v^\flat)^2$.

Proof: It is straightforward to check that C_Σ^{K} is inflationary, monotone and idempotent, for all $\Sigma \in |\mathbf{Sign}^\flat|$. The fact that it is invariant under $\mathbf{Sign}^\flat$-morphisms can be shown in a way similar to that in the proof of Proposition 1959. ■

We call $\mathcal{I}^{\mathsf{K}} = \langle \mathbf{F}, C^{\mathsf{K}}\rangle$ the **behavioral equational π-institution associated with** the class K of $\mathbf{F}$-algebraic systems.

27.3 Behavioral Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system, K a class of $\mathbf{F}$-algebraic systems and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$.

- A **transformation** τ from $\mathcal{I}$ to $\mathcal{I}^\mathsf{K}$ is a collection $\tau = \{\tau^v : v \in V\}$, where, for every $v \in V$, $\tau^v = \{\tau^{v,u} : u \in V\}$ is such that
$$\tau^{v,u} : \mathrm{SEN}^\flat_v \times \prod_{i<\omega} \mathrm{SEN}^\flat_{s_i} \to (\mathrm{SEN}^\flat_u)^2$$
is a collection of natural transformations in $N^\flat$;
- A **transformation** ρ from $\mathcal{I}^\mathsf{K}$ to $\mathcal{I}$ is a collection $\rho = \{\rho^v : v \in V\}$, where, for every $v \in V$, $\rho^v = \{\rho^{v,u} : u \in V\}$ is such that
$$\rho^{v,u} : (\mathrm{SEN}^\flat_v)^2 \times \prod_{i<\omega} \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_u$$
is a collection of natural transformations in $N^\flat$.

A transformation τ from $\mathcal{I}$ to $\mathcal{I}^\mathsf{K}$ is called an **interpretation**, written $\tau : \mathcal{I} \to \mathcal{I}^\mathsf{K}$, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\Phi \cup \{\phi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}_v(\Sigma)$,
$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma[\phi] \subseteq C^\mathsf{K}_\Sigma(\tau_\Sigma[\Phi]).$$
Similarly, a transformation ρ from $\mathcal{I}^\mathsf{K}$ to $\mathcal{I}$ is called an **interpretation**, written $\rho : \mathcal{I}^\mathsf{K} \to \mathcal{I}$, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $E \cup \{\phi \approx \psi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}^\flat_v(\Sigma)^2$,
$$\phi \approx \psi \in C^\mathsf{K}_\Sigma(E) \quad \text{iff} \quad \rho_\Sigma[\phi, \psi] \subseteq C_\Sigma(\rho_\Sigma[E]).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. $\mathcal{I}$ is said to be **behaviorally** (**syntactically WF**) **algebraizable** if there exists a class K of $\mathbf{F}$-algebraic systems and interpretations $\tau : \mathcal{I} \to \mathcal{I}^\mathsf{K}$, $\rho : \mathcal{I}^\mathsf{K} \to \mathcal{I}$, that form a **conjugate pair**, i.e., such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$,

- $C_\Sigma(\phi) = C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]])$;
- $C^\mathsf{K}_\Sigma(\phi \approx \psi) = C^\mathsf{K}_\Sigma(\tau_\Sigma[\rho_\Sigma[\phi, \psi]])$.

In this case we also say that $\mathcal{I}$ and $\mathcal{I}^\mathsf{K}$ are **equivalent via** (τ, ρ) and we write $(\tau, \rho) : \mathcal{I} \rightleftarrows \mathcal{I}^\mathsf{K}$.

Explicitly, $\mathcal{I}$ is behaviorally algebraizable if and only if, there exists a class K of $\mathbf{F}$-algebraic systems and translations τ from $\mathcal{I}$ to $\mathcal{I}^\mathsf{K}$ and ρ from $\mathcal{I}^\mathsf{K}$ to $\mathcal{I}$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\Phi \cup \{\phi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}^\flat_v(\Sigma)$ and all $E \cup \{\phi \approx \psi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}^\flat_v(\Sigma)^2$,

(1) $\phi \in C_\Sigma(\Phi)$ if and only if $\tau_\Sigma[\phi] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\Phi])$;

(2) $\phi \approx \psi \in C^{\mathsf{K}}_\Sigma(E)$ if and only if $\rho_\Sigma[\phi,\psi] \subseteq C_\Sigma(\rho_\Sigma[E])$;

(3) $C_\Sigma(\phi) = C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]])$;

(4) $C^{\mathsf{K}}_\Sigma(\phi \approx \psi) = C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[\phi,\psi]])$.

As in normal syntactic WF algebraizability, it turns out that, in this case as well, Conditions (1) and (4), or dually, Conditions (2) and (3) suffice to establish behavioral algebraizability.

Proposition 1961 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*,* K *a class of* $\mathbf{F}$*-algebraic systems and* τ*,* ρ *translations from* $\mathcal{I}$ *to* $\mathcal{I}^{\mathsf{K}}$ *and from* $\mathcal{I}^{\mathsf{K}}$ *to* $\mathcal{I}$*, respectively. The following statements are equivalent:*

(i) $\tau : \mathcal{I} \to \mathcal{I}^{\mathsf{K}}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi \approx \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,* $C^{\mathsf{K}}_\Sigma(\phi \approx \psi) = C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[\phi,\psi]])$*;*

(ii) $\rho : \mathcal{I}^{\mathsf{K}} \to \mathcal{I}$ *is an interpretation and, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$*,* $C_\Sigma(\phi) = C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]])$*.*

Proof: We only prove that (i) implies (ii), since the converse then follows by the symmetry of the notion of equivalence. Suppose that (i) holds and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $E \cup \{\phi \approx \psi\} \subseteq \bigcup_{v\in V} \mathrm{SEN}^\flat_v(\Sigma)^2$. Then we have

$$\begin{array}{lll} \phi \approx \psi \in C^{\mathsf{K}}_\Sigma(E) & \text{iff} & \tau_\Sigma[\rho_\Sigma[\phi,\psi]] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[E]]) \\ & \text{iff} & \rho_\Sigma[\phi,\psi] \subseteq C_\Sigma(\rho_\Sigma[E]). \end{array}$$

Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$, we have, for all $\psi \in \bigcup_{v\in V} \mathrm{SEN}^\flat_v(\Sigma)$,

$$\begin{array}{lll} \psi \in C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]]) & \text{iff} & \tau_\Sigma[\psi] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\rho_\Sigma[\tau_\Sigma[\phi]]]) \\ & \text{iff} & \tau_\Sigma[\psi] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\phi]) \\ & \text{iff} & \psi \in C_\Sigma(\phi). \end{array}$$

Hence, $C_\Sigma(\phi) = C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]])$. This shows that Condition (ii) holds. ■

We look next at some properties that are entailed by behavioral algebraizability.

Proposition 1962 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$ *and* K *a class of* $\mathbf{F}$*-algebraic systems. If* $(\tau,\rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$ *is a conjugate pair, then, for all* $v, u \in V$*, all* $\sigma : \mathrm{SEN}_v \times \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_u$ *in* $N^\flat$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $\phi, \psi, \chi \in \mathrm{SEN}^\flat_v(\Sigma)$ *and all* $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma)$*,* *(a)* $\rho_\Sigma[\phi,\phi] \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$;

(b) $\rho_\Sigma[\psi,\phi] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$;

(c) $\rho_\Sigma[\phi,\chi] \subseteq C_\Sigma[\rho_\Sigma[\phi,\psi],\rho_\Sigma[\psi,\chi])$;

(d) $\rho_\Sigma[\sigma_\Sigma(\phi,\vec{\chi}),\sigma_\Sigma(\psi,\vec{\chi})] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$;

(e) $\psi \in C_\Sigma(\phi,\rho_\Sigma[\phi,\psi])$.

Proof:

(a) We have $\phi \approx \phi \in C^{\mathsf{K}}_\Sigma(\varnothing)$, whence, since $\rho : \mathcal{I}^{\mathsf{K}} \to \mathcal{I}$ is an interpretation, $\rho_\Sigma[\phi,\phi] \subseteq C_\Sigma(\varnothing)$.

(b) Since $\psi \approx \phi \in C^{\mathsf{K}}_\Sigma(\phi \approx \psi)$, we get, again by the fact $\rho : \mathcal{I}^{\mathsf{K}} \to \mathcal{I}$ is an interpretation, $\rho_\Sigma[\psi,\phi] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$.

(c) Since $\phi \approx \chi \in C^{\mathsf{K}}_\Sigma(\phi \approx \psi,\psi \approx \chi)$ and $\rho : \mathcal{I}^{\mathsf{K}} \to \mathcal{I}$ is an interpretation, we get that $\rho_\Sigma[\phi,\chi] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi],\rho_\Sigma[\psi,\chi])$.

(d) By Proposition 1959, we have, for all $\sigma : \mathrm{SEN}_v \times \prod_{i=1}^k \mathrm{SEN}_{s_i} \to \mathrm{SEN}_u$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma)$, $\sigma_\Sigma(\phi,\vec{\chi}) \approx \sigma_\Sigma(\psi,\vec{\chi}) \in C^{\mathsf{K}}_\Sigma(\phi \approx \psi)$. Hence, again by the fact that $\rho : \mathcal{I}^{\mathsf{K}} \to \mathcal{I}$ is an interpretation, we get that $\rho_\Sigma[\sigma_\Sigma(\phi,\vec{\chi}),\sigma_\Sigma(\psi,\vec{\chi})] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$.

(e) In $\mathcal{I}^{\mathsf{K}}$, we have $\tau_\Sigma[\psi] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\phi],\phi \approx \psi)$. Hence, by Property (4) of equivalence, $\tau_\Sigma[\psi] \subseteq C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\phi],\tau_\Sigma[\rho_\Sigma[\phi,\psi]])$. Thus, by Property (1) of equivalence, we get that $\psi \in C_\Sigma(\phi,\rho_\Sigma[\phi,\psi])$.

■

We can also prove that, if a behavioral π-institution $\mathcal{I}$ is behaviorally algebraizable in two different ways, then the interpretations are, roughly speaking, interderivable and the classes of **F**-algebraic systems serving as behavioral algebraic semantics generate the same behavioral consequence operators.

Theorem 1963 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable via conjugate pairs* $(\tau,\rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$ *and* $(\tau',\rho') : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}'}$*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

(a) $C_\Sigma(\rho_\Sigma[\phi,\psi]) = C_\Sigma(\rho'_\Sigma[\phi,\psi])$;

(b) $C^{\mathsf{K}} = C^{\mathsf{K}'}$;

(c) $C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\phi]) = C^{\mathsf{K}}_\Sigma(\tau'_\Sigma[\phi])$.

Proof:

(a) For all $\sigma' \in \rho'$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma)$, we get

$$\rho_\Sigma[\sigma'_\Sigma(\phi,\phi,\vec{\chi}),\sigma'_\Sigma(\phi,\psi,\vec{\chi})] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi]).$$

But we also have $\rho'_\Sigma[\phi,\phi] \subseteq C_\Sigma(\varnothing) \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$. Thus, by Proposition 1962, Part (e), $\rho'_\Sigma[\phi,\psi] \subseteq C_\Sigma(\rho_\Sigma[\phi,\psi])$. By symmetry, we now get $C_\Sigma(\rho_\Sigma[\phi,\psi]) = C_\Sigma(\rho'_\Sigma[\phi,\psi])$.

(b) Using Part (a), we get, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $E \cup \{\phi \approx \psi\} \subseteq \bigcup_{v\in V}\mathrm{SEN}^\flat_v(\Sigma)^2$,

$$\begin{array}{rll}\phi \approx \psi \in C^{\mathsf{K}}_\Sigma(E) & \text{iff} & \rho_\Sigma[\phi,\psi] \subseteq C_\Sigma(\rho_\Sigma[E]) \\ & \text{iff} & \rho'_\Sigma[\phi,\psi] \subseteq C_\Sigma(\rho'_\Sigma[E]) \\ & \text{iff} & \phi \approx \psi \in C^{\mathsf{K}'}_\Sigma(E).\end{array}$$

(c) Using Parts (a) and (b), we get

$$\begin{array}{rll}C_\Sigma(\phi) = C_\Sigma(\phi) & \text{iff} & C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]]) = C_\Sigma(\rho'_\Sigma[\tau'_\Sigma[\phi]]) \\ & \text{iff} & C_\Sigma(\rho_\Sigma[\tau_\Sigma[\phi]]) = C_\Sigma(\rho_\Sigma[\tau'_\Sigma[\phi]]) \\ & \text{iff} & C^{\mathsf{K}}_\Sigma(\tau_\Sigma[\phi]) = C^{\mathsf{K}}_\Sigma(\tau'_\Sigma[\phi]).\end{array}$$

■

27.4 Behavioral Protoalgebraicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a behavioral π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **behaviorally protoalgebraic** if the behavioral Leibniz operator $\Upsilon : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}(\mathbf{F})$ is monotone on the behavioral theory families of $\mathcal{I}$, i.e., for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Upsilon(T) \leq \Upsilon(T').$$

- $\mathcal{I}$ is **behaviorally syntactically protoalgebraic** if there exists a collection $\rho = \{\rho^v : v \in V\}$, where, for all $v \in V$, $\rho^v = \{\rho^{v,u} : u \in V\}$ is such that $\rho^{v,u} : (\mathrm{SEN}^\flat_v)^2 \times \prod_{i<\omega}\mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_u$ in $N^\flat$ is a collection of natural transformations satisfying, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\langle \phi,\psi\rangle \in \Upsilon_\Sigma(T) \quad \text{iff} \quad \rho^v_\Sigma[\phi,\psi] \leq T.$$

  The set ρ is referred to as the set of **witnessing transformations** for the behavioral syntactic protoalgebraicity of $\mathcal{I}$.

We have the following characterization of behavioral protoalgebraicity.

Proposition 1964 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally protoalgebraic if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T) \quad \textit{implies} \quad C_\Sigma(T_\Sigma, \phi) = C_\Sigma(T_\Sigma, \psi).$$

Proof: Suppose, first, that $\mathcal{I}$ is behaviorally protoalgebraic and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T)$. Let $T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T_\Sigma \subseteq T'_\Sigma$ and $\psi \in T'_\Sigma$. Then, by behavioral protoalgebraicity, we have $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T) \subseteq \Upsilon_\Sigma(T')$. Since, by hypothesis, $\psi \in T'_\Sigma$, we get, by compatibility of $\Upsilon(T')$ with T', that $\phi \in T'_\Sigma$. Thus, $\phi \in C_\Sigma(T_\Sigma, \psi)$ and, by symmetry, $C_\Sigma(T_\Sigma, \phi) = C_\Sigma(T_\Sigma, \psi)$.

Suppose, conversely, that the condition in the statement holds and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$ and $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T)$. Then, since $\Upsilon(T)$ is a congruence system on $\mathbf{F}$, we get, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, all $\sigma : \mathrm{SEN}^\flat_v \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_u$ in $N^\flat$, with $u \in V$, and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\langle \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi})\rangle \in \Upsilon_{\Sigma'}(T).$$

By hypothesis,

$$C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi})) = C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi})).$$

Hence, since $T \leq T'$,

$$C_{\Sigma'}(T'_{\Sigma'}, \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi})) = C_{\Sigma'}(T'_{\Sigma'}, \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi})).$$

We now get

$$\sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi}) \in T'_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi}) \in T'_{\Sigma'}.$$

Therefore, by the characterization in the proof of Theorem 1958, we get that $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T')$. Hence $\Upsilon(T) \leq \Upsilon(T')$ and it follows that $\mathcal{I}$ is behaviorally protoalgebraic. ∎

Behavioral syntactic protoalgebraicity implies behavioral protoalgebraicity.

Theorem 1965 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic, then it is behaviorally protoalgebraic.*

Proof: Suppose $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ, and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, we have

$$\begin{array}{rcl}\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T) & \text{iff} & \rho^v_\Sigma[\phi, \psi] \leq T \\ & \text{implies} & \rho^v_\Sigma[\phi, \psi] \leq T' \\ & \text{iff} & \langle \phi, \psi\rangle \in \Upsilon_\Sigma(T').\end{array}$$

Hence, $\Upsilon(T) \leq \Upsilon(T')$ and, therefore, $\mathcal{I}$ is behaviorally protoalgebraic. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. We define the **behavioral reflexive core of** $\mathcal{I}$

$$A^{\mathcal{I}} = \{A^{\mathcal{I},s} : s \in S\},$$

by letting, for all $s \in S$, $A^{\mathcal{I},s}$ be the collection of all natural transformations $\sigma : (\mathrm{SEN}^\flat_s)^2 \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_v$ in $N^\flat$, with $v \in V$, such that:

For all $\Sigma \in |\mathbf{Sign}^\flat|$, all $s \in S$, all $\phi \in \mathrm{SEN}^\flat_s(\Sigma)$,

$$\sigma_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I}).$$

The importance of the behavioral reflexive core lies, as in previous cases, in the fact that it forms a pool of candidates for drawing witnessing transformations for the behavioral syntactic protoalgebraicity of $\mathcal{I}$.

Lemma 1966 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic, with witnessing transformations* ρ*, then* $\rho \subseteq A^{\mathcal{I}}$*.*

Proof: Suppose $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ. Let $\sigma \in \rho$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$. Since $\langle \phi, \phi \rangle \in \Upsilon_\Sigma(\mathrm{Thm}(\mathcal{I}))$, we get that $\sigma_\Sigma[\phi, \phi] \leq \rho_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I})$. Therefore, we get that $\rho \subseteq A^{\mathcal{I}}$. ■

Moreover, if $\mathcal{I}$ is behaviorally syntactically protoalgebraic, then $A^{\mathcal{I}}$ satisfies a modus ponens property in $\mathcal{I}$.

Theorem 1967 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\psi \in C_\Sigma(\phi, A^{\mathcal{I}}_\Sigma[\phi, \psi]).$$

Proof: Assume $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in T_\Sigma$ and $A^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Then we have $\phi \in T_\Sigma$ and, by Lemma 1966, $\rho_\Sigma[\phi, \psi] \leq A^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$, whence $\phi \in T_\Sigma$ and $\langle \phi, \psi \rangle \in \Upsilon_\Sigma(T)$. Thus, by compatibility of $\Upsilon(T)$ with T, we conclude that $\psi \in T_\Sigma$. Therefore, $\psi \in C_\Sigma(\phi, \mathcal{A}^{\mathcal{I}}_\Sigma[\phi, \psi])$. ■

Define, for all $T \in \mathrm{ThFam}(\mathcal{I})$, a relation family $A^{\mathcal{I}}(T) = \{A^{\mathcal{I}}_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ on $\mathbf{F}$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $s \in S$ and all $\phi, \psi \in \mathrm{SEN}^\flat_s(\Sigma)$,

$$\langle \phi, \psi \rangle \in A^{\mathcal{I}}_\Sigma(T) \quad \text{iff} \quad A^{\mathcal{I},s}_\Sigma[\phi, \psi] \leq T.$$

Then we have

Lemma 1968 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\psi \in C_\Sigma(\phi, A^{\mathcal{I}}_\Sigma[\phi, \psi]),$$

then, for all $T \in \mathrm{ThFam}(\mathcal{I})$*,* $A^{\mathcal{I}}(T)$ *is a congruence system on* $\mathbf{F}$ *compatible with* T*.*

Proof: Fix $T \in \mathrm{ThFam}(\mathcal{I})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi \in \mathrm{SEN}^\flat_s(\Sigma)$. By definition of $\mathcal{A}^{\mathcal{I}}$, we have $A^{\mathcal{I}}_\Sigma[\phi, \phi] \leq \mathrm{Thm}(\mathcal{I}) \leq T$. Therefore, $\langle \phi, \phi \rangle \in A^{\mathcal{I}}_\Sigma(T)$ and, hence, $A^{\mathcal{I}}(T)$ is reflexive.

Let $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi, \psi \in \mathrm{SEN}^\flat_s(\Sigma)$, such that $\langle \phi, \psi \rangle \in A^{\mathcal{I}}_\Sigma(T)$. Then $A^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$. Again by the definition of $A^{\mathcal{I}}$, we get that $A^{\mathcal{I}}_\Sigma[\psi, \phi] = A^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$, whence $\langle \psi, \phi \rangle \in A^{\mathcal{I}}_\Sigma(T)$ and $A^{\mathcal{I}}(T)$ is symmetric.

Let $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat_s(\Sigma)$, such that $\langle \phi, \psi \rangle \in A^{\mathcal{I}}_\Sigma(T)$ and $\langle \psi, \chi \rangle \in A^{\mathcal{I}}_\Sigma(T)$. Then, we have $A^{\mathcal{I}}_\Sigma[\phi, \psi] \leq T$ and $A^{\mathcal{I}}_\Sigma[\psi, \chi] \leq T$. Thus, by hypothesis, we have, for all $\alpha \in A^{\mathcal{I}}$, all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$ of appropriate sorts,

$$\begin{aligned}
&\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\chi}) \\
&\in C_{\Sigma'}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \\
&\qquad A^{\mathcal{I}}_{\Sigma'}[\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \\
&\qquad\qquad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\chi})]) \\
&\subseteq C_{\Sigma'}(A^{\mathcal{I}}_\Sigma[\phi, \psi], A^{\mathcal{I}}_\Sigma[\psi, \chi]) \\
&\subseteq T_{\Sigma'}.
\end{aligned}$$

Hence $A^{\mathcal{I}}_\Sigma[\phi, \chi] \leq T$ and, therefore, $\langle \phi, \chi \rangle \in A^{\mathcal{I}}_\Sigma(T)$ and $A^{\mathcal{I}}(T)$ is also transitive. It is, by its definition, a system. To see that it is a congruence system, suppose $\sigma : \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}_s$ is in N $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi}, \vec{\psi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma)$, such that $\vec{\phi} \prod_{i=1}^k A^{\mathcal{I}, s_i}_\Sigma(T) \vec{\psi}$. Then we have

$$\begin{aligned}
A^{\mathcal{I}}_\Sigma[\sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\vec{\phi})] \leq T \quad &\text{iff} \quad A^{\mathcal{I}}_\Sigma[\sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\psi_1, \phi_2, \phi_3, \ldots, \phi_{k-1}, \phi_k)] \leq T \\
&\text{iff} \quad A^{\mathcal{I}}_\Sigma[\sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\psi_1, \psi_2, \phi_3, \ldots, \phi_{k-1}, \phi_k)] \leq T \\
&\text{iff} \quad \cdots \\
&\text{iff} \quad A^{\mathcal{I}}_\Sigma[\sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\psi_1, \psi_2, \psi_3, \ldots, \psi_{k-1}, \phi_k)] \leq T \\
&\text{iff} \quad A^{\mathcal{I}}_\Sigma[\sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\vec{\psi})] \leq T.
\end{aligned}$$

Therefore, $A^{\mathcal{I}}(T)$ is a congruence system. Finally, by hypothesis, it is compatible with T. ∎

Lemma 1968 enables us to show that, if the behavioral reflexive core of a behavioral π-institution satisfies the modus ponens property postulated in its hypothesis, then it is behaviorally syntactically protoalgebraic, with witnessing transformations $A^{\mathcal{I},V} = \{A^{\mathcal{I},v} : v \in V\}$.

Theorem 1969 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\psi \in C_\Sigma(\phi, A^{\mathcal{I}}_\Sigma[\phi, \psi]),$$

then $\mathcal{I}$ *is behaviorally syntactically protoalgebraic, with witnessing transformations* $A^{\mathcal{I},V} = \{A^{\mathcal{I},v} : v \in V\}$*.*

Proof: Suppose that $\mathcal{I}$ satisfies the condition in the hypothesis. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$.

- Assume, first, that $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T)$. Then, since $\Upsilon(T)$ is a congruence system on $\mathbf{F}$, we have, for all $\sigma : (\mathrm{SEN}^\flat_v)^2 \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_u$ in $A^{\mathcal{I},v}$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,
$$\langle \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi})\rangle \in \Upsilon_{\Sigma'}(T).$$
But, by definition of $A^{\mathcal{I}}$, we also have that
$$\sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \mathrm{SEN}^\flat_v(f)(\phi), \vec{\chi}) \in \mathrm{Thm}_{\Sigma'}(\mathcal{I}) \subseteq T_{\Sigma'}.$$
Hence, by the compatibility property of $\Upsilon(T)$ with T, we get that $\sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi), \mathrm{SEN}^\flat_v(f)(\psi), \vec{\chi}) \in T_{\Sigma'}$. Thus, $A^{\mathcal{I},v}_\Sigma[\phi, \psi] \leq T$.
- Assume, conversely, that $A^{\mathcal{I},v}_\Sigma[\phi, \psi] \leq T$. Then, we get $\langle \phi, \psi\rangle \in A^{\mathcal{I}}_\Sigma(T)$. But, by Lemma 1968 and the hypothesis, $A^{\mathcal{I}}(T)$ is a congruence system on $\mathbf{F}$ compatible with T, whence, by the maximality of $\Upsilon(T)$, $A^{\mathcal{I}}(T) \leq \Upsilon(T)$. Thus, $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T)$.

We now conclude that $\mathcal{I}$ is behaviorally syntactically protoalgebraic. ■

We have now the essential ingredients for formulating a characterization of behavioral syntactic protoalgebraicity.

$\mathcal{I}$ is behaviorally syntactically protoalgebraic $\longleftrightarrow$ $A^{\mathcal{I},V}$ has the MP.

Theorem 1970 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,* $\psi \in C_\Sigma(\phi, A^{\mathcal{I},v}_\Sigma[\phi, \psi])$*.*

Proof: The “only if” is by Theorem 1967. The “if” is by Theorem 1969. ■

It is not difficult to show now that, if a behavioral π-institution is behaviorally syntactically protoalgebraic, then any set of witnessing transformations is deductively equivalent to the visible part of the behavioral reflexive core.

Corollary 1971 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic, with witnessing transformations* ρ*, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$C(A^{\mathcal{I},v}_\Sigma[\phi,\psi]) = C(\rho^v_\Sigma[\phi,\psi]).$$

Proof: Suppose $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ. Then, by Theorems 1967 and 1969, $A^{\mathcal{I},V}$ is also a collection of witnessing transformations for the behavioral syntactic protoalgebraicity of $\mathcal{I}$. Therefore, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, we get

$$\begin{array}{lll} A^{\mathcal{I},v}_\Sigma[\phi,\psi] \leq T & \text{iff} & \langle \phi,\psi \rangle \in \Upsilon_\Sigma(T) \\ & \text{iff} & \rho^v_\Sigma[\phi,\psi] \leq T. \end{array}$$

Hence, we get $C(A^{\mathcal{I},v}_\Sigma[\phi,\psi]) = C(\rho^v_\Sigma[\phi,\psi])$. ■

Another characterizing property, therefore, of behavioral syntactic protoalgebraicity is that the behavioral reflexive core define behavioral Leibniz congruence systems in $\mathcal{I}$.

$\mathcal{I}$ is behaviorally syntactically protoalgebraic
$\longleftrightarrow$ $A^{\mathcal{I},V}$ defines behavioral Leibniz congruence systems.

Theorem 1972 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic if and only if* $A^{\mathcal{I},V}$ *defines behavioral Leibniz congruence systems of theory families in* $\mathcal{I}$*, i.e., for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $A^{\mathcal{I},V}(T) = \Upsilon(T)$*.*

Proof: Suppose, first, that $\mathcal{I}$ is behaviorally syntactically protoalgebraic. Then, by Theorems 1967 and 1969, $A^{\mathcal{I},V}$ is a collection of witnessing transformations for the behavioral syntactic protoalgebraicity of $\mathcal{I}$. Therefore, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $A^{\mathcal{I},V}(T) = \Upsilon(T)$. Conversely, if $A^{\mathcal{I},V}(T) = \Upsilon(T)$, for all $T \in \mathrm{ThFam}(\mathcal{I})$, then $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations $A^{\mathcal{I},V}$. ■

The connection between behavioral syntactic protoalgebraicity and behavioral protoalgebraicity passes through another property of the behavioral Suszko core that we term *Leibniz*.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. We say that the behavioral reflexive core $A^{\mathcal{I}}$ of $\mathcal{I}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\langle \phi,\psi \rangle \in \Upsilon_\Sigma(C(A^{\mathcal{I},v}_\Sigma[\phi,\psi])).$$

It is straightforward to show that, if $A^{\mathcal{I},V}$ has the modus ponens property in $\mathcal{I}$, then it is also Leibniz.

Proposition 1973 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $A^{\mathcal{I}}$ *has the modus ponens in* $\mathcal{I}$*, then it is Leibniz.*

Proof: Suppose that $A^{\mathcal{I}}$ has the modus ponens in $\mathcal{I}$. Then, by Theorem 1969, $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations $A^{\mathcal{I},V}$. Thus, we obtain, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\langle \phi, \psi\rangle \in \Upsilon_\Sigma(C(A^{\mathcal{I},v}_\Sigma[\phi,\psi])) \quad \text{iff} \quad A^{\mathcal{I},v}_\Sigma[\phi,\psi] \le C(A^{\mathcal{I},v}_\Sigma[\phi,\psi]).$$

However, the condition of the right always holds, whence, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(C(A^{\mathcal{I},v}_\Sigma[\phi,\psi]))$, i.e., $A^{\mathcal{I}}$ is Leibniz. ∎

The opposite implication is not true in general. It holds, however, in behaviorally protoalgebraic behavioral π-institutions.

Proposition 1974 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behaviorally protoalgebraic behavioral* π*-institution based on* $\mathbf{F}$*. If* $A^{\mathcal{I}}$ *is Leibniz, then it has the modus ponens in* $\mathcal{I}$*.*

Proof: Suppose that $\mathcal{I}$ is behaviorally protoalgebraic and $A^{\mathcal{I}}$ is Leibniz. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in T_\Sigma$ and $A^{\mathcal{I},v}_\Sigma[\phi,\psi] \le T$. Since $A^{\mathcal{I}}$ is Leibniz, we get that $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(C(A^{\mathcal{I},v}_\Sigma[\phi,\psi]))$. Since $A^{\mathcal{I},v}_\Sigma[\phi,\psi] \le T$, we get, by the hypothesis of behavioral protoalgebraicity, $\Upsilon(C(A^{\mathcal{I},v}_\Sigma[\phi,\psi])) \le \Upsilon(T)$, whence, $\langle \phi, \psi\rangle \in \Upsilon_\Sigma(T)$. Hence, by the compatibility of $\Upsilon(T)$, with T, we get $\psi \in T_\Sigma$. We conclude that $\psi \in C_\Sigma(\phi, A^{\mathcal{I},v}_\Sigma[\phi,\psi])$ and, thus, $A^{\mathcal{I}}$ has the modus ponens in $\mathcal{I}$. ∎

We close by formulating the exact relation between behavioral syntactic protoalgebraicity and behavioral protoalgebraicity.

Behavioral Syntactic Protoalgebraicity
= $A^{\mathcal{I}}$ has the Modus Ponens
= $A^{\mathcal{I}}$ Defines Behavioral Leibniz Congruence Systems
= Behavioral Protoalgebraicity + $A^{\mathcal{I}}$ Leibniz

Theorem 1975 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic if and only if it is behaviorally protoalgebraic and has a Leibniz behavioral reflexive core.*

Proof: If $\mathcal{I}$ is behaviorally syntactically protoalgebraic, then, by Theorem 1965, it is behaviorally protoalgebraic, by Theorem 1967, $A^{\mathcal{I}}$ has the modus ponens and, hence, by Proposition 1973, $A^{\mathcal{I}}$ is Leibniz.

Conversely, if $\mathcal{I}$ is behaviorally protoalgebraic and $A^{\mathcal{I}}$ is Leibniz, then, by Proposition 1974, $A^{\mathcal{I}}$ has the modus ponens in $\mathcal{I}$, whence, by Theorem 1969, $\mathcal{I}$ is behaviorally syntactically protoalgebraic. ∎

27.5 Behavioral Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **behaviorally completely reflective** (or **behaviorally c-reflective**, for short), if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Upsilon(T) \le \Upsilon(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \le T'.$$
- $\mathcal{I}$ is **behaviorally truth equational** if there exists $\tau = \{\tau^v : v \in V\}$, where, for all $v \in V$, $\tau^v = \{\tau^{v,u} : u \in V\}$ is a collection of natural transformations $\tau^{v,u} : \mathrm{SEN}_v^\flat \times \prod_{i<\omega} \mathrm{SEN}_{s_i}^\flat \to (\mathrm{SEN}_u^\flat)^2$ in $N^\flat$, such that, for all $T \in \mathbf{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}_v^\flat(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^v[\phi] \le \Upsilon(T).$$
In this case, the collection τ forms a set of **witnessing transformations for the behavioral truth equationality of** $\mathcal{I}$.

We have the following alternative characterization of behavioral c-reflectivity, involving both the behavioral Suszko and the behavioral Leibniz operator.

Lemma 1976 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is behaviorally c-reflective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{\Upsilon}(T) \le \Upsilon(T') \quad \textit{implies} \quad T \le T'.$$

Proof: Suppose, first, that $\mathcal{I}$ is behaviorally c-reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{\Upsilon}(T) \le \Upsilon(T')$. Then, we have $\bigcap\{\Upsilon(X) : T \le X \in \mathrm{FiFam}(\mathcal{I})\} \le \Upsilon(T')$, whence, by behavioral c-reflectivity, $\bigcap\{X : T \le X \in \mathrm{ThFam}(\mathcal{I})\} \le T'$, i.e., $T \le T'$. Thus, the condition of the statement holds.

Assume, conversely, that the condition of the statement holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Upsilon(T) \le \Upsilon(T')$. Then we get
$$\widetilde{\Upsilon}(\bigcap \mathcal{T}) \le \bigcap\{\Upsilon(T) : T \in \mathcal{T}\} \le \Upsilon(T').$$

Therefore, by the hypothesis, $\bigcap \mathcal{T} \leq T'$ and, hence, $\mathcal{I}$ is behaviorally c-reflective. ∎

It is easy to see that behavioral truth equationality implies behavioral c-reflectivity.

Proposition 1977 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally truth equational, then it is behaviorally c-reflective.*

Proof: Suppose that $\mathcal{I}$ is behaviorally truth equational, with witnessing transformations $\tau = \{\tau^v : v \in V\}$, and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Upsilon(T) \leq \Upsilon(T')$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\begin{array}{rcl}\phi \in \bigcap_{T \in \mathcal{T}} T_\Sigma & \text{iff} & \phi \in T_\Sigma,\ T \in \mathcal{T},\\ & \text{iff} & \tau^v_\Sigma[\phi] \leq \Upsilon(T),\ T \in \mathcal{T},\\ & \text{iff} & \tau^v_\Sigma[\phi] \leq \bigcap_{T \in \mathcal{T}} \Upsilon(T)\\ & \text{implies} & \tau^v_\Sigma[\phi] \leq \Upsilon(T')\\ & \text{iff} & \phi \in T'_\Sigma.\end{array}$$

Therefore, $\bigcap \mathcal{T} \leq T'$ and $\mathcal{I}$ is indeed behaviorally c-reflective. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. We define the **behavioral Suszko core** $\Sigma^{\mathcal{I}} = \{\Sigma^{\mathcal{I},v} : v \in V\}$ **of** $\mathcal{I}$ by setting, for all $v \in V$,

$$\begin{array}{l}\Sigma^{\mathcal{I},v} = \{\sigma : \mathrm{SEN}^\flat_v \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to (\mathrm{SEN}^\flat_u)^2, u \in V :\\ \qquad (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \phi \in \mathrm{SEN}^\flat_v(\Sigma))(\sigma_\Sigma[\phi] \leq \widetilde{\Upsilon}(C(\phi)))\}\end{array}$$

$\Sigma^{\mathcal{I}}$ is a pool for possible candidates witnessing the potential behavioral truth equationality of $\mathcal{I}$.

Lemma 1978 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally truth equational, with witnessing transformations* τ*, then* $\tau \subseteq \Sigma^{\mathcal{I}}$*.*

Proof: Suppose $\mathcal{I}$ is behaviorally truth equational, with witnessing transformations $\tau = \{\tau^v : v \in V\}$ and let $v \in V$, $\sigma \in \tau^v$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$. Then, we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\phi \in T_\Sigma$, $\sigma_\Sigma[\phi] \leq \Upsilon(T)$, whence

$$\sigma_\Sigma[\phi] \leq \bigcap\{\Upsilon(T) : \phi \in T_\Sigma\} = \widetilde{\Upsilon}(C(\phi)).$$

We conclude that $\sigma \in \Sigma^{\mathcal{I},v}$. Therefore, $\tau \subseteq \Sigma^{\mathcal{I}}$. ∎

The behavioral Suszko core $\Sigma^{\mathcal{I}}$ was devised to carry a sentence of visible sort into the behavioral Suszko congruence system of the theory family generated by it. Because of the monotonicity of the behavioral Suszko operator and the fact that the behavioral Suszko operator is universally subsumed by the behavioral Leibniz operator, however, it turns out that the image of any behavioral theory family under the behavioral Suszko core always lies inside the behavioral Leibniz congruence system of the family.

Proposition 1979 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*,* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\Sigma \in |\mathbf{Sign}^\flat|$*,* $v \in V$ *and* $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$*. If* $\phi \in T_\Sigma$*, then*

$$\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in T_\Sigma$. Then, we have

$$\begin{array}{lll}\Sigma^{\mathcal{I},v}_\Sigma[\phi] & \leq & \widetilde{\Upsilon}(C(\phi)) \quad (\text{definition of } \Sigma^{\mathcal{I}})\\ & \leq & \widetilde{\Upsilon}(T) \quad (\text{monotonicity of } \widetilde{\Upsilon})\\ & \leq & \Upsilon(T). \quad (\widetilde{\Upsilon} \leq \Upsilon)\end{array}$$

This proves the conclusion. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. We say that the behavioral Suszko core $\Sigma^{\mathcal{I}}$ of $\mathcal{I}$ is **soluble** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

The solubility of the behavioral Suszko core is a necessary condition for a behavioral π-institution to be behaviorally truth equational.

Theorem 1980 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally truth equational, then* $\Sigma^{\mathcal{I}}$ *is soluble.*

Proof: Suppose $\mathcal{I}$ is behaviorally truth equational, with witnessing transformations $\tau = \{\tau^v : v \in V\}$. Then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)$, we have, by Lemma 1978,

$$\tau^v_\Sigma[\phi] \leq \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T),$$

whence, by the fact that τ witnesses the behavioral truth equationality of $\mathcal{I}$, $\phi \in T_\Sigma$. Therefore, $\Sigma^{\mathcal{I}}$ is indeed soluble. ■

Conversely, the solubility of the behavioral Suszko core ensures that it can serve as a collection of witnessing transformations for the behavioral truth equationality of $\mathcal{I}$.

Theorem 1981 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If the behavioral Suszko core* $\Sigma^{\mathcal{I}}$ *is soluble, then* $\mathcal{I}$ *is behaviorally truth equational, with witnessing transformations* $\Sigma^{\mathcal{I}}$*.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}_v^\flat(\Sigma)$. If $\phi \in T_\Sigma$, then, by Proposition 1979, $\Sigma_\Sigma^{\mathcal{I},v}[\phi] \leq \Upsilon(T)$. On the other hand, if $\Sigma_\Sigma^{\mathcal{I},v}[\phi] \leq \Upsilon(T)$, then, by the postulated solubility of $\Sigma^{\mathcal{I}}$, we get that $\phi \in T_\Sigma$. Hence, we have $\phi \in T_\Sigma$ if and only if $\Sigma_\Sigma^{\mathcal{I},v}[\phi] \leq \Upsilon(T)$, showing that $\Sigma^{\mathcal{I}}$ witnesses the behavioral truth equationality of $\mathcal{I}$. ∎

We now have the following characterization of behavioral truth equationality depending on the behavior (in the ordinary sense) of the behavioral Suszko core.

$$\mathcal{I} \text{ is Behaviorally Truth Equational} \longleftrightarrow \Sigma^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 1982 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally truth equational if and only if it has a soluble behavioral Suszko core.*

Proof: Necessity is by Theorem 1980, whereas sufficiency is proved in Theorem 1981. ∎

We say that the behavioral Suszko core $\Sigma^{\mathcal{I}}$ of a behavioral π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ **defines theory families** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}_v^\flat(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \Sigma_\Sigma^{\mathcal{I},v}[\phi] \leq \Upsilon(T).$$

Then, another characterization of behavioral truth equationality is the following:

$$\mathcal{I} \text{ is Behaviorally Truth Equational} \longleftrightarrow \Sigma^{\mathcal{I}} \text{ Defines Theory Families.}$$

Theorem 1983 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally truth equational if and only if its behavioral Suszko core* $\Sigma^{\mathcal{I}}$ *defines theory families.*

Proof: $\mathcal{I}$ is behaviorally truth equational if and only if, by Theorem 1982 $\Sigma^{\mathcal{I}}$ is soluble if and only if, by Proposition 1979 and the definition of solubility, $\Sigma^{\mathcal{I}}$ defines theory families in $\mathcal{I}$. ∎

We have just seen that behavioral truth equationality of a behavioral π-institution is equivalent to the solubility property of its behavioral Suszko core. The solubility property implies another property, which, taking after similar work in preceding chapters, we call *adequacy*. It says, roughly speaking, that in a behavioral π-institution the category of natural transformations is rich enough to determine behavioral Suszko congruence systems in terms of the behavioral Leibniz congruence systems that it selects by inclusion. The property of adequacy is motivated by the following property that holds in every behavioral π-institution.

Proposition 1984 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. For all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\bigcap\{\Upsilon(T) : \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)\} \leq \widetilde{\Upsilon}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$. Then we have, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{lll}\phi \in T_\Sigma & \text{implies} & \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \widetilde{\Upsilon}(T)\\ & \text{implies} & \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T).\end{array}$$

Thus, we get

$$\begin{array}{lll}\bigcap\{\Upsilon(T) : \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)\} & \leq & \bigcap\{\Upsilon(T) : \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \widetilde{\Upsilon}(T)\}\\ & \leq & \bigcap\{\Upsilon(T) : \phi \in T_\Sigma\}\\ & = & \widetilde{\Upsilon}(C(\phi)).\end{array}$$

Hence, the inclusion in the statement holds. ■

The reverse inclusion is not always guaranteed, but, when it holds, we say that the behavioral Suszko core of $\mathcal{I}$ is *adequate*. The terminology is intended to convey the idea that $\Sigma^{\mathcal{I},v}_\Sigma[\phi]$ suffices to determine the theory families whose behavioral Leibniz congruence systems form a "covering" of the behavioral Suszko congruence system corresponding to the theory family $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a behavioral π-institution based on $\mathbf{F}$. The behavioral Suszko core $\Sigma^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\widetilde{\Upsilon}(C(\phi)) \leq \bigcap\{\Upsilon(T) : \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)\}.$$

We can prove immediately that the solubility of the behavioral Suszko core implies its adequacy.

Proposition 1985 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If the behavioral Suszko core* $\Sigma^{\mathcal{I}}$ *is soluble, then it is adequate.*

Proof: Suppose that $\Sigma^{\mathcal{I}}$ is soluble. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$. By solubility, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

Hence, we get

$$\widetilde{\Upsilon}(C(\phi)) \leq \widetilde{\Upsilon}(T) \leq \Upsilon(T).$$

Since this holds, for all $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)$, we get that

$$\widetilde{\Upsilon}(C(\phi)) \leq \bigcap\{\Upsilon(T) : \Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)\}.$$

Therefore, $\Sigma^{\mathcal{I}}$ is adequate. ∎

Conversely, if a behavioral π-institution is behaviorally c-reflective, then the adequacy of its behavioral Suszko core is sufficient to give its solubility.

Proposition 1986 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally c-reflective and the behavioral Suszko core* $\Sigma^{\mathcal{I}}$ *is adequate, then* $\Sigma^{\mathcal{I}}$ *is soluble.*

Proof: Suppose that $\mathcal{I}$ is behaviorally c-reflective and that the behavioral Suszko core $\Sigma^{\mathcal{I}}$ is adequate. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\Sigma^{\mathcal{I},v}_\Sigma[\phi] \leq \Upsilon(T)$. Then, by the adequacy of the Suszko core, we get that $\widetilde{\Upsilon}(C(\phi)) \leq \Upsilon(T)$, whence, by behavioral c-reflectivity and Lemma 1976, we get $C(\phi) \leq T$, i.e., $\phi \in T_\Sigma$. We conclude that $\Sigma^{\mathcal{I}}$ is soluble. ∎

We can now show that a behavioral π-institution is behaviorally truth equational if and only if it is behaviorally c-reflective and has an adequate behavioral Suszko core.

Behavioral Truth Equationality
= $\Sigma^{\mathcal{I}}$ Soluble
= $\Sigma^{\mathcal{I}}$ Defines Theory Families
= Behavioral c-Reflectivity + $\Sigma^{\mathcal{I}}$ Adequate

Theorem 1987 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally truth equational if and only if it is behaviorally c-reflective and has an adequate behavioral Suszko core.*

Proof: If $\mathcal{I}$ is behaviorally truth equational, then, by Proposition 1977, it is behaviorally c-reflective, by Theorem 1980, its behavioral Suszko core is soluble and, by Proposition 1985, its behavioral Suszko core is adequate. Conversely, if $\mathcal{I}$ is behaviorally c-reflective with an adequate behavioral Suszko core, then, by Proposition 1986, its behavioral Suszko core is soluble and, hence, by Theorem 1981, $\mathcal{I}$ is behaviorally truth equational. ∎

27.6 Behavioral Weak Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a behavioral π-institution based on $\mathbf{F}$. $\mathcal{I}$ is **behaviorally WF algebraizable** if it is behaviorally protoalgebraic and behaviorally c-reflective.

Lemma 1988 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally protoalgebraic, then, for all* $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,*

$$\Upsilon(\bigcap_{i\in I} T^i) = \bigcap_{i\in I} \Upsilon(T^i).$$

Proof: Suppose $\mathcal{I}$ is behaviorally protoalgebraic and let $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$. Then, by hypothesis, $\Upsilon(\bigcap_{i\in I} T^i) \leq \bigcap_{i\in I} \Upsilon(T^i)$. On the other hand, $\bigcap_{i\in I} \Upsilon(T^i)$ is a congruence system on $\mathbf{F}$. Moreover, it is easy to see that it is compatible with $\bigcap_{i\in I} T^i$. Hence, by the maximality property of the behavioral Leibniz congruence system, we get $\bigcap_{i\in I} \Upsilon(T^i) \leq \Upsilon(\bigcap_{i\in I} T^i)$. ■

Lemma 1989 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally protoalgebraic and the behavioral Leibniz operator is injective, then, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,*

$$\bigcap_{T\in\mathcal{T}} \Upsilon(T) \leq \Upsilon(T') \quad \textit{implies} \quad \bigcap \mathcal{T} \leq T'.$$

Proof: Suppose that $\mathcal{I}$ is behaviorally protoalgebraic and that the behavioral Leibniz operator is injective. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Upsilon(T) \leq \Upsilon(T')$. Then we have

$$\begin{array}{rcll}\Upsilon(\bigcap \mathcal{T} \cap T') & = & \bigcap_{T\in\mathcal{T}} \Upsilon(T) \cap \Upsilon(T') & \text{(Lemma 1988)}\\ & = & \bigcap_{T\in\mathcal{T}} \Upsilon(T) & \text{(hypothesis)}\\ & = & \Upsilon(\bigcap \mathcal{T}). & \text{(Lemma 1988)}\end{array}$$

Hence, by the injectivity of the behavioral Leibniz operator, $\bigcap \mathcal{T} \cap T' = \bigcap \mathcal{T}$, showing that $\bigcap \mathcal{T} \leq T'$. ■

Proposition 1990 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally WF algebraizable if and only if the behavioral Leibniz operator is monotone and injective on* $\mathrm{ThFam}(\mathcal{I})$*.*

Proof: Suppose $\mathcal{I}$ is behaviorally WF algebraizable. Then by definition, it is behaviorally protoalgebraic and behaviorally c-reflective. Thus, the behavioral Leibniz operator is monotone and c-reflective on $\mathrm{ThFam}(\mathcal{I})$, whence it is monotone and, a fortiori, injective on $\mathrm{ThFam}(\mathcal{I})$.

If, conversely, Υ is monotone and injective on $\mathrm{ThFam}(\mathcal{I})$, then it is monotone and, by Lemma 1989, c-reflective on $\mathrm{ThFam}(\mathcal{I})$. Hence, $\mathcal{I}$ is behaviorally protoalgebraic and behaviorally c-reflective, i.e., by definition, it is behaviorally WF algebraizable. ∎

Another characterization of behavioral WF algebraizability asserts that it is equivalent to the existence of an isomorphism from the complete lattice of theory families of a behavioral π-institution to the complete lattice of the $\mathcal{I}$-congruence systems on its underlying behavioral algebraic system.

We need the following preparatory definitions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$.

- Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system. A family $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, with $T_\Sigma \subseteq \bigcup_{v \in V} \mathrm{SEN}_v(\Sigma)$, for all $\Sigma \in |\mathbf{Sign}|$, is called an **$\mathcal{I}$-filter family** of $\mathcal{A}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $v \in V$ and all $\Phi \cup \{\phi\} \subseteq \bigcup_{v \in V} \mathrm{SEN}_v^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$,
$$\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)}.$$
The collection of all $\mathcal{I}$-filter families of $\mathcal{A}$ is denoted by $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. It is a complete lattice, whose corresponding closure operator will be denoted by $C^{\mathcal{I},\mathcal{A}}$.

- An $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an **$\mathcal{I}$-algebraic system** if there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Upsilon}(T) = \Delta^{\mathcal{A}}$. The collection of all $\mathcal{I}$-algebraic systems is denoted by $\mathrm{AlgSys}(\mathcal{I})$.

- Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, a congruence system $\theta \in \mathrm{ConSys}(\mathcal{A})$ is a **$\mathcal{I}$-congruence system on $\mathcal{A}$** if $\mathcal{A}/\theta \in \mathrm{AlgSys}(\mathcal{I})$. The collection of all $\mathcal{I}$-congruence systems on $\mathcal{A}$ is denoted by $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$.

Lemma 1991 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}_s^\flat\}_H^{V,V^*}, N^\flat \rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a behavioral π-institution based on $\mathbf{F}$. For every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, such that, for all $\Sigma \in |\mathbf{Sign}|$, $T_\Sigma \subseteq \bigcup_{v \in V} \mathrm{SEN}_v(\Sigma)$,*
$$T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \quad \textit{iff} \quad \alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I}).$$

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, such that, for all $\Sigma \in |\mathbf{Sign}|$, $T_\Sigma \subseteq \bigcup_{v \in V} \mathrm{SEN}_v(\Sigma)$.

Assume, first, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}_v^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)}))$. Then, by the definition of $C^{\mathcal{I},\mathcal{A}}$, we get
$$\alpha_\Sigma(\phi) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)}))) \subseteq C^{\mathcal{I},\mathcal{A}}_{F(\Sigma)}(T_{F(\Sigma)}) = T_{F(\Sigma)}.$$
Hence, we get $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and we conclude that $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$.

Suppose, conversely, that $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \bigcup_{v \in V} \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Then $\Phi \subseteq \alpha^{-1}_\Sigma(T_{F(\Sigma)})$, whence, since $\phi \in C_\Sigma(\Phi)$ and $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that $\phi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$, i.e., $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. We conclude that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Lemma 1992 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\Upsilon(\alpha^{-1}(T)) = \alpha^{-1}(\Upsilon^{\mathcal{A}}(T)).$$

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi, \psi \in \mathrm{SEN}^\flat_s(\Sigma)$, we have $\langle \phi, \psi \rangle \in \Upsilon_\Sigma(\alpha^{-1}(T))$ if and only if, for all $\sigma : \mathrm{SEN}^\flat_s \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_v$, with $v \in V$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\begin{array}{l} \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi), \vec{\chi}) \in \alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}) \\ \qquad \text{iff} \quad \sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi), \vec{\chi}) \in \alpha^{-1}_{\Sigma'}(T_{F(\Sigma')}) \end{array}$$

iff

$$\begin{array}{l} \alpha_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi), \vec{\chi})) \in T_{F(\Sigma')} \\ \qquad \text{iff} \quad \alpha_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi), \vec{\chi})) \in T_{F(\Sigma')} \end{array}$$

iff

$$\begin{array}{l} \sigma^{\mathcal{A}}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \qquad \text{iff} \quad \sigma^{\mathcal{A}}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \end{array}$$

iff

$$\begin{array}{l} \sigma^{\mathcal{A}}_{F(\Sigma')}(\mathrm{SEN}_s(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \qquad \text{iff} \quad \sigma^{\mathcal{A}}_{F(\Sigma')}(\mathrm{SEN}_s(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \end{array}$$

if and only if, by the surjectivity of $\langle F, \alpha \rangle$, $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Upsilon^{\mathcal{A}}_{F(\Sigma)}(T)$ if and only if $\langle \phi, \psi \rangle \in \alpha^{-1}_{F(\Sigma)}(\Upsilon^{\mathcal{A}}_{F(\Sigma)}(T))$. We now conclude that $\Upsilon(\alpha^{-1}(T)) = \alpha^{-1}(\Upsilon^{\mathcal{A}}(T))$. ■

Now we have the following characterization result for behavioral WF algebraizability.

Theorem 1993 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is behaviorally WF algebraizable if and only if* $\Upsilon : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ConSys}^{\mathcal{I}}(\mathcal{F})$ *is an order isomorphism.*

Proof: Suppose that $\mathcal{I}$ is behaviorally WF algebraizable. Then, by Proposition 1990, Υ is monotone and injective on $\mathrm{ThFam}(\mathcal{I})$. Moreover, by definition of behavioral WF algebraizability Υ is c-reflective on $\mathrm{ThFam}(\mathcal{I})$ and, therefore, a fortiori, it is order reflecting. Thus, it suffices to show that it is surjective, i.e., onto $\mathrm{ConSys}^{\mathcal{I}}(\mathcal{F})$. To this end, let $\theta \in \mathrm{ConSys}^{\mathcal{I}}(\mathcal{F})$. By definition, $\mathcal{F}/\theta \in \mathrm{AlgSys}(\mathcal{I})$. Thus, there exists $T^\theta \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$, such that $\widetilde{\Upsilon}^{\mathcal{F}/\theta}(T^\theta) = \Delta^{\mathcal{F}/\theta}$. Let $\langle I, \pi^\theta\rangle : \mathcal{F} \to \mathcal{F}/\theta$ be the quotient morphism. Now, by Lemma 1991, $\pi^{\theta^{-1}}(T^\theta) \in \mathrm{ThFam}(\mathcal{I})$ and

$$\begin{array}{rcll}\Upsilon(\pi^{\theta^{-1}}(T^\theta)) & = & \pi^{\theta^{-1}}(\Upsilon^{\mathcal{F}/\theta}(T^\theta)) & \text{(Lemma 1992)}\\ & = & \pi^{\theta^{-1}}(\Delta^{\mathcal{F}/\theta}) & \text{(hypothesis and protoalgebraicity)}\\ & = & \theta. & \text{(set theory)}\end{array}$$

Therefore, Υ is surjective and, hence, an order isomorphism from $\mathbf{ThFam}(\mathcal{I})$ onto $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{F})$.

Conversely, if $\Upsilon : \mathbf{ThFam}(\mathcal{I}) \to \mathbf{ConSys}^{\mathcal{I}}(\mathcal{F})$ is an order isomorphism, then it is monotone and injective on $\mathrm{ThFam}(\mathcal{I})$ and, hence, by Proposition 1990, $\mathcal{I}$ is behaviorally WF algebraizable. ■

Finally, we close by providing a relation between behavioral algebraizability and behavioral WF algebraizability. Our first step in this direction is to show that behavioral algebraizability implies both behavioral syntactic protoalgebraicity and behavioral truth equationality. To be able to show this, we start by proving two technical results asserting that the binary relation family induced on the underlying behavioral algebraic system of a given behaviorally algebraizable π-institution by one of the two interpretations witnessing the behavioral algebraizability is a congruence system having a compatibility property.

Lemma 1994 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable via a conjugate pair* $(\tau, \rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$*, all* $v \in V$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$*,*

$$\psi \in C_\Sigma(\phi, \rho^v_\Sigma[\phi, \psi]).$$

Proof: Assume $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi, \psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\phi \in T_\Sigma$ and $\rho^v_\Sigma[\phi, \psi] \leq T$. Then we get that

$$\tau^v_\Sigma[\phi] \leq C^{\mathsf{K}}(\tau_\Sigma[T]) \quad \text{and} \quad \langle \phi, \psi\rangle \in C^{\mathsf{K}}(\tau_\Sigma[T]).$$

Hence, by the definition of C^{K}, we get that $\tau^v_\Sigma[\psi] \leq C^{\mathsf{K}}(\tau_\Sigma[T])$ and, therefore, $\psi \in C_\Sigma(T) = T_\Sigma$. We conclude that $\psi \in C_\Sigma(\phi, \rho^v_\Sigma[\phi, \psi])$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ be a behavioral algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a behaviorally algebraizable π-institution, as witnessed by the conjugate pair $(\tau,\rho):\mathcal{I}\rightleftarrows\mathcal{I}^{\mathsf{K}}$, for some class K of $\mathbf{F}$-algebraic systems. We define a class $\rho^+=\{\rho^{+,s}:s\in S\}$ of natural transformations in $N^\flat$ by setting, for all $s\in S$, $\rho^{+,s}$ to be the collection of all natural transformations in $N^\flat$ of the form

$$\sigma^v(\sigma(x,\vec{z}),\sigma(y,\vec{z}),\vec{w}),$$

where

$$\sigma:\mathrm{SEN}^\flat_s\times\prod_{i=1}^k\mathrm{SEN}^\flat_{s_i}\to\mathrm{SEN}^\flat_v,\quad \sigma^v\in\rho^v,\quad v\in V.$$

Moreover, for all $T\in\mathrm{ThFam}(\mathcal{I})$, we define $\rho^{+*}(T)=\{\rho^{+*}_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}^\flat|}$, where, for all $\Sigma\in|\mathbf{Sign}^\flat|$, we set

$$\rho^{+*}_\Sigma(T)=\{\rho^{+*,s}_\Sigma(T):s\in S\}$$

by letting, for all $\Sigma\in|\mathbf{Sign}^\flat|$, all $s\in S$ and all $\phi,\psi\in\mathrm{SEN}^\flat_s(\Sigma)$,

$$\langle\phi,\psi\rangle\in\rho^{+*,s}_\Sigma(T)\quad\text{iff}\quad\rho^{+,s}_\Sigma[\phi,\psi]\le T.$$

Proposition 1995 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\{\mathrm{SEN}^\flat_s\}_H^{V,V^*},N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable via a conjugate pair* $(\tau,\rho):\mathcal{I}\rightleftarrows\mathcal{I}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $T\in\mathrm{ThFam}(\mathcal{I})$*,* $\rho^{+*}(T)$ *is a congruence system on* $\mathbf{F}$ *compatible with* T*.*

Proof: Let $T\in\mathrm{ThFam}(\mathcal{I})$ and $\Sigma\in|\mathbf{Sign}^\flat|$. Then $\rho^{+*}_\Sigma(T)$ is reflexive, symmetric and transitive, by the definition of $\mathcal{I}^{\mathsf{K}}$, the definition of ρ^+ and the fact that ρ is an interpretation.

E.g., to show symmetry, we let $\Sigma\in|\mathbf{Sign}^\flat|$, $s\in S$ and $\phi,\psi\in\mathrm{SEN}^\flat_s(\Sigma)$, such that $\langle\phi,\psi\rangle\in\rho^{+*,s}_\Sigma(T)$. Then, we have $\rho^{+,s}_\Sigma[\phi,\psi]\le T$ and, thus, for all $\sigma:\mathrm{SEN}^\flat_s\times\prod_{i=1}^k\mathrm{SEN}^\flat_{s_i}\to\mathrm{SEN}^\flat_v$ in $N^\flat$, $\Sigma'\in|\mathbf{Sign}^\flat|$, $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi}\in\prod_{i=1}^k\mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\rho^v_{\Sigma'}[\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}),\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi),\vec{\chi})]\le T.$$

This, however, implies that

$$\rho^v_{\Sigma'}[\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi),\vec{\chi}),\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi})]\le T.$$

Reversing the steps above, we get that $\langle\psi,\phi\rangle\in\rho^{+*,s}_\Sigma(T)$. Hence, $\rho^{+*}_\Sigma(T)$ is symmetric.

Moreover, it has, by the same considerations, the congruence property. Finally, it is a system by the definition of $\rho^{+*}(T)$. It is compatible with T due to Lemma 1994. ■

Corollary 1996 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable via a conjugate pair* $(\tau,\rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $v \in V$*,* $\rho^{+*,v}(T) = \rho^{*,v}(T)$*.*

Proof: Let $v \in V$ and suppose $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$, such that $\langle\phi,\psi\rangle \in \rho^{+*,v}_\Sigma(T)$. Then $\rho^{+,v}_\Sigma[\phi,\psi] \leq T$. But, by definition, $\rho \subseteq \rho^+$, whence, $\rho^v_\Sigma[\phi,\psi] \leq T$, Therefore, $\langle\phi,\psi\rangle \in \rho^{*,v}_\Sigma(T)$.

Suppose, conversely, that $\langle\phi,\psi\rangle \in \rho^{*,v}_\Sigma(T)$. Then $\rho^v_\Sigma[\phi,\psi] \leq T$. But this implies that, for all $\sigma : \mathrm{SEN}^\flat_v \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_u$, with $u \in V$, in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$,

$$\rho^u_{\Sigma'}[\sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\phi),\vec{\chi}),\sigma_{\Sigma'}(\mathrm{SEN}^\flat_v(f)(\psi),\vec{\chi})] \leq T.$$

Therefore, we conclude that $\rho^{+,v}_\Sigma[\phi,\psi] \leq T$, giving that $\langle\phi,\psi\rangle \in \rho^{+*,v}_\Sigma(T)$. ■

Proposition 1995 allows us to establish that the congruence system $\rho^{+*}(T)$ coincides with the behavioral Leibniz congruence system $\Upsilon(T)$ of T in $\mathcal{I}$.

Theorem 1997 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable via a conjugate pair* $(\tau,\rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$*, for some class* K *of* $\mathbf{F}$*-algebraic systems, then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\rho^{+*}(T) = \Upsilon(T).$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $s \in S$ and $\phi,\psi \in \mathrm{SEN}^\flat_s(\Sigma)$, such that $\langle\phi,\psi\rangle \in \Upsilon_\Sigma(T)$. Since $\Upsilon(T)$ is a congruence system, we get, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\langle \mathrm{SEN}^\flat_s(f)(\phi), \mathrm{SEN}^\flat_s(f)(\psi)\rangle \in \Upsilon_{\Sigma'}(T)$. Since $\Upsilon(T)$ is a congruence system, we now get, for all $\sigma^v \in \rho^v$, all $\sigma : \mathrm{SEN}^\flat_s \times \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i} \to \mathrm{SEN}^\flat_v$ in $N^\flat$, and all $\vec{\chi} \in \prod_{i=1}^k \mathrm{SEN}^\flat_{s_i}(\Sigma')$, $\vec{\xi} \in \prod_{j<\omega} \mathrm{SEN}^\flat_{s_j}(\Sigma')$,

$$\begin{array}{l}\langle \sigma^v_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}),\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}),\vec{\xi}),\\ \qquad \sigma^v_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\phi),\vec{\chi}),\sigma_{\Sigma'}(\mathrm{SEN}^\flat_s(f)(\psi),\vec{\chi}),\vec{\xi})\rangle \in \Upsilon_{\Sigma'}(T).\end{array}$$

On the other hand, we know that $\rho^{+,s}_\Sigma[\phi,\phi] \leq T$, whence, by the compatibility of $\Upsilon(T)$ with T, we get that $\rho^{+,s}_\Sigma[\phi,\psi] \leq T$. Therefore, $\langle\phi,\psi\rangle \in \rho^{+*}_\Sigma(T)$.

Conversely, since, by Proposition 1995, $\rho^{+*}(T)$ is a congruence system on $\mathbf{F}$ that is compatible with T, we get, by the maximality property of the behavioral Leibniz operator, $\rho^{+*}(T) \leq \Upsilon(T)$. ■

Now, we prove that behavioral algebraizability implies both behavioral syntactic protoalgebraicity and behavioral truth equationality.

Theorem 1998 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally algebraizable, then it is both behaviorally syntactically protoalgebraic and behaviorally truth equational.*

Proof: Suppose $\mathcal{I}$ is behaviorally algebraizable via the conjugate pair $(\tau,\rho) : \mathcal{I} \rightleftarrows \mathcal{I}^{\mathsf{K}}$, for some class K of $\mathbf{F}$-algebraic systems.

Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$. Then we have

$$\begin{array}{llll}\langle\phi,\psi\rangle \in \Upsilon_\Sigma(T) & \text{iff} & \langle\phi,\psi\rangle \in \rho^{+*}_\Sigma(T) & \text{(Theorem 1997)}\\ & \text{iff} & \langle\phi,\psi\rangle \in \rho^*_\Sigma(T) & \text{(by Corollary 1996)}\\ & \text{iff} & \rho_\Sigma[\phi,\psi] \le T. & \text{(definition of } \rho^*)\end{array}$$

Therefore, $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ.

Finally, let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and $\phi \in \mathrm{SEN}^\flat_v(\Sigma)$. Then, we have

$$\begin{array}{llll}\phi \in T_\Sigma & \text{iff} & \rho_\Sigma[\tau_\Sigma[\phi]] \le T & ((\tau,\rho) \text{ conjugate pair})\\ & \text{iff} & \tau_\Sigma[\phi] \subseteq \rho^*_\Sigma(T) & \text{(definition of } \rho^*)\\ & \text{iff} & \tau_\Sigma[\phi] \subseteq \rho^{+*}_\Sigma(T) & \text{(by Corollary 1996)}\\ & \text{iff} & \tau_\Sigma[\phi] \le \Upsilon(T). & \text{(Theorem 1997)}\end{array}$$

Therefore, $\mathcal{I}$ is behaviorally truth equational, with witnessing transformations τ. ■

We show, next, that, conversely, behavioral syntactic protoalgebraicity and behavioral truth equationality guarantee behavioral algebraizability.

Theorem 1999 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}^{V,V^*}_H, N^\flat\rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is behaviorally syntactically protoalgebraic and behaviorally truth equational, then it is behaviorally algebraizable.*

Proof: Suppose that $\mathcal{I}$ is behaviorally syntactically protoalgebraic, with witnessing transformations ρ, and behaviorally truth equational, with witnessing transformations τ. Then, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \bigcup_{v\in V}\mathrm{SEN}^\flat_v(\Sigma)$,

$$\begin{array}{lll}\phi \in C_\Sigma(\Phi) & \text{iff} & \phi \in \bigcap\{T_\Sigma : \Phi \subseteq T_\Sigma\}\\ & \text{iff} & \tau_\Sigma[\phi] \le \bigcap\{\Upsilon(T) : \tau_\Sigma[\Phi] \le \Upsilon(T)\}\\ & \text{iff} & \tau_\Sigma[\phi] \le C^{\mathsf{K}}(\tau_\Sigma[\Phi]).\end{array}$$

Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $v \in V$ and all $\phi,\psi \in \mathrm{SEN}^\flat_v(\Sigma)$,

$$\begin{array}{lll}\langle\phi,\psi\rangle \in \Upsilon_\Sigma(T) & \text{iff} & \rho^v_\Sigma[\phi,\psi] \le T\\ & \text{iff} & \tau[\rho^v_\Sigma[\phi,\psi]] \le \Upsilon(T).\end{array}$$

Hence, we have that $C^{\mathsf{K}}(\phi \approx \psi) = C^{\mathsf{K}}(\tau[\rho^v_\Sigma[\phi,\psi]])$.

We conclude, by Proposition 1961, that $\mathcal{I}$ is equivalent to $\mathcal{I}^{\mathsf{K}}$ and, therefore, $\mathcal{I}$ is behaviorally algebraizable. ■

Now we can formulate the main characterization theorem:

Theorem 2000 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \{\mathrm{SEN}^\flat_s\}_H^{V,V^*}, N^\flat \rangle$ *be a behavioral algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a behavioral* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(i) $\mathcal{I}$ *is behaviorally algebraizable;*

(ii) $\mathcal{I}$ *is behaviorally syntactically protoalgebraic and behaviorally truth equational;*

(iii) $\mathcal{I}$ *is behaviorally WF algebraizable (i.e., behaviorally protoalgebraic and behaviorally c-reflective) and has both a Leibniz behavioral reflexive core and an adequate behavioral Suszko core.*

Proof: If $\mathcal{I}$ is behaviorally algebraizable, then, by Theorem 1998, it is both behaviorally syntactically protoalgebraic and behaviorally truth equational. If $\mathcal{I}$ is behaviorally syntactically protoalgebraic and behaviorally truth equational, then, by Theorems 1975 and 1987, it is behaviorally protoalgebraic, behaviorally c-reflective and has both a Leibniz behavioral reflexive core and an adequate behavioral Suszko core. Finally, if $\mathcal{I}$ is behaviorally WF algebraizable, with a Leibniz behavioral reflexive core and an adequate behavioral Suszko core, then, by Theorems 1975 and 1987, it is behaviorally syntactically protoalgebraic and behaviorally truth equational, whence, by Theorem 1999, it is behaviorally algebraizable. ∎

Chapter 28

List of Problems

A Few Words

We gather some of the problems arising at various places in the main text. They are listed in order of occurrence and no suggestion is made about the degree of their difficulty. In fact, I have not put the same amount of effort in tackling all problems in the list. However, solving them, regardless of difficulty, will definitively inform the theory and the context in which they appear.

Each problem consists of a **task**, which is, in my estimation, the most likely outcome. The **alternative** is also explicitly given. When a task seems a bit involved and I am less certain about its status, I inserted in the list some special subtasks that might be easier to tackle. So, not all problems appearing in the list are independent, and, when aware, I tried to state this explicitly.

As for the format, here is a generic sample, before presenting the list:

Problem X (Chapter 00, Example 00)
This is a special case of Problem Y.
Task: Construct a π-institution in class A but not in class B.
Alternative: Prove that every π-institution in A is also in B.

The List

No problems in the list for the time being.
