Chapter 1

Introduction

1.1 Introduction

The field of *algebraic logic* assumed its modern systematic form, known as *abstract algebraic logic*, with the appearance of the pioneering "Memoirs" monograph of Blok and Pigozzi [35]. In this celebrated monograph one can find clearly discernible the seeds and the foundations of almost all subsequent developments in the field and, consequently, also, the foundations on which most parts of the work and of the developments detailed in the present monograph are based.

Related to the term "abstract algebraic logic", another of the pioneers of the field, Josep Maria Font, in a more recent textbook, titled "Abstract Algebraic Logic An Introductory Textbook" [86], advocates that the name should continue to be simply *algebraic logic* and that, as is the case with most other fields of Mathematics, Logic and Science, the abstraction, to which the term "abstract" refers, is part of the natural evolution of the same field, and should not be construed as constituting a special subfield justifying a special naming or rebranding.

In a similar sense, one may share the same belief for *categorical abstract algebraic logic*, which is also another natural evolution of algebraic logic and, therefore, according to this point of view, should also be referred to, simply, as *algebraic logic*. It may, in fact, be preferable to refer to the underlying formalizations of the logical systems treated in each particular context than to rebrand the entire field. So instead of referring to "abstract algebraic logic", we may say "algebraic logic as applied to sentential logics" (or "to deductive systems") and, similarly, "algebraic logic as applied to logics formalized as institutions or π-institutions", instead of using "categorical abstract algebraic logic" for the latter. For now, however, the traditional names have stuck and have been used widely, with well-discernible meanings, and we use them freely, as is also done in [86].

In "traditional" algebraic logic, which may be viewed to have started with the work of Tarski [5], the underlying formalism consists of *sentential logics* or *deductive systems*. These are pairs $\mathcal{S} = \langle \mathcal{L}, \vdash_{\mathcal{S}} \rangle$, where $\mathcal{L}$ is an algebraic language (a set of operation symbols with specified finite arities) and $\vdash_{\mathcal{S}}$ is a *consequence relation* on the absolutely free algebra $\mathbf{Fm}_{\mathcal{L}}(V)$ generated by a countable set V of variables. That is, $\vdash_{\mathcal{S}} \subseteq \mathcal{P}(\mathrm{Fm}_{\mathcal{L}}(V)) \times \mathrm{Fm}_{\mathcal{L}}(V)$, satisfies the following, for all $\Gamma \cup \Delta \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

Inflation: $\Gamma \vdash_{\mathcal{S}} \varphi$, for all $\varphi \in \Gamma$;

Monotonicity: $\Gamma \vdash_{\mathcal{S}} \varphi$ and $\Gamma \subseteq \Delta$ imply $\Delta \vdash_{\mathcal{S}} \varphi$;

Idempotency: $\Gamma \vdash_{\mathcal{S}} \varphi$ and $\Delta \vdash_{\mathcal{S}} \gamma$, for all $\gamma \in \Gamma$, imply, $\Delta \vdash_{\mathcal{S}} \varphi$;

Structurality: $\Gamma \vdash_{\mathcal{S}} \varphi$ implies $\sigma(\Gamma) \vdash_{\mathcal{S}} \sigma(\varphi)$, for all endomorphisms $\sigma : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{Fm}_{\mathcal{L}}(V)$.

Equivalently, $\mathcal{S}$ may be expressed in terms of a *structural closure operator* $C_{\mathcal{S}}$, i.e., a function $C_{\mathcal{S}} : \mathcal{P}(\mathrm{Fm}_{\mathcal{L}}(V)) \to \mathcal{P}(\mathrm{Fm}_{\mathcal{L}}(V))$, satisfying, for all $\Gamma \cup \Delta \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$:

Inflation: $\Gamma \subseteq C_{\mathcal{S}}(\Gamma)$;

Monotonicity: $C_{\mathcal{S}}(\Gamma) \subseteq C_{\mathcal{S}}(\Delta)$, for all $\Gamma \subseteq \Delta$;

Idempotency: $C_{\mathcal{S}}(C_{\mathcal{S}}(\Gamma)) \subseteq C_{\mathcal{S}}(\Gamma)$;

Structurality: $\sigma(C_{\mathcal{S}}(\Gamma)) \subseteq C_{\mathcal{S}}(\sigma(\Gamma))$, for all endomorphisms $\sigma : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{Fm}_{\mathcal{L}}(V)$.

The equivalence is established by setting, on the one hand, for all $\Gamma \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$C_{\mathcal{S}}(\Gamma) = \{\varphi \in \mathrm{Fm}_{\mathcal{L}}(V) : \Gamma \vdash_{\mathcal{S}} \varphi\},$$

and, on the other, for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\Gamma \vdash_{\mathcal{S}} \varphi \quad \text{iff} \quad \phi \in C_{\mathcal{S}}(\Gamma).$$

The reliance on sentential logics as the underlying formalism of the theory persists when passing to abstract algebraic logic. The reader is referred to the aforementioned [35, 86], as well as to the standard reference [64] by Janusz Czelakowski, another pioneer in the field, all clearly showcasing the primary role of this framework in all related developments and investigations.

By contrast, in this monograph the underlying logical formalism consists of π-institutions [33]. This formalism encompasses systems with varying signatures and quantifiers in a more direct way than allowed by the formalism of sentential logics (see Appendix C of [35], as well as the work on cylindric [15, 27] and polyadic algebras [9] and related work at the institutional level [100, 101, 102, 103] based and/or closely related to these). The structure of a π-institution forms a modification of the structure of an institution [25, 41], which was introduced in computer science to formalize logical systems for specification and programming, based on semantics. Diaconescu's monograph [79] offers a comprehensive advanced study of institutions and presents a multitude of model theoretic results that can be abstracted from first-order, and other specific logical systems, to the institutional level. On the other hand, in π-institutions, the framework is stripped of the semantic, or model theoretic, aspects and the focus is on the syntax, thus recovering the essential features of the sentential logic framework, without, however, shedding the versatility afforded, and the advantage gained, by incorporating in the object language multiple signatures and signature-changing morphisms. In fact, this inclusion is what gives the area its distinctive and unique character inside (abstract) algebraic logic. This is apparent in all aspects of our studies.

To make clearer the exact relationship between sentential logics and π-institutions, and showcase the fact that the former constitute very narrow special cases of the latter, let us recall the definition of a π-institution. A *π-institution*, as originally defined in [33], is a triple $\mathcal{I} = \langle \mathbf{Sign}, \mathrm{SEN}, C\rangle$, where

- $\mathbf{Sign}$ is an arbitrary category, whose objects are called *signatures* and its morphisms *signature morphisms*;
- $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ is a functor giving, for each signature $\Sigma \in |\mathbf{Sign}|$, the set $\mathrm{SEN}(\Sigma)$ of Σ-*sentences*;
- For every $\Sigma \in |\mathbf{Sign}|$, $C_\Sigma : \mathcal{P}(\mathrm{SEN}(\Sigma)) \to \mathcal{P}(\mathrm{SEN}(\Sigma))$ is a closure operator, such that the collection $C = \{C_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ satisfies the property of *structurality*, i.e., for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,
$$\mathrm{SEN}(f)(C_\Sigma(\Phi)) \subseteq C_{\Sigma'}(\mathrm{SEN}(f)(\Phi)).$$

In the modified (enriched) form that is used in the present monograph, and which was (essentially) introduced in [106], there is an additional component N, which represents a *category of natural transformations* on the sentence functor SEN. Roughly speaking, this category corresponds to clones of algebraic operations on $\{\mathrm{SEN}(\Sigma) : \Sigma \in |\mathbf{Sign}|\}$, under the assumption that all operations are defined uniformly and naturally over all $\mathrm{SEN}(\Sigma)$, for $\Sigma \in |\mathbf{Sign}|$. This accords in style with the algebraic theories of Lawvere [10], which are closely related to the Eilenberg-Moore [11] and the Kleisli [12] constructions. For more details on these, one may consult the classic texts by Mac Lane [16], Pareigis [14], Borceux [45] and Barr and Wells [57]. Thus, we are studying logical systems formalized as quadruples $\mathcal{I} = \langle \mathbf{Sign}, \mathrm{SEN}, N, C\rangle$, which are further recast as pairs
$$\mathcal{I} = \langle \mathbf{F}, C\rangle,$$
where

- $\mathbf{F} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ expresses the algebraic structure, corresponding to the absolutely free algebra in the case of deductive systems, and
- $C = \{C_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ is a family of closure operators, satisfying structurality, which is referred to as a *closure system*, and corresponds to the closure $C_{\mathcal{S}}$ in the case of sentential logics.

Suppose now that $\mathcal{S} = \langle \mathcal{L}, C_{\mathcal{S}}\rangle$ is a sentential logic. The standard rendering of it as a π-institution
$$\mathcal{I}^{\mathcal{S}} = \langle \mathbf{F}^{\mathcal{L}}, C^{\mathcal{S}}\rangle,$$
with $\mathbf{F}^{\mathcal{L}} = \langle \mathbf{Sign}^{\mathcal{L}}, \mathrm{SEN}^{\mathcal{L}}, N^{\mathcal{L}}\rangle$, is given by defining the four components as follows:

- $\mathbf{Sign}^{\mathcal{L}}$ is a trivial category, with object, say, V;

- $\mathrm{SEN}^{\mathcal{L}} : \mathbf{Sign}^{\mathcal{L}} \to \mathbf{Set}$ is given by $\mathrm{SEN}^{\mathcal{L}}(V) = \mathrm{Fm}_{\mathcal{L}}(V)$;
- $N^{\mathcal{L}}$ is the clone of all $\mathcal{L}$-operations on $\mathrm{Fm}_{\mathcal{L}}(V)$;
- $C_V^{\mathcal{S}} = C_{\mathcal{S}} : \mathcal{P}(\mathrm{Fm}_{\mathcal{L}}(V)) \to \mathcal{P}(\mathrm{Fm}_{\mathcal{L}}(V))$.

It is worth noting that $\mathbf{F}^{\mathcal{L}}$ only depends on $\mathcal{L}$ and V, as was to be expected (since it was deemed to correspond to the algebraic structure), and the deductive apparatus is reflected entirely in the definition of $C^{\mathcal{S}}$. Moreover, the formalism on the logical side does not incorporate substitutions in the object language, even though, since $C_V^{\mathcal{S}} = C_{\mathcal{S}}$ and the latter is structural, we have, for every endomorphism $\sigma : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{Fm}_{\mathcal{L}}(V)$,

$$\sigma(C_V^{\mathcal{S}}(\Phi)) \subseteq C_V^{\mathcal{S}}(\sigma(\Phi)),$$

for all $\Phi \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$. On the algebraic side, on the other hand, e.g., when congruences are to be determined, the inclusion of the clone $N^{\mathcal{L}}$, reflecting the algebraic $\mathcal{L}$-structure, forces congruences at the institutional level to exactly correspond to the familiar $\mathcal{L}$-congruences on the formula algebra in the universal algebraic sense.

The reasons why one might want to develop a theory of algebraization for logical systems formalized as institutions or π-institutions parallel the motivations provided by Blok and Pigozzi [35] for developing a theory of algebraizability for sentential logics.

One of the main motivations is providing a classification of logical systems based on the strength of the ties of their deductive apparatuses with those corresponding to algebraic deductive systems, i.e., deductive systems whose closure systems are induced by algebraic structures. Preferably, when the definitions applicable in the context of logical systems formalized as π-institutions specialize in the way outlined above to π-institutions associated with deductive systems, one would be able to recover the well-known algebraic (or Leibniz) hierarchy of abstract algebraic logic [64, 86]. The finitary and finitely algebraizable sentential logics of [35] form a special class in this hierarchy. In [86], this property is termed *Blok-Pigozzi algebraizability* (see Definition 3.39 of [86]).

Another desideratum is that the definitions should be as general as possible so that, given virtually any π-institution, one would be able, at least in principle, to classify it in one or more of the classes of the hierarchy, based on the strength of its algebraic properties.

Further, an additional reassurance would be provided if the definitions supplied turned out to be robust in the sense that one would be able to obtain, at least for several, if not for most, of them, different characterizations depending on the various viewpoints taken. This was clearly and successfully undertaken in [35] for the class of algebraizable deductive systems. In fact, Blok and Pigozzi obtained several different characterizations whose variety and strength played a major role in convincing other researchers that their definitions were chosen wisely and, as a result, in establishing firmly the new trends in the field and, thus, contributing, in large part, to virtually all subsequent developments. It is hoped that pursuits along the same lines here will prove, at least moderately, successful with respect to similar criteria. In particular, it is hoped that the characterizations of many of the classes presented in this monograph in a variety of ways will prove to many of the readers and to, present and future, researchers in the field satisfactory and motivating, as was the case with the work of Blok and Pigozzi [35].

One last motivation, equally important, however, in significance, comes by taking an adversarial point of view. As Blok and Pigozzi realized when studying sentential logics, and is certainly true also for logics formalized as π-institutions, since they encompass sentential logics, is the fact that many logical systems of historical and/or practical significance failed to be amenable to classical methods of algebraization, such as, e.g., the Lindenbaum-Tarski process. Naturally one is inclined to ask whether those systems can be algebraized in some alternative way, using different techniques, or whether the failure in their algebraization is due to intrinsic reasons. That is, one would like to investigate whether those systems have some innate characteristics, e.g., pertaining to their structural properties, that many, if not all, of them share and that decide their algebraizability status. This is reminiscent of the extensive and intensive research in computational complexity theory in separating various complexity classes [94, 92, 95, 93, 96, 91], where common features and rigorous criteria are sought for classification of problems in hierarchies of complexity classes. As is the case there, such an analysis and rigorous classification presupposes the existence of a formal definition of algebraizability (and of other related properties) so as to delineate formal boundaries and establish criteria that could potentially be used to falsify claims of algebraizability for some logical systems. Such criteria would point to shortcomings and defects of some logical systems as related to qualitative requirements that a logic should satisfy in order to qualify for membership in a corresponding class. It is believed that the definitions adopted here are helpful in establishing such criteria and in setting up boundaries. The examples that are scattered throughout seem to support this assertion, but, of course, the jury is out as far as gathering further evidence in support of, or in criticism and opposition to, this claim.

The notion of algebraizability adopted in this monograph is inspired by the one established for deductive systems by Blok and Pigozzi in [35]. Apart from the technical complications inherent in passing from the sentential to the institutional framework, one substantial difference is that we distinguish between a treatment based on the Leibniz operator, referred to as **semantic**, as contrasted to the one based on interpretations from logic to algebra and vice-versa, which is termed **syntactic**, since it is based on natural transformations corresponding to term operations on the free algebra of terms. In the sentential logic framework, such a distinction is only apparent, since, as it turns out, the two approaches are equivalent and, hence, interchangeable. On the other hand, in π-institutions, the added flexibility afforded in the relation between morphisms (which are treated in the object language in the category of signatures) and clone operations (also part of the framework, but added a posteriori to enhance the algebraic character of the intended studies) means that the syntactic concepts dominate (i.e., are, in general, stronger) than their corresponding semantic counterparts.

The role that theories play in sentential logics is subsumed here by theory families, which consist of deductively closed sets of sentences, one for each signature. They form a complete lattice $\mathbf{ThFam}(\mathcal{I}) = \langle \mathrm{ThFam}(\mathcal{I}), \leq \rangle$, when ordered by signature-wise inclusion $\leq$. To each theory family is associated a congruence system, a collection of equivalence relations on formulas, one for each signature, that satisfy both the congruence property (or substitution property) and invariance under signature morphisms. These also form a complete lattice under signature-wise inclusions, which is denoted by $\mathbf{ConSys}(\mathcal{I}) = \langle \mathrm{ConSys}(\mathcal{I}), \leq \rangle$. The congruence system selected is the largest one compatible with the given theory family and is termed, by analogy with the sentential logic framework, the *Leibniz congruence system* associated with the theory family.

Starting from **semantics**, we say that a π-institution is *algebraizable* if it satisfies two conditions that impose very intimate ties between the lattice of theory families of the π-institution and that of the congruence systems determined by a class of algebraic systems. The first condition is that the Leibniz operator is monotone on theory families. The second is that it is order-reflecting.

On the **syntactic** side, a π-institution is *algebraizable* if, on the one hand, the Leibniz congruence systems are definable via a collection of natural transformations in two arguments and, on the other, if the theory families are definable via a collection of natural transformations in a single argument. In general, parametric arguments are allowed and, by restricting those, we obtain potentially narrower classes.

One of the main theorems established by Blok and Pigozzi in [35] is the characterization of algebraizable sentential logics via the existence of an isomorphism between the theory lattice of the deductive system and the equational theory lattice associated to a class of algebras, which also commutes with substitutions. A characterization along similar lines is established here for logical systems formalized as π-institutions (see, e.g., Section 4.3 or Section 12.3, even though other related forms appear in other places in the monograph, as will be discussed in the overview). In the literature several forms of this theorem and a host of generalizations of increasing power (or generality) have been discussed. A sample list includes [73, 35, 40, 99, 75, 81, 88]. The majority of these deal with deductive equivalence of logical systems, and related lattice-theoretic algebraic structures. They encompass the characterization of algebraizability mentioned above and deal with the case in which mutual interpretations between logical structures induce isomorphisms between lattices of theories and vice versa, under some constraints and special hypotheses, depending on the context under consideration.

Another major characterization theorem provided in [35] for the notion of algebraizability asserts that, roughly speaking, in the context of sentential logics, the aforementioned analogs of the semantic and of the syntactic notions are equivalent. That is, the algebraization attained via the definability of theories and congruences via sets of equations and formulas, respectively, coincides with that ensured by the Leibniz operator being monotone and order reflecting on the lattice of the theories of the logic. This characterization, when abstracted to logics formalized as π-institutions, continues to hold under special provisos, namely, under the hypotheses that the π-institution under consideration has a rich enough supply of natural transformations or, more formally, as will be studied in detail in the monograph, that it has a Leibniz binary reflexive core and an adequate Suszko core.

In [35] as well as in many other works in the field, a considerable amount of emphasis has been placed on, and a substantial amount of effort expended in, studying specific logical systems of historical and/or practical interest from the point of view of algebraizability. This was only natural, given, on the one hand, the desire to showcase the applicability of the theory on logics of particular interest in traditional studies, and, on the other, the urge to investigate the power of falsifiability that the theory provides for those concrete logical systems that had resisted previous attempts at algebraization.

Our point of view, however, is slightly different and, as a consequence, we do not deal with or present such examples. Firstly, the majority of logical systems of historical and/or practical interest have already been dealt with in existing literature. Secondly, since our treatment abstracts and subsumes that of sentential logics and, considerably generalizes it, as was shown above, our goal is not to look at the more concrete, already encompassed by the study of the algebraization of deductive systems, but, rather, to look into the more abstract and discern what can be carried over to that level and how its validity and its applicability compares when applied to new systems and new examples which do not fit exactly, or do not conform at all to, the sentential logic framework. However, these aims and the mode of treatment they motivate should in no way be construed as underestimating the significance, or underplaying the beauty and elegance, of the studies concerned with the concrete and the more specific. After all, it is on those studies that the abstract is based, to those studies' insights, ideas and methodology that an enormous scientific debt is due, and from those studies' successes, and widespread recognition and appreciation, that a relative confidence is drawn regarding the potential usefulness and applicability of the more general framework presented, and elaborated on, in this monograph.

1.2 Fin de siècle: The Golden Age

We give an account of some of the major developments in abstract algebraic logic that occurred mostly, but not exclusively, around the last two decades of the 20th century. This period may be thought of as constituting the golden age of algebraic logic, in the sense that, during this time, there is clearly discernible a passage from an ad-hoc, case-by-case algebraic treatment of logical systems to a well-organized field, with a powerful arsenal of universally applicable concepts, methods and techniques, culminating to the classification of logics in an algebraic hierarchy, known as the Leibniz hierarchy. Needless to say, the foundations for this success were laid much earlier. Likewise, the development continued, and many important results around, and complementing, the main theory were obtained later, into the new millennium, and the area continues to be active. In order to avoid, in our short exposition, reinventing the wheel, we base this account on preexisting sources. We draw the material primarily from the, perhaps best-known, survey of the field by Font, Jansana and Pigozzi [69] and, when needed and/or convenient, the two existing specialized books on the subject by Czelakowski [64] and by Font [86].

Algebraic logic has its origins in the work of George Boole [1, 2], who formalized the "laws of thought" in an algebraic way. The intuition governing this process was made mathematically precise by Tarski [5, 6, 8]. Tarski used the key idea of Lindenbaum of identifying formulas of a logical language with the terms of the absolutely free algebra formed using the logical connectives as operation symbols [3] to give a precise connection between classical propositional calculus and Boolean algebras. This formed the paradigmatic example from which significant inspiration was drawn and on which subsequent developments were based. Furthermore, it served as a kind of testbed for comparing, trying, modifying and calibrating new ideas, methods and techniques. The way Boolean algebras arose as the algebraic counterparts of classical propositional calculus has become known as the Lindenbaum-Tarski method. It has subsequently been used to "algebraize" a variety of propositional systems.

A conceptual shift occurred around 1950 when Rasiowa and Sikorski [7, 20] (see, also, the historical surveys [59, 74]), among others, realized that the Lindenbaum-Tarski method could be applied not only to isolated logics but, rather, to classes of logical systems with an implication connective satisfying certain properties. In passing from a "per logic" or "a la carte" treatment to one addressing classes specified by some abstract properties, one discerns clearly for the first time the seeds of what, later, became known as "abstract algebraic logic". Papers that may be thought of as protoabstract, in the sense that they advance further the main ideas of Rasiowa and Sikorski towards the modern truly abstract era, were the one by Prucnal and Wronski [19] introducing equivalential logics, the ones by Czelakowski introducing protoalgebraic logics [26, 29] and further studying equivalential logics [23, 24] and the one by Blok and Pigozzi [28] studying protoalgebraic logics.

The seismic shift, one might say, in firmly founding and establishing the modern era came in the 1980s with the work of Blok and Pigozzi, which led eventually to the publication of their famous, seminal "Memoirs" monograph [35]. In a way analogous to the preceding three passages, from classical logic and Boolean algebra to the Lindenbaum-Tarski method, from the Lindenbaum-Tarski method to dealing with implicative logics and from implicative logics to abstract properties of deduction, Blok and Pigozzi were able to distil the essential spirit of the association between logic and algebra and, thus, extract and formalize the concept of an algebraizable logic in modern abstract terms and provide landmark characterizations. On the way, they established a very general process of algebraization, applicable to arbitrary logical systems, which has been, since, further refined and used to create the Leibniz hierarchy, often considered the pinnacle - certainly a milestone and a gem - of algebraic logic in general.

Before returning to provide a more detailed account, we take a small break to recount those features of the theory that distinguish the abstract approach from the more traditional treatments and give it its special character. First, as alluded to previously, instead of applying the Lindenbaum-Tarski process in an ad-hoc way, on a case-by-case basis, or, as in Rasiowa's work, to a class of logics sharing a specific connective satisfying certain properties, it applies the abstract process to arbitrary sentential logics and, according to the outcome, classifies them into classes reflecting the closeness of the ties between them and the corresponding algebraic counterparts. In establishing this association and performing the resulting classification, it opens, in parallel, two distinct but closely interrelated directions. On the one hand, it motivates the study of classes of algebras arising as algebraic counterparts of either single or groups of logical systems. On the other, it allows investigating the exact correspondence between metalogical properties of the logical systems at hand and algebraic properties of the classes of their algebraic counterparts.

By now a plethora of works falling distinctly in each of these three directions exist and many will appear as references in the more detailed account that will follow. But to give some indication and pointers, we mention a few of the earliest ones that may be viewed as ground breaking. Concerning the process of algebraization itself and the classification, one should mention Blok and Pigozzi's [28, 35], Czelakowski's [23, 24], Herrmann's [43, 53, 54] and Font and Jansana's [52]. Concerning the study of classes of algebraic counterparts arising from the abstract algebraization process, one should mention [38, 39] dealing with the conjunction-disjunction fragment of classical propositional calculus, as well as Jansana's study of selfextensional logics in [71, 76], with clear precedents in Font and Jansana's [52]. Finally, paradigmatic examples of the study of metalogical and corresponding algebraic properties constitute several works addressing forms of the deduction-detachment theorem, e.g., Czelakowski's [26, 29] and Blok and Pigozzi's [32, 37, 63], the work of Blok and Hoogland on the Beth poperty [72], as well as the work of Czelakowski and Pigozzi concerning interpolation and amalgamation properties [58].

1.3 Outline of Contents by Chapter

We give an outline of the contents of the monograph focusing on the main points of each chapter and describing them by section, using some formal notation, but without providing formal definitions, which will be presented in the main body of the text. This section is very closely related to other sections. First, in Section 1.4, we give a very concise summary, only mentioning the main overarching topics discussed in each chapter. Second, at the beginning of each chapter, a similar overview is provided focusing only on the specific chapter, with the exception that, in those introductions, being closer to the formal treatment, an even more informal narrative is adopted and a concerted effort is made to keep notation at a minimum.

1.3.1 Chapter 2

Chapter 2 presents the basic elements of the theory of algebraic systems, of π-institutions and of the interaction between logical and algebraic structures. These constitute the foundations and form the backbone of our theory throughout the monograph.

Section 2.1 gives an informal introduction to the chapter, akin to the introduction presented here, only containing a little less of formal notation and being more on the narrative, informal, side.

Section 2.2 is the first main section of the chapter. Here, we start by introducing the notion of a *sentence functor* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$, which is simply a set-valued functor on an arbitrary category of signatures. It formalizes the carriers on which both algebras and logical systems are based, akin to the underlying universe of a universal algebra. Then we consider *sentence families* of sentence functors, which are families $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ of subsets of sentences, one for each signature. These formalize distinguished sets of sentences when one considers logical structures, much like the distinguished sets in logical matrices. A *sentence system* is a sentence family T which is invariant under the action of signature morphisms. Two canonical ways of obtaining from a given sentence family T a sentence system consist of taking the largest sentence system $\overleftarrow{T}$ included in the family T and taking the smallest sentence system $\overrightarrow{T}$ that includes the sentence family T. Sentence functors are related via *sentence morphisms*, which are pairs $\langle F, \alpha \rangle$, F being a functor between the categories of signatures and α a natural transformation mapping sentences to sentences, taking into account the effect of

F. *Special morphisms* are those with surjective and full signature components and *surjective* ones are special ones whose sentence components are also surjective.

We then turn to *relation families* $R = \{R_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ over sentence functors. Those assume the place of binary relations. Of the highest interest and importance are *equivalence families* and *equivalence systems*, i.e., equivalence families invariant under the action of signature morphisms. They induce partitions on the components of sentence functors. Equivalence families and systems have important interactions and connections with both sentence families and with morphisms. The notion that relates an equivalence family with a sentence family is that of *compatibility*. An equivalence family R is *compatible* with a sentence family T if each component of the sentence family is a union of blocks of the equivalence family on the same component. The connection between equivalence systems and morphisms goes through the notion of kernels. Namely, the *kernel* $\mathrm{Ker}(\langle F,\alpha\rangle)$ of a morphism $\langle F,\alpha\rangle$ between two sentence functors forms an equivalence system on the domain.

If a set is equipped with operations, we get an algebraic structure. On this algebraic structure, one may reason in an algebraic way about any of the operations that are in its clone, i.e., that can be generated by applying the fundamental operations and the projections and composing them in arbitrary ways. In an analogous fashion, if a sentence functor $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ is equipped with a category of natural transformations N, which corresponds to the clone of algebraic operations on an algebra, one obtains an *algebraic system* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$. As algebras play a fundamental role in both logical and algebraic aspects of the traditional theory, so do algebraic systems in the theory developed in the monograph. The role of free algebra is played in this context by that of a *base algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$. Moreover, the notion of morphism extends from the context of sentence functors to the context of algebraic systems. The additional stipulation is that they also preserve the algebraic structure that turns the sentence functor into an algebraic system, i.e., that they satisfy the well-known *replacement* or *congruence condition*.

In traditional treatments, in specific contexts, all algebras are considered to be over the same algebraic signature, which is fully captured by the absolutely free algebra over that signature. In the present context, this similarity is captured by fixing a base algebraic system $\mathbf{F}$, as above, and considering only $\mathbf{F}$-*algebraic systems*, which are algebraic systems that, roughly speaking, have similar clones of operations with $\mathbf{F}$ and whose sentences are all images of sentences of $\mathbf{F}$ under a fixed algebraic system morphism $\langle F,\alpha\rangle$. Formally, these are expressed as pairs $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, where $\langle F,\alpha\rangle : \mathbf{F} \to \mathbf{A}$ is a surjective algebraic system morphism. The notion of morphism extends further to morphisms between $\mathbf{F}$-algebraic systems.

In Section 2.3, the limelight falls on *congruence systems*, which play in this context the same role that congruences play in the context of universal algebras. The least congruence system on an algebraic system $\mathbf{A}$ is the identity congruence system $\Delta^{\mathbf{A}}$ and the largest one is the full relation system, written $\nabla^{\mathbf{A}}$. These form the min and max elements, respectively, of the complete lattice of congruence systems $\mathbf{ConSys(A)}$ on $\mathbf{A}$. The kernel $\mathrm{Ker}(\langle F, \alpha\rangle)$ of a morphism $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{B}$ between two algebraic systems forms a congruence system on $\mathbf{A}$. Moreover, congruence systems allow the definition of *quotient algebraic systems*. And, for every algebraic system $\mathbf{A}$ and every one of its quotient systems $\mathbf{A}^\theta := \mathbf{A}/\theta$, there is a canonical morphism $\langle I, \pi^\theta\rangle : \mathbf{A} \to \mathbf{A}^\theta$ onto the quotient algebraic system, whose kernel is exactly the congruence system θ that gave rise to the quotient. All these properties reflect well known properties from the context of congruences and quotients of universal algebras.

Congruence systems inherit from equivalence families the relation of compatibility with given sentence families. The critical property to be established is that for a given sentence family T on an algebraic system $\mathbf{A}$, there exists a largest congruence system on $\mathbf{A}$ that is compatible with T. This is called the *Leibniz congruence system of* T *on* $\mathbf{A}$, is denoted by $\Omega^{\mathbf{A}}(T)$ and plays the role that Leibniz congruences play in the context of traditional abstract algebraic logic. As such, its role in characterizing many of the classes in the algebraic hierarchy studied in the monograph is ubiquitous and, as a consequence, the whole hierarchy is known as the *Leibniz hierarchy*. After introducing the *Leibniz operator* on an algebraic system, we establish two important results concerning it. The first, inspired by a result from the traditional treatment, provides a characterization of the Leibniz operator in terms of the category of natural transformations (i.e., clone operations) of the algebraic system and the sentence family. Roughly speaking it asserts that a pair of sentences are Leibniz related if and only if they are indistinguishable modulo T with respect to the available algebraic apparatus. The second addresses specifically the categorical framework and asserts that the Leibniz congruence system of a sentence family T is dominated by the Leibniz congruence system of the largest sentence system $\overleftarrow{T}$ contained in the sentence family, i.e., that $\Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\overleftarrow{T})$. The value of this observation in establishing refinements of the traditional hierarchy, as reflected in the present context, is critical and hard to overestimate. Also of importance is the fact that the surjective morphisms between algebraic systems, which form the focus of our work, respect Leibniz congruence systems, in the sense that, if $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{B}$ is a surjective morphism and T is a sentence family on $\mathbf{B}$, then $\Omega^{\mathbf{A}}(\alpha^{-1}(T)) = \alpha^{-1}(\Omega^{\mathbf{B}}(T))$. Finally, it is worth noting that, in general, the intersection of the Leibniz congruence systems of a collection of sentence families is contained in the Leibniz congruence of the intersection of those sentence families. Significantly, though, the reverse inclusion holds universally on sentence families if and only if the Leibniz operator is monotone on sentence families, a property that does not always hold. In fact, the latter property is used in a critical way, when restricted to special kinds of sentence families, to determine some of the most important classes of logical systems located close to the bottom of the algebraic hierarchy. In addition, it is of great historical significance in many of the most important classical developments in the field.

In Section 2.4, we focus on *congruence systems relative to given classes of algebraic systems*. Given a class K of algebraic systems, all over the same base algebraic system, that is, possessing, in some sense, the same algebraic signature, a congruence system θ on an algebraic system $\mathbf{A}$, not necessarily belonging to K, is called a *congruence system relative to* K or a K-*congruence system* if the quotient $\mathbf{A}^\theta$ belongs to the class K. Naturally, if $\mathbf{A} \in \mathsf{K}$ and the class K happens to be closed under morphic images, then congruence systems relative to K coincide with arbitrary congruence systems. The section introduces another important notion in this context. That of an algebraic system $\mathbf{A}$ being a *subdirect intersection* of a collection of algebraic systems. This means that there exists surjective morphisms $\langle H^i, \gamma^i\rangle : \mathbf{A} \to \mathbf{A}^i$ from the algebraic system to each of the algebraic systems in the given collection and, moreover, the intersection of the kernels of those morphisms is the identity congruence on $\mathbf{A}$. Closure of a class of algebraic systems under subdirect intersections ensures that the collection of congruence systems relative to the class is closed under intersections. Additionally, if the class K contains a trivial algebraic system, then the nabla congruence system happens to be a relative congruence system. Therefore, possession of a trivial algebraic system together with closure under subdirect intersections ensures that the collection of all congruence systems relative to the class forms a complete lattice under signature-wise inclusion.

Suppose that the class K contains a trivial algebraic system and is closed under subdirect intersections so that it makes sense to associate with a given relation family X on its base algebraic system the least congruence system $\Theta^{\mathsf{K}}(X)$ relative to K containing X. An alternative, equally natural, way to associate a congruence system with X is to consider the closure $D^{\mathsf{K}}(X)$ under equational consequence relative to the algebraic systems in the class K. It is proven in this section that the two closures give rise to the same congruence system on the base algebraic system $\mathbf{F}$.

In Section 2.5, we study *varieties of algebraic systems*. There are two possibilities in adopting a choice for the entities that would play the role of equations in this context. The first is to view pairs of sentences as equations. The second is to adopt pairs of natural transformations in the clone as equations. The ones of the latter type are called *natural equations* to differentiate them from those of the former kind which are simply referred to as *equations*. We define formally the notion of *satisfiability* of a given equation and of a given natural equation in an algebraic system and that of validity of a natural equation in an algebraic system. Depending on whether we use equations or natural equations to determine a class of algebraic systems through satisfiability, we obtain two different kinds of varieties. Varieties determined by families of equations are called *semantic varieties*. Those determined by collections of natural equations are called *syntactic varieties*. It turns out that, in general, every syntactic variety is also a semantic variety. The opposite implication does not hold in general. The section concludes by presenting a sufficient condition on the structure of a base algebraic system that ensures that the classes of semantic and syntactic varieties over it coincide.

Much of the work in the first sections of Chapter 1 focuses on the algebraic framework that underlies both the logical and the algebraic aspects of the theory in the monograph. In Section 2.6, we turn to the study of π-*institutions*, the underlying structure of the logical aspects of our theory. The entire monograph assumes that all logical systems are formalized as π-institutions and its main goal is to study the process of their algebraization and to detail the various classes in the hierarchy that is formed by examining their algebraic character. It is needless, thus, to point out the importance of Section 2.6, as it presents the foundational aspects of the logical side of the theory.

We start, here, by defining the notion of π-*institution*. It is a pair $\mathcal{I} = \langle \mathbf{F}, C \rangle$ consisting of a base algebraic system $\mathbf{F}$ and a closure system C on the sentence functor of $\mathbf{F}$. It generalizes the Tarskian concept of a deductive system in that it allows multiple signatures and accommodates morphisms between signatures. To take into account the logical structure imposed on top of the underlying algebraic structure in this context, sentence families and systems are subsumed by *theory families* and *theory systems*. These are sentence families (systems, respectively) each of whose components is closed under logical deduction. The least among these is called the *theorem system* of $\mathcal{I}$. It turns out that, due to the property of structurality, which is key in the study of π-institutions, given a theory family T, $\overleftarrow{T}$ is also closed under deduction, whence it forms that largest theory system included in T. On the other hand, $\overrightarrow{T}$ fails to be closed under deduction in general. That is the reason why the smallest theory system including T is not simply $\overrightarrow{T}$ but, rather, $C(\overrightarrow{T})$.

An important derived concept is that of the π-institution that has as its theory families those theory families of $\mathcal{I} = \langle \mathbf{F}, C \rangle$ which include a given theory system T of $\mathcal{I}$. This is denoted by $\mathcal{I}^T = \langle \mathbf{F}, C^T \rangle$. The construction results in a π-institution whose theorem system is identical with the theory system T of $\mathcal{I}$.

As is the case in most mathematical contexts, objects are accompanied by morphisms between them that preserve the structure of interest in each particular context. *Morphisms between* π-*institutions* are algebraic morphisms between the underlying algebraic systems that, in addition, preserve the logical structure in the sense that the forward image of the logical closure of a set of sentences is included in the closure of the image of the same set of sentences. Among the most useful characterizations is that a given algebraic morphism is logical if and only if preimages of theory families of the target institution under the morphism constitute theory families of the domain π-institution.

In Section 2.7, we turn to those structures that are intermediate between logic and algebra and facilitate the interplay and the establishment of meaningful ties between the two domains. These are *matrix families*, which correspond to the ordinary logical matrices in the traditional treatment. Roughly speaking a *matrix family* $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ consists of an algebraic system $\mathcal{A}$ together with a sentence family T of the algebraic system. If the sentence family is a system, i.e., invariant under signature morphisms, then the matrix family is called a *matrix system*. Their role is twofold. On the one hand, a given collection of matrix families M, over a base algebraic system $\mathbf{F}$, may be used to define a closure system C^{M}, and hence a π-institution structure $\mathcal{I}^{\mathsf{M}} = \langle \mathbf{F}, C^{\mathsf{M}} \rangle$, on $\mathbf{F}$. On the other, given a π-institution structure $\mathcal{I}$ on $\mathbf{F}$, we may define the class $\mathrm{MatFam}(\mathcal{I})$ of all matrix families whose sentence families are closed under the deductive apparatus of the π-institution. Such sentence families are termed *$\mathcal{I}$-filter families* and, if they happen to be systems, then they are called *$\mathcal{I}$-filter systems*. The collection $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ of all filter families over the same underlying algebraic system $\mathcal{A}$, ordered by component-wise inclusion, forms a complete lattice and the collection of all filter systems on that same algebraic system forms a complete sublattice of the complete lattice of all filter families.

Among the main results presented in this section are the ones relating morphisms between algebraic systems with preservation of filter families. More precisely, the inverse image of a filter family is a filter family. The situation is more complicated when it comes to direct images. First of all, it only makes sense to define the direct image of a filter family in case the signature functor is an isomorphism. Second, it turns out that, in that case, for the image to also be a filter family on the target algebraic system, we must require additional restrictions. A sufficient condition is that the kernel system of the algebraic morphism be compatible with the filter family in the domain.

This result has particular consequences for the most important type of morphisms considered in the monograph, the canonical quotient morphisms associated with congruence systems on an algebraic system. It asserts that, given a filter family T on the quotient $\mathcal{A}^\theta$, the inverse image $\pi^{\theta^{-1}}(T)$ under the quotient morphism $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}^\theta$ is a filter family on $\mathcal{A}$ and that, moreover, if the congruence system θ is compatible with a filter family T on $\mathcal{A}$, then the quotient T/θ is a filter family on $\mathcal{A}^\theta$.

We consider, by particularizing even further, the Leibniz quotient morphisms, which are those morphisms defined using the Leibniz congruence system that is compatible with a given filter family on the domain. Since, by definition, the Leibniz congruence system $\Omega^{\mathcal{A}}(T)$ associated with a given sentence family T is compatible with that sentence family, it follows that a filter family T on $\mathcal{A}$ gives rise, by passing to the Leibniz quotient $\mathcal{A}/\Omega^{\mathcal{A}}(T)$, to a filter family in the quotient. The corresponding matrix family $\mathfrak{A}/\theta = \langle\mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T)\rangle$ is called a (*Leibniz*) *reduced matrix family*.

The section closes by defining two classes of matrix families and two classes of algebraic systems that play a key role when investigating the algebraic nature of a given π-institution $\mathcal{I}$. The first is the class $\mathrm{MatFam}^*(\mathcal{I})$ of all *Leibniz reduced matrix families* associated with the given π-institution. The second is the class $\mathrm{MatSys}^*(\mathcal{I})$ of all *Leibniz reduced matrix systems*. Finally, on the algebraic side, by considering all algebraic system reducts of the reduced matrix families, we get the class $\mathrm{AlgSys}^*(\mathcal{I})$ of all *family reduced algebraic systems* and, by considering all algebraic system reducts of the reduced matrix systems, we get the class $\mathrm{AlgSys}^\bullet(\mathcal{I})$ of all *system reduced algebraic systems*.

Section 2.8 studies the two related concepts of *axiomatic extensions* and of *filter extensions*. An *axiomatic extension* $\mathcal{I}'$ of a given π-institution $\mathcal{I}$ is a π-institution over the same base algebraic system whose closure system is obtained by that of $\mathcal{I}$ by adding more axioms. More precisely, the consequences $C'(X)$ of a family of sentences X under $\mathcal{I}'$ are the consequences under $\mathcal{I}$ of the same family of sentences, augmented by some fixed family of sentences T, i.e., $C'(X) = C(X \cup T)$. The sentences in T are viewed as axioms in $\mathcal{I}'$. A *filter extension* arises in a similar way. The difference is that one considers filter families over arbitrary algebraic systems and not just theory families over the base algebraic system.

One of the first results in this section provides a characterization of axiomatic extensions. It asserts that axiomatic extensions are characterized by preservation of all those theories that include the theorem system of the extension. An alternative, lifting the condition to arbitrary algebraic systems, asserts that being an axiomatic extension is tantamount to the preservation of filterhood over all algebraic systems, for all those filters that include the least filter over the extension.

The last part of the section deals with *filter generation* over a given matrix family modulo a given π-institution $\mathcal{I}$. It defines the concept and formalizes, in a rather technical proposition, how generation of filters and surjective matrix family morphisms interact.

Section 2.9 turns the focus back to those structures that, like matrix families, play a critical role as intermediate structures in connecting the logical with the algebraic aspects of the theory. *Generalized matrix families* correspond to the generalized matrices of classical algebraic logic and, like generalized matrices, play a critical role in identifying classes of algebraic systems that may be naturally associated with given π-institutions (or classes of π-institutions). The way this association is established sheds light on the strength of ties between the two and on the nature of their interaction, e.g., by revealing which properties may be expected to be shared by the two or transferred from one to the other.

A *generalized matrix family* $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ consists of an underlying algebraic system $\mathcal{A}$ and a collection of sentence families $\mathcal{T}$ of the algebraic system. Such structures may also be used in two ways. They may serve in defining a closure system on a base algebraic system and, therefore, a π-institution structure. On the other hand, given a π-institution $\mathcal{I}$, we may associate with it the collection $\mathrm{GMatFam}(\mathcal{I})$ of those generalized matrices all of whose sentence families are filter families of the π-institution. With any generalized matrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$, one may associate its *Tarski congruence system* $\widetilde{\Omega}(\mathbb{A})$ or $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$, an abstraction of the Tarski congruence systems associated with generalized matrices in classical abstract algebraic logic. *Tarski congruence systems* constitute the largest congruence systems on the base algebraic system compatible with all sentence families of the generalized matrix family. Taking the quotient $\mathbb{A}/\widetilde{\Omega}(\mathbb{A})$ of the generalized matrix family by its Tarski congruence system gives a new generalized matrix family $\mathbb{A}^*$, which is called the *Tarski reduction* of $\mathbb{A}$. A *Tarski reduced matrix family* is one that is isomorphic to its reduction, i.e., one whose Tarski congruence system is the identity congruence system on the underlying algebraic system.

There is a close connection between Tarski congruence systems and Leibniz congruence systems. Each generalized matrix system $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ may be viewed as a bundle of matrix families $\{\langle \mathcal{A}, T \rangle : T \in \mathcal{T}\}$, i.e., of those matrix families whose sentence families belong to the collection of sentence families of the generalized matrix family. In that case, the Tarksi congruence system of the generalized matrix family is the intersection (in the component-wise sense) of the Leibniz congruence systems of all matrix families in the corresponding bundle, i.e., $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

In a similar way to Tarski congruence systems, one may also consider *Suszko congruence systems* $\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T)$ associated with ordinary matrix families $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, and these are also introduced in Section 2.9. Suszko congruence systems of matrix families are defined only in a relative way, by viewing the matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ as being part of a bundle expressed as a generalized matrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$. Then the *Suszko congruence system* of the matrix family is identical to the Tarski congruence system $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}^T)$ of the bundle $\langle \mathcal{A}, \mathcal{T}^T \rangle$ consisting of only those sentence families that include (in the component-wise ordering) the sentence family T of the matrix family. Of course, expressed in terms of Lebniz congruence systems, the Suszko congruence system is the intersection of the Leibniz congruence systems of all matrix families determined by the sentence families in the given bundle that include that of the matrix family under consideration, i.e., $\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T) = \bigcap_{T \leq T' \in \mathcal{T}} \Omega^{\mathcal{A}}(T')$. As was the case with Tarski congruence systems, we may consider the *Suszko reduction* $\mathfrak{A}^{\mathsf{Su}}$ of a given matrix family $\mathfrak{A}$, obtained by dividing out by the Suszko congruence system $\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T)$. And, likewise, we call a matrix family *Suszko reduced*, when its Suszko congruence system is the identity congruence system on the underlying algebraic system.

Part of the significance of the Tarski and of the Suszko operators in algebraic logic is that they form one of the main mechanisms of selecting the "natural" class of algebraic systems to be associated with a given π-institution. Briefly and sketchily, starting from a π-institution $\mathcal{I}$, we obtain the collection $\mathrm{GMatFam}(\mathcal{I})$ of all generalized matrix families $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ whose sentence families $T \in \mathcal{T}$ are filter families of the π-institution. We then compute the Tarski reductions $\mathbb{A}^*$ by dividing out by the corresponding Tarski congruences $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$. This process gives rise to the class $\mathrm{GMatFam}^*(\mathcal{I})$ of all Tarski reduced generalized matrix families and to the class $\mathrm{AlgSys}(\mathcal{I})$ of all their underlying algebraic systems. This class subsumes, in the π-institution framework, the class of algebras which has long been viewed, in the traditional framework, as the most appropriate one to be associated with a given logic and, hence, as constituting the "natural" choice for the algebraic counterpart of the sentential logic. As it turns out, using a similar path, but relying on the Suszko operator, rather than on the Tarski operator, gives rise to exactly the same class of algebraic systems. Tracing the analogous process, one starts from a given π-institution $\mathcal{I}$ and considers all matrix families $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, viewed as part of the bundle $\mathbb{A} = \langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ of all matrix families associated with the π-institution. Then, one considers the Suszko reductions $\mathfrak{A}^{\mathsf{Su}}$ by dividing out by the corresponding Suszko congruence systems $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$. The class of Suszko reduced matrix families obtained in this way is denoted by $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$. It can then be shown that the class of all algebraic reducts of the matrix families in $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$ coincides with the class $\mathrm{AlgSys}(\mathcal{I})$.

In Sections 2.7 and 2.9, using the classes of Leibniz reduced matrix families and of Tarski reduced generalized matrix families associated with a given π-institution $\mathcal{I}$, we are able to define the two classes $\mathrm{AlgSys}^*(\mathcal{I})$ and $\mathrm{AlgSys}(\mathcal{I})$ of algebraic systems associated with the π-institution. In Section 2.10, we take up the study of two additional classes of algebraic systems that may be perceived as counterparts of a given π-institution and compare them with those already defined.

Both new classes are based on a single algebraic system, namely the algebraic system $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$ resulting by considering the quotient of the base algebraic system $\mathcal{F}$ by the Tarski congruence of the collection of all theory families of $\mathcal{I}$. Using this quotient algebraic system, the two classes are formed as the two kinds of varieties that may be generated by it. The first type, called the *semantic variety*, denoted by $\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) = \mathbb{V}^{\mathsf{Sem}}(\mathcal{F}/\widetilde{\Omega}(\mathcal{I}))$, is the class of all algebraic systems that satisfy all equations that are satisfied by $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$, i.e., all equations included in $\widetilde{\Omega}(\mathcal{I})$. The second type, called the *syntactic variety*, denoted by $\mathbb{V}^{\mathsf{Syn}}(\mathcal{I}) = \mathbb{V}^{\mathsf{Syn}}(\mathcal{F}/\widetilde{\Omega}(\mathcal{I}))$, is the class of all algebraic systems that satisfy all natural equations that are satisfied by $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$.

Some results relating the four classes are presented. There is a linear hierarchy of inclusions that is not very difficult to establish. The class $\mathrm{AlgSys}^*(\mathcal{I})$ is the smallest class, followed by $\mathrm{AlgSys}(\mathcal{I})$, which is, in turn, included in

$\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})$, whereas $\mathbb{V}^{\mathsf{Syn}}(\mathcal{I})$ is the largest of the four classes considered. It turns out that all four classes generate the same syntactic variety of algebraic systems, which is identical to $\mathbb{V}^{\mathsf{Syn}}(\mathcal{I})$, since it constitutes already a syntactic variety by definition. The section concludes with an important result showing that the class $\mathrm{AlgSys}(\mathcal{I})$ - perhaps the most important class associated with $\mathcal{I}$ - is closed under subdirect intersections and contains a trivial algebraic system. The usefulness of this fact is that it enables consideration, on any given algebraic system, of the least congruence system relative to $\mathrm{AlgSys}(\mathcal{I})$ generated by a prespecified relation family.

In Section 2.11, we study *equivalence families* and *systems* that are induced by sentence families or collections of sentence families of an algebraic system. The most fundamental among these is the *Frege equivalence family* $\lambda^{\mathbf{A}}(T)$ associated with a sentence family T of an algebraic system $\mathbf{A}$. It identifies two sentences if they are both inside or both outside the sentence family. Its companion *Frege equivalence system* $\Lambda^{\mathbf{A}}(T)$ is the largest equivalence system included in $\lambda^{\mathbf{A}}(T)$. The two Frege equivalences are intimately connected with the Leibniz congruence system $\Omega^{\mathbf{A}}(T)$, the latter being the largest congruence system contained in either of $\lambda^{\mathbf{A}}(T)$ or $\Lambda^{\mathbf{A}}(T)$.

In a way analogous to the extensions of the Leibniz congruence system that give rise to the Tarski and Suszko congruence systems, the Frege relations give rise to two more equivalences with similar roles. Given a collection $\mathcal{T}$ of sentence families of $\mathbf{A}$, the *Carnap equivalence family* $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$ identifies two sentences if they are equivalent modulo T (in the Frege sense) for all $T \in \mathcal{T}$, i.e., $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T}) = \bigcap_{T \in \mathcal{T}} \lambda^{\mathbf{A}}(T)$. The *Carnap equivalence system* $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$ is the largest equivalence system included in $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$. The relation connecting Leibniz congruence systems with the Frege equivalences persists here as well, but with the Suszko congruence system in place of the Leibniz one. That is, the Suszko congruence system $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ is the largest congruence system contained in either of $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$ or $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$.

Finally, reminiscent of the passage from the Tarski to the Suszko congruence system, given a collection of sentence families $\mathcal{T}$ and $T \in \mathcal{T}$, the *Lindenbaum equivalence family* $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(T)$ is the relation family identifying two sentences if they are equivalent modulo every $T' \in \mathcal{T}$, such that $T \leq T'$. The *Lindenbaum equivalence system* $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(T)$ is the largest equivalence system contained in $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(T)$, and the Suszko congruence system $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(T)$ turns out to be the largest congruence system included in either of $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(T)$ or $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(T)$.

The Carnap operators, viewed as operators on collections of sentence families on the same algebraic system, are monotone. The same applies to the Lindenbaum operators, viewed as operators on sentence families relative to the same collection of sentence families. However, the Frege operators do not satisfy a monotonicity property.

In Section 2.12, we are discussing *algebraic subsystems* and *π-subinstitutions*. The starting point is the observation that an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ may contain a *universe*, i.e., a functor $\mathrm{SEN}' : \mathbf{Sign} \to \mathbf{Set}$, such that $\mathrm{SEN}' \leq \mathrm{SEN}$ and closed under the action of natural transformations in N. Then, it is clear that this universe may be used to define an *algebraic subsystem* $\mathbf{A}'$ of $\mathbf{A}$ and, as it turns out, there exists a *canonical injection morphism* $\langle I, j\rangle : \mathbf{A}' \to \mathbf{A}$. Apart from detecting the existence of universes, there is a natural way to generate a universe starting from a given sentence family T of $\mathbf{A}$. This consists of passing, first, to the least sentence system $\overrightarrow{T}$ containing T and, then, closing $\overrightarrow{T}$ under the clone operations in N. This two-step process gives rise to a universe $\nu^{\mathbf{A}}(\overrightarrow{T})$. In case the algebraic system $\mathbf{A}$ supports a π-institution $\mathcal{I} = \langle \mathbf{A}, C\rangle$, then one obtains, for each algebraic subsystem $\mathbf{A}'$ of $\mathbf{A}$, a *π-subsinstitution* $\mathcal{I}' = \langle \mathbf{A}', C'\rangle$ by restricting the action of C on elements of $\mathbf{A}'$. It can be shown that the theory families of $\mathcal{I}'$ are exactly the restrictions of those of $\mathcal{I}$ on the universe giving rise to $\mathbf{A}'$. The section ends with some results relating Leibniz congruence systems of theory families of $\mathcal{I}$ with those of the corresponding theory families of $\mathcal{I}'$. A similar result also holds for Leibniz congruence systems of corresponding filter families of the two π-institutions.

Sections 2.13-2.15 deal with aspects of the "syntactic" apparatus of an algebraic system, i.e., with properties of the natural transformations viewed as term functions. Section 2.13 introduces the framework and studies some connections with the definability of the Leibniz congruence systems. Section 2.14 explores various modes of definability and details their relative power. Section 2.15 studies the effect of parameters and shows that two different possible ways of obtain a parameterless collection of natural transformations out of a given parametric one are essentially equivalent. We provide, next, some more details by section.

Section 2.13 introduces the concepts of *distinguished arguments* and of *parametric arguments* of a collection E of natural transformations. This is a conceptual distinction which becomes important in practice when one differentiates the role they each play when the collection of natural transformations is used to transform sentences, i.e., to produce new sets of sentences from tuples of given ones. The new family of sentences produced from a tuple of sentences $\vec{\phi}$ (possibly with the aid of parameters) is denoted by $E_\Sigma[\vec{\phi}]$, where Σ is the signature of $\vec{\phi}$. Another mode of transformation uses a dual or inverse construction. Namely, given a sentence family T, we consider the set $\overleftarrow{E}(T)$ consisting of all tuples $\vec{\phi}$, such that $E_\Sigma[\vec{\phi}] \leq T$. These tuples all share the same length, which equals the number of distinguished arguments of the transformations in E. The construction has some important properties, e.g., $\overleftarrow{E}$, viewed as an operator on sentence families is monotone and, moreover, commutes with inverse surjective morphisms. But, perhaps, its most important property is that, if E has two distinguished arguments and T is such that $\overleftarrow{E}(T)$ is reflexive, then $\overleftarrow{E}(T)$ includes the Leibniz congruence system $\Omega^{\mathbf{A}}(T)$ of T. Consequently, if $\overleftarrow{E}(T)$ is itself a congruence system compatible with T, then it coincides with $\Omega^{\mathbf{A}}(T)$. Thus, in this case, we may say that, in a specific sense, the Leibniz operator of T is *definable* using the natural transformations in E. We view this as a syntactic definability condition, which plays an important role in establishing the algebraic classification of π-institutions "by syntactic means" in subsequent chapters.

In Section 2.14 we continue the study of natural transformations as means of transforming tuples of sentences to sentences. We look as four possible ways of relating, via a fixed collection E of natural transformations with k distinguished arguments, a k-tuple of sentences $\vec{\phi}$ to a sentence family T. The simplest, *E-local membership*, asserts that $E_\Sigma(\vec{\phi}, \vec{\chi}) \subseteq T_\Sigma$, for all values $\vec{\chi}$ of the parametric arguments. The second, *E-global membership*, asserts that $E_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}), \vec{\chi}) \subseteq T_{\Sigma'}$ holds for all signatures Σ', all morphisms $f : \Sigma \to \Sigma'$ and all appropriate values of the parameters $\vec{\chi}$. The remaining two, *left E-local membership* and *left E-global membership* mimic the preceding ones except that they use membership in $\overleftarrow{T}$ instead of membership in T. Closer scrutiny of the four modes reveals that the two global memberships are equivalent, followed in strength by left local membership, which, in turn, implies local membership. When a membership property holds for all $\vec{\phi}$, then we attribute it to the collection E itself. In this sense, it turns out that global, local, left global and left local memberships of E in T all coincide.

In Section 2.15, starting from a given collection S of natural transformations, possibly including parametric arguments, we study ways of obtaining a collection that is parameter-free. Here, two of the most natural, for our purposes, ways of doing this turn out to be equivalent, and, hence, release us from the obligation to distinguish between which one is applied in any specific context. Let us assume that S is taken to have k distinguished arguments. Then one way of obtaining from S a parameter-free collection is to replace all parametric arguments with k-ary natural transformations. This results in a collection $\dot{S}$ of k-ary, i.e., parameter-free, natural transformations. The second method builds on the notion of an *anti-monotone property* of natural transformations. These are properties P that a natural transformation either does or does not satisfy and for which an anti-monotonicity property holds, namely, if for all tuples of sentences $\vec{\phi}$, the family of transforms of $\vec{\phi}$ under σ is included in the family of transforms of $\vec{\phi}$ under τ, then τ satisfying P implies that σ also satisfies P. If P also denotes the class of all natural transformations satisfying property P, then we let $\widehat{P}$ be the subclass of P consisting of the parameter-free members of P. The section concludes with the assertion that, for anti-monotone properties P, both constructions $\dot{P}$ and $\widehat{P}$ give the same class of parameter-free natural transformations associated with P.

In Section 2.16, we study *finitarity*. This property holds for a π-institution $\mathcal{I}$ if every sentence ϕ that is derivable from a set Φ of sentences can be derived from some finite subset Φ' of Φ. Finitarity holds for the overwhelming majority of the logics considered in the literature. So it has played a central role in algebraic logic, even though much of the more abstract body of the theory is formalized and developed in a way that encompasses arbitrary, that is, not necessarily finitary, logical systems. A characterization of finitarity using the property of *continuity* is provided. We say that a collection of theory families is *directed* if every finite subcollection is included in some theory family in the collection. A π-institution is *continuous* if the union of a directed collection of theory families is also a theory family. Finitarity and continuity, as it turns out, are equivalent properties.

In the second part of the section, given a finitary π-institution $\mathcal{I}$, we provide a construction of the filter family $C^{\mathcal{I},\mathcal{A}}(X)$ generated by a sentence family X of $\mathcal{A}$. Taking advantage of the finitarity of $\mathcal{I}$, the filter family may be obtained by an incremental process, each step of which adds in the filter family sentences of $\mathcal{A}$ which are derivable, in a certain sense, by finite subsets of sentences that have already been included in the filter family at previous stages of the construction. In this way, the family $\Xi^{\mathcal{I},\mathcal{A}}(X)$ is obtained as the union of the families obtained at all stages and it can be shown that $C^{\mathcal{I},\mathcal{A}}(X) = \Xi^{\mathcal{I},\mathcal{A}}(X)$.

In the last two sections, Sections 2.17 and 2.18, we study *equational consequences* and provide analogs of some well-known fundamental results of universal algebra for classes of algebraic systems.

In Section 2.17, we look at closure families on pairs of sentences, i.e., equations, over a base algebraic system $\mathbf{F}$ that are induced by classes of $\mathbf{F}$-algebraic systems. Given a class K of $\mathbf{F}$-algebraic systems, we say that an equation $\phi \approx \psi$ is a *consequence* of a set E of equations *relative to* K if every algebraic system in K satisfying E also satisfies $\phi \approx \psi$. The resulting consequence family is denoted by D^{K}. It is not necessarily a closure system since it may fail to be structural. It is shown, however, that its theory families are exactly the congruence systems on $\mathbf{F}$ relative to the class K.

The second part of the section deals with a process of generating the closure of a family of equations E relative to an equational axiomatic system Q in an incremental way. Roughly speaking, it formalizes the process of closing under reflexivity, symmetry and transitivity, as well as under replacement and the action of signature morphisms. The family of equations obtained under this step-wise process from axioms Q and hypotheses E is denoted by $\Xi^Q(E)$. In the final result of the section, it is shown that the operator Ξ^Q coincides with D^{K} when Q is taken to be the collection of all equations satisfied by all algebraic systems in K.

Section 2.18, the closing section of the chapter, is inspired by universal algebra. It provides characterizations, in the spirit of Birkhoff's variety and Mal'cev's quasivariety theorems, of classes of algebraic systems defined by equations, quasiequations and generalized quasiequations, also referred to as guasiequations. The section begins by formally defining *equations*, *quasiequations* and *guasiequations* in the context of π-institutions. The relation of *satisfaction* of a syntactic entity of either of the above types in an algebraic system is also formally defined. In the usual way, these satisfaction relations establish Galois connections. The closed sets on the syntactic side form *equational*, *quasiequational* and *guasiequational theories*, whereas, on the semantic side, one obtains *equational*, *quasiequational* and *guasiequational classes of algebraic systems*, respectively. These are, respectively, the classes closed under the semantic variety $\mathbb{V}^{\mathsf{Sem}}$, semantic quasivariety $\mathbb{Q}^{\mathsf{Sem}}$ and semantic guasivariety $\mathbb{G}^{\mathsf{Sem}}$ operators.

To formulate characterizations of these classes, we introduce and study four operators on classes of algebraic systems. Let K be a class of algebraic systems. First, we say that an algebraic system $\mathcal{A}$ is K-*certified* if, for each signature Σ, there exists an algebraic system $\mathcal{A}^\Sigma$ in the class K that satisfies exactly the same equations of signature Σ as $\mathcal{A}$. The class K is said to be *abstract* or *closed under* K-*certifications* if every K-certified algebraic system is in K. The operator $\mathbb{C}$ is a closure operator and, if $\mathcal{A} \in \mathbb{C}(\mathsf{K})$, then $\mathcal{A}$ satisfies all guasiequations satisfied by K. Moreover, if K is guasiequational, then it is an abstract class. Next, we say that an algebraic system $\mathcal{A}$ is *directedly* K-*certified* if, for each signature Σ, there exists a collection of algebraic systems $\{\mathcal{A}^{\Sigma,i} : i \in I\}$ in the class K that satisfy two conditions: On the one hand, the collection of all finite sets of equations satisfied by some $\mathcal{A}^{\Sigma,i}$, $i \in I$, is directed and, on the other, the union of all those sets is exactly the set of equations of signature Σ satisfied by $\mathcal{A}$. The class K is said to be *directedly abstract* or *closed under directed* K-*certifications* if every directedly K-certified algebraic system is in K. The operator $\mathbb{C}^*$ is a closure operator. It is shown that, if $\mathcal{A}$ is directedly K-certified, then it satisfies all quasiequations satisfied by K and, furthermore, that directed abstraction is a necessary condition for a class of algebraic systems to be a quasiequational class.

The third operator on classes of algebraic systems is that of taking *subdirect intersections* $\overset{\triangleleft}{\mathbb{I}\mathbb{I}}$. *Subdirect intersections* are collections of morphisms $\langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^i$, $i \in I$, with the same domain, the intersection of whose kernels is the identity system on $\mathcal{A}$. In that case, we also say that $\mathcal{A}$ is a *subdirect intersection* of the $\mathcal{A}^i$'s. This also turns out to be a closure operator on classes of algebraic systems and, in fact, closure under $\overset{\triangleleft}{\mathbb{I}\mathbb{I}}$ is necessary for a class to be guasiequational. The last operator considered is that of taking *morphic images*, denoted by $\mathbb{H}$. It also forms a closure operator on classes of algebraic systems and closure under $\mathbb{H}$ is necessary for a class to be an equational class.

The four operators serve in formulating the Birkhoff-style characterizations referred to previously for equational, quasiequational and guasiequational classes. Guasiequational classes are characterized as those that are abstract and closed under subdirect intersections. Quasiequational classes are those that are directedly abstract and closed under subdirect intersections. Finally, equational classes are characterized as those that are closed under subdirect intersections and morphic images. The section concludes with some additional characterizations of these three classes involving the structure of the subcollection $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ of the complete lattice $\mathrm{ConSys}(\mathcal{F})$. All of those additional results are based on the main characterizations described above.

1.3.2 Chapter 3

In Chapter 3 we start in earnest the study of the Leibniz hierarchy of π-institutions. Chapters 3-9 deal with the *semantic Leibniz hierarchy*. Here the classes are defined using properties of the Leibniz operator on theory families/systems of a π-institution. Chapters 11-**??**, on the other hand, deal with the *syntactic Leibniz hierarchy* in which classes are defined using collections of natural transformations satisfying specific definability properties. We shall see that "corresponding" classes in the two hierarchies may not coincide, but, nevertheless, the two hierarchies are closely connected - in fact may be seen as forming parts of a single hierarchy - and they are both modeled on the Leibniz hierarchy of sentential logics.

In Section 3.2, we study three properties. The first two are fundamental because they introduce concepts and terminology that play a critical role throughout the monograph. The third is used to establish classes of π-institutions at the very bottom of the hierarchy which abstract all other classes considered later in this and in subsequent chapters.

The first property if *systemicity*. A π-institution $\mathcal{I}$ is called *systemic* if every theory family of $\mathcal{I}$ is actually a theory system, i.e., if $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$. Recalling from Chapter 2 that, given a theory family T of $\mathcal{I}$, $\overleftarrow{T}$ is the largest theory system included in T, $\mathcal{I}$ is systemic if and only if, for every theory family T, $\overleftarrow{T} = T$. Yet another characterization asserts that, for every Σ-sentence ϕ of $\mathcal{I}$, the least theory family $C(\phi)$ of $\mathcal{I}$ generated by ϕ contains all translates of ϕ under arbitrary signature morphisms. One of the reasons why systemicity plays such a critical role is that, for a systemic π-institution, it suffices to restrict attention to theory systems, i.e., one may take invariance under signature morphisms for granted.

The second property is *stability*. It may be thought of as the counterpart of systemicity when focus shifts from theory families to corresponding Leibniz congruence systems. A π-institution $\mathcal{I}$ is *stable* if, for all theory families T, $\Omega(\overleftarrow{T}) = \Omega(T)$. Of course, every systemic π-institution is stable, and this implication is proper. Both systemicity and stability *transfer*. This means that a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is systemic if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, every $\mathcal{I}$-filter family of $\mathcal{A}$ is a filter system. Similarly, $\mathcal{I}$ is stable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and every $\mathcal{I}$-filter family T of $\mathcal{A}$, $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(T)$. These two transfer results are only the first of a host of, so-called, *transfer theorems* that are proved in the sequel for the majority of properties used to define classes in the Leibniz hierarchy. Having established the pattern and exhibited the main idea, we only mention such results briefly from now on, postponing the details for the main account in the relevant sections of the text.

The third property we study in Section 3.2 is *loyalty*. Unlike systemicity and stability, loyalty comes, as is typical for many subsequently introduced properties, in multiple flavors. To establish the pattern that will be followed in the presentation throughout, we introduce, first, the four versions, termed *family*, *left*, *right* and *system*. They may or may not be all different. So we study their properties, show which ones, if any, coincide, establish general implications between those that are not equivalent, and show, via examples, that these implications are proper, i.e., that no further collapsing of the subhierarchy based on these properties is possible.

A π-institution $\mathcal{I}$ is *family loyal* if, for all theory families T, T' of $\mathcal{I}$, $T \nless T'$ or $\Omega(T) \ngtr \Omega(T')$, or, equivalently, if it is not the case that $T < T'$ and $\Omega(T) > \Omega(T')$. If Ω, viewed as an operator mapping theory families to congruence systems, is either order preserving or order reflecting, then it is necessarily family loyal. So this property abstracts both monotonicity and reflectivity of Ω. Since both monotonicity and reflectivity play important roles in specifying classes in the Leibniz hierarchy, this observation provides partial justification for considering loyalty as a common abstraction. Here, as in all subsequently defined properties, once the family version is introduced, the other three versions follow by applying similar modifications. To obtain the *left version* one replaces, on the theory family side, all theory families by their arrow versions. So $\mathcal{I}$ is *left loyal* if, for all theory families T, T', $\overleftarrow{T} \nless \overleftarrow{T'}$ or $\Omega(T) \ngtr \Omega(T')$. To obtain the *right version*, a similar replacement is applied on the congruence system side. Thus, $\mathcal{I}$ is *right loyal* if, for all theory families T, T', $T \nless T'$ or $\Omega(\overleftarrow{T}) \ngtr \Omega(\overleftarrow{T'})$. Finally, the *system version* is obtained by imposing the same condition as in the family version, but restricting its application to theory systems, instead of insisting that it hold for all theory families. Accordingly, $\mathcal{I}$ is *system loyal* if, for all theory *systems* T, T' of $\mathcal{I}$, $T \nless T'$ or $\Omega(T) \ngtr \Omega(T')$.

Family loyalty properly implies stability. Moreover, family loyalty implies left loyalty, which, in turn, implies system and right loyalty, the latter two being equivalent properties. System loyalty, together with systemicity, imply family loyalty. That is, as is the case with virtually all properties introduced in the monograph, imposing systemicity has the effect of collapsing the entire four-class subhierarchy into a single class. This observation can be applied to obtain a backbone - or a bird's eye view - of the Leibniz hierarchy without worrying about the refinements and subdivisions due to the different flavors of each property. Section 3.2 concludes by showing that all three distinct versions of loyalty transfer, i.e., that a given π-institution has a certain loyalty property if the corresponding defining condition holds for all pairs of filter families (or systems) on arbitrary $\mathbf{F}$-algebraic systems.

In Section 3.3, we study *monotonicity properties*. A π-institution $\mathcal{I}$ is *family monotone* if, for all theory families T, T', $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$, i.e., if the Leibniz operator on theory families is order preserving. In accordance with the general framework outlined above for loyalty, $\mathcal{I}$ is *left monotone* if, for all T, T', $\overleftarrow{T} \leq \overleftarrow{T'}$ implies $\Omega(T) \leq \Omega(T')$, *right monotone* if, for all T, T', $T \leq T'$ implies $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$ and *system monotone* if the same condition defining family monotonicity is restricted to theory systems, i.e., if the Leibniz operator on theory systems is order preserving. It is shown that family monotonicity implies stability. Most importantly, family and left monotonicity coincide as do system and right monotonicity. Following terminology inherited from sentential logics, we term π-institutions that satisfy family monotonicity *protoalgebraic* and those that satisfy the system version *prealgebraic*. Protoalgebraicity is equivalent to prealgebraicity plus stability. In particular, every protoalgebraic π-institution is prealgebraic, and this inclusion is proper. Both monotonicity properties transfer. Finally, pursuing connections with classes introduced in Section 3.2, we show that protoalgebraicity implies family loyalty, whereas prealgebraicity is sufficient for system loyalty.

In Sections 3.4 and 3.5, we study versions of a property called *complete monotonicity*. This is a property dual to complete order reflectivity, a property that characterizes truth equationality in the sentential framework. Given a sentential logic $\mathcal{S}$, complete order reflectivity stipulates that, for every collection $\mathcal{T} \cup \{T'\}$ of theories of $\mathcal{S}$, if $\bigcap_{T\in\mathcal{T}} \Omega(T) \subseteq \Omega(T')$, then $\bigcap \mathcal{T} \subseteq T'$. Since, in both the lattice of theories and that of congruences, meet and intersection coincide, but, on both theories and congruences, join is not the same as union, one may obtain two "dual" versions of complete order reflectivity. The first, following a set-theoretic approach, says that, for all $\mathcal{T} \cup \{T'\}$, $T' \subseteq \bigcup \mathcal{T}$ implies $\Omega(T') \subseteq \bigcup_{T\in\mathcal{T}} \Omega(T)$. The second, taking a lattice-theoretic point of view, asserts that, for all $\mathcal{T} \cup \{T'\}$, $T' \leq \bigvee \mathcal{T}$ implies $\Omega(T') \leq \bigvee_{T\in\mathcal{T}} \Omega(T)$, where the join in the hypothesis is taken in the complete lattice of theories of $\mathcal{S}$ and the one in the conclusion in the complete lattice of congruences on the formula algebra. In Section 3.4 we study an analog of the former property and in Section 3.5 an analog of the latter in the context of logics formalized as π-institutions. A few more details follow in the next two paragraphs.

In Section 3.4, we look at *complete* $\bigcup$*-monotonicity*, which is abbreviated as *c*$^\cup$*-monotonicity* or, simply, *c-monotonicity*. A π-institution is *family c*$^\cup$*-monotone* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families, $T' \leq \bigcup \mathcal{T}$ implies $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$. *Left* and *right c*$^\cup$*-monotonicities* are obtained by replacing in the hypothesis and in the conclusion, respectively, every theory family occurring by its arrow version. Finally, *system c*$^\cup$*-monotonicity* is defined by the same condition as the family version, but applied exclusively to collections of theory systems. Family c$^\cup$-monotonicity implies stability, as does left c$^\cup$-monotonicity. Moreover, the family version is equivalent to the conjunction of the left and right versions and either of the latter implies system $c^\cup$-monotonicity. All four $c^\cup$-monotonicity properties transfer. And, whereas the left version is sufficient for protoalgebraicity, the system version implies only prealgebraicity.

In Section 3.5, we continue the study of complete monotonicity but switch from complete $\bigcup$-monotonicity to *complete* $\bigvee$*-monotonicity*, which is abbreviated as $c^\vee$*-monotonicity*. A π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is *family* $c^\vee$*-monotone* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families, $T' \leq \bigvee^{\mathcal{I}} \mathcal{T}$ implies $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$, where $\bigvee^{\mathcal{I}}$ denotes the join in the complete lattice of theory families of $\mathcal{I}$ and $\bigvee^{\mathbf{F}}$ the join in the complete lattice of congruence systems on $\mathbf{F}$. Again, following the general pattern, $\mathcal{I}$ is *left* $c^\vee$*-monotone* if, for all $\mathcal{T} \cup \{T'\}$, $\overleftarrow{T'} \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T}$ implies $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$ and is *right* $c^\vee$*-monotone* if, for all $\mathcal{T} \cup \{T'\}$, $T' \leq \bigvee^{\mathcal{I}} \mathcal{T}$ implies $\Omega(\overleftarrow{T'}) \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. Finally, $\mathcal{I}$ is *system* $c^\vee$*-monotone* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory *systems* of $\mathcal{I}$, $T' \leq \bigvee^{\mathcal{I}} \mathcal{T}$ implies $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$. Again, either family or left $c^\vee$-monotonicity implies stability. The family version is equivalent to the conjunction of the left and right versions and either of those two implies system $c^\vee$-monotonicity. Left $c^\vee$-monotonicity implies protoalgebraicity and system $c^\vee$-monotonicity implies prealgebraicity.

Contrary to what the similarities of results pertaining to $c^\vee$-monotonicity with those of Section 3.4 on $c^\cup$-monotonicity may suggest, there are also significant differences between the two complete monotonicity properties. One instance concerns transfer theorems. Unlike $c^\cup$-monotonicity, $c^\vee$-monotonicity properties do not transfer in general. This is due to the fact that, unlike unions, joins do not commute with inverse surjective morphisms between algebraic systems. A second difference, which affords, perhaps, partial justification for introducing and discussing both types of properties in some detail, is that corresponding classes of π-institutions are incomparable. E.g., there exists a family $c^\vee$-monotone π-institution which is not family $c^\cup$-monotone and vice-versa.

In Section 3.6, we study *injectivity*. A π-institution $\mathcal{I}$ is *family injective* if, for all theory families T, T', $\Omega(T) = \Omega(T')$ implies $T = T'$, i.e., if the Leibniz operator is injective on theory families. It is *left injective* if, for all T, T', $\Omega(T) = \Omega(T')$ implies $\overleftarrow{T} = \overleftarrow{T'}$ and *right injective* if, for all T, T', $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$ implies $T = T'$. Finally, it is *system injective* if the Leibniz operator is injective on theory systems. Right injectivity is the strongest of the four injectivity properties and it implies systemicity. It is followed by family injectivity, then left injectivity, which implies system injectivity. System injectivity together with systemicity is equivalent to right injectivity, whereas, together with stability, which is weaker than systemicity, it implies left injectivity. All four injectivity properties transfer.

In Section 3.7, we turn to *reflectivity properties*. A π-institution $\mathcal{I}$ is *family reflective* if, for all theory families T, T' of $\mathcal{I}$, $\Omega(T) \leq \Omega(T')$ implies

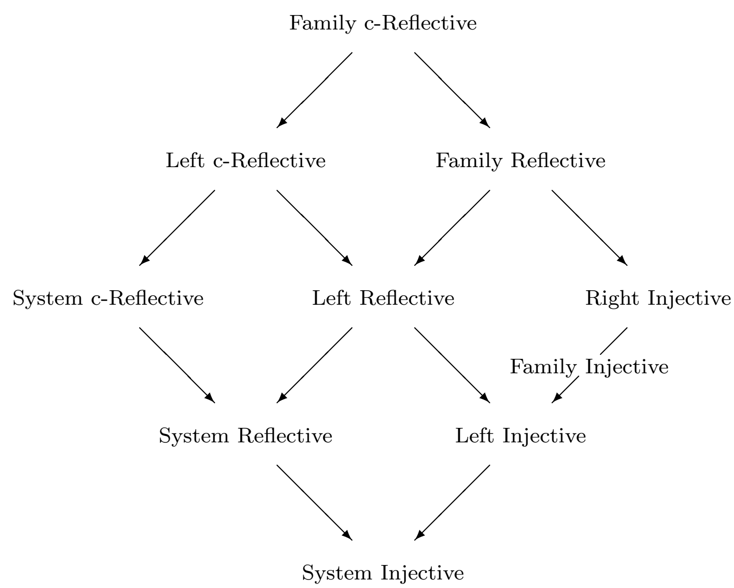
$T \leq T'$, i.e., if the Leibniz operator on theory families is order reflecting. If, for all T, T', $\Omega(T) \leq \Omega(T')$ implies $\overleftarrow{T} \leq \overleftarrow{T'}$, then $\mathcal{I}$ is *left reflective*, whereas, if, for all T, T', $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$ implies $T \leq T'$, $\mathcal{I}$ is *right reflective*. *System reflectivity* stipulates the order reflectivity of the Leibniz operator on theory systems. It turns out that family or right reflectivity imply systemicity. This allows showing that the two are actually equivalent properties. They imply left reflectivity, which, in turn, implies system reflectivity. System reflectivity, coupled with stability, implies left reflectivity, whereas, together with systemicity, it becomes equivalent to family reflectivity. All four versions transfer. Section 3.7 ends by relating reflectivity with the injectivity properties, introduced in Section 3.6, and with the loyalty properties, introduced in Section 3.2. More precisely, it is shown that family/right, left and system reflectivity imply, respectively, right, left and system injectivity and that family/right, left and system reflectivity imply, respectively, family, left and system loyalty.

Section 3.8, the last section of Chapter 3, introduces *complete reflectivity properties*, abbreviated to *c-reflectivity*. These form a generalization of the reflectivity properties of Section 3.7. Complete reflectivity originates in the work of Raftery, where it is used to characterize truth equationality in the context of sentential logics. A π-institution is *family c-reflective* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families of $\mathcal{I}$, $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap \mathcal{T} \leq T'$. It is *left c-reflective* if, for all $\mathcal{T} \cup \{T'\}$, $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$ and *right c-reflective* if, for all $\mathcal{T} \cup \{T'\}$, $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$ implies $\bigcap_{T\in\mathcal{T}} \mathcal{T} \leq T'$. *System c-reflectivity* is defined using the same condition as family c-reflectivity restricted to collections of theory systems. As was the case with reflectivity, either family or right c-reflectivity implies systemicity and this enables showing that the family and right versions are equivalent. They imply left c-reflectivity, which, in turn, implies the system version. System c-reflectivity and systemicity are jointly equivalent to family c-reflectivity, whereas system c-reflectivity, augmented with stability, implies left c-reflectivity. All complete reflectivity properties transfer and, as is apparent from the relevant definitions, each version of c-reflectivity implies the corresponding reflectivity version.

1.3.3 Chapter 4

In Chapter 4, we visit weak prealgebraizability and weak algebraizability properties of π-institutions. These create a subhierarchy of π-institutions whose members roughly correspond to the weakly algebraizable logics in the sentential logic framework. Weak prealgebraizability classes arise when coupling family monotonicity with either of injectivity, reflectivity or complete reflectivity properties. Analogously, weak algebraizability results by combining system monotonicity with injectivity, reflectivity or complete reflectivity.

Before describing the versions of weak prealgebraizability and algebraizability in more detail, we mention, firstly, that the term "weak" refers to the use of monotonicity, as opposed to the stronger notion of equivalentiality, in the definitions, and remind, secondly, the reader of the hierarchy, established in Chapter 3, of the various flavors of injectivity, reflectivity and c-reflectivity properties, which assumed the form depicted in the diagram.



In Section 4.2, we define the classes of *weakly prealgebraizable π-institutions*. Each class results by imposing prealgebraicity (system monotonicity) and one of the ten flavors of injectivity, reflectivity and complete reflectivity shown in the preceding hierarchy. Since prealgebraicity is shared by all classes, the deciding factor in the subhierarchy is the type of injectivity, reflectivity or c-reflectivity imposed. Thus, a priori, one obtains ten potentially distinct classes whose hierarchy reflects that shown in the preceding diagram. We name the corresponding property "weak X prealgebraizability", or "WX prealgebraizability" for short, where the string X stands for one of SI, LI, FI, RI for system, left, family, right injectivity, respectively, SR, LR, FR for system, left, family reflectivity, respectively, or SC, LC, FC for system, left, family c-reflectivity, respectively.

In our first result, we show that prealgebraicity is sufficient to identify all system versions, which forces the collapsing of the classes of WSI, WSR and WSC prealgebraizable π-institutions. We call the corresponding property *WS prealgebraizability*. In what sets a pattern for subsequent work in this chapter, it is shown that WS prealgebraizability transfers and, further, a characterization is obtained via properties of the Leibniz operator $\Omega^{\mathcal{A}}$, viewed as a mapping between ordered sets, for arbitrary $\mathbf{F}$-algebraic systems $\mathcal{A}$. More precisely, it is shown that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is WS prealgebraizable iff, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$

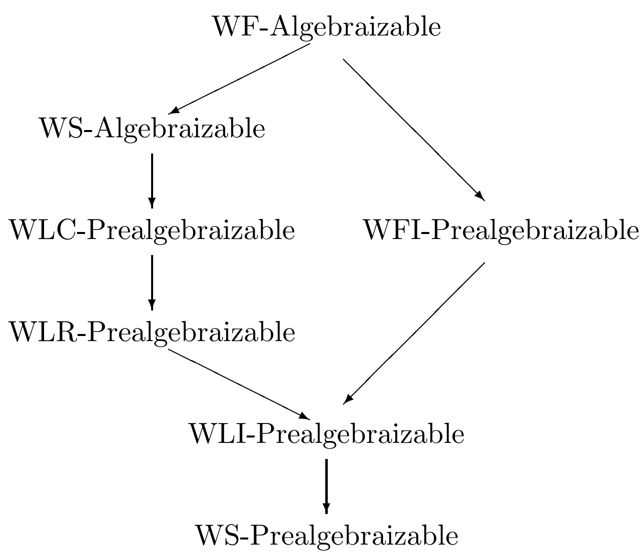
is an order embedding. Next, it is shown that, in view of prealgebraicity, family reflectivity implies family c-reflectivity and this leads to the identification of WFR prealgebraizability and WFC prealgebraizability. Moreover, under protoalgebraicity, family injectivity implies family reflectivity. This enables showing that both WFR and WRI prealgebraizability are characterized as the conjunction of WFI prealgebraizability and systemicity and, hence, are identical properties. Both WFR and WFI prealgebraizability transfer. Moreover, the WFI version is characterized by the property that, for all $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is a bijection on filter families, restricting to an order embedding on filter systems, whereas the WFR version is characterized by the condition that, for all $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is an order isomorphism.

At this point, the hierarchy has been reduced to six classes, since, as it turned out, all three system classes are identical and the three family plus the WRI prealgebraizability collapse down to two classes. The only classes not put under the microscope yet are those defined using the left versions of injectivity, reflectivity and c-reflectivity. We return to them after a short break that gives a glimpse of further possible reductions under special circumstances. Namely, it is proven that, under systemicity, the entire hierarchy collapses to a single class and that, under stability, it collapses down to two classes, as the only properties that can be distinguished are the family (but including also WRI prealgebraizability) from the remaining versions.

Returning to the left properties, Section 4.2 concludes by showing that all three transfer and by providing characterizations along the lines outlined previously, using $\Omega^{\mathcal{A}}$. More precisely, it is shown that $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is WLC (WLR, WLI, respectively) prealgebraizable iff, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left completely order reflecting (left order reflecting, left injective, respectively) surjection, restricting to an order embedding on theory systems.

In Section 4.3, we study versions of weak algebraizability. These combine protoalgebraicity (family monotonicity) with the various versions of injectivity, reflectivity and complete reflectivity. Since protoalgebraicity dominates prealgebraicity, it is clear that one obtains at least as many identifications between the ten apparent weak algebraizability properties as those established between corresponding weak prealgebraizability properties in Section 4.2. However, the situation under closer scrutiny turns out to be much more radical. Since protoalgebraicity is strong enough to yield stability, the emerging landscape was anticipated by the previously mentioned collapse of the weak prealgebraizability hierarchy down to two classes in the presence of stability. Similarly, under protoalgebraicity and, hence, stability, all three weak family algebraizability properties together with WRI algebraizability collapse to a single property, termed *WF algebraizability*. Further, all remaining six left and system versions also collapse to a single property we call *WS algebraizability*. Both of these properties transfer. Also, for both one may obtain Leibniz operator type characterizations. More specifically, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is WS algebraizable iff it is stable and, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism, whereas it is WF algebraizable iff, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism.

Observing that the characterization of WF algebraizability is identical with that obtained for WF prealgebraizability, we conclude that the top classes in the weak prealgebraizability and weak algebraizability subhierarchies actually coincide. Thus, by fusing these two subhierarchies, one obtains a total of seven potentially distinct classes, which form the combined hierarchy depicted in the diagram.



1.3.4 Chapter 5

In Chapter 5, we deal with classes of π-institutions that result from weakly prealgebraizable and weakly algebraizable π-institutions when the properties of prealgebraicity (system monotonicity) and protoalgebraicity (family monotonicity) are strengthened to preequivalentiality and equivalentiality, respectively. The strengthening, i.e., the passage from proto- (or pre-) algebraicity to (pre)equivalentiality, involves adding the condition of either family or system extensionality. Depending on which of these two properties is imposed, one obtains two parallel hierarchies, one on top of the other, both of which reflect the structure of the weak (pre)algebraizability hierarchy, described in Chapter 4.

In Section 5.2, we introduce and study *extensionality*. The definition requires the notion of subsystem of an algebraic system $\mathbf{F}$ generated by a given sentence family X, which is denoted by $\langle X\rangle$ and was introduced in Section 2.12. A π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is called *family extensional* if, for all sentence families X of $\mathbf{F}$ and all theory families T of $\mathcal{I}$, $\Omega(T) \cap \langle X\rangle^2 = \Omega^{\langle X\rangle}(T \cap \langle X\rangle)$.

It is called *system extensional* if the same condition holds, but T is quantified over all theory systems of $\mathcal{I}$, instead of ranging over arbitrary theory families. Since system extensionality specializes family extensionality, every family extensional π-institution is also system extensional. It is, moreover, the case that system extensionality, coupled with stability, implies family extensionality. Extensionality is very useful because, when satisfied, it causes certain properties that hold in a π-institution to be inherited by all its subinstitutions. For instance, under system extensionality, stability propagates from a π-institution $\mathcal{I}$ to all its subinstitutions $\mathcal{I}' \leq \mathcal{I}$. Additionally, system or family extensionality causes prealgebraicity or protoalgebraicity, respectively, to be inherited by all subinstitutions of a given π-institution. Both versions of extensionality transfer. The section closes by looking at *2-extensionality*, an apparently weaker condition than extensionality, which, however, turns out to be equivalent to it. A π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is *family 2-extensional* if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ and every theory family T of $\mathcal{I}$, $\langle \phi, \psi\rangle \in \Omega_\Sigma(T)$ if and only if $\langle \phi, \psi\rangle \in \Omega_\Sigma^{\langle \phi,\psi\rangle}(T \cap \langle \phi, \psi\rangle)$. *System 2-extensionality* is defined by the same condition in which T is quantified over theory systems. A π-institution is family/system extensional if and only if it is family/system 2-extensional, respectively.

In Section 5.3, we study *Leibniz commutativity*. The notion relies on the concepts of *extension* and *logical extension*. Given an algebraic system $\mathbf{F}$ and a sentence family X of $\mathbf{F}$, an *extension* is an algebraic system morphism of the form $\langle I, \alpha\rangle : \langle X\rangle \to \mathbf{F}$, where $\langle X\rangle$ is the algebraic subsystem of $\mathbf{F}$ generated by X and I is the identity functor on signatures. Given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, an extension $\langle I, \alpha\rangle : \langle X\rangle \to \mathbf{F}$ is called *logical*, denoted $\langle I, \alpha\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$, if, for every signature Σ and all $\Phi \subseteq \langle X\rangle_\Sigma$, $\alpha_\Sigma(C_\Sigma^{\langle X\rangle}(\Phi)) \subseteq C_\Sigma(\alpha_\Sigma(\Phi))$, where $C^{\langle X\rangle}$ is the restriction of C on $\langle X\rangle$, discussed in detail in Section 2.12. A characterization of this notion asserts that $\langle I, \alpha\rangle$ is logical if and only if α^{-1} preserves theory families, i.e., if $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I}^{\langle X\rangle})$, for every $T \in \mathrm{ThFam}(\mathcal{I})$.

Logical extensions form the background for introducing the property of *Leibniz commutativity*, or, simply, *commutativity*. A π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is called *family commuting* if the Leibniz operator on theory families commutes with logical extensions, i.e., if, for every sentence family X of $\mathbf{F}$, every logical extension $\langle I, \alpha\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$ and all $T' \in \mathrm{ThFam}(\mathcal{I}^{\langle X\rangle})$, $\alpha(\Omega^{\langle X\rangle}(T')) \leq \Omega(C(\alpha(T')))$. Applying the same condition, where T' ranges over all theory systems of $\mathcal{I}^{\langle X\rangle}$, defines *system commutativity*. A closely related concept is that of *inverse Leibniz commutativity*, or, simply, *inverse commutativity*. A π-institution $\mathcal{I}$ is *family inverse commuting* if, for every sentence family X, every logical extension $\langle I, \alpha\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$, and all $T \in \mathrm{ThFam}(\mathcal{I})$, $\alpha^{-1}(\Omega(T)) = \Omega^{\langle X\rangle}(\alpha^{-1}(T))$. The same condition, imposed on theory systems only, defines *system inverse commutativity*. The fact that injection morphisms $\langle I, j\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$ of subinstitutions into their parent institutions are logical extensions allows us to show that family/system inverse commutativity implies family/system extensionality, respectively. It is clear that the family version implies the system version and, as it turns out, the system version augmented by stability implies the family version. What is important for our purposes, and the reason why both direct and inverse commutativity properties are studied, is that under pre/proto-algebraicity, respectively, system/family commutativity is equivalent to system/family inverse commutativity. Moreover, in a result strengthening the relationship mentioned above, it is proven that family/system inverse commutativity and family/system extensionality, respectively, are actually equivalent properties. This section concludes by showing that both versions of inverse commutativity transfer.

In Section 5.4, we introduce *equivalentiality*. This is the section we have been preparing for by studying extensionality and commutativity in Sections 5.2 and 5.3, respectively. *Equivalentiality* is the result of coupling monotonicity with extensionality. Since each of those two properties comes in two flavors, there are, a priori, four possible versions of equivalentiality. *Family equivalentiality* combines protoalgebraicity with family extensionality. *System equivalentiality* keeps protoalgebraicity but uses system extensionality. *Family* and *system preequivalentiality* are defined analogously, but here one uses prealgebraicity instead of protoalgebraicity. Since protoalgebraicity is strong enough to imply stability, it turns out that family and system equivalentiality coincide. This property is referred to simply as *equivalentiality*. Thus, we get three properties in this hierarchy, namely, in decreasing order of potency, equivalentiality, family preequivalentiality and system preequivalentiality. Moreover, equivalentiality is equivalent to system preequivalentiality plus stability. All three properties transfer. There also exist characterizations of equivalentiality and preequivalentiality by conditions imposed on the Leibniz operator on filter families/systems, respectively, on arbitrary **F**-algebraic systems. Finally, as is clear by the corresponding definitions, equivalentiality dominates protoalgebraicity and preequivalentiality dominates prealgebraicity.

In Section 5.5, by replacing prealgebraicity by preequivalentiality, we obtain from the weak prealgebraizability hierarchy of Section 4.2 two parallel *prealgebraizability hierarchies*. The term "prealgebraizability" in both refers to the fact that preequivalentiality, as opposed to equivalentiality, is applied. In one of the two hierarchies, "family prealgebraizability" refers to the application of family preequivalentiality, whereas in "prealgebraizability", it is understood that (system) preequivalentiality is applied. The five classes in the first hierarchy are termed *XF prealgebraizable* and in the second *X prealgebraizable*, where X is one of the following strings, suggesting the imposition of an additional property on the Leibniz operator.

- LC for left completely reflective;
- LR for left reflective;

- FI for family injective;
- LI for left injective; and
- S for system (system completely reflective, system reflective or system injective, which are all equivalent in view of prealgebraicity).

It is shown that systemicity causes the total collapse of the hierarchy into a single class, whereas stability collapses the two family injectivity classes, FI and FIF prealgebraizability, and, also, all eight remaining classes and, therefore, leads to a 2-class hierarchy. Moreover, it is proven that all ten properties transfer. The remainder of this section is devoted to providing characterizations of each of the ten classes using order theoretic properties of the Leibniz operator viewed as a mapping from lattices of filters systems/families to lattices of congruence systems over arbitrary **F**-algebraic systems. We focus only on a couple of pairs to give a flavor of the type of results obtained, and refer the reader to the main text for a full account. A π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is FIF prealgebraizable if and only if, for all **F**-algebraic systems $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a bijection commuting with inverse logical extensions, which restricts to an order embedding on filter systems. A similar characterization is obtained for FI prealgebraizability, but with a subtle important change: $\mathcal{I}$ is FI prealgebraizable if and only if, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a bijection, which restricts to an order embedding commuting with inverse logical morphisms on filter systems. Analogously, for the left reflectivity classes, we get, on the one hand, that $\mathcal{I}$ is LRF prealgebraizable if and only if, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left order reflecting surjection commuting with inverse logical extensions, which restricts to an order embedding on filter systems, and, on the other, noting again the same subtle change, $\mathcal{I}$ is LR prealgebraizable if and only if, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left order reflecting surjection, which restricts to an order embedding commuting with inverse logical extensions on filter systems. Characterizations of the remaining six classes follow a similar pattern.

In Section 5.6, we switch from prealgebraizability to *algebraizability*. Dropping "pre" signifies using equivalentiality instead of the weaker preequivalentiality property. Equivalentiality encompasses protoalgebraicity and, under protoalgebraicity, only two classes of the ten potentially different ones are actually distinct. Accordingly, we get *family algebraizability*, or, simply, *F algebraizability*, when family injectivity is added, and *system algebraizability*, or, simply, *algebraizability*, when system injectivity is added. Family algebraizability is equivalent to algebraizability plus systemicity. Both properties transfer. Finally, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is algebraizable if and only if it is stable and, for every **F**-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions, whereas $\mathcal{I}$ is family algebraizable if and only if, for all $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions.

1.3.5 Chapter 6

The motivating force behind the considerations in this chapter is the observation that, since for a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, with $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$, $\Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat)$, no π-institution without theorems can satisfy any of the injectivity, reflectivity of complete reflectivity properties introduced in Chapter 3. The question naturally arises whether, in that case, the existence of theory families with empty components is the only reason causing the lack of these properties or whether the π-institution in question would still not satisfy them even if theory families with empty components were in some way "discarded" or "bypassed". We choose two ways in which this circumvention may be accomplished, and study the various flavors of injectivity, reflectivity and complete reflectivity properties that result.

In Section 6.2, we introduce and study the relation of rough equivalence between theory families of a π-institution. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Given a theory family T of $\mathcal{I}$, we define the *rough companion* (*rough associate* or *rough representative*) $\widetilde{T}$ of T as the theory family resulting from T by replacing all empty Σ-components of T by the corresponding set $\mathrm{SEN}^\flat(\Sigma)$ of Σ-sentences. We say that two theory families T and T' are *roughly equivalent*, written $T \sim T'$, if $\widetilde{T} = \widetilde{T'}$. The rough equivalence class of T is denoted by $\widetilde{[T]}$ and $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ denotes the collection of all rough equivalence classes. When one considers the restriction of rough equivalence on theory systems, the corresponding rough equivalence class is denoted by $\widetilde{\lfloor T\rfloor}$ and the collection of all these classes by $\widetilde{\mathrm{ThSys}}(\mathcal{I})$. Reasoning with rough equivalence classes is one way of bypassing theory families with empty components. An alternative way is to ignore those theory families that have at least one empty component. This is accomplished by considering the collections $\mathrm{ThFam}^{\not\flat}(\mathcal{I})$ and $\mathrm{ThSys}^{\not\flat}(\mathcal{I})$ of all theory families and theory systems, respectively, none of whose components is empty.

The usefulness of rough equivalence in considering properties of the Leibniz operator stems from the fact that, for every theory family T, $\Omega(T) = \Omega(\widetilde{T})$. As a consequence, the Leibniz operator is constant on each rough equivalence class. It is fairly obvious that the rough companion $\widetilde{T}$ of a theory family T is the maximum element in the class $\widetilde{[T]}$. However, even if T happens to be a theory system, $\widetilde{T}$ may not be one. On the other hand, it can be shown that, even in that case, $\widetilde{\lfloor T\rfloor}$ has a maximum element, which, of course, does not coincide with $\widetilde{T}$. An unfortunate fact, when considering the operators $\overleftarrow{\ }$ and $\widetilde{\ }$ in the same context is that, even if two theory families T and T' are roughly equivalent, the same may not hold for $\overleftarrow{T}$ and $\overleftarrow{T'}$. On the positive side, if $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ is an $\mathbf{F}$-algebraic system and T is an $\mathcal{I}$-filter family of $\mathcal{A}$, we do have $\alpha^{-1}(\widetilde{T}) = \widetilde{\alpha^{-1}(T)}$. This implies that the action of α^{-1} preserves rough equivalence, i.e., if T and T' are $\mathcal{I}$-filter families of $\mathcal{A}$, with $T \sim T'$, then $\alpha^{-1}(T) \sim \alpha^{-1}(T')$, the latter being roughly equivalent theory families of $\mathcal{I}$.

In Section 6.3, we look at some notions combining systemicity with rough equivalence. They form a hierarchy weakening systemicity in the absence of theorems. In the presence of theorems, however, all concepts considered coincide. We say that a π-institution $\mathcal{I}$ is *roughly systemic* if, for every theory family T, $\overleftarrow{T}$ is roughly equivalent to T, i.e., $\overleftarrow{T} \sim T$. We say $\mathcal{I}$ is *narrowly systemic* if, for every theory family T in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$ (i.e., with all components nonempty), $\overleftarrow{T} = T$. Finally, we say that $\mathcal{I}$ is *exclusively systemic* if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, $\overleftarrow{T} = T$. Systemicity is the strongest of these four conditions, followed by rough and narrow systemicity, which are incomparable in strength, and each of these two implies exclusive systemicity. Moreover, as mentioned previously, exclusive systemicity in the presence of theorems implies systemicity and, therefore, in that case, the entire hierarchy collapses to a single class.

In Section 6.4, we formalize and study various versions of rough injectivity, resulting by combining injectivity of the Leibniz operator with rough equivalence. The easiest to grasp is rough family injectivity. A π-institution $\mathcal{I}$ is *roughly family injective* if, for all theory families T, T', $\Omega(T) = \Omega(T')$ implies $T \sim T'$. *Rough left injectivity* results by replacing in the conclusion of the implication defining rough family injectivity T and T' by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively. *Rough right injectivity* arises by a similar replacement in the hypothesis. Finally, *rough system injectivity* imposes the same condition as the family version, but restricts its application to theory systems. Rough right injectivity implies rough systemicity, but the converse fails in general. The rough injectivity hierarchy turns out to be more complex than the injectivity hierarchy studied in Section 3.6. There, it was shown that right injectivity implies family injectivity, which implies left injectivity, which, in turn, implies system injectivity, giving rise to a linear injectivity hierarchy. On the other hand, in the rough case, it is shown that rough right injectivity implies rough family injectivity, which implies the system version, and, in addition, rough left injectivity also implies the system version. Moreover, rough right injectivity is equivalent to rough system injectivity plus rough systemicity. Rough system injectivity, supplemented with stability, implies rough left injectivity. Each of the four rough injectivity properties, together with the availability of theorems, is equivalent to the corresponding injectivity property. The section concludes by establishing that all four rough injectivity properties transfer and by providing characterizations of rough family and rough system injectivity via the Leibniz operator Ω, viewed as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 6.5, we switch to a different version of injectivity properties, the overarching motivation still remaining that of bypassing theory families with empty components. *Narrow family injectivity* is defined by imposing the injectivity of the Leibniz operator on $\mathrm{ThFam}^{\nleq}(\mathcal{I})$, i.e., by stipulating that, for all $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Omega(T) = \Omega(T')$ implies $T = T'$. *Narrow left injectivity* replaces T, T' in the conclusion by $\overleftarrow{T}, \overleftarrow{T'}$, respectively, whereas *narrow right injectivity* applies the same replacement in the hypothesis. Finally, *narrow system injectivity* enforces the same condition as that of narrow family injectivity, but restricts its scope on theory systems in $\mathrm{ThSys}^{\nleq}(\mathcal{I})$. Narrow right injectivity implies exclusive systemicity, but does not imply any of the stronger versions of rough or narrow systemicity. With narrow injectivity, we recover the linearity of the injectivity hierarchy that was lost in passing to rough injectivity. That is, narrow right injectivity implies narrow family injectivity, which implies narrow left injectivity, which, in turn, implies the system version. Moreover, narrow system injectivity, supplemented by narrow systemicity, implies narrow right injectivity. It turns out that narrow family injectivity is equivalent to rough family injectivity. On the other hand, the two left injectivity properties, narrow left and rough left injectivity, ar incomparable, i.e., none implies the other. Some order is regained when looking at the right versions, where rough right injectivity implies narrow right injectivity. This order is maintained at the system level in which rough system injectivity also implies narrow system injectivity. As was the case with rough injectivity, each narrow injectivity property, supplemented with the existence of theorems, is equivalent to the corresponding injectivity property. Moreover, all four narrow injectivity properties transfer. Finally, the family and system versions have characterizations in terms of the injectivity of Ω, viewed as a mapping from $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Sections 6.4 and 6.5, we looked at the rough and narrow injectivity hierarchies. Following this paradigm, in Sections 6.6 and 6.7, we introduce and study the rough and narrow reflectivity properties and, then, in Sections 6.8 and 6.9, the rough and narrow complete reflectivity properties.

In Section 6.6, we turn to rough reflectivity. Once more, the family version is the easiest to describe. A π-institution is called *roughly family reflective* if, for all theory families T, T', $\Omega(T) \leq \Omega(T')$ implies $\widetilde{T} \leq \widetilde{T'}$. *Rough left reflectivity* results by replacing T, T' in the conclusion by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively. *Rough right reflectivity* applies the same change in the hypothesis. Finally, *rough system reflectivity* imposes the same implication as the family version, but only on theory systems. Rough right reflectivity implies rough systemicity. It also implies rough family reflectivity, which implies rough system reflectivity. Rough left reflectivity also implies the system version. Rough right reflectivity is actually equivalent to the system version plus rough systemicity. On the other hand, rough system reflectivity and stability imply rough left reflectivity. It is straightforward to see, based on the relevant defining conditions, that each of the four rough reflectivity versions implies the corresponding rough injectivity version. Furthermore, each rough reflectivity version, supplemented by the existence of theorems, is equivalent to the corresponding reflectivity property. The section concludes with a proof that all four rough reflectivity properties transfer and with characterizations of rough family and rough system reflectivity in terms of the Leibniz operator, viewed as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 6.7, we look at narrow reflectivity properties. These constitute alternatives to rough reflectivity when dealing with reflectivity properties while attempting to bypass theory families with empty components. A π-institution is *narrowly family reflective* if, for all theory families T, T' in $\mathrm{ThFam}^{\nleftrightarrow}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ implies $T \leq T'$. As before, *narrow left reflectivity* results by replacing T, T' in the conclusion by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively, and *narrow right reflectivity* by performing the same replacement in the hypothesis instead. Finally, *narrow system reflectivity* stipulates that, for all $T, T' \in \mathrm{ThSys}^{\nleftrightarrow}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ implies $T \leq T'$. Narrow family reflectivity implies exclusive systemicity. As was the case with narrow injectivity properties, narrow reflectivity properties also align into a linear hierarchy. The strongest is narrow right reflectivity, followed by narrow family reflectivity, then by the left version and, at the tail, by narrow system reflectivity. The weakest one, narrow system reflectivity, supplemented by narrow systemicity, implies narrow right reflectivity. The relationships between corresponding rough and narrow versions of reflectivity follow those established in Section 6.5 between corresponding rough and narrow injectivity properties. First, rough family and narrow family reflectivity are equivalent. On the opposite end, the left versions turn out to be incomparable. Somewhere in between, for both the right and system versions, it turns out that the rough property implies the narrow one. Not surprisingly, each narrow reflectivity property implies the corresponding narrow injectivity property. Moreover, a given narrow reflectivity property is equivalent to the corresponding reflectivity property in the presence of theorems. All four narrow reflectivity properties transfer. Finally, characterizations are provided of narrow family and narrow system reflectivity in terms of the Leibniz operator seen as a mapping from $\mathrm{ThFam}^{\nleftrightarrow}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleftrightarrow}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 6.8, we turn to complete reflectivity (c-reflectivity) properties starting with rough complete reflectivity. A π-institution $\mathcal{I}$ is *roughly family c-reflective* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T}'$. The *left version* results by replacing each theory family by its arrow counterpart in the conclusion, whereas the *right one* by applying the same change in the hypothesis instead. Finally, the *system version* stipulates that the same condition as that defining the family version applies, but $\mathcal{T} \cup \{T'\}$ is allowed to range over collections of theory systems instead of arbitrary theory families. Paralleling the rough reflectivity hierarchy, rough right c-reflectivity implies rough family c-reflectivity, which implies rough system c-reflectivity, while the left version also implies the system version. In fact, rough right c-reflectivity is equivalent to rough system c-reflectivity plus rough systemicity, whereas rough system c-reflectivity, together with stability, imply rough left c-reflectivity. It is clear that each rough c-reflectivity property generalizes the corresponding rough reflectivity property. It is also not difficult to show that each rough c-reflectivity property, in the presence of theorems, coincides with the corresponding c-reflectivity property. All four rough c-reflectivity properties transfer and, as before, characterizations may be formulated of the family and system versions in terms of the Leibniz operator, perceived as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

Section 6.9 deals with narrow complete reflectivity. A π-institution $\mathcal{I}$ is *narrowly family c-reflective* if, for every collection $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap \mathcal{T} \leq T'$. Once more, the *left version* arises by replacing all theory families in the conclusion by their arrow counterparts and, similarly, the *right version* by performing the same change in the hypothesis. *Narrow system c-reflectivity* imposes the same condition as the family version, but restricted to collections $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\lightning}(\mathcal{I})$. As with narrow reflectivity, the narrow c-reflectivity hierarchy is linear. The right version is the strongest, followed by the family, then the left and, finally, the system version. In addition, narrow system c-reflectivity, together with narrow systemicity, implies the right version. Comparisons between the rough c-reflectivity and the narrow c-reflectivity classes also follow the pattern revealed for corresponding reflectivity properties. In accordance, rough family and narrow family c-reflectivity are equivalent, rough left and narrow left c-reflectivity are incomparable, whereas the rough right and rough system versions imply, respectively, the narrow right and narrow system versions. As with their rough counterparts in Section 6.8, all four narrow c-reflectivity properties coincide with the corresponding c-reflectivity properties in the presence of theorems. Furthermore, all four narrow c-reflectivity properties transfer. The family and system versions have characterizations via the Leibniz operator seen as a mapping from $\mathrm{ThFam}^{\lightning}(\mathcal{I})$ and $\mathrm{ThSys}^{\lightning}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$, analogous to the ones obtained for both narrow injectivity and narrow reflectivity.

The last section of the chapter, Section 6.10, contains some characterizations of the property of a π-institution possessing theorems. This is closely connected to the overarching ideas governing the properties investigated in Sections 6.2-6.9, which aimed at rectifying the "pathologies" introduced by the absence of theorems. The availability of theorems is characterized by the injectivity of the Frege equivalence family operator, as well as by both the injectivity and the complete reflectivity of the Lindenbaum equivalence family operator, both applied to the collection of theory families of the π-

institution. These operators were introduced in Section 2.11. Possession of theorems transfers to the collections of all $\mathcal{I}$-filter families over arbitrary **F**-algebraic systems.

1.3.6 Chapter 7

In Chapter 7, we further pursue our endeavor of making properties in the lower bottom of the algebraic hierarchy suitable for the study of π-institutions that do not have theorems. Similarly to Chapter 6, we employ rough equivalence and narrowness to achieve this goal, but, unlike in Chapter 6, the focus here is on monotonicity and complete monotonicity properties, rather than on injectivity, reflectivity and complete reflectivity properties.

In Section 7.2, we define a *stability hierarchy*, which serves, in the sequel, to formalize properties of some of the classes in the monotonicity and complete monotonicity hierarchies. Recall that a π-institution $\mathcal{I}$ is *stable* if, for all theory families $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\overleftarrow{T}) = \Omega(T)$. Weakening this notion, we call $\mathcal{I}$ *narrowly stable* if the same equation holds, provided $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, i.e., the scope is restricted to theory families all of whose components are nonempty. A further weakening insists that the same equation hold for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, i.e., it further restricts the scope of the quantification to theory families all of whose components are nonempty and whose arrow counterparts also have all components nonempty. Clearly, stability implies narrow stability, which, in turn, implies the last property, which is termed *exclusive stability*. It is shown that both implications are strict.

In Section 7.3, we study the *rough monotonicity hierarchy*. Recall that, given a π-institution $\mathcal{I}$ and a theory family T of $\mathcal{I}$, $\widetilde{T}$ denotes the *rough companion* of the theory family T, which is the theory family resulting from T by replacing all empty Σ-components of T by $\mathrm{SEN}^\flat(\Sigma)$. Two theory families T and T' are *roughly equivalent* if they have the same rough companion. This is equivalent to saying that if T and T' differ at some signature Σ, they one has an empty Σ-component, whereas the other has $\mathrm{SEN}^\flat(\Sigma)$ as its Σ-component. A π-institution $\mathcal{I}$ is *roughly family monotone* if, for all theory families $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega(T) \leq \Omega(T')$. *Rough left monotonicity* results by replacing T, T' in the hypothesis by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively, and *rough right monotonicity* by applying the same replacement in the conclusion. *Rough system monotonicity* stipulates that the original implication hold, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$. It turns out that rough left monotonicity implies both rough family and rough right monotonicity and that each of the latter two implies the system version. Additionally, the strongest version, rough left monotonicity, is equivalent to the weakest, system, version, together with stability. Recall from Section 3.3 that family and left monotonicity are equivalent and this property was termed *protoalgebraicity*.

Recall also, from the same section, that system and right monotonicity are equivalent and this property was called *prealgebraicity*. Protoalgebraicity implies rough left monotonicity, whereas prealgebraicity implies rough right monotonicity. Tighter connections can be established under some fairly general hypotheses. For non almost inconsistent π-institutions, protoalgebraicity is equivalent to rough family or rough left monotonicity, coupled with the availability of theorems. Similarly, for π-institutions having a theory family $T \neq \mathrm{SEN}^\flat$, with $\overleftarrow{T} \neq \overline{\varnothing}$, prealgebraicity is equivalent to rough right or rough system monotonicity, supplemented with the availability of theorems. All four rough monotonicity properties transfer. E.g., $\mathcal{I}$ is roughly family monotone if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{I}$-filter families $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T} \leq \widetilde{T}'$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Both rough family and rough system monotonicity can be characterized using properties of the Leibniz operator viewed as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 7.4, we switch from rough monotonicity to *narrow monotonicity properties*. These constitute an alternative approach to bypassing theory families and theory systems with one or more empty components. We say that a π-institution $\mathcal{I}$ is *narrowly family monotone* if, for all theory families T, T', with all components nonempty, $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$. The *left version* results by replacing T, T' by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively, in the hypothesis and the *right version* by performing the same replacement in the conclusion instead. *Narrow system monotonicity* stipulates that, for all $T, T' \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$, $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$. Narrow left monotonicity implies narrow family monotonicity, which implies narrow system monotonicity, while the latter is also a consequence of narrow right monotonicity. Narrow left monotonicity is strong enough to yield exclusive stability, which, however, is the weakest of the three stability versions studied in Section 7.2. Under narrow systemicity, introduced in Section 6.3, the narrow monotonicity hierarchy collapses to a single class. Protoalgebraicity implies narrow left monotonicity and prealgebraicity implies the right version. In this case as well, tighter connections are possible under additional, fairly general, hypotheses, as was the case with rough monotonicity properties. Namely, under the hypothesis that $\mathcal{I}$ is not almost inconsistent, protoalgebraicity is equivalent to narrow left or narrow family monotonicity, coupled with the existence of theorems. And, provided that $\mathcal{I}$ possess a theory system $T \neq \overline{\varnothing}, \mathrm{SEN}^\flat$, prealgebraicity is equivalent to narrow right or narrow system monotonicity, together with the availability of theorems. Of central interest here is whether and how the rough monotonicity properties are related to the narrow monotonicity properties. In comparing the two hierarchies, we discover that the two family versions are equivalent, whereas each of the three remaining rough monotonicity properties implies the corresponding narrow monotonicity property. All four narrow monotonicity properties transfer. Finally, characterizations of the family and the system versions may be formulated in terms of the Leibniz operator seen as a mapping from $\mathrm{ThFam}^{\lightning}(\mathcal{I})$ and $\mathrm{ThSys}^{\lightning}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 7.5, we return to roughness, but study complete monotonicity (c-monotonicity) instead of monotonicity properties. *Rough family c-monotonicity* stipulates that, for all collections $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ implies $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. *Rough left c-monotonicity* and *rough right c-monotonicity* result by replacing in the hypothesis and in the conclusion, respectively, all theory families by their arrow versions. *Rough system c-monotonicity* imposes the same condition as does the family version, but restricts its applicability on collections $\mathcal{T} \cup \{T'\}$ consisting of theory systems. Here, it turns out that each of the left, family and right versions implies the system version. Moreover, rough left c-monotonicity is equivalent to the conjunction of rough system c-monotonicity and stability. It is also the case that, under stability, the rough family and rough right c-monotonicity properties coincide and that, under rough systemicity, the entire rough c-monotonicity hierarchy collapses to a single class. From the definitions, it is obvious that each of the four rough c-monotonicity properties implies the corresponding rough monotonicity version. It is also the case that each c-monotonicity property implies its rough c-monotonicity counterpart. Once more, for non almost inconsistent π-institutions, family (left c-monotonicity, respectively) is equivalent to the conjunction of rough family (rough left, respectively) c-monotonicity and the existence of theorems. Furthermore, if $\mathcal{I}$ possesses a theory family $T \neq \mathrm{SEN}^\flat$, such that $\overleftarrow{T} \neq \overline{\varnothing}$, then system (right, respectively) c-monotonicity is equivalent to rough system (right, respectively) c-monotonicity plus the existence of theorems. All four rough c-monotonicity properties transfer and one may, in this case also, recast the family and system versions in terms of properties of the Leibniz operator seen as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 7.6, we switch from rough versions of c-monotonicity to narrow versions of the same property. A π-institution $\mathcal{I}$ is called *narrowly family c-monotone* if, for all collections $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $T' \leq \bigcup_{T \in \mathcal{T}} T$ implies $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. In the *left version*, all theory families are replaced in the hypothesis by their arrow counterparts and, in the *right version*, the same change is applied in the conclusion. The *system version* stipulates that the implication above hold for all collections $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\lightning}(\mathcal{I})$. Each of the left, family and right versions implies the system version. Moreover, each of the four c-monotonicity versions implies the corresponding narrow c-monotonicity version. As was the case in relating rough and narrow monotonicity classes in Section 7.4, rough family c-monotonicity is equivalent to narrow family c-monotonicity, whereas each of the other three rough c-monotonicity properties implies the corresponding narrow c-monotonicity version. From the definitions, it is clear that a narrow c-monotonicity property implies its narrow monotonicity counterpart, the latter being a specialization of the former. All four narrow c-monotonicity properties transfer. In closing, both the family and the system versions have characterizations in terms of properties of the Leibniz operator perceived as a mapping from $\mathrm{ThFam}^{\nmid}(\mathcal{I})$ and $\mathrm{ThSys}^{\nmid}(\mathcal{I})$, respectively, into $\mathrm{ConSys}^*(\mathcal{I})$.

1.3.7 Chapter 8

In Chapter 8, we undertake the study of *regularity*. Roughly speaking, it is the property stipulating that, whenever two sentences belong to a theory family of a given π-institution, they must be identified modulo the Leibniz congruence system relative to that theory family. When, in addition to regularity, availability of theorems is also postulated, the property of *assertionality* is obtained. Assertionality strengthens complete reflectivity and, as a result, it can be used to strengthen (weak) (pre)algebraizability properties. These strengthenings and their associated hierarchies are under the microscope in Sections 8.4-8.7. The classes of π-institutions obtained here are among the most powerful classes in the semantic hierarchy of π-institutions, i.e., satisfy the strongest properties and are included in most of the other classes in the hierarchy.

In Section 8.2, we introduce *regularity*. As was the case with other properties in preceding chapters, regularity comes in four different versions. Once more, we begin from the easiest to describe, the family version. A π-institution $\mathcal{I}$ is *family regular* if, for all theory families T, all signatures Σ and all Σ-sentences ϕ an ψ, if $\phi,\psi \in T_\Sigma$, then $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$. *Left regularity* results by replacing T in the hypothesis by $\overleftarrow{T}$, *right regularity* by performing the same replacement in the conclusion instead, whereas *system regularity* stipulates that the implication hold for all theory systems T. Family regularity is the strongest of the four properties, followed by right regularity, which implies left regularity, which, in turn, implies the system version. Thus, regularity properties are stratified into a linear hierarchy. System regularity plus stability imply left regularity, and right regularity plus stability yield family regularity. It follows that, under stability, the four-class hierarchy is reduced to two classes. On the other hand, system regularity plus systemicity clearly yield family regularity, whence, systemicity leads to a collapse of the regularity hierarchy into a single class. The family, left and system versions have elegant characterizations in terms of the Suszko operator and one of its variants. E.g., a π-institution $\mathcal{I}$ is family regular if and only if, for every signature Σ and all Σ-sentences ϕ and ψ, $\langle\phi,\psi\rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi,\psi))$, where $C(\phi,\psi)$ is the least theory family of $\mathcal{I}$ containing ϕ and ψ. All four regularity properties transfer. For instance, with regards to the right version, $\mathcal{I}$ is right regular if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $\mathcal{I}$-filter families T of $\mathcal{A}$, all signatures Σ in $\mathcal{A}$ and all Σ-sentences ϕ and ψ, $\phi,\psi \in T_\Sigma$ implies $\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(\overleftarrow{T})$. The other three transfer results are formalized similarly.

Finally, the family and system versions may be characterized by the property that the filter family (system, respectively) in any reduced matrix family (system, respectively) is at most a singleton, in the sense that it consists of components with at most one element each.

In Section 8.3, we study *assertionality*. This is the property resulting from regularity by adding the requirement that theorems exist. Accordingly, four versions of assertionality are a priori obtained, depending on which of the four versions of regularity is postulated. They are termed *family*, *right*, *left* and *system assertionality* and, based on the hierarchy of regularity properties of Section 8.2, these also form a linear hierarchy, with the family version at the top, followed by the right, then the left and, finally, the system version at the bottom of the hierarchy. Assertionality is characterized by asserting, roughly speaking, that each theory family is fully determined by its Leibniz congruence system as the equivalence class of any theorem. Even though, a priori, there are four assertionality versions, there is a reduction holding without proviso. More precisely, it can be shown that right assertionality implies systemicity and this entails that right and family assertionality are equivalent. This property implies left assertionality, which, in turn, implies the system version. Moreover, the latter supplied with systemicity, implies family assertionality. By the definitions, it is clear that each assertionality version implies the corresponding regularity version. What is, however, more interesting, albeit not much more challenging to demonstrate, is that each assertionality property implies the corresponding complete reflectivity (c-reflectivity) property (see Section 3.8). So the assertionality properties may be viewed as further strengthening the hierarchy of reflectivity and c-reflectivity properties, studied in Sections 3.7 and 3.8. All three different assertionality properties transfer. Again, indicative of the flavor, a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is, e.g., left assertional if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the π-institution $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ is left assertional, meaning that, on the one hand, the least $\mathcal{I}$-filter family of $\mathcal{A}$ has all components nonempty and, on the other, that, for all $\mathcal{I}$-filter families T of $\mathcal{A}$, all signatures Σ and all Σ-sentences ϕ and ψ, such that $\phi, \psi \in T_\Sigma$, one has $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$. The section concludes with characterizations of the family and system versions, analogous to the ones provided in the conclusion of Section 8.2 for regularity. Namely, it is shown that $\mathcal{I}$ is family (system) assertional if and only if the filter family (system, respectively) of every reduced matrix family (system, respectively) is a singleton (i.e., consists of singleton components).

In Sections 8.4-8.7, we take advantage of the role of assertionality in strengthening of c-reflectivity to obtain strengthened versions of weak (pre)-algebraizability and (pre)algebraizability properties. The first two are obtained by combining assertionality properties with pre- or protoalgebraicity, whereas the latter are obtained by using (pre)equivalentiality instead.

In Section 8.4, we look at *regular weak prealgebraizability* properties. These result from adding to prealgebraicity (i.e., system monotonicity) a version of assertionality. Since there are three distinct versions of assertionality, one obtains three distinct corresponding versions of regular weak prealgebraizability. A π-institution $\mathcal{I}$ is *regularly weakly family* (RWF) *prealgebraizable* if it is prealgebraic and family assertional. It is *regularly weakly left* (RWL) *prealgebraizable* if it is prealgebraic and left assertional and it is *regularly weakly system* (RWS) *prealgebraizable* if it is prealgebraic and system assertional. Since the distinguishing feature between these three properties is the type of assertionality imposed, the assertionality hierarchy immediately yields that RWF prealgebraizability implies RWL prealgebraizability, which, in turn, implies RWS prealgebraizability. Equally clear from the definitions is the fact that RWF/L/S prealgebraizability implies, respectively, family/left/system assertionality. Additionally, the fact that each assertionality property implies its c-reflectivity counterpart entails that RWF/L/S prealgebraizability implies, respectively, WF/L/SC prealgebraizability (see Section 4.2). All three versions of regular weak prealgebraizability transfer. The section concludes with characterizations of the three versions based on the Leibniz operator viewed as a mapping between ordered sets of filter families/systems and congruence systems. To provide a flavor, we look at RWF prealgebraizability. The characterization states that $\mathcal{I}$ is RWF prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T)$ is a singleton.

In Section 8.5, we study *regular weak algebraizability*. The properties here are obtained from the regular weak prealgebraizability properties of Section 8.4 by upgrading prealgebraicity to protoalgebraicity. Accordingly, a π-institution $\mathcal{I}$ is *regularly weakly family* (RWF) *algebraizable* if it is protoalgebraic and family assertional, it is *regularly weakly left* (RWL) *algebraizable* if it is protoalgebraic and left assertional and it is *regularly weakly system* (RWS) *algebraizable* if it is protoalgebraic and system assertional. Notice that, since these properties constitute enhancements of the properties of Section 8.4, the right version has been absorbed within the family version. Here, however, protoalgebraicity, which, unlike prealgebraicity, implies stability, forces, in addition, the identification of the left and the system versions. Thus, there are only two distinct regular weak algebraizability properties, regular weak family (equivalently, right) algebraizability being the strongest and regular weak system (equivalently, left) algebraizability the weakest of the two. In comparing this two-step hierarchy with that of regular weak prealgebraizability properties, we discover that the two family versions coincide, whereas regular weak system algebraizability implies regular weak left prealgebraizability. As a consequence, the combined regular weak (pre)algebraizability hierarchy consists of four classes that are linearly ordered. Moreover, essentially due to the fact that assertionality properties imply c-reflectivity properties, each of the two regular weak algebraizability classes are included in the corresponding weak algebraizability classes. Both regular weak algebraizability properties transfer. Finally, both have characterizations in terms of the Leibniz operator seen as a mapping between ordered sets. E.g., $\mathcal{I}$ is RWS algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphim, such that, for all $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T)$ is a singleton.

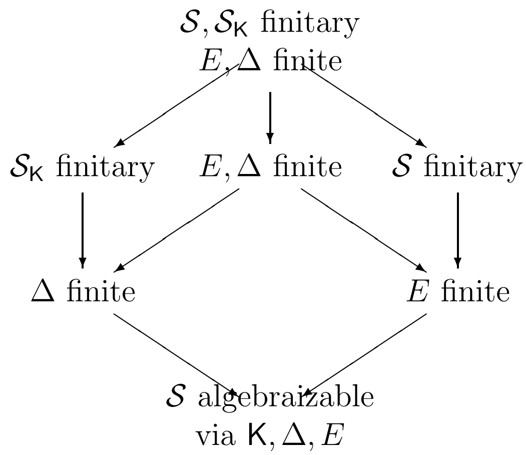
In Section 8.6, we introduce *regular prealgebraizability* properties. These are obtained by combining assertionality properties with preequivalentiality. Recalling that preequivalentiality is obtained by adding system extensionality to prealgebraicity, an alternative point of view is that regular prealgebraizability is obtained from regular weak prealgebraizability, studied in Section 8.4, by adding system extensionality. A π-institution $\mathcal{I}$ is *regularly family* (RF) *prealgebraizable* if it is preequivalential and family assertional, it is *regularly left* (RL) *prealgebraizable* if it is preequivalential and left assertional and it is *regularly system* (RS) *prealgebraizable* if it is preequivalential and system assertional. Based on the linear hierarchy of assertionality properties, we obtain a linear hierarchy of regular prealgebraizability properties, with RF prealgebraizability at the apex, followed by RL prealgebraizability, while RS prealgebraizability is at the bottom. Since preequivalentiality strengthens prealgebraicity, RF/L/S prealgebraizability implies, respectively, RWF/L/S prealgebraizability. Moreover, since each version of assertionality implies the corresponding c-reflectivity version, RF/L/S prealgebraizability implies, respectively, family/ left c-reflective/ system prealgebraizability (see Section 5.5). All three versions transfer. Finally, characterization theorems may be formulated for each of the three properties in terms of the Leibniz operator viewed as a mapping between ordered sets. To provide, once more, a preview, we mention the form this characterization takes in the case of regular left prealgebraizability. A π-institution $\mathcal{I}$ is regularly left prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system, $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding, commuting with inverse logical extensions, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\overleftarrow{T}/\Omega^{\mathcal{A}}(T)$ is a singleton.

In Section 8.7, the last section of Chapter 8, we turn to the study of *regular algebraizability* properties, which combine equivalentiality with assertionality. Equivalentiality forms a common strengthening of both protoalgebraicity and preequivalentiality. Even though one obtains, a priori, three versions of regular algebraizability, only two are distinct. We say that $\mathcal{I}$ is *regularly family* (RF) *algebraizable* if it is equivalential and family assertional, *regularly left* (RL) *algebraizable* if it is equivalential and left assertional, and *regularly system* (RS) *algebraizable* if it is equivalential and system assertional. Regular left and regular system algebraizability coincide and, as a result, the regular algebraizability hierarchy consists of the class of RF algebraizable π-institutions and its proper subclass of RS algebraizable π-institutions. In comparing regular algebraizability with regular prealgebraizability properties, we discover that the two family versions are equivalent and that regular system algebraizability implies regular left prealgebraizability. Further, in comparing regular algebraizability with regular weak algebraizability properties, we obtain, based on equivalentiality's dominant position over protoalgebraicity, that RF/S algebraizability implies, respectively, RWF/S algebraizability. In the ultimate comparison between subhierarchies, based on the fact that assertionality implies c-reflectivity, we obtain that RF/S algebraizability implies, respectively, F/S algebraizability. The section closes with the same type of theorems as previous sections. Namely, it is shown that both versions of regular algebraizability transfer from a π-institution to the filter families/systems over arbitrary $\mathbf{F}$-algebraic systems and characterizations of both versions are obtained in terms of the Leibniz operator perceived as a mapping between ordered sets. The family version, e.g., asserts that $\mathcal{I}$ is regularly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T)$ is a singleton.

1.3.8 Chapter 9

In Chapter 9, we undertake the study of finitarity properties of weakly family algebraizable π-institutions. Here we draw inspiration by the analysis of corresponding properties of algebraizable sentential logics.

According to the theory of algebraization of sentential logics, a, not necessarily finitary, algebraizable sentential logic $\mathcal{S}$ is algebraized via an equivalence that relates its consequence relation with the equational consequence of a generalized quasivariety K. The relation of equivalence is established via a possibly infinite set of defining equations $E(x)$ in a single variable x, which serve to translate formulas into equations, and a possibly infinite set $\Delta(x,y)$ of equivalence formulas in two variables x and y, which serve to translate equations into formulas. Besides constituting interpretations between the two consequences, they should be mutually inverse in a specific sense. In examining the relationships between the various finitarity conditions that may hold, namely, $\mathcal{S}$ finitary, $\mathcal{S}_{\mathsf{K}}$ (the equational deductive system induced by K) finitary, $E(x)$ finite and $\Delta(x,y)$ finite, one may show that they are related by the implications depicted in the following diagram (see p. 137 in Section 3.4 of [86]).

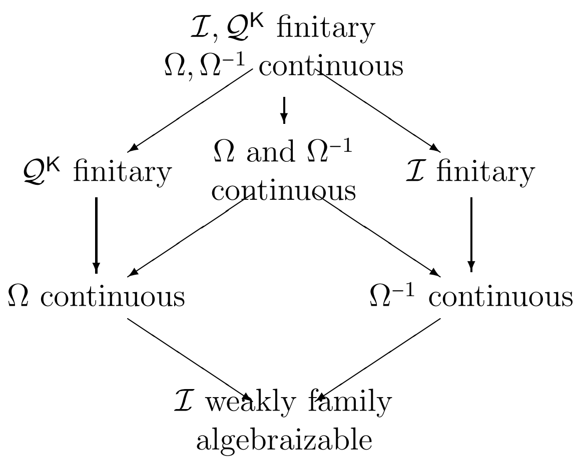


In the framework of sentential logics, roughly speaking, syntactic and semantic properties, i.e., those imposing the existence of transformations, such as $E(x)$ and $\Delta(x, y)$, satisfying certain properties, and those defined by order-theoretic properties of the Leibniz operator go hand-in-hand, in a tight correspondence. This is not the case in the framework of logics formalized as π-institutions. So in this chapter, the goal is to translate the sentential finitarity conditions to corresponding semantic properties and to establish an analogous hierarchy for weakly family algebraizable π-institutions. We also use examples from the sentential framework, recasting them as π-institutions, to obtain logical systems that serve to separate the classes of π-institutions specified by these finitarity properties.

In Section 9.2, the concept of *π-structure* is introduced, which abstracts that of a π-institution by removing the requirement of structurality. For π-structures, and, hence, also for π-institutions, the *finitary companion* is constructed, which is the π-structure over the same base algebraic system that has the largest finitary closure family included in the closure family of the given π-structure. *Locally finitely generated theory families* are defined and they are used to characterize those sentence families of a π-structure that are theory families of its finitary companion. These turn out to be exactly those sentence families that are unions of directed collections of locally finitely generated theory families of the given π-structure.

In Section 9.3, we investigate under which provisos, if any, the properties that define weak family algebraizability, i.e., protoalgebraicity and family reflectivity, are inherited by the finitay companion from the original π-structure and vice-versa. It is shown, first, that protoalgebraicity and family reflectivity are propagated from the finitary companion up to the parent π-structure unconditionally. On the other hand, the reverse inheritance requires additional conditions. To this end, the concept of *continuity* of the Leibniz and of the inverse Leibniz operator are introduced. The latter, of course, makes sense only if the π-institution under consideration is such that its Leibniz operator is an isomorphism, e.g., when it is weakly family algebraizable, which is precisely the case we focus on. If the Leibniz operator is continuous, it is easy to see that the π-institution is protoalgebraic. So continuity of the Leibniz operator actually strengthens protoalgebraicity. If, in addition to continuity, finiteness of the signature category is postulated, then the finitary companion is also protoalgebraic. Finally, it is shown that, if a π-institution, with a finite category of signatures, is weakly family algebraizable and both its Leibniz and inverse Leibniz operators are continuous, then its finitary companion is also weakly family algebraizable.

In Section 9.4, we undertake a detailed study of the interrelationships of the four finitarity properties pertaining to weakly family algebraizable π-institutions. These are the finitarity of the π-institution itself, the finitarity of its equational counterpart, the continuity of the Leibniz operator and the continuity of the inverse Leibniz operator, which is well-defined precisely because the π-institution is assumed to be weakly family algebraizable. These four properties are appropriate abstractions in the semantical institutional context of the properties of an algebraizable sentential logic being finitary, of its equivalent algebraic semantics being a quasivariety, of the set of equivalence formulas being finite and of the set of defining equations being finite, respectively. The close analogy is reflected in the fact that the results and hierarchy obtained here parallel the ones that hold for the corresponding properties in the sentential context. Our results come, as do their sentential counterparts, in dual pairs. In the first, it is shown that, for a weakly family algebraizable π-institution $\mathcal{I}$, the finitarity of $\mathcal{I}$ implies the continuity of its inverse Leibniz operator and, dually, the finitarity of the equational π-structure $\mathcal{Q}^{\mathsf{K}}$ induced by $\mathsf{K} := \mathrm{AlgSys}(\mathcal{I})$ implies the continuity of the Leibniz operator itself. Next, it is shown that, under weak family algebraizability, the finitarity of $\mathcal{I}$ and the continuity of the Leibniz operator imply that the equational counterpart is also finitary. Dually, the finitarity of the equational counterpart and the continuity of the inverse Leibniz operator imply that $\mathcal{I}$ itself is finitary. These implications lead to the following conditional equivalences, all applying to weakly family algebraizable π-institutions. For continuous Leibniz and inverse Leibniz operators, a π-institution is finitary if and only if its algebraic counterpart is finitary. For a finitary π-institution, its counterpart is finitary if and only if its Leibniz operator is continuous. Finally, if the algebraic counterpart of a π-institution is finitary, then the π-institution itself is finitary if and only if its inverse Leibniz operator is continuous. These outcomes lead to a finitarity hierarchy for weakly family algebraizable π-institutions paralleling the hierarchy depicted above for sentential logics.



What remains to be done is separate the classes of π-institutions constituting the finitarity hierarchy. For this task, given the analogies established with the sentential framework, we seek inspiration from the realm of sentential logics.

In Section 9.5, we revisit three sentential logics that serve in separating the classes that form the finitarity hierarchy in the sentential framework. The classes related by the vertical arrows are separated by Łukasiewicz's infinite valued logic. This is a non-finitary, semantically defined sentential logic. It is algebraizable with a non-finitary equivalent algebraic semantics. On the other hand, both sets of defining equations and equivalence formulas are finite. The classes connected by the southeast arrows are separated using a finitary logic introduced by Dellunde and defined via a Hilbert calculus. It is regularly algebraizable via a singleton set of defining equations but a necessarily infinite set of equivalence formulas. Finally, the classes related by the southwest arrows of the diagram are separated using a non-finitary logic semantically defined by Raftery. This logic has a finitary equivalent algebraic semantics (actually a variety) and is algebraized via a finite set of equivalence formulas but a necessarily infinite set of defining equations. Even though we could certainly rely on well-written accounts from the literature to simply refer to these logics, we chose to recount all details, based on those original references. The Introduction to Chapter 9 and the main body contain more information, as well as appropriate references.

In Section 9.6, the three sentential logics of Section 9.5 are recast as π-institutions, according to the general procedure outlined in Section 1.1. The resulting π-institutions serve, in turn, in separating the corresponding classes appearing in the finitarity hierarchy of weakly family algebraizable π-institutions. Further evidencing the analogies described between the two finitarity hierarchies, the π-institution encapsulating Łukasiewicz's logic separates the classes of π-institutions connected via vertical arrows, the one incorporating Dellunde's logic separates classes along the southeast arrows, while the one arising from Raftery's logic separates classes related by the southwest arrows in the institutional finitarity hierarchy.

1.4 A Very Concise Summary of Contents

In Chapter 2, we introduce the basic definitions and fundamental results of algebra and logic and some indispensable notions and results pertaining to their interaction. These form the necessary background and the prerequisites for the general theory of algebraization of logics formalized as π-institutions that is presented in the monograph.

In Chapter 3, we introduce fundamental classes of the semantic Leibniz hierarchy. The term semantic alludes to the fact that they are defined purely by properties of the Leibniz operator on the complete lattices of the theory families or theory systems of π-institutions. Very central to our studies throughout, partly because they equip us with indispensable terminology regarding crucial properties, are the classes of systemic and stable π-institutions. At the bottom center of the hierarchy lie the loyalty properties. These simultaneously abstract monotonicity properties, on the one side, and reflectivity properties, on the other side. On the monotonicity side, we study monotonicity and two kinds of complete monotonicity, complete $\bigcup$-monotonicity, using the union operation, and complete $\bigvee$-monotonicity, using the join operation. In crossing over to the reflectivity side, we pass through, and study, injectivity properties. On the other side, we look, first, at reflectivity and, finally, at complete reflectivity properties. In Chapter 3, we not only define various flavors of each of these properties and compare their various strengths, but we also investigate the relations across those different kinds of properties. On the way, we also present many concrete examples, some of which are reused throughout the monograph to illustrate concepts, but, also - and mainly - to separate classes in the various hierarchies.

In Chapter 4, we study weak prealgebraizability and weak algebraizability properties. Weak prealgebraizability arises by combining prealgebraicity (system monotonicity) with one of the ten possible versions of injectivity, reflectivity or complete reflectivity. On the other hand, weal algebraizability results when combining protoalgebraiciy (family monotonicity) with one of those ten versions. Taking into account the combined hierarchy of injectivity, reflectivity and complete reflectivity properties, established in Chapter 3, we obtain a hierarchy of ten potentially different classes of weak prealgebraizability and a similar one consisting of ten potentially different classes of weak algebraizability. However, it is shown that the weak prealgebraizability hierarchy collapses down to six classes, whereas the one of weak algebraizability down to only two. Moreover, the top classes in the two hierarchies are identical. Therefore, when the two hierarchies are merged, a combined hierarchy consisting of seven distinct classes is obtained. The chapter includes, inter alia, characterizations of these seven classes using the Leibniz operator perceived as a mapping from the lattice of filter families to the poset of congruence systems over arbitrary algebraic systems.

In Chapter 5, we study the hierarchies of prealgebraizable and of algebraizable π-institutions. We look, first, at the property of extensionality and the seemingly weaker property of 2-extensionality and show that they are equivalent. Roughly speaking, extensionality relates Leibniz congruence systems of theories of an institution with those of corresponding theories of subinstitutions. Then, we look at the closely related properties of (Leibniz) commutativity and inverse (Leibniz) commutativity. These two properties are equivalent under monotonicity and, moreover, inverse commutativity is equivalent to extensionality. By combining monotonicity with extensionality properties, we build the hierarchy of equivalential π-institutions. Depending on which of the available versions of monotonicity or extensionality are imposed, three versions of equivalentiality arise, namely, equivalentiality, family preequivalentiality and (system) preequivalentiality in decreasing strength. By combining versions of preequivalentiality with injectivity, reflectivity or complete reflectivity properties, the ten classes of the prealgebraizability hierarchy are obtained. Similarly, by combining equivalentiality with injectivity properties (which are, in the presence of equivalentiality, equivalent to corresponding reflectivity or complete reflectivity properties), we get the two classes of algebraizable π-institutions.

In Chapter 6, we look at classes of the Leibniz hierarchy lying below the classes of injective, reflective and completely reflective π-institutions, which were introduced in Chapter 3. The motivating observation is that, if a π-institution satisfies injectivity or, a fortiori, reflectivity or complete reflectivity, then it must possess theorems. Thus, π-institutions without theorems are automatically excluded from consideration in contexts where these properties are postulated or studied. To bypass this hurdle, we define and study weakened versions of injectivity, reflectivity and complete reflectivity that can accommodate absence of theorems, but are equivalent to injectivity, reflectivity and complete reflectivity, respectively, in the presence of theorems. For each of those three properties, we study the rough versions and the narrow versions and carefully compare them to the original versions, as well as to each other, to obtain the hierarchies of injectivity, rough injectivity, narrow injectivity, reflectivity, rough reflectivity and narrow reflectivity, and c-reflectivity, rough c-reflectivity and narrow c-reflectivity classes of π-institutions. Roughly speaking, roughness identifies two theory families if their Σ-components are either equal or one is $\varnothing$ and the other is $\mathrm{SEN}^\flat(\Sigma)$. Those turn out to have identical Leibniz congruence systems. On the other hand, narrowness excludes from consideration altogether theory families with at least one empty component.

In Chapter 7, we continue the study of properties of π-institutions obtained by combining properties lying at the bottom of the Leibniz hierarchy with rough equivalence, on the one hand, and with narrowness, on the other. As opposed to Chapter 6, which considered properties lying below injectivity, reflectivity and complete reflectivity, this chapter undertakes the study of properties lying below monotonicity and complete monotonicity (c-monotonicity) properties. In a nutshell, roughly monotone and roughly c-monotone π-institutions form super classes, respectively, of the classes of monotone and c-monotone π-institutions. Additionally, narrowly monotone and narrow c-monotone π-institutions encompass respectively, roughly monotone and roughly c-monotone ones. By studying all four versions of each of these properties, we obtain a mixed hierarchy of rough and narrow monotonicity and rough and narrow c-monotonicity properties.

In Chapter 8, we study properties obtained by combining pre- or protoalgebraicity or (pre)equivalentiality, on the one hand, with assertionality, on the other. The latter, a property that strengthen complete reflectivity asserts, roughly speaking, that a π-institution has theorems and, in addition, each of its theory families is determined by its associated Leibniz congruence system as the equivalence class of a theorem. The chapter starts with the study of regularity, a property similar to assertionality, except that it does not require existence of theorems. It holds when any two sentences belonging to a theory family are identified modulo the Leibniz congruence system relative to that theory family. Assertionality properties are formalized next. The hierarchy they form and its interrelationships with the classes of the regularity hierarchy are explored in detail. Prealgebraicity, coupled with asserrtionality, gives rise to regular weak prealgebraizability, strengthening the classes of weak prealgebraizability properties. Protoalgebraicity, together with assertionality, leads to regular weak algebraizability properties. This hierarchy strengthens both regular weak prealgebraizability and weak algebraizability properties. Preequivalentiality and assertionality give rise to regular prealgebraizability, which strengthens both regular weak prealgebraizability and prealgebraizability. The chapter concludes with the study of regular algebraizability, which combines equivalentiality with assertionality. The classes of this hierarchy form subclasses of both those consisting of regularly prealgebraizable and those consisting of algebraizable π-institutions.

Chapter 9 starts with the introduction of the finitary companion of a π-institution. It is the largest finitary π-institution below the given one in the $\leq$ ordering of π-institutions based on the same algebraic system. The focus is on those properties defining weak family algebraizability, namely protoalgebraicity and family reflectivity. We investigate under which conditions, if any, those properties are passed from a π-institution to its finitary companion and vice-versa. In the second part, the focus shifts to the study of finitarity properties of weakly family algebraizable π-institutions. This class of π-institutions is chosen because, on its members, the Leibniz operator is an isomorphism and, hence, it makes sense to consider the inverse Leibniz operator. The four finitarity properties under investigation are the finitarity of the π-institution itself, the finitarity of its algebraic counterpart and the continuity of the Leibniz operator and of the inverse Leibniz operator. The implications holding between these properties give rise to the finitarity hierarchy of weakly family algebraizable π-institutions. The chapter also revisits some examples of sentential logics and formalizes them as π-institutions. The latter are then used to separate the various classes in the finitarity hierarchy. The three examples are Łukasiewicz's infinite valued logic, Dellunde's logic and a logic due to Raftery.

1.5 Further Reading

This is the first attempt to systematize the body of knowledge gathered over the years concerning the algebraization of logics formalized as π-institutions. However, for the readers interested in learning much more about the origins, history, concepts, results and developments in algebraic logic as applied to deductive systems, i.e., "abstract algebraic logic", there are a few excellent sources available that have served well over the years in educating the second and third generations of "abstract algebraic logicians".

Starting tangentially to the subject, but of interest, since they provide a comprehensive study of logical calculi and of institutions, respectively, the latter being the precursors of π-institutions used here, are the monographs by Wójcicki [34] and Diaconescu [79].

Two of the first sources that played a critical role in establishing and solidifying the discipline in its present form were the seminal "Memoirs" monograph of Blok and Pigozzi [35], in which algebraizable logics were introduced, and the pioneering monograph of Font and Jansana [52], in which generalized matrices were studied in a systematic way and the notion of Tarski congruence and accompanying reduced class of generalized matrices and underlying class of algebras were defined and studied in detail.

More at the textbook, rather than at the research, level, are the books of Czelakowski [64] and the more recent textbook by Font [86]. These are the only two books, to my knowledge, that are focused on systematically treating and presenting the most important results in the abstract setting. It goes, of course, without saying, that they both contain a plethora of concrete examples that have been studied in the literature, showcasing various aspects of the general theory and exemplifying the wide reach of its applicability.

Apart from research monographs and books, a few surveys have also appeared that provide overviews of, and/or details on, significant parts of the theory. Among them are [40], [68], [69, 80] and [90].

Finally, there have been a few, as far as I am aware, Ph.D. Dissertations which have dealt, either in their introductions or in their main corpus, with expositions and/or overviews of significant parts of the theory. Among them, some that have helped my own understanding and enhanced and/or diversified my point of view of various aspects of the theory are, in chronological order, those of Herrmann [43], Elgueta [47], Rebagliato [49], Dellunde [51], Gyuris [60], Martins [70], Russo [78], Albuquerque [85] and Moraschini [87].

The algebraization of logics formalized as π-institutions may be said to have started with the Ph.D. Dissertation by the author [97] (see, also, [98]), under the influence of preceding unpublished work by Zinovy Diskin [46] (see, also, [51]), which had been communicated to Professor Don Pigozzi, the author's Ph.D. Dissertation advisor, and used with Zinovy's kind permission and encouragement.

Chapter 2

Algebra and Logic

2.1 Introduction

In Section 2.2, we introduce the basic algebraic machinery that underlies all structures considered in the monograph. We start with *sentence functors*, which are arbitrary **Set**-valued functors on a category of signatures. *Sentence families* are families of sets over sentence functors. They are called *systems* in case they are invariant under signature morphisms. Associated with a sentence family T is the largest sentence system $\overleftarrow{T}$ included in T and the smallest sentence system $\overrightarrow{T}$ which includes T. We also introduce and discuss *morphisms* between sentence functors and, in particular, distinguish the key class of *surjective morphisms*. By analogy to sentence families, one may also consider *relation families* over sentence functors, i.e., families of relations on sentences. Relation families satisfying the requisite properties constitute *equivalence families*. A fundamental notion, pervasive throughout our treatise, is that of *compatibility* of an equivalence family with a given sentence family. The importance of compatibility was exemplified in [35] (see, e.g., Section 1.4 of [35], where the notion is defined). Whereas sentence functors capture the underlying carriers of all algebraic and logical structures we consider, the earnest algebraic treatment begins when they get endowed with *categories of natural transformations* which correspond to clones of algebraic operations [31, 44]. These enriched structures are termed *algebraic systems*. Appropriate mappings, preserving the relevant features, are also called *morphisms* (of algebraic systems). In most contexts, it is required that all algebraic systems under consideration are over the same algebraic signature. This is ensured by adopting a base algebraic system $\mathbf{F}$, which fixes the signature, and, then, considering only algebraic systems whose sentences and clones of operations are, in a certain sense, interpretations of the basic one. These play an important role and are termed *interpreted algebraic systems* or $\mathbf{F}$-*algebraic systems*.

In Section 2.3, we introduce and study *congruence systems*. These are equivalence systems on an underlying algebraic system that satisfy a suitably adapted version of the congruence (sometimes also called compatibility or replacement) property. They play in this context the role that congruences play in universal algebra [22, 13, 21, 30, 84]. The collection of congruence systems on a given algebraic system forms a complete lattice. Of utmost importance is the process of constructing the *quotient* of an algebraic system by a congruence system and of the accompanying *canonical quotient morphism*. Equally important, in fact indispensable for the development of the theory, is the fact that the collection of congruence systems on a given algebraic system $\mathbf{A}$ that are compatible with a given sentence family T of $\mathbf{A}$ form a complete lattice. This fact allows considering the largest congruence system on $\mathbf{A}$ compatible with T, which is denoted by $\Omega^{\mathbf{A}}(T)$ and termed the *Leibniz congruence system of T on $\mathbf{A}$* [35]. A property that is worth mentioning, since it plays a critical role in establishing pieces of the various hierarchies considered in subsequent chapters, is that the Leibniz congruence system of a sentence family T is always included in that of the largest sentence system contained in T, i.e., $\Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\overleftarrow{T})$.

In Section 2.4, we look at a special class of congruence systems whose definition presupposes fixed in the background a class K of algebraic systems. Given an arbitrary algebraic system, a congruence system on it is said to be a K-*congruence system* or a *congruence system relative to* K if the quotient algebraic system it induces belongs to the class K (see, e.g., Chapter Q of [64]). Two important concepts in this context are *closure of a class under morphic images* and *closure under subdirect intersections*. If the class K is closed under morphic images, then, for every algebraic system in K, the absolute and relative concepts of congruence system coincide. On the other hand, if K happens to be closed under subdirect intersections and contains a trivial algebraic system, then the collection of all K-congruence systems on any algebraic system forms a complete lattice. In this case, it makes sense to consider, given a relation system X on an algebraic system $\mathcal{A}$, the *least* K-*congruence system on* $\mathcal{A}$ *including* X, also known as the K- *congruence system generated by* X, and denoted by $\Theta^{\mathsf{K},\mathcal{A}}(X)$. In the main result of the section, it is shown that this congruence system coincides with the equational closure of X relative to the class K.

In Section 2.5, we introduce *semantic* and *syntactic varieties* of algebraic systems. These play the role that varieties play in universal algebra (see, e.g., [21, 30, 84]). All algebraic systems are understood to be over a fixed signature specified by a base algebraic system $\mathbf{F}$. To define the two types of varieties, we look at *equations*, consisting of pairs of sentences, and at *natural equations*, which are pairs of natural transformations. Given a class K of algebraic systems, the *semantic variety* generated by K is the class of all algebraic systems satisfying all equations valid in all members of K. The *syntactic variety* generated by K is defined analogously with reference to natural equations. It turns out that the semantic variety generated by K is subsumed by the corresponding syntactic one. A technical definition, that of a *transformational algebraic system*, is introduced as a way to establish a sufficient condition for semantic and syntactic varieties to coincide.

In Section 2.6, we switch from purely algebraic to logical considerations. We define *systems of closure operators* on algebraic systems, which give rise to π-*institutions* [33] (see, also, [25, 41]). Those constitute the basic underlying logical structures on which all subsequent studies will be founded. Many well-known fundamental logical concepts are adapted to this framework, among them, *theorem systems*, *theory families* and *inconsistent*, *almost inconsistent* and *trivial* π-*institutions* (see, e.g., [64, 86] for the counterparts in abstract algebraic logic). Concerning theory families, it is worth mentioning that in case T is a theory family of a given π-institution, the construction of $\overleftarrow{T}$ gives rise to a theory system, and not merely a sentence system, but this is not the case for $\overrightarrow{T}$. Therefore, $\overleftarrow{T}$ does constitute the largest theory system included in T, but to construct the smallest theory system including T, one has to apply the closure operator and obtain $C(\overrightarrow{T})$. Comparing closure systems over the same underlying algebraic system, the notions of *extension* and *weakening* are introduced, as well as that of the closure system obtained as the intersection of a family of closure systems. Given a closure system C and one of its theory systems T, we also consider the extension C^T of C that is induced by adopting the given theory system as a system of axioms. Finally, we look at *logical morphisms* between π-institutions. These are morphisms that preserve the logical structure, i.e., map closures into closures in a formal sense, or, what turns out to be equivalent, morphisms whose inverses preserve theory families.

In Section 2.7, after having discussed the algebraic and logical prerequisites, we turn into developing the first rudiments of their interaction. We look at *matrix families* which serve both to define closure systems, and, hence, also, π-institutions, but also as algebraically based models of given π-institutions. They are pairs consisting of an underlying algebraic system together with a sentence family over it and correspond to the ordinary logical matrices of abstract algebraic logic [64, 86]. For a given π-institution $\mathcal{I}$, its matrix family models are termed *$\mathcal{I}$-matrix families* and the corresponding sentence families are called *$\mathcal{I}$-filter families*. Some characterizations of these families are provided along with the observation that the collection of all $\mathcal{I}$-filter families on a given algebraic system forms a complete lattice. A discussion follows on when and under which conditions morphisms between the underlying algebraic systems preserve, under taking direct or inverse images, $\mathcal{I}$-filter families. In closing the Section, we look at *quotients of matrix families* under the Leibniz congruence systems of their filter families. These are referred to as *Leibniz reductions* (see, e.g., Section 4.3 of [86]). We say that a matrix family is *Leibniz reduced* when the Leibniz congruence system of its filter family is the identity. Leibniz reductions give rise to the fundamental collection of *Leibniz reduced $\mathcal{I}$-matrix families* and the accompanying collection of their algebraic system reducts. Two more related subcollections are obtained if one restricts attention to *$\mathcal{I}$-filter systems* and *$\mathcal{I}$-matrix systems*, i.e., those that consist of filter families that are invariant under the action of signature morphisms.

In Section 2.8, continuing the study of filter families and matrix families, we introduce *axiomatic extensions*, or *axiomatic strengthenings*, and the closely related concept of *filter extension* (see Section 0.8 of [64] and Sections 1.3 and 1.4 of [86]). We provide characterizations and study interactions with morphisms, looking, in particular, into some preservation properties.

In Section 2.9, a generalization of matrix families and filter families is introduced. Namely, we consider structures consisting of an underlying algebraic system together with a collection of sentence families over it. These are called *generalized matrix families* or *gmatrix families*, for short. They play the role that generalized matrices play in the traditional treatment [52] (see, also, Chapter 5 of [86]). As was the case with matrix families, gmatrix families serve a dual purpose. They may be used to define closure systems, but they also serve as models of π-institutions. In the latter case, if a gmatrix family is a model of a given π-institution $\mathcal{I}$, we say that it is an *$\mathcal{I}$-gmatrix family*. By analogy with $\mathcal{I}$-matrix families, one may consider reductions of gmatrix families. The *Tarski congruence system* of a gmatrix family is the largest congruence system on its underlying algebraic system which is compatible with all filter families of the gmatrix family [52]. Equivalently, it may be characterized as the intersection of all Leibniz congruence systems of its constituent filter families. The process of taking the quotient of a gmatrix family by its Tarski congruence system is called *Tarski reduction*. We say that a gmatrix family is *Tarski reduced* if its Tarski congruence system in the identity. The construction gives rise to the class of all Tarski reduced $\mathcal{I}$-gmatrix families and the class of the corresponding algebraic system reducts. Both are of critical importance in the study of algebraization of π-institutional logics. Very intimately related to Tarski congruence systems is the notion of *Suszko congruence systems* [67] (see, also, Section 1.5 of [64] and Section 5.3 of [86]). Here, one considers the filter family subcollection $\mathcal{T}^T$ of a filter family collection $\mathcal{T}$ by keeping only those filter families containing a fixed filter family $T \in \mathcal{T}$. The *Suszko congruence system of T relative to $\mathcal{T}$* is the Tarski congruence system of $\mathcal{T}^T$. Conversely, assuming that $\mathcal{T}$ has a smallest filter family T, the Tarski congruence system of $\mathcal{T}$ coincides with the Susko congruence system of T in $\mathcal{T}$. As before, one may consider *Suszko reductions* and *Suszko reduced $\mathcal{I}$-matrix families*, where the reductions are taken relative to the collection of all $\mathcal{I}$-filter families. Even though, given a π-institution $\mathcal{I}$, this process results in the new class of Suszko reduced $\mathcal{I}$-matrix families, the class of corresponding algebraic system reducts turns out to be identical with that obtained from the process of Tarski reduction.

In Section 2.10, we continue the study of classes of algebraic systems associated with a given π-institution $\mathcal{I}$. In Section 2.7, we introduced the class of all algebraic system reducts of all Leibniz reduced $\mathcal{I}$-matrix families. This class is known as the class of *$\mathcal{I}^*$-algebraic systems*. In Section 2.9, we looked at the class of all algebraic system reducts of all Tarski reduced $\mathcal{I}$-gmatrix families. These are known as *$\mathcal{I}$-algebraic systems*. The two classes correspond, respectively, to the classes $\mathrm{Alg}^*\mathcal{S}$ and $\mathrm{Alg}\mathcal{S}$ in the case of a sentential logic $\mathcal{S}$ [52]. On top of these two classes of algebraic systems, two more classes considered in relation to a π-institution $\mathcal{I}$ are the semantic and syntactic varieties generated by the underlying algebraic system of the Tarski reduction of the $\mathcal{I}$-gmatrix system consisting of the collection of all theory families of $\mathcal{I}$. The first is termed the *semantic* and the second the *syntactic variety of $\mathcal{I}$*. It turns out that, in general, the class of $\mathcal{I}^*$-algebraic systems forms the smallest class, followed by the class of $\mathcal{I}$-algebraic systems, followed by the semantic variety of $\mathcal{I}$, while the syntactic variety of $\mathcal{I}$ constitutes the largest of these four classes. An interesting result is that any of these four classes generates the same syntactic variety, namely, the syntactic variety of $\mathcal{I}$. The section concludes with the observation that the class of all $\mathcal{I}$-algebraic systems is closed under subdirect intersections and contains a trivial algebraic system. Consequently, one is justified in considering congruence systems generated by any relation system on any given algebraic system relative to this class.

In Section 2.11, we switch from the study of congruence systems associated with a given π-institution and of their quotients to the study of equivalence families and systems resulting by considering mutual membership or non-membership in theory families. The reader is warned that the terminology here deviates from the standard one for sentential logics (Section 2.4 of [52] and Section 1.3 of [86]). This is done in an attempt to streamline the theory of these equivalence families with the theory based on the Leibniz, Tarski and Suszko congruence systems. The most basic equivalence family is the *Frege equivalence family* of a given theory family, which identifies sentences if they are both inside or both outside the given theory family. Sometimes, this is expressed by saying that the sentences are *equivalent modulo the theory family*. The *Frege relation system* is the largest equivalence system included in the Frege equivalence family. There is a close connection between Leibniz congruence systems and Frege relation families/systems. The Leibniz congruence system of a given theory family is the largest congruence system contained in the Frege equivalence family or system associated with the theory family. In a way analogous to the passage from Leibniz congruence systems of single theory families to the Tarski congruence systems of collections of theory families, one transitions from Frege equivalence families to *Carnap equivalence families*. These express equivalence of sentences modulo collections of theory families. The Carnap equivalence family turns out to be the intersection of the Frege equivalence families of all theory families in the collection. Here, again, the *Carnap equivalence system* is the largest equivalence system included in the Carnap equivalence family. Further, extending the relation between Leibniz congruence systems and Frege equivalence families, the Tarski congruence system of a collection is the largest congruence system included in either the Carnap equivalence family or the Carnap equivalence system of the same collection. The same paradigm gives rise to *Lindenbaum equivalence families/systems*, which formalize the equivalence of sentences modulo a theory family, relative to a given collection of theory families. This is identical to the intersection of all Frege equivalence families/systems of those theory families in the collection including the given one. Similar relations as before hold in this case as well, with the role of Leibniz and Tarski congruence systems played by Suszko congruence systems. A small table at the end of the section summarizes the three congruence systems and the three corresponding pairs of equivalence families/systems that are considered in this context. Hopefully, the analogies outlined between congruence systems and equivalence families/systems provide some justification for introducing distinct names for the Carnap equivalences and the Lindenbaum equivalences, which are all referred to as Frege equivalences in the literature.

In Section 2.12, we look at *subsystems* of algebraic systems and induced π-*subsinstitutions*. Given an algebraic system, a *universe* is a sentence subfunctor over the same category of signatures that is also closed under the algebraic operations. In a natural way, a universe gives rise to an *algebraic subsystem*. With each subsystem, there is associated a *natural injection morphism*. Given a sentence family of an algebraic system, by closing successively under the action of signature morphisms and under the action of natural transformations, one obtains the *universe* of the algebraic system *generated by* the given sentence family. If the given algebraic system happens to be the underlying system of a π-institution, which is a case of central interest, then, by restricting the action of the closure system of the π-institution on sentences of the universe, we obtain a π-*subinstitution*. Its theory families turn out to be exactly the restrictions of the theory families of the original π-institution on the universe. The section concludes by establishing some connections between the Leibniz congruences of theory families of the original π-institution and those of the induced theory families of the subinstitution. These relations extend in a natural way to filter families of the two institutions.

Up to Section 2.12, only cursory attention is paid to natural transformations. They are used in establishing syntactic varieties of algebraic systems via natural equations, but they are not thoroughly studied as "syntactic" objects of interest in their own right. This deficiency is rectified by devoting Sections 2.13-2.15 to their study and to particular aspects of their properties and behavior that are of interest for subsequent considerations.

In Section 2.13, we consider the role played by collections of natural transformations. In general, in the context of collections of natural transformations, a number of arguments is fixed and they are considered as *primary* or *distinguished arguments*. The remaining positions play an auxiliary role and are perceived as *parametric* (see, e.g., Section 1.2 of [64] and Section 6.2 of [86]). In accordance with this paradigm, if E is a collection of natural transformations, of which k positions are considered distinguished, then, for any k-tuple of sentences $\vec{\phi}$ over a signature Σ, $E_\Sigma[\vec{\phi}]$ denotes the sentence family consisting of all sentences of the form $\varepsilon_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}),\vec{\chi})$, for $\varepsilon \in E$, $f : \Sigma \to \Sigma'$ a signature morphism and $\vec{\chi}$ an arbitrary tuple of sentences over Σ'. In this way a tuple, or a collection of tuples, of sentences gives rise to a sentence family. Dually, given a sentence family T, one may consider the family of all k-tuples $\vec{\phi}$, such that $\varepsilon_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}),\vec{\chi}) \in T_{\Sigma'}$, for all ε, f and $\vec{\chi}$. This gives rise to a k-ary relation system, depending on both E and T, denoted $\overleftarrow{E}(T)$. $\overleftarrow{E}$, viewed as an operator from sentence families to relation systems, is monotone and commutes with inverse surjective morphisms. For the purposes of relating logical with algebraic systems, critical is the role played by $\overleftarrow{E}$ as a potential means of defining Leibniz congruence systems of theory families. Along those lines, it is shown that, if $k = 2$ and $\overleftarrow{E}(T)$ defines a reflexive relation system, then this includes the Leibniz congruence system of T. Consequently, if $\overleftarrow{E}(T)$ is itself a congruence system compatible with T, then it necessarily coincides with the Leibniz congruence system of T (see, e.g., Theorem 1.6 of [35]).

In Section 2.14, taking a cue from the definition of the operator $\overleftarrow{E}$ in Section 2.13, we investigate membership relations of k-tuples of sentences in theory families of a π-institution induced by a fixed set E of natural transformations, taken to possess k distinguished arguments. Four modes are considered, namely, *E-local*, *E-global*, *left E-local* and *left E-global* membership. It is shown that E-global and left E-global memberships are equivalent, that they imply left E-local membership, which, in turn, implies E-local membership. Both implications are shown to be strict in general. If a membership property holds for all k-tuples of sentences (for the same E), then that property is attributed to the set E itself. It turns out that, in that case, all three resulting modes of membership of E in a theory family T are actually equivalent properties.

Section 2.15 is the last of the three sections that are devoted exclusively to the analysis of syntactic definability properties via sets of natural transformations. In this section, we consider two possible ways which may be used to obtain, starting from a parametric collection S of natural transformations, a related one that is parameter-free. The first is effectuated by replacing all parametric arguments by k-ary terms, where k is the number of distinguished arguments of S. This process gives rise to a new collection $\dot{S}$ of natural transformations with k arguments altogether and, therefore, without parameters. The second process is more abstract. It is defined via the use of, so called, *anti-monotone global properties* of natural transformations. These are properties that satisfy a technical anti-monotonicity condition. Given such a property P, by slightly abusing notation, we also denote by P the collection of all natural transformations (possibly with parameters) satisfying P. Then $\widehat{P}$ denotes the subcollection of P of parameter-free natural transformations satisfying P. In the main result of Section 2.15, it is shown that, given such a property P, both constructors $\dot{P}$ and $\widehat{P}$ result in identical de-parameterizations of the collection P.

The last three sections of Chapter 2 deal with more specialized topics. Section 2.16 addresses the special case of π-institutions whose closure systems are *finitary*. Most applied logical systems encountered in the literature fall under this case. Section 2.17 deals with *equational π-institutions*. These are π-institutions whose sets of sentences are pairs of sentences drawn from a base algebraic system and whose closure operators reflect the equational consequence determined by a class of algebraic systems. Finally, Section 2.18 adapts some of the rudiments pertaining to *varieties*, *quasivarieties* and *generalized quasivarieties* of universal algebra and their generation to the context of algebraic systems.

In Section 2.16, we study *finitarity* (see, e.g., Section 0.1 of [64] and Section 1.4 of [86]). This is the property of a closure system (or π-institution) that holds when every sentence which is a consequence of a set of sentences is also a consequence of some finite subset of that set. Some characterizations of finitarity are provided based on the properties of *local continuity* and *continuity* of a π-institution which, in turn, are defined using *local directedness* and *directedness* of collections of theory families. The last part of the section provides a step-wise, inductive construction of the filter family of a finitary π-institution on an arbitrary algebraic system generated by a give sentence family of the algebraic system.

In Section 2.17, we introduce *equational consequences* based on fixed classes of algebraic systems and show that all their theory families happen to be theory systems and that, moreover, they coincide with the congruence systems relative to the class of algebraic systems inducing the equational consequence. Then, as in Section 2.16, we present a step-wise construction of the equational consequence generated by a given family of equations, considered as axioms. We show that, if this defining family of equations is taken to be the family of equations that holds in a class K of algebraic systems, then the equational consequence they generate, according to this step-wise process, coincides with the equational consequence induced by the class K.

The final section, Section 2.18, translates some of the classical results of universal algebra pertaining to *varieties*, *quasivarieties* and *generalized quasivarieties* [21, 30, 84] (see, also, Chapter Q of [64]) to the context of classes of algebraic systems. We revisit *equations* and, in addition, consider *quasiequations* and *generalized quasiequations*, referred to as *guasiequations*. *Satisfaction* of an equation, quasiequation or guasiequation by a given algebraic system is defined. These relations give rise to Galois connections (see, e.g., Chapter 11 of [36]). The closed sets on the algebraic side form, respectively, *equational*, *quasiequational* and *guasiequational classes* of algebraic systems. Equivalently, these are the classes of algebraic systems defined by equations, quasiequations and guasiequations. When they are thought of as classes generated by given collections of algebraic systems, they are termed *varieties*, *quasivarieties* and *guasivarieties*, respectively. The second part of Section 2.18 is dedicated to proving Birkhoff [4] and Mal'cev [18] style characterization theorems of these classes using closures under class operators (see, also, [21, 30, 84]). The four operators considered are taking *certifications*, *directed certifications*, *subdirect intersections* and *morphic images*. It is shown that a given class of algebraic systems is a variety if it is closed under subdirect intersections and morphic images, it is a quasivariety if it is closed under directed certifications and subdirect intersections and it is a guasivariety if it is closed under certifications and subdirect intersections. In the last part of the section, we translate the conditions of closure under subdirect intersections and morphic images into properties of the subcollection of the collection of all congruence systems on the base algebraic system relative to the class under consideration. On the other hand, certifications and directed certifications are abstraction conditions (akin to closure under isomorphisms) and do not seem to have such intrinsic equivalent formalizations.

Chapter 2, in a nutshell, includes the majority of the very basic concepts and results that constitute the prerequisites for following the developments recounted in subsequent chapters of the monograph.

2.2 Algebraic Systems

A **sentence functor** $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ is a **Set**-valued functor, with the property that, for every $\Sigma \in |\mathbf{Sign}|$, $\mathrm{SEN}(\Sigma) \neq \varnothing$. We say that a sentence functor $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ is **trivial** if $|\mathrm{SEN}(\Sigma)| = 1$, for all $\Sigma \in |\mathbf{Sign}|$.

A **sentence family** of SEN is a collection $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, such that $T_\Sigma \subseteq \mathrm{SEN}(\Sigma)$, for all $\Sigma \in |\mathbf{Sign}|$. The collection of all sentence families of SEN is denoted by SenFam(SEN). Sentence families can be ordered by signature-wise inclusion. More precisely, given $T, T' \in \mathrm{SenFam}(\mathrm{SEN})$, we define

$$T \leq T' \text{ iff } \quad T_\Sigma \subseteq T'_\Sigma, \text{ for all } \Sigma \in |\mathbf{Sign}|.$$

Under this ordering sentence families form a complete lattice which is denoted by $\mathbf{SenFam}(\mathrm{SEN}) = \langle \mathrm{SenFam}(\mathrm{SEN}), \leq \rangle$.

A sentence family T of SEN is called a **sentence system** if it is invariant under signature morphisms, i.e., if, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, we have

$$\mathrm{SEN}(f)(T_\Sigma) \subseteq T_{\Sigma'}.$$

The collection of all sentence systems of SEN is denoted by SenSys(SEN). It forms a complete sublattice of the lattice of sentence families under $\leq$, denoted by $\mathbf{SenSys}(\mathrm{SEN}) = \langle \mathrm{SenSys}(\mathrm{SEN}), \leq \rangle$.

Let $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ be a sentence functor and $T \in \mathrm{SenFam}(\mathrm{SEN})$. We define, based on T, two important sentence families of SEN:

- $\overleftarrow{T} = \{\overleftarrow{T}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\overleftarrow{T}_\Sigma = \{\phi \in \mathrm{SEN}(\Sigma) : \text{for all } \Sigma' \in |\mathbf{Sign}| \text{ and all } f \in \mathbf{Sign}(\Sigma, \Sigma'), \ \mathrm{SEN}(f)(\phi) \in T_{\Sigma'}\}.$$

  Sometimes, we abbreviate this using the notation

$$\overleftarrow{T}_\Sigma = \{\phi \in \mathrm{SEN}(\Sigma) : (\forall f)(\mathrm{SEN}(f)(\phi) \in T_{\Sigma'})\}$$

- $\overrightarrow{T} = \{\overrightarrow{T}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\overrightarrow{T}_\Sigma = \{\mathrm{SEN}(f)(\phi) : \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma',\Sigma), \phi \in T_{\Sigma'}\}$$

First, it is clear that both operators on sentence families are monotone.

Lemma 1 *Let* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *be a sentence functor and consider* $T, T' \in \mathrm{SenFam}(\mathrm{SEN})$. *If* $T \leq T'$, *then* $\overleftarrow{T} \leq \overleftarrow{T'}$ *and* $\overrightarrow{T} \leq \overrightarrow{T'}$.

Proof: Both implications are quite obvious. For the second, e.g., consider $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \overrightarrow{T}_\Sigma$. Thus, there exists $\Sigma_0 \in |\mathbf{Sign}|$, $\phi_0 \in T_{\Sigma_0}$ and $f_0 \in \mathbf{Sign}(\Sigma_0,\Sigma)$ such that $\phi = \mathrm{SEN}(f_0)(\phi_0)$.

$$\begin{array}{ccc} \Sigma_0 & \xrightarrow{f_0} & \Sigma \\ T'_{\Sigma_0} \supseteq T_{\Sigma_0} \ni \phi_0 & \longmapsto & \phi \end{array}$$

Since $T_{\Sigma_0} \subseteq T'_{\Sigma_0}$, $\phi_0 \in T'_{\Sigma_0}$ and we conclude that $\phi \in \overrightarrow{T'}_\Sigma$. ∎

The importance of $\overleftarrow{T}$ and $\overrightarrow{T}$ stems, in part, from their relationship with T, which is described in the following proposition, but also from the critical role they play in the theory presented here.

Proposition 2 *Let* $\mathbf{Sign}$ *be a category,* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *a sentence functor and suppose that* $T \in \mathrm{SenFam}(\mathrm{SEN})$.

(a) $\overleftarrow{T}$ *is the largest sentence system of* SEN *included in* T;

(b) $\overrightarrow{T}$ *is the smallest sentence system of* SEN *that contains* T.

Proof:

(a) It is obvious that $\overleftarrow{T} \leq T$. We must show that $\overleftarrow{T}$ is a sentence system and that it is the largest one included in T.

To show that it is a sentence system, consider $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma,\Sigma')$ and $\phi \in \overleftarrow{T}_\Sigma$. We must show that $\mathrm{SEN}(f)(\phi) \in \overleftarrow{T}_{\Sigma'}$. To this end, let $\Sigma'' \in |\mathbf{Sign}|$ and $g \in \mathbf{Sign}(\Sigma',\Sigma'')$.

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

Then we have

$$\mathrm{SEN}(g)(\mathrm{SEN}(f)(\phi)) = \mathrm{SEN}(gf)(\phi) \overset{\phi\in\overleftarrow{T}_\Sigma}{\in} T_{\Sigma''}.$$

Since this holds for all $\Sigma'' \in |\mathbf{Sign}|$ and all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$, we conclude that $\mathrm{SEN}(f)(\phi) \in \overleftarrow{T}_{\Sigma'}$.

To show that $\overleftarrow{T}$ is the largest sentence system in T, consider $T' \in \mathrm{SenSys}(\mathrm{SEN})$, such that $T' \le T$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in T'_\Sigma$. Since T' is a sentence system, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, we get $\mathrm{SEN}(f)(\phi) \in T'_{\Sigma'}$. Now since $T' \le T$, we get that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathrm{SEN}(f)(\phi) \in T_{\Sigma'}$. But this shows that $\phi \in \overleftarrow{T}_\Sigma$. Thus, $T' \le \overleftarrow{T}$ and $\overleftarrow{T}$ is the largest sentence system included in T.

(b) It is obvious that $T \le \overrightarrow{T}$. We must show that $\overrightarrow{T}$ is a sentence system and that it is the smallest one containing T.

To show that $\overrightarrow{T}$ is a sentence system, consider $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \overrightarrow{T}_\Sigma$. Let $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$. We must show that $\mathrm{SEN}(f)(\phi) \in \overrightarrow{T}_{\Sigma'}$. Since $\phi \in \overrightarrow{T}_\Sigma$, there exists $\Sigma_0 \in |\mathbf{Sign}|$, $f_0 \in \mathbf{Sign}(\Sigma_0, \Sigma)$ and $\phi_0 \in T_{\Sigma_0}$, such that $\mathrm{SEN}(f_0)(\phi_0) = \phi$.

$$\Sigma_0 \xrightarrow{f_0} \Sigma \xrightarrow{f} \Sigma'$$

Thus, we get

$$\mathrm{SEN}(f)(\phi) = \mathrm{SEN}(f)(\mathrm{SEN}(f_0)(\phi_0)) = \mathrm{SEN}(f f_0)(\phi_0) \in \overrightarrow{T}_{\Sigma'}.$$

Finally, we must show that $\overrightarrow{T}$ is the smallest sentence system that contains T. To this end, suppose that $T' \in \mathrm{SenSys}(\mathrm{SEN})$, such that $T \le T'$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \overrightarrow{T}_\Sigma$. Then, there exist $\Sigma_0 \in |\mathbf{Sign}|$, $f_0 \in \mathbf{Sign}(\Sigma_0, \Sigma)$ and $\phi_0 \in T_{\Sigma_0}$, such that $\phi = \mathrm{SEN}(f_0)(\phi_0)$. Now, since $T \le T'$, we get $\phi_0 \in T'_{\Sigma_0}$. Moreover, since T' is a sentence system, we get $\mathrm{SEN}(f_0)(\phi_0) \in T'_\Sigma$. But this means $\phi = \mathrm{SEN}(f_0)(\phi_0) \in T'_\Sigma$. This proves that $\overrightarrow{T} \le T'$ and, hence, $\overrightarrow{T}$ is the least sentence system that contains T.

■

It is also of interest to observe that the back arrow operator commutes with intersections:

Lemma 3 *Let* **Sign** *be a category,* SEN : **Sign** → **Set** *a sentence functor and consider* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathrm{SEN})$*. Then*

$$\overleftarrow{\bigcap_{T \in \mathcal{T}} T} = \bigcap_{T \in \mathcal{T}} \overleftarrow{T}.$$

Proof: First, by Lemma 1, we have, for all $T \in \mathcal{T}$, $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \overleftarrow{T}$. Therefore, we conclude that $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \bigcap_{T \in \mathcal{T}} \overleftarrow{T}$.

On the other hand, we have, by Proposition 2, $\overleftarrow{T} \leq T$, for all $T \in \mathcal{T}$. Therefore $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \bigcap_{T \in \mathcal{T}} T$. Now, since $\bigcap_{T \in \mathcal{T}} \overleftarrow{T}$ is a sentence system (Proposition 2) included in $\bigcap_{T \in \mathcal{T}} T$, it must lie below the largest such, which, by Proposition 2, is $\overleftarrow{\bigcap_{T \in \mathcal{T}} T}$. Thus, we have $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{\bigcap_{T \in \mathcal{T}} T}$. ■

On the other hand, the back arrow does not commute, in general, with unions. We first prove a lemma showing the there is an inclusion relation governing the interaction between the back arrow and unions and, then, provide an example to show that this inclusion may be proper.

Lemma 4 *Let* **Sign** *be a category,* SEN : **Sign** → **Set** *a sentence functor and consider* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathrm{SEN})$. *Then*

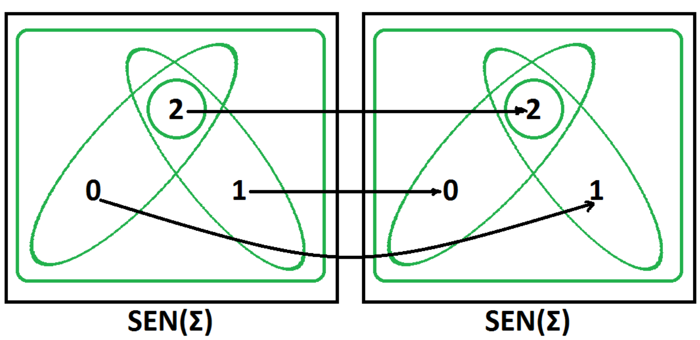
$$\bigcup_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{\bigcup_{T \in \mathcal{T}} T}.$$

Proof: Since, for all $T \in \mathcal{T}$, $T \leq \bigcup_{T \in \mathcal{T}} T$, we get, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{\bigcup_{T \in \mathcal{T}} T}$. Since this holds for all $T \in \mathcal{T}$, we conclude that $\bigcup_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{\bigcup_{T \in \mathcal{T}} T}$. ■

That the inclusion of Lemma 4 is, in general, a proper inclusion is showcased by the following example.

Example 5 *Let* **Sign** *be the category with a single object* Σ *and a single (non-identity) arrow* $f : \Sigma \to \Sigma$, *such that* $f \circ f = i_\Sigma$.

Let SEN : **Sign** → **Set** *be the functor defined by setting* $\mathrm{SEN}(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}(f)(0) = 1$, $\mathrm{SEN}(f)(1) = 0$ *and* $\mathrm{SEN}(f)(2) = 2$. *Consider the col-*



lection $\{T, T'\} \subseteq \mathrm{SenFam}(\mathrm{SEN})$, *with* $T_\Sigma = \{0, 2\}$ *and* $T'_\Sigma = \{1, 2\}$. *Then we have* $\overleftarrow{T}_\Sigma = \{2\} = \overleftarrow{T}_{\Sigma'}$ *and, therefore*

$$\overleftarrow{T}_\Sigma \cup \overleftarrow{T'}_\Sigma = \{2\} \cup \{2\} = \{2\}.$$

On the other hand,

$$\overleftarrow{T \cup T'}_\Sigma = \overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\}.$$

Thus, we get $\bigcup_{T \in \mathcal{T}} \overleftarrow{T} \lneq \overleftarrow{\bigcup_{T \in \mathcal{T}} T}$.

Let **Sign**, **Sign′** be categories and $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ and $\mathrm{SEN}' : \mathbf{Sign}' \to \mathbf{Set}$ be two sentence functors. A **morphism** (of sentence functors) $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ consists of:

- A functor $F : \mathbf{Sign} \to \mathbf{Sign}'$;
- A natural transformation $\alpha : \mathrm{SEN} \to \mathrm{SEN}' \circ F$.

We will make heavy use of the following particular types of morphisms:

- A morphism $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ is **special** if $F : \mathbf{Sign} \to \mathbf{Sign}'$ is surjective on objects and full.
- A morphism $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ is **surjective** if it is special and $\alpha_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SEN}'(F(\Sigma))$ is surjective, for all $\Sigma \in |\mathbf{Sign}|$.

Let **Sign**, **Sign′** be categories, $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ and $\mathrm{SEN}' : \mathbf{Sign}' \to \mathbf{Set}$ be two sentence functors and $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ be a morphism. Given a sentence family $T \in \mathrm{SenFam}(\mathrm{SEN}')$, define the sentence family $\alpha^{-1}(T) = \{\alpha^{-1}(T)_\Sigma\}_{\Sigma \in |\mathbf{Sign}|} \in \mathrm{SenFam}(\mathrm{SEN})$ by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha^{-1}(T)_\Sigma = \alpha_\Sigma^{-1}(T_{F(\Sigma)}).$$

In the next lemma, we prove some useful properties concerning this operator.

Lemma 6 *Let* **Sign**, **Sign′** *be categories,* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *and* $\mathrm{SEN}' : \mathbf{Sign}' \to \mathbf{Set}$ *be two sentence functors,* $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ *be a morphism and* $T \in \mathrm{SenFam}(\mathrm{SEN}')$.

(a) If $T \in \mathrm{SenSys}(\mathrm{SEN}')$, *then* $\alpha^{-1}(T) \in \mathrm{SenSys}(\mathrm{SEN})$, *with equivalence holding if* $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$ *is surjective;*

(b) $\alpha^{-1}(\overleftarrow{T}) \leq \overleftarrow{\alpha^{-1}(T)}$, *with equality holding if* $\langle F, \alpha \rangle$ *is special;*

(c) $\overrightarrow{\alpha^{-1}(T)} \leq \alpha^{-1}(\overrightarrow{T})$, *with equality holding if* $\langle F, \alpha \rangle$ *is surjective.*

Proof:

(a) Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Then, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, we have

$$\begin{array}{rcl}\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) \\ & & (\alpha \text{ natural transformation}) \\ & \in & \mathrm{SEN}'(F(f))(T_{F(\Sigma)}) \quad (\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})) \\ & \subseteq & T_{F(\Sigma')} \quad (T \in \mathrm{SenSys}(\mathrm{SEN}')).\end{array}$$

This shows that $\mathrm{SEN}(f)(\phi) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')})$. We now conclude that $\alpha^{-1}(T) \in \mathrm{SenSys}(\mathrm{SEN})$.

Suppose, next, that $\langle F, \alpha\rangle : \mathrm{SEN} \to \mathrm{SEN}'$ is surjective and $\alpha^{-1}(T) \in \mathrm{SenSys}(\mathrm{SEN})$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. Note that this implies that $\phi \in \alpha^{-1}(T_{F(\Sigma)})$. So, by hypothesis, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\phi) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}).$$

Therefore,

$$\begin{array}{rcl}\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) & = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \\ & \in & \alpha_{\Sigma'}(\alpha_{\Sigma'}^{-1}(T_{F(\Sigma')})) \\ & \subseteq & T_{F(\Sigma')}.\end{array}$$

Since $\langle F, \alpha\rangle$ is surjective, we conclude that, for all $\Sigma, \Sigma' \in |\mathbf{Sign}'|$ and all $f \in \mathbf{Sign}'(\Sigma, \Sigma')$,

$$\mathrm{SEN}'(f)(T_\Sigma) \subseteq T_{\Sigma'}.$$

Therefore, $T \in \mathrm{SenSys}(\mathrm{SEN}')$.

(b) Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \alpha_\Sigma^{-1}(\overleftarrow{T}_{F(\Sigma)})$. Then we get that $\alpha_\Sigma(\phi) \in \overleftarrow{T}_{F(\Sigma)}$. Thus, by definition of $\overleftarrow{T}$, for all $\Sigma' \in |\mathbf{Sign}'|$ and all $f \in \mathbf{Sign}'(F(\Sigma), \Sigma')$,

$$\mathrm{SEN}'(f)(\alpha_\Sigma(\phi)) \in T_{\Sigma'}.$$

This implies, in particular, that, for all $\Sigma'' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma'')$, $\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) \in T_{F(\Sigma'')}$. So we get $\alpha_{\Sigma''}(\mathrm{SEN}(f)(\phi)) \in T_{F(\Sigma'')}$, i.e., $\mathrm{SEN}(f)(\phi) \in \alpha_{\Sigma''}^{-1}(T_{F(\Sigma'')})$. Since Σ'' and f were arbitrary, we finally obtain $\phi \in \overleftarrow{\alpha_\Sigma^{-1}(T_{F(\Sigma)})}$.

It is straightforward to see that, if $\langle F, \alpha\rangle$ is special, then the above chain of implications is reversible and, by following it, we get the reverse inclusion.

(c) Let $\Sigma \in |\mathbf{Sign}|$, Then we have

$$\begin{array}{l}\alpha_\Sigma(\overrightarrow{\alpha_\Sigma^{-1}(T_{F(\Sigma)})})\\ = \alpha_\Sigma(\{\mathrm{SEN}(f_0)(\phi_0) : f_0 \in \mathbf{Sign}(\Sigma_0,\Sigma), \phi_0 \in \alpha_{\Sigma_0}^{-1}(T_{F(\Sigma_0)})\})\\ = \{\alpha_\Sigma(\mathrm{SEN}(f_0)(\phi_0)) : f_0 \in \mathbf{Sign}(\Sigma_0,\Sigma), \phi_0 \in \alpha_{\Sigma_0}^{-1}(T_{F(\Sigma_0)})\}\\ = \{\mathrm{SEN}'(F(f_0))(\alpha_{\Sigma_0}(\phi_0)) : f_0 \in \mathbf{Sign}(\Sigma_0,\Sigma), \phi_0 \in \alpha_{\Sigma_0}^{-1}(T_{F(\Sigma_0)})\}\\ \subseteq \{\mathrm{SEN}'(f_0')(\phi_0') : f_0' \in \mathbf{Sign}'(\Sigma_0', F(\Sigma)), \phi_0' \in T_{\Sigma_0'}\}\\ = \overrightarrow{T}_{F(\Sigma)}.\end{array}$$

Again, it is easy to see that the only inclusion becomes an equality in case $\langle F,\alpha\rangle$ is a surjective morphism.

■

Let **Sign** be a category and $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ be a sentence functor. A **relation family on** SEN is a collection $R = \{R_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$, such that $R_\Sigma \subseteq \mathrm{SEN}(\Sigma)^2$, for all $\Sigma \in |\mathbf{Sign}|$. A relation family is a **relation system** if it is invariant under **Sign**-morphisms, i.e., if for all $\Sigma,\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma,\Sigma')$,

$$\mathrm{SEN}(f)(R_\Sigma) \subseteq R_{\Sigma'}.$$

The collection of all relation families on SEN is denoted by RelFam(SEN) and, similarly, the collection of all relation systems by RelSys(SEN). A relation family/system on SEN is an **equivalence family/system on** SEN if, for all $\Sigma \in |\mathbf{Sign}|$, R_Σ is an equivalence relation on $\mathrm{SEN}(\Sigma)$. As with relation families/systems, we denote the collection of all equivalence families on SEN by EqvFam(SEN) and the collection of all equivalence systems on SEN by EqvSys(SEN).

Given a sentence family $T \in \mathrm{SenFam(SEN)}$, we say that the equivalence family R on SEN is **compatible with** T, if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi,\psi \in \mathrm{SEN}(\Sigma)$,

$$\langle\phi,\psi\rangle \in R_\Sigma \quad\text{and}\quad \phi \in T_\Sigma \quad\text{imply}\quad \psi \in T_\Sigma.$$

Lemma 7 *Let* **Sign** *be a category,* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *a sentence functor,* $T \in \mathrm{SenFam(SEN)}$ *and* θ *a relation system on* SEN*. If* θ *is compatible with* T*, then it is also compatible with* $\overleftarrow{T}$*.*

Proof: Suppose that θ is compatible with T. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \theta_\Sigma$ and $\phi \in \overleftarrow{T}_\Sigma$. Let $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma,\Sigma')$. Since θ is a relation system, we get $\langle\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi)\rangle \in \theta_{\Sigma'}$. Since $\phi \in \overleftarrow{T}_\Sigma$, $\mathrm{SEN}(f)(\phi) \in T_{\Sigma'}$. Thus, by compatibility, we get $\mathrm{SEN}(f)(\psi) \in T_{\Sigma'}$. Since $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma,\Sigma')$ were arbitrary, we conclude that $\psi \in \overleftarrow{T}_\Sigma$, showing that θ is also compatible with $\overleftarrow{T}$. ■

Let **Sign**, **Sign′** be categories, $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ and $\mathrm{SEN}' : \mathbf{Sign}' \to \mathbf{Set}$ be sentence functors and $\langle F,\alpha\rangle : \mathrm{SEN} \to \mathrm{SEN}'$ be a morphism. Define the

kernel system of $\langle F,\alpha\rangle$, denoted $\mathrm{Ker}(\langle F,\alpha\rangle)=\{\mathrm{Ker}_\Sigma(\langle F,\alpha\rangle)\}_{\Sigma\in|\mathbf{Sign}|}$, by letting, for all $\Sigma\in|\mathbf{Sign}|$ and all $\phi,\psi\in\mathrm{SEN}(\Sigma)$,

$$\langle\phi,\psi\rangle\in\mathrm{Ker}_\Sigma(\langle F,\alpha\rangle)\quad\text{iff}\quad\alpha_\Sigma(\phi)=\alpha_\Sigma(\psi).$$

The kernel system $\mathrm{Ker}(\langle F,\alpha\rangle)$ is sometimes denoted more compactly by $\theta^{\langle F,\alpha\rangle}=\{\theta^{\langle F,\alpha\rangle}_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$.

Lemma 8 *Let* **Sign**, **Sign′** *be categories,* $\mathrm{SEN}:\mathbf{Sign}\to\mathbf{Set}$, $\mathrm{SEN}':\mathbf{Sign}'\to\mathbf{Set}$ *be sentence functors and* $\langle F,\alpha\rangle:\mathrm{SEN}\to\mathrm{SEN}'$ *a morphism. Then* $\mathrm{Ker}(\langle F,\alpha\rangle)$ *is an equivalence system on* SEN*.*

Proof: It is obvious from the definition that $\mathrm{Ker}(\langle F,\alpha\rangle)$ is an equivalence family of SEN. The system property follows from the fact that α is a natural transformation. Let $\Sigma\in|\mathbf{Sign}|$ and $\phi,\psi\in\mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle\in\mathrm{Ker}_\Sigma(\langle F,\alpha\rangle)$. Then, for all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$,

$$\begin{array}{rcll}\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) & \text{(naturality of }\alpha)\\ & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi)) & (\langle\phi,\psi\rangle\in\mathrm{Ker}_\Sigma(\langle F,\alpha\rangle))\\ & = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\psi)) & \text{(naturality of }\alpha).\end{array}$$

Therefore, we get that $\langle\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi)\rangle\in\mathrm{Ker}_{\Sigma'}(\langle F,\alpha\rangle)$, showing that $\mathrm{Ker}(\langle F,\alpha\rangle)$ is an equivalence system. ∎

Let **Sign**, **Sign′** be categories, $\mathrm{SEN}:\mathbf{Sign}\to\mathbf{Set}$ and $\mathrm{SEN}':\mathbf{Sign}'\to\mathbf{Set}$ be sentence functors and $\langle F,\alpha\rangle:\mathrm{SEN}\to\mathrm{SEN}'$ be a morphism, with F an isomorphism. Given a sentence family $T\in\mathrm{SenFam}(\mathrm{SEN})$, define the sentence family $\alpha(T)=\{\alpha(T)_{F(\Sigma)}\}_{\Sigma\in|\mathbf{Sign}|}\in\mathrm{SenFam}(\mathrm{SEN}')$ by setting, for all $\Sigma\in|\mathbf{Sign}|$,

$$\alpha(T)_{F(\Sigma)}=\alpha_\Sigma(T_\Sigma).$$

In the next lemma, we prove some useful properties concerning this operator.

Lemma 9 *Let* **Sign**, **Sign′** *be categories,* $\mathrm{SEN}:\mathbf{Sign}\to\mathbf{Set}$ *and* $\mathrm{SEN}':\mathbf{Sign}'\to\mathbf{Set}$ *be sentence functors,* $\langle F,\alpha\rangle:\mathrm{SEN}\to\mathrm{SEN}'$ *a surjective morphism, with* F *an isomorphism, and* $T\in\mathrm{SenFam}(\mathrm{SEN})$*, such that the kernel* $\mathrm{Ker}(\langle F,\alpha\rangle)$ *of* $\langle F,\alpha\rangle$ *is compatible with* T*.*

(a) $\alpha(T)\in\mathrm{SenSys}(\mathrm{SEN}')$ *iff* $T\in\mathrm{SenSys}(\mathrm{SEN})$*;*

(b) $\alpha(\overleftarrow{T})=\overleftarrow{\alpha(T)}$*;*

(c) $\overrightarrow{\alpha(T)}=\alpha(\overrightarrow{T})$*.*

Proof:

(a) Exploiting the surjectivity of $\langle F,\alpha\rangle$, $\alpha(T)\in\mathrm{SenSys}(\mathrm{SEN}')$ holds if and only if, for all $\Sigma\in|\mathbf{Sign}|$, all $\phi\in\mathrm{SEN}(\Sigma)$, all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$,

$$\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi))\in\alpha_{\Sigma'}(T_{\Sigma'}).$$

By the naturality of α, the latter is equivalent to

$$\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi))\in\alpha_{\Sigma'}(T_{\Sigma'}).$$

Finally, by compatibility of $\mathrm{Ker}(\langle F,\alpha\rangle)$ with T, this is equivalent to $\mathrm{SEN}(f)(\phi)\in T_{\Sigma'}$. But this holds for all $\Sigma\in|\mathbf{Sign}|$, all $\phi\in\mathrm{SEN}(\Sigma)$, all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$ if and only if $T\in\mathrm{SenSys}(\mathrm{SEN})$.

(b) Again we exploit the surjectivity of $\langle F,\alpha\rangle$. We have, for all $\Sigma\in|\mathbf{Sign}|$ and all $\phi\in\mathrm{SEN}(\Sigma)$, $\alpha_\Sigma(\phi)\in\overleftarrow{\alpha_\Sigma(T_\Sigma)}$ iff, for all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$, $\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi))\in\alpha_{\Sigma'}(T_{\Sigma'})$ iff, by the naturality of α, $\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi))\in\alpha_{\Sigma'}(T_{\Sigma'})$ iff, by the compatibility of $\mathrm{Ker}(\langle F,\alpha\rangle)$ with T, $\mathrm{SEN}(f)(\phi)\in T_{\Sigma'}$ iff, by the definition of $\overleftarrow{T}$, $\phi\in\overleftarrow{T}_\Sigma$ iff, by the compatibility of $\mathrm{Ker}(\langle F,\alpha\rangle)$ with $\overleftarrow{T}$, which follows from Lemmas 7 and 8, $\alpha_\Sigma(\phi)\in\alpha_\Sigma(\overleftarrow{T}_\Sigma)$. Thus, we conclude that $\alpha(\overleftarrow{T})=\overleftarrow{\alpha(T)}$.

(c) Suppose, first, that $\alpha_\Sigma(\phi)\in\overrightarrow{\alpha_\Sigma(T_\Sigma)}$. Then, there exist, by surjectivity, $\Sigma_0\in|\mathbf{Sign}|$, $f_0\in\mathbf{Sign}(\Sigma_0,\Sigma)$ and $\phi_0\in T_{\Sigma_0}$, such that

$$\begin{array}{rcl}\alpha_\Sigma(\phi)&=&\mathrm{SEN}'(F(f_0))(\alpha_{\Sigma_0}(\phi_0))\\&=&\alpha_\Sigma(\mathrm{SEN}(f_0)(\phi_0))\\&\in&\alpha_\Sigma(\overrightarrow{T}_\Sigma).\end{array}$$

Suppose, conversely, that $\alpha_\Sigma(\phi)\in\alpha_\Sigma(\overrightarrow{T}_\Sigma)$. Then, there exist $\Sigma_0\in|\mathbf{Sign}|$, $f_0\in\mathbf{Sign}(\Sigma_0,\Sigma)$ and $\phi_0\in T_{\Sigma_0}$, such that

$$\begin{array}{rcl}\alpha_\Sigma(\phi)&=&\alpha_\Sigma(\mathrm{SEN}(f_0)(\phi_0))\\&=&\mathrm{SEN}'(F(f_0))(\alpha_{\Sigma_0}(\phi_0))\\&\in&\overrightarrow{\alpha_\Sigma(T_\Sigma)}.\end{array}$$

■

By analogy to the case of sentence families, we may also define the inverse of a relation family under a morphism of sentence functors. Let $\mathbf{Sign}$, $\mathbf{Sign}'$ be categories, $\mathrm{SEN}:\mathbf{Sign}\to\mathbf{Set}$ and $\mathrm{SEN}':\mathbf{Sign}'\to\mathbf{Set}$ be sentence functors and $\langle F,\alpha\rangle:\mathrm{SEN}\to\mathrm{SEN}'$ a morphism. Let, also, $R=\{R_\Sigma\}_{\Sigma\in|\mathbf{Sign}'|}$ be a relation family on SEN'. Define the relation family $\alpha^{-1}(R)=\{\alpha^{-1}(R)_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ on SEN by setting, for all $\Sigma\in|\mathbf{Sign}|$,

$$\alpha^{-1}(R)_\Sigma=\alpha_\Sigma^{-1}(R_{F(\Sigma)}).$$

Proposition 10 *Let* **Sign**, **Sign**$'$ *be categories,* SEN : **Sign** → **Set** *and* SEN$'$: **Sign**$'$ → **Set** *be sentence functors,* $\langle F,\alpha\rangle$: SEN → SEN$'$ *a morphism and* R *a relation family on* SEN$'$.

(a) If R is a relation system, then $\alpha^{-1}(R)$ is also a relation system;

(b) If R is an equivalence family, then α^{-1} is also an equivalence family.

Proof:

(a) Let $\Sigma\in|\mathbf{Sign}|$, $\phi,\psi\in\mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$. Then, we have $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle\in R_{F(\Sigma)}$. Since R is a relation system, for all $\Sigma'\in|\mathbf{Sign}|$ and all $f\in\mathbf{Sign}(\Sigma,\Sigma')$, we get

$$\langle\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)),\mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi))\rangle\in R_{F(\Sigma')}.$$

Thus, by the naturality of α,

$$\langle\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)),\alpha_{\Sigma'}(\mathrm{SEN}(f)(\psi))\rangle\in R_{F(\Sigma')}.$$

Now we get $\langle\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi)\rangle\in\alpha_{\Sigma'}^{-1}(R_{F(\Sigma')})$. This proves that $\alpha^{-1}(R)$ is a relation system on SEN.

(b) Let $\Sigma\in|\mathbf{Sign}|$ and $\phi,\chi,\psi\in\mathrm{SEN}(\Sigma)$ be arbitrary. Then we have:

Reflexivity By the reflexivity of R, $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\phi)\rangle\in R_{F(\Sigma)}$. Therefore, $\langle\phi,\phi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$.

Symmetry If $\langle\phi,\psi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$, then $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle\in R_{F(\Sigma)}$, whence, by the symmetry of R, $\langle\alpha_\Sigma(\psi),\alpha_\Sigma(\phi)\rangle\in R_{F(\Sigma)}$, showing that $\langle\psi,\phi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$.

Transitivity If $\langle\phi,\chi\rangle,\langle\chi,\psi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$, then, we get

$$\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\chi)\rangle,\langle\alpha_\Sigma(\chi),\alpha_\Sigma(\psi)\rangle\in R_{F(\Sigma)},$$

whence, by the transitivity of R, we get $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle\in R_{F(\Sigma)}$, showing that $\langle\phi,\psi\rangle\in\alpha_\Sigma^{-1}(R_{F(\Sigma)})$.

■

Let **Sign** be a category and SEN : **Sign** → **Set** a sentence functor. The **clone of all natural transformations** on SEN is the category **Cln**(SEN) with collection of objects $\{\mathrm{SEN}^\alpha:\alpha\text{ an ordinal}\}$ and collection of morphisms $\tau:\mathrm{SEN}^\alpha\to\mathrm{SEN}^\beta$ β-sequences of natural transformations $\tau^i:\mathrm{SEN}^\alpha\to\mathrm{SEN}$, $i<\beta$. Composition of $\langle\tau^i:i<\beta\rangle:\mathrm{SEN}^\alpha\to\mathrm{SEN}^\beta$ with $\langle\sigma^j:j<\gamma\rangle:\mathrm{SEN}^\beta\to\mathrm{SEN}^\gamma$

$$\mathrm{SEN}^\alpha\xrightarrow{\langle\tau^i:i<\beta\rangle}\mathrm{SEN}^\beta\xrightarrow{\langle\sigma^j:j<\gamma\rangle}\mathrm{SEN}^\gamma$$

is defined by

$$\langle\sigma^j:j<\gamma\rangle\circ\langle\tau^i:i<\beta\rangle=\langle\sigma^j(\langle\tau^i:i<\beta\rangle:j<\gamma\rangle.$$

A **clone** (or a **category**) **of natural transformations** on SEN is a subcategory N of the category **Cln**(SEN), such that:

- Its objects are those in $\{\mathrm{SEN}^k : k < \omega\}$;
- Its morphisms include all projection natural transformations

  $$p^{k,i} : \mathrm{SEN}^k \to \mathrm{SEN}, i < k, k < \omega,$$

  with $p^{k,i}_\Sigma : \mathrm{SEN}(\Sigma)^k \to \mathrm{SEN}(\Sigma)$ given by

  $$p^{k,i}_\Sigma(\vec{\phi}) = \phi_i, \text{ for all } \vec{\phi} \in \mathrm{SEN}(\Sigma)^k,$$

  and are such that, for every family $\{\tau^i : \mathrm{SEN}^k \to \mathrm{SEN} : i < \ell\}$ of natural transformations in N, $\langle\tau^i : i < \ell\rangle : \mathrm{SEN}^k \to \mathrm{SEN}^\ell$ is also in N.

This definition has two important consequences that we now make explicit. Let **Sign** be a category, SEN : **Sign** → **Set** a sentence functor and $k \in \omega$. Consider a function

$$\pi : \{0, 1, \dots, k-1\} \to \{0, 1, \dots, k-1\}.$$

Given $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi} = \langle\phi_0, \phi_1, \dots, \phi_{k-1}\rangle \in \mathrm{SEN}(\Sigma)^k$, we define

$$\vec{\phi}^\pi = \langle\phi_{\pi(0)}, \phi_{\pi(1)}, \dots, \phi_{\pi(k-1)}\rangle.$$

Now, consider, in addition, a clone N of natural transformations on SEN and $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N. Define the natural transformation

$$\sigma^\pi : \mathrm{SEN}^k \to \mathrm{SEN}$$

by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$,

$$\sigma^\pi_\Sigma(\vec{\phi}) = \sigma_\Sigma(\vec{\phi}^\pi).$$

That this is a natural transformation is easy to see: For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$, we have

$$\begin{array}{ccc}
\mathrm{SEN}(\Sigma)^k & \xrightarrow{\sigma^\pi_\Sigma} & \mathrm{SEN}(\Sigma) \\
{\scriptstyle \mathrm{SEN}(f)^k}\downarrow & & \downarrow{\scriptstyle \mathrm{SEN}(f)} \\
\mathrm{SEN}(\Sigma')^k & \xrightarrow[\sigma^\pi_{\Sigma'}]{} & \mathrm{SEN}(\Sigma')
\end{array}$$

$$\begin{array}{rcl}
\mathrm{SEN}(f)(\sigma^\pi_\Sigma(\vec{\phi})) & = & \mathrm{SEN}(f)(\sigma_\Sigma(\vec{\phi}^\pi)) \\
& = & \sigma_{\Sigma'}(\mathrm{SEN}(f)^k(\vec{\phi}^\pi)) \\
& = & \sigma_{\Sigma'}(\mathrm{SEN}(f)^k(\vec{\phi})^\pi) \\
& = & \sigma^\pi_{\Sigma'}(\mathrm{SEN}(f)^k(\vec{\phi})).
\end{array}$$

Proposition 11 *Let* **Sign** *be a category,* SEN : **Sign** → **Set** *a sentence functor and* N *a clone of natural transformations on* SEN*. If* $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ *is in* N*, then, for all functions* $\pi : \{0, \dots, k-1\} \to \{0, \dots, k-1\}$*,* $\sigma^\pi : \mathrm{SEN}^k \to \mathrm{SEN}$ *is also in* N*.*

Proof: The key is to observe that

$$\sigma^\pi = \sigma \circ \langle p^{k,\pi(0)}, \dots, p^{k,\pi(k-1)} \rangle.$$

Since all projections are in N and N is closed under formation of tuples, we get that $\langle p^{k,\pi(0)}, \dots, p^{k,\pi(k-1)} \rangle : \mathrm{SEN}^k \to \mathrm{SEN}^k$ is in N. Therefore, since N is a category and, by hypothesis, σ is in N, we get that σ^π is also in N. ■

The following is a very useful consequence that allows simplifying quantifications.

Corollary 12 *Let* **Sign** *be a category,* SEN : **Sign** → **Set** *a sentence functor and* N *a clone of natural transformations on* SEN*. The statement*

$$\text{For all } \sigma : \mathrm{SEN}^k \to \mathrm{SEN} \text{ in } N, \text{ all } i < k \text{ and all } \Sigma \in |\mathbf{Sign}|, \ \phi, \vec{\chi} \in \mathrm{SEN}(\Sigma),$$
$$\mathrm{Property}(\sigma_\Sigma(\chi_0, \dots, \chi_{i-1}, \phi, \chi_{i+1}, \dots, \chi_{k-1}))$$

is equivalent to the simpler statement

$$\text{For all } \sigma : \mathrm{SEN}^k \to \mathrm{SEN} \text{ in } N \text{ and all } \Sigma \in |\mathbf{Sign}|, \ \phi, \vec{\chi} \in \mathrm{SEN}(\Sigma),$$
$$\mathrm{Property}(\sigma_\Sigma(\phi, \vec{\chi})).$$

Proof: The left-to-right implication is trivial. The right-to-left implication follows from Proposition 11, since $\sigma^{\pi_i} : \mathrm{SEN}^k \to \mathrm{SEN}$, with π_i being the permutation

$$\begin{pmatrix} 0 & 1 & \cdots & i-1 & i & i+1 & \cdots & k-1 \\ 1 & 2 & \cdots & i & 0 & i+1 & \cdots & k-1 \end{pmatrix},$$

is also in N, for every $i < k$. ■

An **algebraic system** is a triple $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, where:

- **Sign** is an arbitrary category;
- SEN : **Sign** → **Set** is a sentence functor;
- N is a clone on SEN.

An algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ is said to be **trivial** if its underlying sentence functor SEN : **Sign** → **Set** is trivial, i.e., if all its sets of sentences are singletons.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. An $N^\flat$**-algebraic system** $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ is an algebraic system, such that there exists a surjective functor $\Xi : N^\flat \to N$ that preserves all projection natural transformations, i.e., such that, for all $k < \omega$ and all $i < k$, if $p^{k,i^\flat} : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ denotes the i-th projection natural transformation on $(\mathrm{SEN}^\flat)^k$, then $\Xi(p^{k,i^\flat}) : \mathrm{SEN}^k \to \mathrm{SEN}$ is the i-th projection $p^{k,i}$ on SEN^k.

This condition implies that Ξ also preserves the arities of all natural transformations involved. Given $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, the image $\Xi(\sigma^\flat) : \mathrm{SEN}^k \to \mathrm{SEN}$ in N will be denoted by σ, keeping the same lowercase Greek letter, but adjusting superscripts, subscripts, primes, etc., as demanded by context. Occasionally, to simplify notation, we might drop superscripts, subscripts, etc., overloading the notation of the lowercase Greek letter, allowing the context to make the interpretation of each occurrence clear (and hoping that, because of this, confusion can be avoided).

In the context where $N^\flat$-algebraic systems are under consideration, the algebraic system $\mathbf{F}$ will be referred to as the **base algebraic system**, since the clones on all other systems under consideration are images of the clone of $\mathbf{F}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system and $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be $N^\flat$-algebraic systems. A **morphism** (of $N^\flat$-algebraic systems) $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ is a morphism of sentence functors $\langle F, \alpha \rangle : \mathrm{SEN} \to \mathrm{SEN}'$, such that, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$ (meaning $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$),

$$\begin{array}{ccc}
\mathrm{SEN}(\Sigma)^k & \xrightarrow{\sigma_\Sigma} & \mathrm{SEN}(\Sigma) \\
\downarrow{\scriptstyle \alpha_\Sigma^k} & & \downarrow{\scriptstyle \alpha_\Sigma} \\
\mathrm{SEN}'(F(\Sigma))^k & \xrightarrow[\sigma'_{F(\Sigma)}]{} & \mathrm{SEN}'(F(\Sigma))
\end{array}$$

$$\alpha_\Sigma(\sigma_\Sigma(\vec{\phi})) = \sigma'_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})).$$

We call this the **morphism property**.

Concerning algebraic systems, we will have occasion to make use of the following useful construction and properties.

Let again $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system and $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ be $N^\flat$-algebraic systems and $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ an algebraic system morphism, with $F : \mathbf{Sign} \to \mathbf{Sign}'$ an isomorphism. We define the algebraic system $\alpha(\mathbf{A}) = \langle \mathbf{Sign}', \mathrm{SEN}'^\alpha, N'^\alpha \rangle$ as follows:

- For all $\Sigma \in |\mathbf{Sign}|$,

$$\mathrm{SEN}'^\alpha(F(\Sigma)) = \alpha_\Sigma(\mathrm{SEN}(\Sigma));$$

For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}'^{\alpha}(F(f)) : \mathrm{SEN}'^{\alpha}(F(\Sigma)) \to \mathrm{SEN}'^{\alpha}(F(\Sigma'))$$

is given by setting, for all $\phi \in \mathrm{SEN}'^{\alpha}(F(\Sigma))$,

$$\mathrm{SEN}'^{\alpha}(F(f))(\phi) = \mathrm{SEN}'(F(f))(\phi).$$

- For every $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, we let $\sigma'^{\alpha} : (\mathrm{SEN}'^{\alpha})^k \to \mathrm{SEN}'^{\alpha}$ be the restriction of $\sigma' : \mathrm{SEN}'^k \to \mathrm{SEN}'$ to SEN'^{α}.

  Composition works as expected, i.e., for all $\tau^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$ and all $\sigma^\flat : (\mathrm{SEN}^\flat)^\ell \to (\mathrm{SEN}^\flat)^m$ in $N^\flat$,

$$\sigma'^{\alpha} \circ \tau'^{\alpha} = (\sigma' \circ \tau')^{\alpha}.$$

It is not difficult to see that $\alpha(\mathbf{A})$, thus defined, is an $N^\flat$-algebraic system.

Lemma 13 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems and* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ *an algebraic system morphism, with* $F : \mathbf{Sign} \to \mathbf{Sign}'$ *an isomorphism. Then* $\alpha(\mathbf{A}) = \langle \mathbf{Sign}', \mathrm{SEN}'^{\alpha}, N'^{\alpha} \rangle$ *is an* $N^\flat$*-algebraic system.*

Proof: The critical step is to show that $\mathrm{SEN}'^{\alpha} : \mathbf{Sign}' \to \mathbf{Set}$ is a well-defined functor and that N'^{α} consists in fact of natural transformations on SEN'^{α}.

For the first, let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \mathrm{SEN}(\Sigma)$. Then we have

$$\begin{array}{rcl}
\mathrm{SEN}'^{\alpha}(F(f))(\alpha_\Sigma(\phi)) & = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)) \\
& = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)) \\
& \in & \mathrm{SEN}'^{\alpha}(F(\Sigma')).
\end{array}$$

So SEN'^{α} is a well-defined functor.

Similarly, for $\sigma^\flat \in N^\flat$, $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\phi} \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc}
\mathrm{SEN}'^{\alpha}(F(\Sigma))^k & \xrightarrow{\sigma'^{\alpha}_{F(\Sigma)}} & \mathrm{SEN}'^{\alpha}(F(\Sigma)) \\
\mathrm{SEN}'^{\alpha}(F(f))^k \downarrow & & \downarrow \mathrm{SEN}'^{\alpha}(F(f)) \\
\mathrm{SEN}'^{\alpha}(F(\Sigma'))^k & \xrightarrow[\sigma'^{\alpha}_{F(\Sigma')}]{} & \mathrm{SEN}'^{\alpha}(F(\Sigma'))
\end{array}$$

$$\begin{array}{rcl}
\mathrm{SEN}'^{\alpha}(F(f))(\sigma'^{\alpha}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi}))) & = & \mathrm{SEN}'^{\alpha}(F(f))(\sigma'_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi}))) \\
& = & \mathrm{SEN}'^{\alpha}(F(f))(\alpha_\Sigma(\sigma_\Sigma(\vec{\phi}))) \\
& = & \mathrm{SEN}'(F(f))(\alpha_\Sigma(\sigma_\Sigma(\vec{\phi}))) \\
& = & \alpha_{\Sigma'}(\mathrm{SEN}(f)(\sigma_\Sigma(\vec{\phi}))) \\
& = & \alpha_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}))) \\
& = & \sigma'_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}))) \\
& = & \sigma'^{\alpha}_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\vec{\phi}))) \\
& = & \sigma'^{\alpha}_{F(\Sigma')}(\mathrm{SEN}'^{\alpha}(F(f))(\alpha_\Sigma(\vec{\phi}))).
\end{array}$$

Thus, $\sigma'^{\alpha} : (\mathrm{SEN}'^{\alpha})^k \to (\mathrm{SEN}'^{\alpha})$ is a well-defined natural transformation on SEN'^{α}. ■

We call $\alpha(\mathbf{A})$ the **image algebraic system** of $\mathbf{A}$ under $\langle F, \alpha\rangle$.

It is not difficult to see that, additionally, one may construct a surjective morphism from $\mathbf{A}$ to $\alpha(\mathbf{A})$. In fact, we define $\langle F, \alpha'\rangle : \mathbf{A} \to \alpha(\mathbf{A})$ by letting $\alpha' : \mathrm{SEN} \to \mathrm{SEN}'^{\alpha} \circ F$ be given, for all $\Sigma \in |\mathbf{Sign}|$, by

$$\alpha'_\Sigma(\phi) = \alpha_\Sigma(\phi), \text{ for all } \phi \in \mathrm{SEN}(\Sigma).$$

Lemma 14 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be* $N^\flat$*-algebraic systems and* $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{A}'$ *an algebraic system morphism, with* $F : \mathbf{Sign} \to \mathbf{Sign}'$ *an isomorphism. Then* $\langle F, \alpha'\rangle : \mathbf{A} \to \alpha(\mathbf{A})$ *is a surjective algebraic system morphism.*

Proof: The fact that $\alpha' : \mathrm{SEN} \to \mathrm{SEN}'^{\alpha} \circ F$ is a natural transformation follows from the corresponding property of α. Moreover, the fact that $\langle F, \alpha'\rangle$ has the morphism property also follows from the corresponding property of $\langle F, \alpha\rangle$. Finally, surjectivity of $\alpha'_\Sigma : \mathrm{SEN}(\Sigma) \to \mathrm{SEN}'^{\alpha}(F(\Sigma))$, for all $\Sigma \in |\mathbf{Sign}|$, follows by the definition of SEN'^{α}. ■

Let again $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system. An **F-algebraic system** (or an **interpreted algebraic system**) $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ consists of:

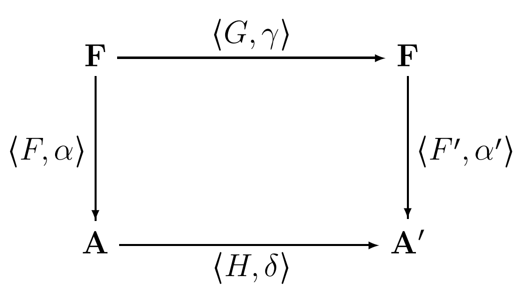
- An $N^\flat$-algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$;
- A surjective algebraic system morphism $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{A}$.

We denote the class of all $\mathbf{F}$-algebraic systems by $\mathrm{AlgSys}(\mathbf{F})$.

Given two $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$, a **morphism** (of $\mathbf{F}$-algebraic systems) $\langle\langle G, \gamma\rangle, \langle H, \delta\rangle\rangle : \mathcal{A} \to \mathcal{A}'$ consists of:

- A morphism of $N^\flat$-algebraic systems $\langle G, \gamma\rangle : \mathbf{F} \to \mathbf{F}$;
- A morphism of $N^\flat$-algebraic systems $\langle H, \delta\rangle : \mathbf{A} \to \mathbf{A}'$

such that the following diagram commutes



We call a morphism $\langle\langle G, \gamma\rangle, \langle H, \delta\rangle\rangle : \mathcal{A} \to \mathcal{A}'$ **special** if $\langle G, \gamma\rangle : \mathbf{F} \to \mathbf{F}$ is special and we call it **surjective** if $\langle G, \gamma\rangle : \mathbf{F} \to \mathbf{F}$ is surjective.

We show that these properties propagate to $\langle H, \delta\rangle : \mathbf{A} \to \mathbf{A}'$.

Lemma 15 *Consider a base algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$. *Let* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *be* $\mathbf{F}$*-algebraic systems and* $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$ *a morphism.*

(a) If $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$ *is special, then* $\langle H, \delta \rangle : \mathbf{A} \to \mathbf{A}'$ *is special;*

(b) If $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$ *is surjective, then* $\langle H, \delta \rangle : \mathbf{A} \to \mathbf{A}'$ *is surjective.*

Proof:

(a) Suppose $\langle G, \gamma \rangle$ is special. We show, first, that H is surjective on objects and, then, that it is full. Surjectivity on objects is easy. Since F' and G are surjective on objects, $H \circ F = F' \circ G$ is also surjective on objects. This implies that H is surjective on objects.

For fullness, recall that it suffices to show that, for all $Y, Y' \in |\mathbf{Sign}|$,

$$H : \mathbf{Sign}(Y, Y') \to \mathbf{Sign}'(H(Y), H(Y'))$$

is surjective. So let $k \in \mathbf{Sign}'(H(Y), H(Y'))$. Then, by the surjectivity of F, there exist $X, X' \in |\mathbf{Sign}^\flat|$, such that $F(X) = Y$ and $F(X') = Y'$. Thus, we get

$$k \in \mathbf{Sign}'(H(F(X)), H(F(X'))) = \mathbf{Sign}'(F'(G(X)), F'(G(X'))).$$

Since G and F' are full, there exists $f \in \mathbf{Sign}^\flat(X, X')$, such that $F'(G(f)) = k$. So we have that $H(F(f)) = k$ and $F(f) \in \mathbf{Sign}(F(X), F(X')) = \mathbf{Sign}(Y, Y')$. Therefore H is full.

(b) By Part (a), it suffices to show that, for all $Y \in |\mathbf{Sign}|$, $\delta_Y : \mathrm{SEN}(Y) \to \mathrm{SEN}'(H(Y))$ is surjective. Let $\chi \in \mathrm{SEN}'(H(Y))$. Since F is surjective, there exists $X \in |\mathbf{Sign}^\flat|$, such that $F(X) = Y$. So we get $\chi \in \mathrm{SEN}'(H(F(X))) = \mathrm{SEN}'(F'(G(X)))$. Since both $\gamma_X : \mathrm{SEN}^\flat(X) \to \mathrm{SEN}^\flat(G(X))$ and $\alpha'_{G(X)} : \mathrm{SEN}^\flat(G(X)) \to \mathrm{SEN}'(F'(G(X)))$ are surjective, we get that $\alpha'_{G(X)} \circ \gamma_X : \mathrm{SEN}^\flat(X) \to \mathrm{SEN}'(F'(G(X)))$ is surjective. Thus, there exists $\phi \in \mathrm{SEN}^\flat(X)$, such that

$$\chi = \alpha'_{G(X)}(\gamma_X(\phi)) = \delta_{F(X)}(\alpha_X(\phi)) = \delta_Y(\alpha_X(\phi)).$$

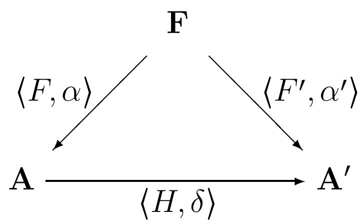
So $\delta_Y : \mathrm{SEN}(Y) \to \mathrm{SEN}'(H(Y))$ is also surjective.

■

In the future, we will restrict attention mostly to $\mathbf{F}$-algebraic system morphisms $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$, with

$$\langle G, \gamma \rangle = \langle I, \iota \rangle : \mathbf{F} \to \mathbf{F},$$

where $\langle I, \iota\rangle : \mathbf{F} \to \mathbf{F}$ denotes the identity morphism on $\mathbf{F}$. Since this morphism is surjective, by Lemma 15, this property will automatically hold for $\langle H, \delta\rangle : \mathbf{A} \to \mathbf{A}'$ as well. In this case, we also use the simplified notation $\langle H, \delta\rangle : \mathcal{A} \to \mathcal{A}'$



and even though we might say a "surjective" morphism $\langle H, \delta\rangle : \mathcal{A} \to \mathcal{A}'$ for emphasis, it is understood that this will always be the case, even without this specification.

2.3 Congruence Systems

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system. A **relation family on A** is a relation family on SEN, i.e., a collection $R = \{R_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, such that $R_\Sigma \subseteq \mathrm{SEN}(\Sigma)^2$, for all $\Sigma \in |\mathbf{Sign}|$. A relation family on $\mathbf{A}$ is a **relation system** if it is a relation system on SEN, i.e., if it is invariant under **Sign**-morphisms; that is, if for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(R_\Sigma) \subseteq R_{\Sigma'}.$$

A relation family/system on $\mathbf{A}$ is an **equivalence family/system on A** if it is an equivalence family/system on SEN, i.e., for all $\Sigma \in |\mathbf{Sign}|$, R_Σ is an equivalence relation on $\mathrm{SEN}(\Sigma)$. Finally, an equivalence system is called a **congruence system on A** if, for all $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi_i, \psi_i\rangle \in R_\Sigma, i < k, \text{ implies } \langle \sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\vec{\psi})\rangle \in R_\Sigma.$$

We call this the **congruence property**.

The collection of all congruence systems on the algebraic system $\mathbf{A}$ will be denoted by $\mathrm{ConSys}(\mathbf{A})$. Ordered under signature-wise inclusion $\leq$, it forms a complete lattice, which is denoted by $\mathbf{ConSys(A)} = \langle \mathrm{ConSys}(\mathbf{A}), \leq\rangle$.

The least congruence system on $\mathbf{A}$ is the **identity congruence system**, which denoted by $\Delta^{\mathbf{A}} = \{\Delta^{\mathbf{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, where, for all $\Sigma \in |\mathbf{Sign}|$,

$$\Delta^{\mathbf{A}}_\Sigma = \{\langle \phi, \phi\rangle : \phi \in \mathrm{SEN}(\Sigma)\}.$$

The largest congruence system is the **nabla congruence system**, denoted $\nabla^{\mathbf{A}}$ or SEN^2, and defined by $\nabla^{\mathbf{A}} = \{\nabla^{\mathbf{A}}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$, such that, for all $\Sigma \in |\mathbf{Sign}|$,

$$\nabla^{\mathbf{A}}_\Sigma = \{\langle \phi, \psi\rangle : \phi, \psi \in \mathrm{SEN}(\Sigma)\} = \mathrm{SEN}(\Sigma)^2.$$

The infimum of a family $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}(\mathbf{A})$ is given by signature-wise intersection $\bigcap_{i\in I}\theta^i$, while the supremum is the congruence system generated by the signature-wise union of the θ^i, $\bigvee_{i\in I}\theta^i = \{\Theta(\bigcup_{i\in I}\theta^i_\Sigma)\}_{\Sigma\in|\mathbf{Sign}|}$, where $\Theta(\bigcup_{i\in I}\theta^i_\Sigma)$ denotes the congruence on $\mathrm{SEN}(\Sigma)$ (viewed as an ordinary algebra with operations $\sigma_\Sigma : \mathrm{SEN}(\Sigma)^k \to \mathrm{SEN}(\Sigma)$, for $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N) generated by $\bigcup_{i\in I}\theta^i$.

Proposition 16 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *two* $N^\flat$*-algebraic systems and* $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{A}'$ *a morphism of* $N^\flat$*-algebraic systems. If* $\theta \in \mathrm{ConSys}(\mathbf{A}')$*, then* $\alpha^{-1}(\theta) \in \mathrm{ConSys}(\mathbf{A})$*.*

Proof: By Proposition 10 it suffices to show that, if θ has the congruence property, then $\alpha^{-1}(\theta)$ also has the congruence property. To see this, consider $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi_i, \psi_i\rangle \in \alpha_\Sigma^{-1}(\theta_{F(\Sigma)})$, for all $i < k$. Then we get $\langle \alpha_\Sigma(\phi_i), \alpha_\Sigma(\psi_i)\rangle \in \theta_{F(\Sigma)}$, for all $i < k$. Thus, by the congruence property of θ,

$$\langle \sigma'_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})), \sigma'_{F(\Sigma)}(\alpha_\Sigma(\vec{\psi}))\rangle \in \theta_{F(\Sigma)}.$$

By the morphism property, we get

$$\langle \alpha_\Sigma(\sigma_\Sigma(\vec{\phi})), \alpha_\Sigma(\sigma_\Sigma(\vec{\psi}))\rangle \in \theta_{F(\Sigma)}.$$

Hence $\langle \sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\vec{\psi})\rangle \in \alpha_\Sigma^{-1}(\theta_{F(\Sigma)})$, showing that $\alpha^{-1}(\theta)$ also satisfies the congruence property. ∎

As a special case of Proposition 16, we obtain that kernels of morphisms are congruence systems.

Corollary 17 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *two* $N^\flat$*-algebraic systems and* $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{A}'$ *a morphism of* $N^\flat$*-algebraic systems. Then* $\mathrm{Ker}(\langle F, \alpha\rangle) \in \mathrm{ConSys}(\mathbf{A})$*.*

Proof: This follows by Proposition 16 by taking $\theta = \Delta^{\mathcal{A}'}$. Then, obviously, $\alpha^{-1}(\theta) = \mathrm{Ker}(\langle F, \alpha\rangle)$. ∎

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $\theta \in \mathrm{ConSys}(\mathbf{A})$. The **quotient** $\mathbf{A}^\theta$ (or $\mathbf{A}/\theta$) **of A by** θ is the algebraic system $\mathbf{A}^\theta = \langle \mathbf{Sign}, \mathrm{SEN}^\theta, N^\theta\rangle$, defined as follows:

- For all $\Sigma \in |\mathbf{Sign}|$,

$$\mathrm{SEN}^\theta(\Sigma) = \mathrm{SEN}(\Sigma)/\theta_\Sigma = \{\phi/\theta_\Sigma : \phi \in \mathrm{SEN}(\Sigma)\}.$$

  For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\mathrm{SEN}^\theta(f)(\phi/\theta_\Sigma) = \mathrm{SEN}(f)(\phi)/\theta_{\Sigma'}.$$

- N^θ is the category of natural transformations on SEN^θ of the form $\sigma^\theta : (\mathrm{SEN}^\theta)^k \to \mathrm{SEN}^\theta$, where $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ is in N, defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$, by
$$\sigma^\theta_\Sigma(\vec{\phi}/\theta_\Sigma) = \sigma_\Sigma(\vec{\phi})/\theta_\Sigma.$$

The fact that θ is an equivalence system makes the functor SEN^θ well-defined at both the object and the morphism level. Moreover, the fact that θ is a congruence system makes the definition of each natural transformation in N^θ sound. Finally, the identities, projections and the composition in N^θ are the images of the corresponding operations and of the composition in N under $\cdot \mapsto \cdot^\theta$: For all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, $\vec{\phi} \in \mathrm{SEN}(\Sigma)$,

- $i^\theta_\Sigma(\phi/\theta_\Sigma) = \phi/\theta_\Sigma = i_\Sigma(\phi)/\theta_\Sigma$;
- $p^{k,i^\theta}_\Sigma(\vec{\phi}/\theta_\Sigma) = \phi_i/\theta_\Sigma = p^{k,i}_\Sigma(\vec{\phi})/\theta_\Sigma$;
- $\tau^\theta_\Sigma(\sigma^{0^\theta}_\Sigma(\vec{\phi}/\theta_\Sigma), \dots, \sigma^{k-1^\theta}_\Sigma(\vec{\phi}/\theta_\Sigma)) = \tau^\theta_\Sigma(\sigma^0_\Sigma(\vec{\phi})/\theta_\Sigma, \dots, \sigma^{k-1}_\Sigma(\vec{\phi})/\theta_\Sigma)$
$= \tau_\Sigma(\sigma^0_\Sigma(\vec{\phi}), \dots, \sigma^{k-1}_\Sigma(\vec{\phi}))/\theta_\Sigma$.

We denote by $\langle I, \pi^\theta\rangle : \mathbf{A} \to \mathbf{A}^\theta$ the **quotient morphism**, defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by
$$\pi^\theta_\Sigma(\phi) = \phi/\theta_\Sigma.$$
To see that it is well-defined, we must show that $\pi^\theta : \mathrm{SEN} \to \mathrm{SEN}^\theta$ is a natural transformation and that it satisfies the morphism property. In fact, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc}
\mathrm{SEN}(\Sigma) & \xrightarrow{\pi^\theta_\Sigma} & \mathrm{SEN}^\theta(\Sigma) \\
{\scriptstyle \mathrm{SEN}(f)}\downarrow & & \downarrow{\scriptstyle \mathrm{SEN}^\theta(f)} \\
\mathrm{SEN}(\Sigma') & \xrightarrow[\pi^\theta_{\Sigma'}]{} & \mathrm{SEN}^\theta(\Sigma')
\end{array}$$

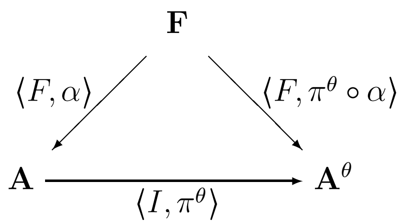
$$\begin{array}{rcl}
\pi^\theta_{\Sigma'}(\mathrm{SEN}(f)(\phi)) & = & \mathrm{SEN}(f)(\phi)/\theta_{\Sigma'} \\
& = & \mathrm{SEN}^\theta(f)(\phi/\theta_\Sigma) \\
& = & \mathrm{SEN}^\theta(f)(\pi^\theta_\Sigma(\phi)).
\end{array}$$

And for all $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$,

$$\begin{array}{ccc}
\mathrm{SEN}(\Sigma)^k & \xrightarrow{\pi^{\theta^k}_\Sigma} & \mathrm{SEN}^\theta(\Sigma)^k \\
{\scriptstyle \sigma_\Sigma}\downarrow & & \downarrow{\scriptstyle \sigma^\theta_\Sigma} \\
\mathrm{SEN}(\Sigma) & \xrightarrow[\pi^\theta_\Sigma]{} & \mathrm{SEN}^\theta(\Sigma)
\end{array}$$

$$\pi^\theta_\Sigma(\sigma_\Sigma(\vec{\phi})) = \sigma_\Sigma(\vec{\phi})/\theta_\Sigma = \sigma^\theta_\Sigma(\vec{\phi}/\theta_\Sigma) = \sigma^\theta_\Sigma(\pi^\theta_\Sigma(\vec{\phi})).$$

Note that this construction allows us to discuss also quotients of **F**-algebraic systems. More precisely, consider a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system and let $\theta \in \mathrm{ConSys}(\mathcal{A}) \coloneqq \mathrm{ConSys}(\mathbf{A})$. The **quotient F-algebraic system of $\mathcal{A}$ by θ** is defined as $\mathcal{A}^\theta = \langle \mathbf{A}^\theta, \langle F, \pi^\theta \circ \alpha \rangle \rangle$.



Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system and let $T \in \mathrm{SenFam}(\mathbf{A})$. We say that a congruence system θ on $\mathbf{A}$ is **compatible with** T if it is compatible with T as an equivalence system on SEN, i.e., if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi, \psi \rangle \in \theta_\Sigma \quad \text{and} \quad \phi \in T_\Sigma \quad \text{imply} \quad \psi \in T_\Sigma.$$

Note that, for every $T \in \mathrm{SenFam}(\mathbf{A})$, $\Delta^{\mathbf{A}}$ is compatible with T. We denote the collection of all congruence systems on $\mathbf{A}$ that are compatible with T by $\mathrm{ConSys}^{\mathbf{A}}(T)$.

Proposition 18 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system and* $T \in \mathrm{SenFam}(\mathbf{A})$. *The collection* $\mathrm{ConSys}^{\mathbf{A}}(T)$, *of all congruence systems on* $\mathbf{A}$ *that are compatible with* T, *forms a complete lattice*

$$\mathbf{ConSys}^{\mathbf{A}}(T) = \langle \mathrm{ConSys}^{\mathbf{A}}(T), \leq \rangle$$

under signature-wise inclusion.

Proof: First, the collection $\mathrm{ConSys}^{\mathbf{A}}(T)$ is closed under arbitrary intersections: Let θ^i, $i \in I$, be in $\mathrm{ConSys}^{\mathbf{A}}(T)$. Suppose that $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \bigcap_{i \in I} \theta^i_\Sigma$ and $\phi \in T_\Sigma$. Then $\langle \phi, \psi \rangle \in \theta^i_\Sigma$, for all $i \in I$. Since θ^i is compatible with T, we get $\psi \in T_\Sigma$. This shows that $\bigcap_{i \in I} \theta^i$ is compatible with T.

It suffices, therefore, to show that $\mathrm{ConSys}^{\mathbf{A}}(T)$ has a greatest element. The signature-wise union of every directed subset of $\mathrm{ConSys}^{\mathbf{A}}(T)$ is an upper bound for the subset in $\mathrm{ConSys}(\mathbf{A})$. Moreover, it is in $\mathrm{ConSys}^{\mathbf{A}}(T)$ since every member of the subset is. So, by Zorn's Lemma, $\mathrm{ConSys}^{\mathbf{A}}(T)$ has a maximal element.

Suppose, for the sake of obtaining a contradiction, that $\theta \neq \theta'$ are two such maximal elements. Recall that their join $\theta \vee \theta'$ is given by $\theta \vee \theta' =$

$\{\theta_\Sigma \vee \theta'_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$, where

$$\theta_\Sigma \vee \theta'_\Sigma = \bigcup_{k=0}^{\infty} \underbrace{\theta_\Sigma \circ \theta'_\Sigma \circ \cdots \circ \theta_\Sigma}_{k \text{ factors}}.$$

Thus, their join $\theta \vee \theta'$ as congruence systems on $\mathbf{A}$ is also compatible with T. This, however, contradicts the maximality of θ and θ', since, clearly, $\theta < \theta \vee \theta'$ and $\theta' < \theta \vee \theta'$. Therefore, the unique maximal element of $\mathrm{ConSys}^{\mathbf{A}}(T)$ is a largest element. ■

The largest congruence system on an algebraic system $\mathbf{A}$ compatible with $T \in \mathrm{SenFam}(\mathbf{A})$ is called the **Leibniz congruence system** of T on $\mathbf{A}$ and is denoted by $\Omega^{\mathbf{A}}(T)$.

The following theorem provides an explicit characterization of the Leibniz congruence system of a sentence family T on an algebraic system $\mathbf{A}$.

Theorem 19 *Suppose that $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ is an algebraic system and $T \in \mathrm{SenFam}(\mathbf{A})$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,*

$$\begin{array}{lll}\langle\phi,\psi\rangle \in \Omega^{\mathbf{A}}_\Sigma(T) & \textit{iff} & \textit{for all } \sigma : \mathrm{SEN}^k \to \mathrm{SEN} \textit{ in } N, \textit{ all } \Sigma' \in |\mathbf{Sign}|,\\ & & \textit{all } f \in \mathbf{Sign}(\Sigma,\Sigma') \textit{ and all } \vec{\chi} \in \mathrm{SEN}(\Sigma'), \textit{ we have}\\ & & \sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \in T_{\Sigma'} \textit{ iff } \sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \in T_{\Sigma'}.\end{array}$$

Proof: Let $R = \{R_\Sigma\}_{\Sigma\in|\mathbf{Sign}|}$ be the relation system on $\mathbf{A}$ defined by the given condition, i.e., for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{array}{ll}R_\Sigma = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : & \\ & \text{for all } \sigma : \mathrm{SEN}^k \to \mathrm{SEN} \text{ in } N, \text{ all } \Sigma' \in |\mathbf{Sign}|,\\ & \text{all } f \in \mathbf{Sign}(\Sigma,\Sigma') \text{ and all } \vec{\chi} \in \mathrm{SEN}(\Sigma'),\\ & \sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \in T_{\Sigma'} \text{ iff } \sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \in T_{\Sigma'}\}.\end{array}$$

First, we show that $\Omega^{\mathbf{A}}(T) \le R$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \Omega^{\mathbf{A}}_\Sigma(T)$. Since $\Omega^{\mathbf{A}}(T)$ is a congruence system, we get that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma,\Sigma')$, $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi)\rangle \in \Omega^{\mathbf{A}}_{\Sigma'}(T)$. Now, since $\Omega^{\mathbf{A}}(T)$ is a congruence system, we get that, for all $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\langle \sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}), \sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi})\rangle \in \Omega^{\mathbf{A}}_{\Sigma'}(T).$$

Finally, since $\Omega^{\mathbf{A}}(T)$ is compatible with T, we get that

$$\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi),\vec{\chi}) \in T_{\Sigma'}.$$

But the last condition, being universally quantified on $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma,\Sigma')$, σ in N and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$, yields $\langle\phi,\psi\rangle \in R_\Sigma$. Therefore, we get that $\Omega^{\mathbf{A}}(T) \le R$.

Finally, we show that $R \leq \Omega^{\mathbf{A}}(T)$. For this inclusion, it suffices to show that R is a congruence system on $\mathbf{A}$ that is compatible with T. Then the conclusion would follow from the fact that $\Omega^{\mathbf{A}}(T)$ is, by definition, the largest congruence system on $\mathbf{A}$ that is compatible with T.

It is clear from its definition that R is an equivalence family on $\mathbf{A}$.

To see that it is an equivalence system, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in R_\Sigma$. Consider $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$. Then, for all $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N, all $\Sigma'' \in |\mathbf{Sign}|$, all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma'')$,

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

we have

$$\begin{array}{ll} \multicolumn{2}{l}{\sigma_{\Sigma''}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\phi)), \vec{\chi}) \in T_{\Sigma''}} \\ \text{iff} & \sigma_{\Sigma''}(\mathrm{SEN}(gf)(\phi), \vec{\chi}) \in T_{\Sigma''} \\ \text{iff} & \sigma_{\Sigma''}(\mathrm{SEN}(gf)(\psi), \vec{\chi}) \in T_{\Sigma''} \quad (\text{since } \langle \phi, \psi \rangle \in R_\Sigma) \\ \text{iff} & \sigma_{\Sigma''}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\psi)), \vec{\chi}) \in T_{\Sigma''}. \end{array}$$

Thus, we conclude that $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \rangle \in R_{\Sigma'}$, showing that R is an equivalence system.

Next, to see that R is a congruence system, consider $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ in N, $\Sigma \in |\mathbf{Sign}|$, and $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi_i, \psi_i \rangle \in R_\Sigma$, $i < k$. Let $\tau : \mathrm{SEN}^\ell \to \mathrm{SEN}$ be in N, $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$. Then, we have

$$\begin{array}{ll} \multicolumn{2}{l}{\tau_{\Sigma'}(\mathrm{SEN}(f)(\sigma_\Sigma(\vec{\phi})), \vec{\chi}) \in T_{\Sigma'}} \\ \text{iff} & \tau_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi})), \vec{\chi}) \in T_{\Sigma'} \\ \text{iff} & \tau_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}(f)(\vec{\psi})), \vec{\chi}) \in T_{\Sigma'} \\ & (\tau \circ \langle \sigma \circ \langle p^{k+\ell-1,0}, \ldots, p^{k+\ell-1,k} \rangle, p^{k+\ell-1,k+1}, \ldots, p^{k+\ell-1,k+\ell-2} \rangle \text{ in } N \\ & \text{together with Corollary 12, applied } k \text{ times}) \\ \text{iff} & \tau_{\Sigma'}(\mathrm{SEN}(f)(\sigma_\Sigma(\vec{\psi})), \vec{\chi}) \in T_{\Sigma'}. \end{array}$$

This shows that $\langle \sigma_\Sigma(\vec{\phi}), \sigma_\Sigma(\vec{\psi}) \rangle \in R_\Sigma$, whence R is a congruence system.

Finally, upon setting in the defining condition $\sigma = p^{1,0} : \mathrm{SEN} \to \mathrm{SEN}$ in N, $\Sigma' = \Sigma$, $f = i_\Sigma$, the identity **Sign**-morphism, we get that for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, with $\langle \phi, \psi \rangle \in R_\Sigma$

$$\phi \in T_\Sigma \quad \text{iff} \quad \psi \in T_\Sigma.$$

Thus, R is compatible with T. ∎

The characterization of the Leibniz congruence system, presented in Theorem 19, provides a justification for an alternative name that is sometimes attributed to the Leibniz congruence system of a sentence family T on an algebraic system $\mathbf{A}$. Given $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, we say that ϕ and ψ are **indiscernible modulo** T if

$$\langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathbf{A}}(T).$$

Therefore $\Omega^{\mathbf{A}}(T)$ is also referred to as the **indiscernibility relation on A modulo** T.

We can now prove a proposition asserting that the Leibniz congruence system of a sentence family T is included in that of the sentence system $\overleftarrow{T}$.

Proposition 20 *Suppose that* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *is an algebraic system and* $T \in \mathrm{SenFam}(\mathbf{A})$. *Then*

$$\Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\overleftarrow{T}).$$

Proof: To prove this inclusion, it suffices to show that $\Omega^{\mathbf{A}}(T)$ is compatible with $\overleftarrow{T}$. We can invoke Lemma 7, but we also give a direct proof due to the heavy significance of this result. Let $\Sigma \in |\mathbf{Sign}|$, and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathbf{A}}(T)$ and $\phi \in \overleftarrow{T}_\Sigma$. Since $\Omega^{\mathbf{A}}(T)$ is a congruence system and by the definition of $\overleftarrow{T}$, we get that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \rangle \in \Omega_{\Sigma'}^{\mathbf{A}}(T) \quad \text{and} \quad \mathrm{SEN}(f)(\phi) \in T_{\Sigma'}.$$

Thus, by the compatibility of $\Omega^{\mathbf{A}}(T)$ with T, we obtain $\mathrm{SEN}(f)(\psi) \in T_{\Sigma'}$. Since this holds for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, we get $\psi \in \overleftarrow{T}_\Sigma$. Thus, $\Omega^{\mathbf{A}}(T)$ is compatible with $\overleftarrow{T}$, showing that $\Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\overleftarrow{T})$. ■

We exhibit, next, an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ together with a sentence family $T \in \mathrm{SenFam}(\mathbf{A})$, such that $\Omega^{\mathbf{A}}(T) \lneq \Omega^{\mathbf{A}}(\overleftarrow{T})$.

Example 21 *Define* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *as follows:*

- $\mathbf{Sign}$ *is a category with two objects* Σ, Σ' *and a single (non-identity) morphism* $f : \Sigma \to \Sigma'$.
- $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}(\Sigma) = \{0, 1\}$, $\mathrm{SEN}(\Sigma') = \{a, b\}$, $\mathrm{SEN}(f)(0) = a$ *and* $\mathrm{SEN}(f)(1) = b$.
- *The clone* N *of natural transformations is trivial, i.e., consists of the projection natural transformations only.*

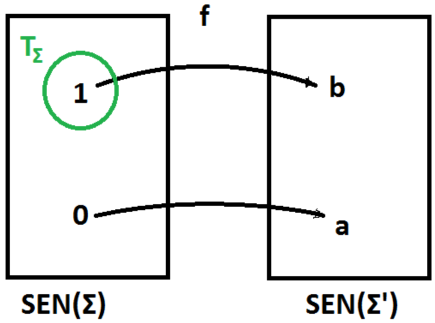
Finally, let $T = \{T_\Sigma, T_{\Sigma'}\}$ *be specified by setting* $T_\Sigma = \{1\}$ *and* $T_{\Sigma'} = \varnothing$. *Then it is not difficult to see that* $\overleftarrow{T}_\Sigma = \varnothing = \overleftarrow{T}_{\Sigma'}$ *and, therefore, that*

$$\Omega_\Sigma^{\mathbf{A}}(\overleftarrow{T}) = \nabla_\Sigma^{\mathbf{A}} \quad \textit{and} \quad \Omega_{\Sigma'}^{\mathbf{A}}(\overleftarrow{T}) = \nabla_{\Sigma'}^{\mathbf{A}},$$

whereas

$$\Omega_\Sigma^{\mathbf{A}}(T) = \Delta_\Sigma^{\mathbf{A}} \quad \textit{and} \quad \Omega_{\Sigma'}^{\mathbf{A}}(T) = \nabla_{\Sigma'}^{\mathbf{A}}.$$

Hence, we have $\Omega^{\mathbf{A}}(T) \lneq \Omega^{\mathbf{A}}(\overleftarrow{T})$.



Proposition 20 and Example 21 have important consequences. We give a brief account here, as is proper after proving these facts, but postpone further treatment for subsequent chapters.

1. Note that, given an algebraic system $\mathbf{A}$, for any sentence family T of $\mathbf{A}$, both $T, \overleftarrow{T}$ are sentence families of $\mathbf{A}$, such that, in general,
$$\overleftarrow{T} \leq T \quad \text{and} \quad \Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\overleftarrow{T}).$$
But it is an accepted wisdom in abstract algebraic logic that a logic is amenable to a meaningful algebraic treatment and, thus, deserves a place in the algebraic (Leibniz) hierarchy, if it is at least *protoalgebraic* or *truth-equational*, meaning that the Leibniz operator on its collection of theories is at least monotone of completely order reflecting. The displayed relations between T and $\overleftarrow{T}$, therefore, force us to define a new class of π-institutional logics, fulfilling a minimum, in some sense, condition for amenability to algebraic treatment and techniques, which we shall call **stable**, if their Leibniz operator satisfies, for all theory families T of the π-institution,
$$\Omega(T) = \Omega(\overleftarrow{T}).$$
The term "stable" is adopted to insinuate contrast to *inverting* or *changing* the order, since, given that $\overleftarrow{T} \leq T$ and that $\Omega(T) \leq \Omega(\overleftarrow{T})$, for all theory families T, an inversion in the order would occur in case $\Omega(T) \neq \Omega(\overleftarrow{T})$ for some theory family T.

2. Now note the remarkable fact that, for a stable π-institution, the range of the Leibniz operator is entirely covered by its values on theory systems of the π-institution, since, given a theory family T, one can work with its Leibniz congruence system by working with the congruence system $\Omega(\overleftarrow{T})$ of the theory system $\overleftarrow{T}$.

These two remarkable facts form an enticement, a preview and a justification for some of the upcoming definitions and concepts regarding classes of π-institutions, forming the semantic Leibniz hierarchy, in subsequent chapters.

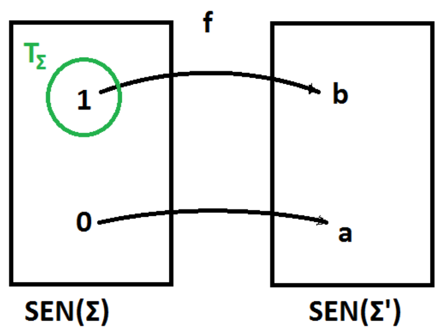
In the next example it is shown that the Leibniz congruence system of a sentence family T of an algebraic system $\mathbf{A}$ does not stand in a definite relationship with that of the sentence system $\overrightarrow{T}$.

Example 22 *We exhibit, first, an algebraic system* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *together with a sentence family* $T \in \mathrm{SenFam}(\mathbf{A})$, *such that* $\Omega^{\mathbf{A}}(\overrightarrow{T}) \subsetneq \Omega^{\mathbf{A}}(T)$.

We use the same algebraic system and the same sentence family as in Example 21. Define $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *as follows:*

- $\mathbf{Sign}$ *is a category with two objects* Σ, Σ' *and a single (non-identity) morphism* $f : \Sigma \to \Sigma'$.
- $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}(\Sigma) = \{0,1\}$, $\mathrm{SEN}(\Sigma') = \{a,b\}$, $\mathrm{SEN}(f)(0) = a$ *and* $\mathrm{SEN}(f)(1) = b$.
- *The clone* N *of natural transformations is trivial, i.e., consists of the projection natural transformations only.*

Finally, let $T = \{T_\Sigma, T_{\Sigma'}\}$ *be specified by setting* $T_\Sigma = \{1\}$ *and* $T_{\Sigma'} = \varnothing$.



Note that $\overrightarrow{T}_\Sigma = \{1\}$ *and* $\overrightarrow{T}_{\Sigma'} = \{b\}$. *So in this case we have*

$$\Omega^{\mathbf{A}}_\Sigma(\overrightarrow{T}) = \Delta^{\mathbf{A}}_\Sigma \quad \textit{and} \quad \Omega^{\mathbf{A}}_{\Sigma'}(\overrightarrow{T}) = \Delta^{\mathbf{A}}_{\Sigma'},$$

whereas, as pointed out in Example 21,

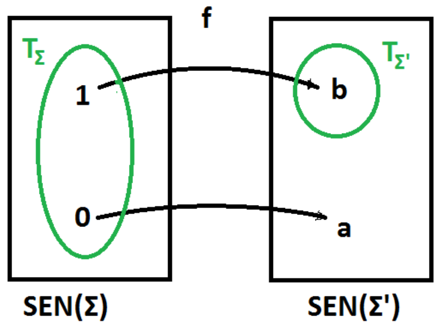
$$\Omega^{\mathbf{A}}_\Sigma(T) = \Delta^{\mathbf{A}}_\Sigma \quad \textit{and} \quad \Omega^{\mathbf{A}}_{\Sigma'}(T) = \nabla^{\mathbf{A}}_{\Sigma'}.$$

So we see that $\Omega^{\mathbf{A}}(\overrightarrow{T}) \subsetneq \Omega^{\mathbf{A}}(T)$.

Finally, we construct an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *together with a sentence family* $T \in \mathrm{SenFam}(T)$, *such that* $\Omega^{\mathbf{A}}(T) \subsetneq \Omega^{\mathbf{A}}(\overrightarrow{T})$.

The algebraic system is the same algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, *defined above. But now the sentence family* $T = \{T_\Sigma, T_{\Sigma'}\}$ *is defined by*

$$T_\Sigma = \{0,1\} \quad \textit{and} \quad T_{\Sigma'} = \{b\}.$$



It is clear that $\overrightarrow{T}_\Sigma = \{0,1\}$ *and* $\overrightarrow{T}_{\Sigma'} = \{a,b\}$. *Thus, we have*

$$\Omega^{\mathbf{A}}(T) = \Delta^{\mathbf{A}}_\Sigma \quad \textit{and} \quad \Omega^{\mathbf{A}}_{\Sigma'}(T) = \Delta^{\mathbf{A}}_{\Sigma'},$$

whereas

$$\Omega^{\mathbf{A}}_\Sigma(\overrightarrow{T}) = \nabla^{\mathbf{A}}_\Sigma \quad \textit{and} \quad \Omega^{\mathbf{A}}_{\Sigma'}(\overrightarrow{T}) = \nabla^{\mathbf{A}}_{\Sigma'}.$$

Thus we see that, in this case, $\Omega^{\mathbf{A}}(T) \lneq \Omega^{\mathbf{A}}(\overrightarrow{T})$.

It turns out that the Leibniz congruence system of the intersection of two sentence families of an algebraic system is at least as large as the intersection of the corresponding Leibniz congruence systems.

Lemma 23 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and let* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathbf{A})$. *Then*

$$\bigcap_{T\in\mathcal{T}} \Omega^{\mathbf{A}}(T) \leq \Omega^{\mathbf{A}}(\bigcap_{T\in\mathcal{T}} T).$$

Proof: The Leibniz congruence system of $\bigcap_{T\in\mathcal{T}} T$ is, by definition, the largest congruence system on $\mathbf{A}$ that is compatible with $\bigcap_{T\in\mathcal{T}} T \in \mathrm{SenFam}(\mathbf{A})$. So to prove the conclusion it suffices to show that $\bigcap_{T\in\mathcal{T}} \Omega^{\mathbf{A}}(T)$ is a congruence system on $\mathbf{A}$ that is compatible with $\bigcap_{T\in\mathcal{T}} T$. That it is a congruence system follows from the fact that $\mathbf{ConSys}(\mathbf{A})$ has the structure of a complete lattice with signature-wise intersection as its infimum. For compatibility, Let $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \bigcap_{T\in\mathcal{T}} \Omega^{\mathbf{A}}_\Sigma(T)$ and $\phi \in \bigcap_{T\in\mathcal{T}} T_\Sigma$. These two imply the following relations:

$$\langle\phi,\psi\rangle \in \Omega^{\mathbf{A}}_\Sigma(T), \quad \phi \in T_\Sigma, \quad \text{for all } T \in \mathcal{T}.$$

Now, using the compatibility property of $\Omega^{\mathbf{A}}(T)$, $T \in \mathcal{T}$, we get $\psi \in T_\Sigma$, for all $T \in \mathcal{T}$. So $\psi \in \bigcap_{T\in\mathcal{T}} T_\Sigma$ and, therefore, $\bigcap_{T\in\mathcal{T}} \Omega^{\mathbf{A}}(T)$ is compatible with $\bigcap_{T\in\mathcal{T}} T$. ∎

An important property of the Leibniz operator is that it commutes with inverse surjective morphisms of $N^\flat$-algebraic systems.

Proposition 24 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *two* $N^\flat$*-algebraic systems,* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ *an algebraic system morphism and* $T \in \mathrm{SenFam}(\mathbf{A}')$*. We have:*

(a) $\alpha^{-1}(\Omega^{\mathbf{A}'}(T)) \leq \Omega^{\mathbf{A}}(\alpha^{-1}(T))$;

(b) If $\langle F, \alpha \rangle$ *is surjective,* $\alpha^{-1}(\Omega^{\mathbf{A}'}(T)) = \Omega^{\mathbf{A}}(\alpha^{-1}(T))$.

Proof:

(a) Since $\Omega^{\mathbf{A}}(\alpha^{-1}(T))$ is the largest congruence system that is compatible with $\alpha^{-1}(T)$, it suffices to show that $\alpha^{-1}(\Omega^{\mathbf{A}'}(T))$ is a congruence system on $\mathbf{A}$ that is compatible with $\alpha^{-1}(T)$. The fact that it is a congruence system on $\mathbf{A}$ is guaranteed by Proposition 16. So it suffices to show its compatibility with $\alpha^{-1}(T)$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\Omega_{F(\Sigma)}^{\mathbf{A}'}(T))$ and $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Now we get $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega_{F(\Sigma)}^{\mathbf{A}'}(T)$ and $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. By compatibility of $\Omega^{\mathbf{A}'}(T)$ with T, we get $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Therefore $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, which proves compatibility of $\alpha^{-1}(\Omega^{\mathbf{A}'}(T))$ with $\alpha^{-1}(T)$.

(b) By Part (a), it suffices to prove, under the hypothesis that $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ is surjective, the inclusion $\Omega^{\mathbf{A}}(\alpha^{-1}(T)) \leq \alpha^{-1}(\Omega^{\mathbf{A}'}(T))$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathbf{A}}(\alpha^{-1}(T))$. Then, by Theorem 19, we get that, for all $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\begin{array}{l}\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}) \\ \qquad\text{iff}\quad \sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi}) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}).\end{array}$$

Equivalently,

$$\begin{array}{l}\alpha_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi})) \in T_{F(\Sigma')} \\ \qquad\text{iff}\quad \alpha_{\Sigma'}(\sigma_{\Sigma'}(\mathrm{SEN}(f)(\psi), \vec{\chi})) \in T_{F(\Sigma')}.\end{array}$$

Equivalently, by the morphism property,

$$\begin{array}{l}\sigma'_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \qquad\text{iff}\quad \sigma'_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}(f)(\psi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')}.\end{array}$$

Equivalently, by the naturality of α,

$$\begin{array}{l}\sigma'_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \qquad\text{iff}\quad \sigma'_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')}.\end{array}$$

Equivalently, by Theorem 19 and the surjectivity of $\langle F, \alpha \rangle$, we get that

$$\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega_{F(\Sigma)}^{\mathbf{A}'}(T),$$

which finishes the proof.

■

2.4 Relative Congruence Systems

We look at a variety of results related to congruence systems in this section. First, we give a condition that ensures that, given a morphism $\langle H,\gamma\rangle : \mathbf{A} \to \mathbf{A}'$ of $N^\flat$-algebraic systems, with an isomorphic functor component, and an equivalence family θ on $\mathbf{A}$, we have $\gamma^{-1}(\gamma(\theta)) = \theta$.

Lemma 25 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be* $N^\flat$*-algebraic systems,* $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$ *a morphism, with* F *an isomorphism, and* $\theta \in \mathrm{EqvFam}(\mathbf{A})$*. Then*

$$\mathrm{Ker}(\langle F,\alpha\rangle) \leq \theta \quad \textit{iff} \quad \alpha^{-1}(\alpha(\theta)) = \theta.$$

Proof: Suppose, first, that $\mathrm{Ker}(\langle F,\alpha\rangle) \leq \theta$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \alpha_\Sigma^{-1}(\alpha_\Sigma(\theta_\Sigma))$. Then, by definition, we get

$$\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle \in \alpha_\Sigma(\theta_\Sigma).$$

Thus, there exist $\phi',\psi' \in \mathrm{SEN}(\Sigma)$, such that

$$\langle\phi',\psi'\rangle \in \theta_\Sigma \quad \text{and} \quad \langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle = \langle\alpha_\Sigma(\phi'),\alpha_\Sigma(\psi')\rangle.$$

Thus, we get

$$\langle\phi',\psi'\rangle \in \theta_\Sigma \quad \text{and} \quad \langle\phi,\phi'\rangle,\langle\psi,\psi'\rangle \in \mathrm{Ker}_\Sigma(\langle F,\alpha\rangle).$$

Since $\mathrm{Ker}(\langle F,\alpha\rangle) \leq \theta$ and θ is an equivalence family, we get that $\langle\phi,\psi\rangle \in \theta_\Sigma$. Thus, we conclude that $\alpha^{-1}(\alpha(\theta)) \leq \theta$. Since the reverse inclusion always holds, $\alpha^{-1}(\alpha(\theta)) = \theta$.

Assume, conversely, that $\alpha^{-1}(\alpha(\theta)) = \theta$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\langle F,\alpha\rangle)$. Then, by definition, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Therefore, since θ is an equivalence family, we get

$$\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle = \langle\alpha_\Sigma(\phi),\alpha_\Sigma(\phi)\rangle \in \alpha_\Sigma(\theta).$$

Now we get $\langle\phi,\psi\rangle \in \alpha_\Sigma^{-1}(\alpha_\Sigma(\theta_\Sigma))$ and, by hypothesis, $\langle\phi,\psi\rangle \in \theta_\Sigma$. We conclude that $\mathrm{Ker}(\langle F,\alpha\rangle) \leq \theta$. ∎

Next we show that, given algebraic systems $\mathbf{A}$ and $\mathbf{A}'$, a surjective morphism $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$, with an isomorphic functor component, and a congruence system θ on $\mathbf{A}$, its image under $\langle F,\alpha\rangle$ is a congruence system on $\mathbf{A}'$, provided that θ contains the kernel system of $\langle F,\alpha\rangle$.

Lemma 26 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ *be* $N^\flat$*-algebraic systems,* $\langle F,\alpha\rangle : \mathbf{A} \to \mathbf{A}'$ *a surjective morphism, with* F *an isomorphism, and* $\theta \in \mathrm{ConSys}(\mathbf{A})$*, such that* $\mathrm{Ker}(\langle F,\alpha\rangle) \leq \theta$*. Then* $\alpha(\theta) \in \mathrm{ConSys}(\mathbf{A}')$*.*

Proof: We first show that $\alpha(\theta)$ is an equivalence family on $\mathbf{A}'$. To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi, \psi', \chi \in \mathrm{SEN}(\Sigma)$.

- By hypothesis, $\theta \in \mathrm{ConSys}(\mathbf{A})$. Hence, $\langle \phi, \phi \rangle \in \theta_\Sigma$. Thus, $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\phi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$. Since $\langle F, \alpha \rangle$ is surjective, $\alpha(\theta)$ is reflexive.

- Suppose $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$. Then $\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\alpha_\Sigma(\theta_\Sigma))$. By Lemma 25, $\langle \phi, \psi \rangle \in \theta_\Sigma$. Since $\theta \in \mathrm{ConSys}(\mathbf{A})$, $\langle \psi, \phi \rangle \in \theta_\Sigma$. Hence, $\langle \alpha_\Sigma(\psi), \alpha_\Sigma(\phi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$. Thus, by the surjectivity of $\langle F, \alpha \rangle$, $\alpha(\theta)$ is also symmetric.

- Finally, suppose that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$ and $\langle \alpha_\Sigma(\psi'), \alpha_\Sigma(\chi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$, with $\alpha_\Sigma(\psi) = \alpha_\Sigma(\psi')$. Then, by Lemma 25, $\langle \phi, \psi \rangle \in \theta_\Sigma$ and $\langle \psi', \chi \rangle \in \theta_\Sigma$. Moreover, by hypothesis, $\langle \psi, \psi' \rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha \rangle) \subseteq \theta_\Sigma$. Since $\theta \in \mathrm{ConSys}(\mathbf{A})$, we get $\langle \phi, \chi \rangle \in \theta_\Sigma$ and, therefore, $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\chi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\alpha(\theta)$ is also transitive.

We showed that $\alpha(\theta) \in \mathrm{EqvFam}(\mathbf{A}')$.

Next, we show that $\alpha(\theta)$ is also a system. To this end, suppose $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \alpha_\Sigma(\theta_\Sigma)$. Then, by Lemma 25, $\langle \phi, \psi \rangle \in \theta_\Sigma$. Since $\theta \in \mathrm{ConSys}(\mathbf{A})$, we get $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \rangle \in \theta_{\Sigma'}$. Thus,

$$\begin{aligned}&\langle \mathrm{SEN}'(F(f))(\alpha_\Sigma(\phi)), \mathrm{SEN}'(F(f))(\alpha_\Sigma(\psi)) \rangle \\ &\quad = \langle \alpha_{\Sigma'}(\mathrm{SEN}(f)(\phi)), \alpha_{\Sigma'}(\mathrm{SEN}(f)(\psi)) \rangle \in \alpha_{\Sigma'}(\theta_{\Sigma'}).\end{aligned}$$

Since $\langle F, \alpha \rangle$ is surjective, we get that $\alpha(\theta)$ is invariant under $\mathbf{Sign}'$-morphisms. Now we have that $\alpha(\theta) \in \mathrm{EqvSys}(\mathbf{A}')$.

Finally, it remains to see that it is also a congruence system. To this end, let $\sigma^\flat$ be a natural transformation in $N^\flat$, $\Sigma \in |\mathbf{Sign}|$, $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}(\Sigma)$, such that $\langle \alpha_\Sigma(\phi_i), \alpha_\Sigma(\psi_i) \rangle \in \alpha_\Sigma(\theta_\Sigma)$, for all $i < k$. We get, by Lemma 25, $\langle \phi_i, \psi_i \rangle \in \theta_\Sigma$, whence, since $\theta \in \mathrm{ConSys}(\mathbf{A})$, $\langle \sigma^{\mathbf{A}}_\Sigma(\vec{\phi}), \sigma^{\mathbf{A}}_\Sigma(\vec{\psi}) \rangle \in \theta_\Sigma$. Now, applying the morphism property, we get

$$\langle \sigma^{\mathbf{A}'}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})), \sigma^{\mathbf{A}'}_{F(\Sigma)}(\alpha_\Sigma(\vec{\psi})) \rangle = \langle \alpha_\Sigma(\sigma^{\mathbf{A}}_\Sigma(\vec{\phi})), \alpha_\Sigma(\sigma^{\mathbf{A}}_\Sigma(\vec{\psi})) \rangle \in \alpha_\Sigma(\theta_\Sigma).$$

Again, taking into account the surjectivity of $\langle F, \alpha \rangle$, we get that $\alpha(\theta)$ has the congruence property. We conclude that $\alpha(\theta) \in \mathrm{ConSys}(\mathbf{A}')$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system, K be a class of $\mathbf{F}$-algebraic systems and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. A congruence system θ on $\mathbf{A}$ is called a K-**congruence system**, or a **congruence system relative to** K, if the quotient algebraic system $\mathcal{A}/\theta$ is a member of the class K, i.e., $\mathcal{A}/\theta = \mathcal{A}^\theta \in \mathsf{K}$. Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, we denote by $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ the collection of all K-congruence systems on $\mathcal{A}$:

$$\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathcal{A}) : \mathcal{A}/\theta \in \mathsf{K}\}.$$

Let K be a class of $\mathbf{F}$-algebraic systems. We write $\mathbb{H}(\mathsf{K})$ for the class of all $\mathbf{F}$-algebraic systems $\mathcal{B}$, such that, there exists $\mathcal{A} \in \mathsf{K}$ and a (surjective) $\mathbf{F}$-algebraic system morphism $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$:

$$\mathbb{H}(\mathsf{K}) = \{\mathcal{B} \in \mathrm{AlgSys}(\mathbf{F}) : (\exists \mathcal{A} \in \mathsf{K})(\exists \langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B})\}.$$

We show that, if K is a class that is closed under the operator $\mathbb{H}$, then the K-congruence systems on any $\mathbf{F}$-algebraic system in K coincide with the ordinary congruence systems on $\mathcal{A}$.

Proposition 27 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems, such that* $\mathbb{H}(\mathsf{K}) \subseteq \mathsf{K}$*. Then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} \in \mathsf{K}$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) = \mathrm{ConSys}(\mathcal{A})$.

Proof: Clearly, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) \subseteq \mathrm{ConSys}(\mathcal{A})$. Suppose $\theta \in \mathrm{ConSys}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi^\theta\rangle : \mathcal{A} \to \mathcal{A}/\theta.$$

Since $\mathcal{A} \in \mathsf{K}$, $\mathcal{A}/\theta \in \mathbb{H}(\mathsf{K}) \subseteq \mathsf{K}$. Thus, by definition, $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i\rangle\rangle$, $i \in I$, be $\mathbf{F}$-algebraic systems and, for all $i \in I$,

$$\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i$$

a surjective morphism. We say that $\{\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i : i \in I\}$ is a **subdirect intersection** if

$$\bigcap_{i\in I} \mathrm{Ker}(\langle H^i, \gamma^i\rangle) = \Delta^{\mathcal{A}}.$$

Given a class K of $\mathbf{F}$-algebraic systems, we write $\overset{\triangleleft}{\mathbb{P}}(\mathsf{K})$ to denote the class of all $\mathbf{F}$-algebraic systems $\mathcal{A}$, for which there exists a subdirect intersection $\{\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i : i \in I\}$, with $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$.

We show that if a class K is closed under subdirect intersections, then the collection of all K-congruence systems on any $\mathbf{F}$-algebraic system $\mathcal{A}$ is closed under intersections. If, in addition, K contains a trivial $\mathbf{F}$-algebraic system, then $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ becomes a closure family on $\mathcal{A}^2$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

Proposition 28 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *be a class of* $\mathbf{F}$*-algebraic systems, such that* $\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}) \subseteq \mathsf{K}$.

(a) For every $\mathbf{F}$*-algebraic system* $\mathcal{A}$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is closed under signature-wise intersections;*

(b) If, in addition, K *contains a trivial* $\mathbf{F}$*-algebraic system, then, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is a closure family on* $\mathcal{A}^2$.

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Then $\mathcal{A}/\theta^i \in \mathsf{K}$, for all $i \in I$. Consider the canonical morphisms

$$\langle I, \pi^i\rangle : \mathcal{A}/\bigcap_{i\in I}\theta^i \to \mathcal{A}/\theta^i, \quad i \in I.$$

Clearly, we have

$$\bigcap_{i\in I}\mathrm{Ker}(\langle I,\pi^i\rangle) = \bigcap_{i\in I}(\theta^i/\bigcap_{i\in I}\theta^i) = \bigcap_{i\in I}\theta^i/\bigcap_{i\in I}\theta^i = \Delta^{\mathcal{A}/\bigcap_{i\in I}\theta^i}.$$

Thus, $\{\langle I,\pi^i\rangle : \mathcal{A}/\bigcap_{i\in I}\theta^i \to \mathcal{A}/\theta^i : i \in I\}$ is a subdirect intersection. Since $\mathcal{A}/\theta^i \in \mathsf{K}$, for all $i \in I$, we get $\mathcal{A}/\bigcap_{i\in I}\theta^i \in \overset{\triangleleft}{\mathbb{I}\mathrm{I}}(\mathsf{K}) \subseteq \mathsf{K}$. Therefore, $\bigcap_{i\in I}\theta^i \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$.

Suppose, in addition, that K contains a trivial $\mathbf{F}$-algebraic system. Then $\nabla^{\mathcal{A}} \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, whence $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is a closure family on $\mathcal{A}^2$. ■

By Proposition 28, for a class K of $\mathbf{F}$-algebraic systems closed under $\overset{\triangleleft}{\mathbb{I}\mathrm{I}}$ and containing a trivial $\mathbf{F}$-algebraic system, it makes sense to define, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $X \in \mathrm{SenFam}(\mathcal{A}^2)$,

$$\Theta^{\mathsf{K},\mathcal{A}}(X) = \bigcap\{\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) : X \leq \theta\}.$$

When $\mathcal{A}$ coincides with the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$, where $\langle I,\iota\rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism, we write simply Θ^{K}.

We now provide a different characterization of the operator $\Theta^{\mathsf{K},\mathcal{A}}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system and K a class of $\mathbf{F}$-algebraic systems. Define the operator $D^{\mathsf{K}} : \mathcal{P}(\mathrm{SEN}^\flat)^2 \to \mathcal{P}(\mathrm{SEN}^\flat)^2$, by letting, for all $X \leq (\mathrm{SEN}^\flat)^2$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\langle \phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma)^2$,

$$\langle \phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X) \quad \text{iff} \quad \begin{array}{l}\text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle \in \mathsf{K},\\ \alpha(X) \leq \Delta^{\mathcal{A}} \text{ implies } \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).\end{array}$$

We show that D^{K} is a closure family on $(\mathrm{SEN}^\flat)^2$.

Proposition 29 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* D^{K} *is a closure family on* $(\mathrm{SEN}^\flat)^2$.

Proof: We must show that D^{K} is inflationary, monotone and idempotent.

Let $X \leq (\mathrm{SEN}^\flat)^2$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\langle \phi,\psi\rangle \in X_\Sigma$. Then, for all $\mathcal{A} \in \mathsf{K}$, if $\alpha(X) \leq \Delta^{\mathcal{A}}$, we clearly have $\alpha(\phi) = \alpha(\psi)$. Hence, $\langle \phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X)$ and D^{K} is inflationary.

Suppose $X \leq Y \leq (\mathrm{SEN}^\flat)^2$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\langle \phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma)^2$, such that $\langle \phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X)$. Let $\mathcal{A} \in \mathsf{K}$, such that $\alpha(Y) \leq \Delta^{\mathcal{A}}$. Then, we get $\alpha(X) \leq \alpha(Y) \leq \Delta^{\mathcal{A}}$, whence, by hypothesis, $\alpha(\phi) = \alpha(\psi)$. Therefore, $\langle \phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(Y)$ and D^{K} is also monotone.

Finally, suppose $X \leq (\mathrm{SEN}^\flat)^2$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\langle\phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(D^{\mathsf{K}}(X))$. Let $\mathcal{A} \in \mathsf{K}$, such that $\alpha(X) \leq \Delta^{\mathcal{A}}$. Then, by definition, $\alpha(D^{\mathsf{K}}(X)) \leq \Delta^{\mathcal{A}}$, whence, by hypothesis, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Thus, $\langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X)$ and D^{K} is also idempotent.

We conclude that D^{K} is a closure family on $(\mathrm{SEN}^\flat)^2$. ■

We show, next, that, for all $X \leq (\mathrm{SEN}^\flat)^2$, the sentence family $D^{\mathsf{K}}(X)$ is a congruence system on the algebraic system $\mathbf{F}$ and that, moreover, it is a congruence system relative to the class K.

Proposition 30 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system and K a class of $\mathbf{F}$-algebraic systems. For all $X \leq (\mathrm{SEN}^\flat)^2$, $D^{\mathsf{K}}(X) \in \mathrm{ConSys}(\mathbf{F})$.*

Proof: We first show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $D^{\mathsf{K}}_\Sigma(X)$ is an equivalence family.

- Let $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since, for all $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\phi)$, we get that $\langle\phi,\phi\rangle \in D^{\mathsf{K}}_\Sigma(X)$, whence $D^{\mathsf{K}}_\Sigma(X)$ is reflexive.

- Suppose $\langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X)$ and let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, such that $\alpha(X) \leq \Delta^{\mathcal{A}}$. Then, by hypothesis, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$, giving $\alpha_\Sigma(\psi) = \alpha_\Sigma(\phi)$. Hence, $\langle\psi,\phi\rangle \in D^{\mathsf{K}}_\Sigma(X)$, showing that $D^{\mathsf{K}}_\Sigma(X)$ is also symmetric.

- Finally, suppose $\langle\phi,\psi\rangle$, $\langle\psi,\chi\rangle \in D^{\mathsf{K}}_\Sigma(X)$. Let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, such that $\alpha(X) \leq \Delta^{\mathcal{A}}$. By hypothesis, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$ and $\alpha_\Sigma(\psi) = \alpha_\Sigma(\chi)$. Therefore, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\chi)$, showing that $\langle\phi,\chi\rangle \in D^{\mathsf{K}}_\Sigma(X)$. Hence, $D^{\mathsf{K}}_\Sigma(X)$ is also transitive.

We show, next, that $D^{\mathsf{K}}(X)$ is an equivalence system, i.e., invariant under signature morphisms. Let $\Sigma,\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X)$. Let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, such that $\alpha(X) \leq \Delta^{\mathcal{A}}$. Then, by hypothesis, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Thus, we get

$$\begin{array}{rcl}\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) &=& \mathrm{SEN}(F(f))(\alpha_\Sigma(\phi))\\ &=& \mathrm{SEN}(F(f))(\alpha_\Sigma(\psi))\\ &=& \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi)).\end{array}$$

Hence, $\langle\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)\rangle \in D^{\mathsf{K}}_{\Sigma'}(X)$.

Finally, to see that it also satisfies the congruence property, let $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ be in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi},\vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle\phi_i,\psi_i\rangle \in D^{\mathsf{K}}_\Sigma(X)$, for all $i < k$. Let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, such that $\alpha(X) \leq \Delta^{\mathcal{A}}$. then, by hypothesis, $\alpha_\Sigma(\phi_i) = \alpha_\Sigma(\psi_i)$, for all $i < k$. Therefore,

$$\begin{array}{rcl}\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) &=& \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi}))\\ &=& \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\psi}))\\ &=& \alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\psi})).\end{array}$$

We conclude that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\sigma^\flat_\Sigma(\vec{\psi})\rangle \in D^{\mathsf{K}}_\Sigma(X)$ and, therefore, $D^{\mathsf{K}}(X)$ is indeed a congruence system on $\mathbf{F}$. ■

Furthermore, if K happens to contain a trivial $\mathbf{F}$-algebraic system and be closed under subdirect intersections, we can show that $D^{\mathsf{K}}(X)$ is a K-congruence system on $\mathbf{F}$.

Proposition 31 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems, containing a trivial* $\mathbf{F}$*-algebraic system and closed under* $\overset{\triangleleft}{\amalg}$. *For all* $X \leq (\mathrm{SEN}^\flat)^2$, $D^{\mathsf{K}}(X) \in \mathrm{ConSys}^{\mathsf{K}}(\mathbf{F})$.

Proof: By Proposition 30, we know that $D^{\mathsf{K}}(X)$ is a congruence system on $\mathbf{F}$. Therefore, it suffices to show that it is a congruence system relative to K. For this, let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K}$, such that $X \leq \mathrm{Ker}(\langle F,\alpha\rangle)$. Define the morphism

$$\langle F,\alpha^{\mathsf{K}}\rangle : \mathcal{F}/D^{\mathsf{K}}(X) \to \mathcal{A}$$

by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)/D^{\mathsf{K}}_\Sigma(X)$,

$$\alpha^{\mathsf{K}}_\Sigma(\phi/D^{\mathsf{K}}_\Sigma(X)) = \alpha_\Sigma(\phi).$$

This morphism is well defined, since, if $\mathcal{A} \in \mathsf{K}$, with $X \leq \mathrm{Ker}(\langle F,\alpha\rangle)$, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X) \quad \text{implies} \quad \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).$$

Now consider the collection

$$\langle F,\alpha^{\mathsf{K}}\rangle : \mathcal{F}/D^{\mathsf{K}}(X) \to \mathcal{A},\ \mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle \in \mathsf{K},\ X \leq \mathrm{Ker}(\langle F,\alpha\rangle).$$

We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{aligned}
&\langle\phi/D^{\mathsf{K}}_\Sigma(X),\psi/D^{\mathsf{K}}_\Sigma(X)\rangle \in \textstyle\bigcap_{\langle F,\alpha^{\mathsf{K}}\rangle}\mathrm{Ker}_\Sigma(\langle F,\alpha^{\mathsf{K}}\rangle)\\
&\quad\text{iff}\quad \alpha^{\mathsf{K}}_\Sigma(\phi/D^{\mathsf{K}}_\Sigma(X)) = \alpha^{\mathsf{K}}_\Sigma(\psi/D^{\mathsf{K}}_\Sigma(X)),\ \text{for all } \langle F,\alpha^{\mathsf{K}}\rangle\\
&\quad\text{iff}\quad \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)\ \text{for all } \langle F,\alpha^{\mathsf{K}}\rangle\\
&\quad\text{iff}\quad \langle\phi,\psi\rangle \in D^{\mathsf{K}}_\Sigma(X).
\end{aligned}$$

Therefore, the displayed collection above constitutes a subdirect intersection and, since $\mathcal{A} \in \mathsf{K}$, for all $\langle F,\alpha^{\mathsf{K}}\rangle$, and K is closed under subdirect intersections, we get that $\mathcal{F}/D^{\mathsf{K}}(X) \in \mathsf{K}$, and, therefore, $D^{\mathsf{K}}(X) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$. ■

We are now in a position to show the promised alternative characterization of the operator Θ^{K}. It turns out that it coincides with D^{K}.

Theorem 32 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems, containing a trivial* $\mathbf{F}$*-algebraic system and closed under subdirect intersections. For all* $X \leq (\mathrm{SEN}^\flat)^2$, $\Theta^{\mathsf{K}}(X) = D^{\mathsf{K}}(X)$.

Proof: Let $X \leq (\mathrm{SEN}^\flat)^2$. By Proposition 31, $D^{\mathsf{K}}(X) \in \mathrm{ConSys}^{\mathsf{K}}(X)$ and, by Proposition 29, $X \leq D^{\mathsf{K}}(X)$. Therefore, by the minimality of $\Theta^{\mathsf{K}}(X)$, we get that $\Theta^{\mathsf{K}}(X) \leq D^{\mathsf{K}}(X)$. To show the reverse inclusion, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in D^{\mathsf{K}}_\Sigma(X)$. Consider $\mathcal{F}/\Theta^{\mathsf{K}}(X) \in \mathsf{K}$. Since $\pi^{\Theta^{\mathsf{K}}(X)}(X) \leq \Delta^{\mathcal{F}/\Theta^{\mathsf{K}}(X)}$, we get, by hypothesis, $\pi^{\Theta^{\mathsf{K}}(X)}_\Sigma(\phi) = \pi^{\Theta^{\mathsf{K}}(X)}_\Sigma(\psi)$, i.e., $\langle \phi, \psi \rangle \in \Theta^{\mathsf{K}}_\Sigma(X)$. We conclude that $D^{\mathsf{K}}(X) \leq \Theta^{\mathsf{K}}(X)$. ∎

We look, next, at how the operator Θ^{K} interacts with morphisms.

Proposition 33 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K be a class of $\mathbf{F}$-algebraic systems, containing a trivial $\mathbf{F}$-algebraic system and such that $\overset{\triangleleft}{\mathbb{IP}}(\mathsf{K}) \subseteq \mathsf{K}$. Let also $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ be $\mathbf{F}$-algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism.*

(a) If $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B})$, then $\gamma^{-1}(\theta) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$;

(b) If H is an isomorphism, $\mathrm{Ker}(\langle H, \gamma \rangle) \leq \theta$ and $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, then $\gamma(\theta) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B})$.

Proof:

(a) By Proposition 16, $\gamma^{-1}(\theta) \in \mathrm{ConSys}(\mathcal{A})$. Consider the morphism

$$\langle H, \gamma^* \rangle : \mathcal{A}/\gamma^{-1}(\theta) \to \mathcal{B}/\theta,$$

defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\gamma^*_\Sigma(\phi/\gamma^{-1}_\Sigma(\theta_{H(\Sigma)})) = \gamma_\Sigma(\phi)/\theta_{H(\Sigma)}.$$

This is well-defined, since, if $\langle \phi, \psi \rangle \in \gamma^{-1}_\Sigma(\theta_{H(\Sigma)})$, then $\langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \theta_{H(\Sigma)}$. Moreover,

$$\mathrm{Ker}(\langle H, \gamma^* \rangle) = {\gamma^*}^{-1}(\Delta^{\mathcal{B}/\theta}) = \Delta^{\mathcal{A}/\gamma^{-1}(\theta)}.$$

Thus, $\{\langle H, \gamma^* \rangle : \mathcal{A}/\gamma^{-1}(\theta) \to \mathcal{B}/\theta\}$ is a subdirect intersection and, since, by hypothesis, $\mathcal{B}/\theta \in \mathsf{K}$, $\mathcal{A}/\gamma^{-1}(\theta) \in \overset{\triangleleft}{\mathbb{IP}}(\mathsf{K}) \subseteq \mathsf{K}$. Therefore, $\gamma^{-1}(\theta) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$.

(b) By Lemma 26, $\gamma(\theta) \in \mathrm{ConSys}(\mathcal{B})$. Moreover, it is not difficult to see that

$$\langle H, \gamma^* \rangle : \mathcal{A}/\theta \to \mathcal{B}/\gamma(\theta),$$

defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\gamma^*_\Sigma(\phi/\theta_\Sigma) = \gamma_\Sigma(\phi)/\gamma_\Sigma(\theta_\Sigma)$$

is an isomorphism of $\mathbf{F}$-algebraic systems, since, by Lemma 25, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$,

$$\langle \phi, \psi \rangle \in \theta_\Sigma \quad \text{iff} \quad \langle \gamma_\Sigma(\phi), \gamma_\Sigma(\psi) \rangle \in \gamma_\Sigma(\theta_\Sigma).$$

Therefore, $\{\langle H,\gamma\rangle^{-1} : \mathcal{B}/\gamma(\theta) \to \mathcal{A}/\theta\}$ is a subdirect intersection. Since $\mathcal{A}/\theta \in \mathsf{K}$, it follows that $\mathcal{B}/\gamma(\theta) \in \overset{\triangleleft}{\amalg}(\mathsf{K}) \subseteq \mathsf{K}$. Therefore, $\gamma(\theta) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{B})$.

■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system, $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ be a collection of natural transformations in $N^\flat$ and $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ an $\mathbf{F}$-algebraic system. If $\tau^\flat$ is perceived as having a single distinguished argument, with the remaining arguments as parameters, we define, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, the sentence family

$$\tau^{\mathcal{A}}_\Sigma[\phi] = \{\tau^{\mathcal{A}}_{\Sigma,\Sigma'}[\phi]\}_{\Sigma'\in|\mathbf{Sign}|},$$

by setting, for all $\Sigma' \in |\mathbf{Sign}|$,

$$\tau^{\mathcal{A}}_{\Sigma,\Sigma'}[\phi] = \bigcup\{\tau^{\mathcal{A}}_{\Sigma'}(\mathrm{SEN}(f)(\phi), \vec{\chi}) : f \in \mathbf{Sign}(\Sigma,\Sigma'), \vec{\chi} \in \mathrm{SEN}(\Sigma')\}.$$

Given $\Phi \subseteq \mathrm{SEN}(\Sigma)$, we set

$$\tau^{\mathcal{A}}_\Sigma[\Phi] = \bigcup\{\tau^{\mathcal{A}}_\Sigma[\phi] : \phi \in \Phi\}$$

and, given a sentence family $X \in \mathrm{SenFam}(\mathcal{A})$, we set

$$\tau^{\mathcal{A}}[X] = \bigcup\{\tau^{\mathcal{A}}_\Sigma[X_\Sigma] : \Sigma \in |\mathbf{Sign}|\}.$$

We will revisit these and similar definitions in more depth in Section 2.13. For now, we only use them to establish a result that involves the relative congruence system operator Θ^{K}, introduced in this section, and direct images under morphisms of $\mathbf{F}$-algebraic systems with isomorphic functor components.

Proposition 34 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, with $\tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$ and K be a class of $\mathbf{F}$-algebraic systems, containing a trivial $\mathbf{F}$-algebraic system and such that $\overset{\triangleleft}{\amalg}(\mathsf{K}) \subseteq \mathsf{K}$. Let also $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G,\beta\rangle\rangle$ be $\mathbf{F}$-algebraic systems and $\langle H,\gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism, with H an isomorphism. Then, for all $X \in \mathrm{SenFam}(\mathcal{A})$,*

$$\Theta^{\mathsf{K},\mathcal{B}}(\gamma(\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X]))) = \Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]).$$

Proof: Taking into account the surjectivity of $\langle H,\gamma\rangle$, we have $\tau^{\mathcal{B}}[\gamma(X)] = \gamma(\tau^{\mathcal{A}}[X]) \leq \gamma(\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X]))$. Hence

$$\Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]) \leq \Theta^{\mathsf{K},\mathcal{B}}(\gamma(\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X]))).$$

On the other hand, $\gamma^{-1}(\Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]))$ is, by Proposition 33, a K-congruence system on $\mathcal{A}$, and, moreover, it contains $\tau^{\mathcal{A}}[X]$, since

$$\gamma(\tau^{\mathcal{A}}[X]) = \tau^{\mathcal{B}}[\gamma(X)] \leq \Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]).$$

Hence, $\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X]) \leq \gamma^{-1}(\Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]))$, i.e.,

$$\gamma(\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X])) \leq \Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)]).$$

This yields $\Theta^{\mathsf{K},\mathcal{B}}(\gamma(\Theta^{\mathsf{K},\mathcal{A}}(\tau^{\mathcal{A}}[X]))) \leq \Theta^{\mathsf{K},\mathcal{B}}(\tau^{\mathcal{B}}[\gamma(X)])$. ■

We conclude the section by showing that the relative congruence system generated by a family of pairs may be expressed as the join in the complete lattice of relative congruence systems of those relative congruence systems generated by the single pairs of elements in the generating family.

Proposition 35 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *be a class of* $\mathbf{F}$*-algebraic systems, containing a trivial* $\mathbf{F}$*-algebraic system and such that* $\overset{\triangleleft}{\mathbb{II}}(\mathsf{K}) \subseteq \mathsf{K}$*. For every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $X \in \mathrm{SenFam}(\mathcal{A}^2)$*,*

$$\Theta^{\mathsf{K},\mathcal{A}}(X) = \bigvee \{\Theta^{\mathsf{K},\mathcal{A}}(\phi, \psi) : \langle \phi, \psi \rangle \in X_\Sigma, \Sigma \in |\mathbf{Sign}|\}.$$

Proof: Set

$$\theta := \bigvee \{\Theta^{\mathsf{K},\mathcal{A}}(\phi, \psi) : \langle \phi, \psi \rangle \in X_\Sigma, \Sigma \in |\mathbf{Sign}|\}.$$

For all $\Sigma \in |\mathbf{Sign}|$ and all $\langle \phi, \psi \rangle \in X_\Sigma$, we have $\langle \phi, \psi \rangle \in \Theta^{\mathsf{K},\mathcal{A}}_\Sigma(X)$. So $\Theta^{\mathsf{K},\mathcal{A}}(\phi, \psi) \leq \Theta^{\mathsf{K},\mathcal{A}}(X)$ and, therefore, $\theta \leq \Theta^{\mathsf{K},\mathcal{A}}(X)$. Conversely, for all $\Sigma \in |\mathbf{Sign}|$ and all $\langle \phi, \psi \rangle \in X_\Sigma$, we have $\langle \phi, \psi \rangle \in \Theta^{\mathsf{K},\mathcal{A}}_\Sigma(\phi, \psi) \subseteq \theta_\Sigma$. Hence, $X \leq \theta$, which implies that $\Theta^{\mathsf{K},\mathcal{A}}(X) \leq \theta$. ■

2.5 Varieties of F-Algebraic Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system.

An **natural F-equation** (sometimes, referred to, simply, as **natural equation**, **F-equation** or just **equation**, if the meaning is made clear from context) is a pair $\langle \sigma^\flat, \tau^\flat \rangle$, where $\sigma^\flat, \tau^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ are natural transformations in $N^\flat$. The $\mathbf{F}$-equation $\langle \sigma^\flat, \tau^\flat \rangle$ will be denoted also by $\sigma^\flat \approx \tau^\flat$. Sometimes notation such as $\tau^\flat := \tau^{0\flat} \approx \tau^{1\flat}$ may also become handy. We denote by $\mathrm{NEq}(\mathbf{F})$ the collection of all natural $\mathbf{F}$-equations.

Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system. Then, given $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, we write $\mathcal{A} \vDash_\Sigma \sigma^\flat \approx \tau^\flat[\vec{\phi}]$ and say that $\vec{\phi}$ **Σ-satisfies** $\sigma^\flat \approx \tau^\flat$ **in** $\mathcal{A}$ if

$$\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})).$$

The following is a useful lemma concerning satisfiability of an equation.

Lemma 36 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\sigma^\flat \approx \tau^\flat$ *a natural* $\mathbf{F}$*-equation and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. The following statements are equivalent:*

(a) $\mathcal{A} \vDash_\Sigma \sigma^\flat \approx \tau^\flat[\vec{\phi}]$;

(b) $\sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) = \tau^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi}))$;

(c) *For all* $\Sigma' \in |\mathbf{Sign}^\flat|$, *all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))) = \alpha_{\Sigma'}(\tau^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))).$$

Proof:

(a)⇔(b) By the homomorphism property,

$$\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) \quad \text{and} \quad \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})) = \tau^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})).$$

So we get

$$\begin{array}{lll} \mathcal{A} \vDash_\Sigma \sigma^\flat \approx \tau^\flat[\vec{\phi}] & \text{iff} & \alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})) \\ & \text{iff} & \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) = \tau^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})). \end{array}$$

(c)⇒(a) This implication is trivial by taking $\Sigma' = \Sigma$ and $f = i_\Sigma$.

(b)⇒(c) We have

$$\begin{array}{l} \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) = \tau^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi})) \\ \text{implies} \quad \alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})) \\ \text{implies, for all } \Sigma' \in |\mathbf{Sign}^\flat| \text{ and all } f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \\ \qquad \mathrm{SEN}(F(f))(\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi}))) = \mathrm{SEN}(F(f))(\alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi}))) \\ \text{implies, for all } \Sigma' \in |\mathbf{Sign}^\flat| \text{ and all } f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \\ \qquad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\sigma^\flat_\Sigma(\vec{\phi}))) = \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\tau^\flat_\Sigma(\vec{\phi}))) \\ \text{implies, for all } \Sigma' \in |\mathbf{Sign}^\flat| \text{ and all } f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \\ \qquad \alpha_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))) = \alpha_{\Sigma'}(\tau^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))). \end{array}$$

■

Given a natural **F**-equation $\sigma^\flat \approx \tau^\flat$ and an **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ we write

$$\mathcal{A} \vDash \sigma^\flat \approx \tau^\flat$$

and say that $\mathcal{A}$ **satisfies** $\sigma^\flat \approx \tau^\flat$ or that $\sigma^\flat \approx \tau^\flat$ is **satisfied in** $\mathcal{A}$ or is **valid in** $\mathcal{A}$, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\mathcal{A} \vDash_\Sigma \sigma^\flat \approx \tau^\flat[\vec{\phi}]$.

Let K be a class of **F**-algebraic systems and $E^\flat$ a set of natural **F**-equations. We write $\mathsf{K} \vDash E^\flat$ for

$$\mathcal{A} \vDash \sigma^\flat \approx \tau^\flat, \text{ for all } \mathcal{A} \in \mathsf{K} \text{ and all } \sigma^\flat \approx \tau^\flat \in E^\flat.$$

Given an **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, we define the **kernel** $\mathrm{Ker}(\mathcal{A})$ **of** $\mathcal{A}$ to be the kernel of the morphism $\langle F, \alpha \rangle : \mathbf{F} \to \mathbf{A}$, i.e., we let

$$\mathrm{Ker}(\mathcal{A}) := \mathrm{Ker}(\langle F, \alpha \rangle).$$

Moreover, given a class K of $\mathbf{F}$-algebraic systems, we let

$$\mathrm{Ker}(\mathsf{K}) = \bigcap_{\mathcal{A}\in\mathsf{K}} \mathrm{Ker}(\mathcal{A}).$$

Now we are in a position to define two kinds of classes of $\mathbf{F}$-algebraic systems generated by a given class K of $\mathbf{F}$-algebraic systems. In other words, we introduce two class operators on classes of $\mathbf{F}$-algebraic systems.

Definition 37 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system and* K *be a class of* $\mathbf{F}$*-algebraic systems.*

- *The* **semantic variety** $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$ **generated by** K *is defined by*

$$\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{A})\};$$

- *The* **syntactic variety** $\mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$ **generated by** K *is defined by*

$$\mathbb{V}^{\mathsf{Syn}}(\mathsf{K}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\forall \sigma^\flat \approx \tau^\flat)(\mathsf{K} \vDash \sigma^\flat \approx \tau^\flat \;\Rightarrow\; \mathcal{A} \vDash \sigma^\flat \approx \tau^\flat)\}.$$

It is relatively easy to see that both $\mathbb{V}^{\mathsf{Sem}}$ and $\mathbb{V}^{\mathsf{Syn}}$ are closure operators on the class of $\mathbf{F}$-algebraic systems.

Proposition 38 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system. Then* $\mathbb{V}^{\mathsf{Sem}}$ *and* $\mathbb{V}^{\mathsf{Syn}}$ *are closure operators on* $\mathrm{AlgSys}(\mathbf{F})$*.*

Proof: We work, first, with $\mathbb{V}^{\mathsf{Sem}}$.

- If $\mathcal{A} \in \mathsf{K}$, then, by definition, we have $\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{A})$. Thus, $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. So $\mathsf{K} \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$.

- Suppose $\mathsf{K} \subseteq \mathsf{L}$ and $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Then we have

$$\mathrm{Ker}(\mathsf{L}) \le \mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{A}).$$

  So $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{L})$. Hence, if $\mathsf{K} \subseteq \mathsf{L}$ then $\mathbb{V}^{\mathsf{Sem}}(\mathrm{K}) \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathrm{L})$.

- Finally, suppose $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}))$. Then $\mathrm{Ker}(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})) \le \mathrm{Ker}(\mathcal{A})$. But, note that, for all $\mathcal{B} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, we have $\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathcal{B})$, whence $\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}))$. Combining the two inclusions, we get

$$\mathrm{Ker}(\mathsf{K}) \le \mathrm{Ker}(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})) \le \mathrm{Ker}(\mathcal{A}).$$

  Thus, $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. We conclude that $\mathbb{V}^{\mathsf{Sem}}(\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})) \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$.

We work, next, with $\mathbb{V}^{\mathsf{Syn}}$. Consider the two mappings

$$\begin{array}{c}\mathrm{NEq}:\mathcal{P}(\mathrm{AlgSys}(\mathbf{F}))\to\mathcal{P}(\mathrm{NEq}(\mathbf{F})),\\ \mathrm{NMod}:\mathcal{P}(\mathrm{NEq}(\mathbf{F}))\to\mathcal{P}(\mathrm{AlgSys}(\mathbf{F})),\end{array}$$

defined by

$$\begin{array}{rcl}\mathrm{NEq}(\mathsf{K}) & = & \{\sigma^\flat\approx\tau^\flat\in\mathrm{NEq}(\mathbf{F}):\mathsf{K}\vDash\sigma^\flat\approx\tau^\flat\},\quad \mathsf{K}\subseteq\mathrm{AlgSys}(\mathbf{F});\\ \mathrm{NMod}(E) & = & \{\mathcal{A}\in\mathrm{AlgSys}(\mathbf{F}):\mathcal{A}\vDash E\},\quad E\subseteq\mathrm{NEq}(\mathbf{F}).\end{array}$$

It is not difficult to see that NEq and NMod form a Galois connection. Thus, $\mathbb{V}^{\mathsf{Syn}}=\mathrm{NMod}\circ\mathrm{NEq}$ is a closure operator on $\mathrm{AlgSys}(\mathbf{F})$. ■

We prove that the semantic variety is always included in the syntactic variety generated by the same class of $\mathbf{F}$-algebraic systems.

Theorem 39 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be a base algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. Then*

$$\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})\subseteq\mathbb{V}^{\mathsf{Syn}}(\mathsf{K}).$$

Proof: Suppose that $\mathcal{A}\in\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Let $\sigma^\flat\approx\tau^\flat$ be a natural $\mathbf{F}$-equation, such that $\mathsf{K}\vDash\sigma^\flat\approx\tau^\flat$. We must show that $\mathcal{A}\vDash\sigma^\flat\approx\tau^\flat$. To this end, let $\Sigma\in|\mathbf{Sign}^\flat|$ and $\vec{\phi}\in\mathrm{SEN}^\flat(\Sigma)$. Since $\mathsf{K}\vDash\sigma^\flat\approx\tau^\flat$, we have, for all $\mathcal{K}=\langle\mathbf{K},\langle K,\kappa\rangle\rangle\in\mathsf{K}$,

$$\kappa_\Sigma(\sigma^\flat_\Sigma(\vec{\phi}))=\kappa_\Sigma(\tau^\flat_\Sigma(\vec{\phi})).$$

This means that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\tau^\flat_\Sigma(\vec{\phi})\rangle\in\mathrm{Ker}_\Sigma(\mathcal{K})$. Since this holds for all $\mathcal{K}\in\mathsf{K}$, we conclude that $\langle\sigma^\flat_\Sigma(\vec{\phi}),\tau^\flat_\Sigma(\vec{\phi})\rangle\in\mathrm{Ker}_\Sigma(\mathsf{K})$. But, by hypothesis, $\mathrm{Ker}(\mathsf{K})\leq\mathrm{Ker}(\mathcal{A})$. Therefore, we get $\langle\sigma^\flat_\Sigma(\vec{\phi}),\tau^\flat_\Sigma(\vec{\phi})\rangle\in\mathrm{Ker}_\Sigma(\mathcal{A})$. This means that

$$\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi}))=\alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})).$$

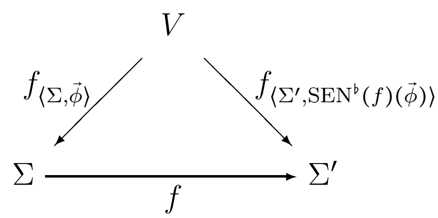
Since $\Sigma\in|\mathbf{Sign}^\flat|$ and $\vec{\phi}\in\mathrm{SEN}^\flat(\Sigma)$ were arbitrary, we get that $\mathcal{A}\vDash\sigma^\flat\approx\tau^\flat$. Now we conclude that $\mathcal{A}\in\mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$. Thus, $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K})\subseteq\mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$. ■

Now we look at some sufficient conditions that ensure that these two variety operators generate the same class of $\mathbf{F}$-algebraic systems. However, the terminology, methodology and work presented in the rest of the section have proven very useful in many contexts and can be used to reconcile results that hold in more restricted contexts with partial analogs that hold in this very abstract setting.

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be a base algebraic system and consider a cardinal κ (which will usually be taken to be either finite or ω). A **source signature κ-variable pair** (**ssv**$^\kappa$ for short) $\langle V,\vec{v}\rangle$ consists of a signature $V\in|\mathbf{Sign}^\flat|$ and a vector $\vec{v}\in\mathrm{SEN}^\flat(V)^\kappa$, satisfying the following conditions:

1. For all $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^\kappa$, there exists $f_{\langle\Sigma,\vec{\phi}\rangle} \in \mathbf{Sign}^\flat(V,\Sigma)$, such that
$$\mathrm{SEN}^\flat(f_{\langle\Sigma,\vec{\phi}\rangle})(\vec{v}) = \vec{\phi};$$

2. For all $\Sigma,\Sigma' \in |\mathbf{Sign}^\flat|$, $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^\kappa$ and $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,



$$f \circ f_{\langle\Sigma,\vec{\phi}\rangle} = f_{\langle\Sigma',\mathrm{SEN}^\flat(f)(\vec{\phi})\rangle}.$$

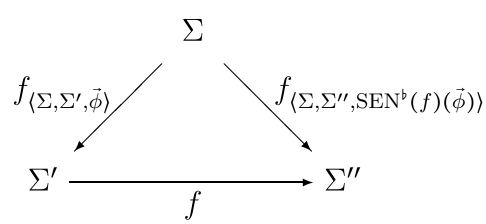
An algebraic system $\mathbf{F}$ is called κ-**term** if it has an ssv$^\kappa$. The morphisms $f_{\langle\Sigma,\vec{\phi}\rangle} : V \to \Sigma$ are referred to as the **ssv**$^\kappa$ **maps**.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system. We say that $\mathbf{F}$ **has** κ**-variables** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$, there exists $\vec{v}^\Sigma \in \mathrm{SEN}^\flat(\Sigma)^\kappa$, such that $\langle\Sigma,\vec{v}^\Sigma\rangle$ is an ssv$^\kappa$, with ssv$^\kappa$ maps $f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle} : \Sigma \to \Sigma'$, for all $\Sigma,\Sigma' \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')^\kappa$. The algebraic system $\mathbf{F}$ is called κ-**formulaic** if it has κ-variables.

It follows, according to the preceding definitions, that $\mathbf{F}$ is κ-formulaic, with Σ-κ-variables $\vec{v}^\Sigma$ and ssv$^\kappa$ maps $f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle}$ if:

- For all $\Sigma,\Sigma' \in |\mathbf{Sign}^\flat|$, $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')^\kappa$,
$$f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle}(\vec{v}^\Sigma) = \vec{\phi};$$

- For all $\Sigma,\Sigma',\Sigma'' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma',\Sigma'')$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')^\kappa$,



$$f \circ f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle} = f_{\langle\Sigma,\Sigma'',\mathrm{SEN}^\flat(f)(\vec{\phi})\rangle}.$$

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a κ-formulaic algebraic system, with κ-variables $\vec{v}^\Sigma$, $\Sigma \in |\mathbf{Sign}^\flat|$. $\mathbf{F}$ will be called κ-**transformational** (**modulo the given** κ**-variables**) if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, there exists $\sigma^{\langle\Sigma,\phi\rangle} : (\mathrm{SEN}^\flat)^\kappa \to \mathrm{SEN}^\flat$, such that:

- $\sigma^{\langle\Sigma,\phi\rangle}$ depends on only finitely may variables;

- $\phi = \sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma)$.

We have the following relation now that serves, so to speak, in bridging the gap between the semantical and syntactical definitions of varieties of algebraic systems.

Lemma 40 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a transformational algebraic system and* $\mathcal{A} = \langle\mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathcal{A}) \quad \textit{iff} \quad \mathcal{A} \vDash \sigma^{\langle\Sigma,\phi\rangle} \approx \sigma^{\langle\Sigma,\psi\rangle}.$$

Proof: Suppose, first, that $\mathcal{A} \vDash \sigma^{\langle\Sigma,\phi\rangle} \approx \sigma^{\langle\Sigma,\psi\rangle}$. This means that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\alpha_{\Sigma'}(\sigma^{\langle\Sigma,\phi\rangle}_{\Sigma'}(\vec{\phi})) = \alpha_{\Sigma'}(\sigma^{\langle\Sigma,\psi\rangle}_{\Sigma'}(\vec{\phi})).$$

Taking $\Sigma' = \Sigma$ and $\vec{\phi} = \vec{v}^\Sigma$, we get $\alpha_\Sigma(\sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma)) = \alpha_\Sigma(\sigma^{\langle\Sigma,\psi\rangle}_\Sigma(\vec{v}^\Sigma))$, or, what amounts to the same, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Hence, $\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathcal{A})$.

Suppose, conversely, that $\langle\phi,\psi\rangle \in \mathrm{Ker}_\Sigma(\mathcal{A})$. This means that $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Since $\mathbf{F}$ is assumed to be transformational, there exist $\sigma^{\langle\Sigma,\phi\rangle}$ and $\sigma^{\langle\Sigma,\psi\rangle}$ in $N^\flat$, such that $\sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma) = \phi$ and $\sigma^{\langle\Sigma,\psi\rangle}_\Sigma(\vec{v}^\Sigma) = \psi$. Thus, we get

$$\alpha_\Sigma(\sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma)) = \alpha_\Sigma(\sigma^{\langle\Sigma,\psi\rangle}_\Sigma(\vec{v}^\Sigma)).$$

Now, by formulaicity, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')$, we get an ssv$^\kappa$ map $f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle} : \Sigma \to \Sigma'$, for which we have

$$\mathrm{SEN}(F(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle}))(\alpha_\Sigma(\sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma))) = \mathrm{SEN}(F(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle}))(\alpha_\Sigma(\sigma^{\langle\Sigma,\psi\rangle}_\Sigma(\vec{v}^\Sigma))).$$

Hence, since α is a natural transformation,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle})(\sigma^{\langle\Sigma,\phi\rangle}_\Sigma(\vec{v}^\Sigma))) = \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle})(\sigma^{\langle\Sigma,\psi\rangle}_\Sigma(\vec{v}^\Sigma))).$$

And since $\sigma^{\langle\Sigma,\phi\rangle}$, $\sigma^{\langle\Sigma,\psi\rangle}$ are also natural transformations, we get

$$\alpha_{\Sigma'}(\sigma^{\langle\Sigma,\phi\rangle}_{\Sigma'}(\mathrm{SEN}^\flat(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle})(\vec{v}^\Sigma))) = \alpha_{\Sigma'}(\sigma^{\langle\Sigma,\psi\rangle}_{\Sigma'}(\mathrm{SEN}^\flat(f_{\langle\Sigma,\Sigma',\vec{\phi}\rangle})(\vec{v}^\Sigma))).$$

Finally, by the κ-variable property, we get

$$\alpha_{\Sigma'}(\sigma^{\langle\Sigma,\phi\rangle}_{\Sigma'}(\vec{\phi})) = \alpha_{\Sigma'}(\sigma^{\langle\Sigma,\psi\rangle}_{\Sigma'}(\vec{\phi})).$$

Since $\Sigma' \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma')$ were arbitrary, we conclude that $\mathcal{A} \vDash \sigma^{\langle\Sigma,\phi\rangle} \approx \sigma^{\langle\Sigma,\psi\rangle}$. ■

Now we are in a position to prove that, for algebraic systems over transformational base algebraic systems, the semantic and syntactic variety operators coincide.

Theorem 41 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a transformational algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. Then*

$$\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathbb{V}^{\mathsf{Syn}}(\mathsf{K}).$$

Proof: By Theorem 39, $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$ always holds. For the reverse inclusion, suppose that $\mathcal{A} \in \mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$. We must show that $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, i.e., that $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$. Then, by Lemma 40, $\mathsf{K} \vDash \sigma^{\langle \Sigma, \phi \rangle} \approx \sigma^{\langle \Sigma, \psi \rangle}$. Since $\mathcal{A} \in \mathbb{V}^{\mathsf{Syn}}(\mathsf{K})$, we get that $\mathcal{A} \vDash \sigma^{\langle \Sigma, \phi \rangle} \approx \sigma^{\langle \Sigma, \psi \rangle}$. Using Lemma 40 again, we infer that $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathcal{A})$. Thus, $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$. Hence, $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. ■

2.6 π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A **closure** (**operator**) **system** on $\mathbf{F}$ is a collection $C = \{C_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, such that

$$C_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$$

is a closure operator on $\mathrm{SEN}^\flat(\Sigma)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$, and, moreover, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\mathrm{SEN}^\flat(f)(C_\Sigma(\Phi)) \subseteq C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)).$$

This condition is often referred to as **structurality**.

A **π-institution** is a pair $\mathcal{I} = \langle \mathbf{F}, C \rangle$, where $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ is an algebraic system and C is a closure system on $\mathbf{F}$. We say that the π-institution $\mathcal{I}$ is **based on** the algebraic system $\mathbf{F}$. The following assumption is adopted throughout our treatise, unless explicitly stated otherwise:

> **Global Assumption**: If, for some $\Sigma \in |\mathbf{Sign}^\flat|$, $C_\Sigma(\varnothing) \neq \varnothing$, then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $C_\Sigma(\varnothing) \neq \varnothing$. (2.1)

The set of **Σ-theorems**, denoted $\mathrm{Thm}_\Sigma(\mathcal{I})$, is defined by

$$\mathrm{Thm}_\Sigma(\mathcal{I}) = C_\Sigma(\varnothing).$$

We then set $\mathrm{Thm}(\mathcal{I}) = \{\mathrm{Thm}_\Sigma(\mathcal{I})\}_{\Sigma \in |\mathbf{Sign}|}$. We denote by $\overline{\varnothing}$ the $|\mathbf{Sign}^\flat|$-indexed collection $\overline{\varnothing} = \{\varnothing\}_{\Sigma \in |\mathbf{Sign}^\flat|}$. The Global Assumption (2.1), adopted above, says that, if a π-institution has Σ-theorems, for some signature Σ, then it has Σ-theorems, for every signature Σ.

A **natural theorem of** $\mathcal{I}$ is a natural transformation

$$\top^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$$

in $N^\flat$, for some $k \geq 0$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$,

$$\top^\flat_\Sigma(\vec{\phi}) \in \mathrm{Thm}_\Sigma(\mathcal{I}).$$

That is, a natural theorem of $\mathcal{I}$ is a natural transformation in $N^\flat$ all of whose values are theorems. We denote by $\mathrm{NThm}(\mathcal{I})$ the collection of all natural theorems of a π-institution $\mathcal{I}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution, based on $\mathbf{F}$, and $\Sigma \in |\mathbf{Sign}^\flat|$. A subset $T_\Sigma \subseteq \mathrm{SEN}^\flat(\Sigma)$ is called a **Σ-theory** if

$$C_\Sigma(T_\Sigma) = T_\Sigma.$$

We use $\mathrm{Th}_\Sigma(\mathcal{I})$ to denote the collection of all Σ-theories of the π-institution $\mathcal{I}$. A **theory family** of $\mathcal{I}$ is a sentence family $T = \{T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of $\mathbf{F}$, such that $T_\Sigma \in \mathrm{Th}_\Sigma(\mathcal{I})$, for all $\Sigma \in |\mathbf{Sign}^\flat|$. The collection of all theory families of $\mathcal{I}$ will be denoted by $\mathrm{ThFam}(\mathcal{I})$. Ordered by signature-wise inclusion $\leq$, it forms a complete lattice, denoted $\mathbf{ThFam}(\mathcal{I}) = \langle \mathrm{ThFam}(\mathcal{I}), \leq \rangle$.

A theory family of $\mathcal{I}$ is called a **theory system** of $\mathcal{I}$ if it is a sentence system, i.e., if it is invariant under signature morphisms. We denote by $\mathrm{ThSys}(\mathcal{I})$, the collection of all theory systems of $\mathcal{I}$. This collection forms a complete sublattice $\mathbf{ThSys}(\mathcal{I}) = \langle \mathrm{ThSys}(\mathcal{I}), \leq \rangle$ of the complete lattice $\mathbf{ThFam}(\mathcal{I})$.

Note that the minimum element of both $\mathbf{ThFam}(\mathcal{I})$ and $\mathbf{ThSys}(\mathcal{I})$ is $\mathrm{Thm}(\mathcal{I})$, the **theorem system** of $\mathcal{I}$, and the maximum element is

$$\mathrm{SEN}^\flat = \{\mathrm{SEN}^\flat(\Sigma)\}_{\Sigma \in |\mathbf{Sign}^\flat|}.$$

Thus, $\mathrm{SEN}^\flat$ is used to denote both the sentence functor of the base algebraic system $\mathbf{F}$ of the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and the maximum theory family (system) $\mathrm{SEN}^\flat = \{\mathrm{SEN}^\flat(\Sigma)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of $\mathcal{I}$. This overloading will not, hopefully, cause any confusion, since the context can be used to clarify the meaning.

Proposition 42 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution and $T \in \mathrm{ThFam}(\mathcal{I})$. Then $\overleftarrow{T}$ is the largest theory system of $\mathcal{I}$ included in T.*

Proof: Since, by Proposition 2, $\overleftarrow{T}$ is the largest sentence system included in T, it suffices to show that $\overleftarrow{T}$ is a theory system. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\overleftarrow{T}_\Sigma)$. We must show that $\phi \in \overleftarrow{T}_\Sigma$. So let $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then we have

$$\begin{array}{lll}\mathrm{SEN}^\flat(f)(\phi) & \in & \mathrm{SEN}(f)(C_\Sigma(\overleftarrow{T}_\Sigma)) \quad \text{(hypothesis)}\\ & \subseteq & C_{\Sigma'}(\mathrm{SEN}(f)(\overleftarrow{T}_\Sigma)) \quad \text{(structurality)}\\ & \subseteq & C_{\Sigma'}(T_{\Sigma'}) \quad (\text{definition of } \overleftarrow{T})\\ & = & T_{\Sigma'} \quad (T \in \mathrm{ThFam}(\mathcal{I})).\end{array}$$

We now conclude, by the definition of $\overleftarrow{T}$, that $\phi \in \overleftarrow{T}_\Sigma$. ■

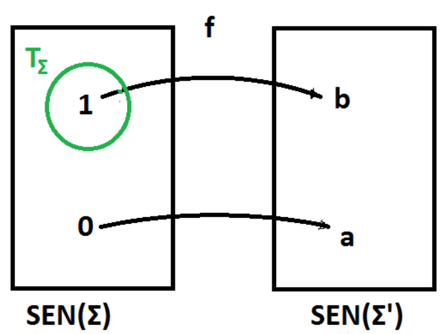
On the negative side, it is not true, in general, that, given a theory family T of a π-institution $\mathcal{I}$, the least sentence system $\overrightarrow{T}$, containing T, is a theory system. We show that this is the case via an example.

Example 43 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *consists of two signatures* Σ *and* Σ' *and the only (non-identity) morphism is* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign} \to \mathbf{Set}$ *is defined by setting*

$$\mathrm{SEN}^\flat(\Sigma) = \{0,1\}, \quad \mathrm{SEN}^\flat(\Sigma') = \{a,b\}$$

  and $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *consists of only the projection natural transformations.*



Consider the closure system C *on* $\mathbf{F}$ *defined by setting*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a,b\}\}$$

and let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the associated* π*-institution.*

Finally, take $T = \{T_\Sigma, T_{\Sigma'}\} \in \mathrm{ThFam}(\mathcal{I})$ *to be the theory family specified by*

$$T_\Sigma = \{1\} \quad \textit{and} \quad T_{\Sigma'} = \varnothing.$$

Then we have

$$\overrightarrow{T}_\Sigma = \{1\} \quad \textit{and} \quad \overrightarrow{T}_{\Sigma'} = \{b\}.$$

Since clearly

$$C_{\Sigma'}(\overrightarrow{T}_{\Sigma'}) = C_{\Sigma'}(\{b\}) = \{a,b\} \neq \overrightarrow{T}_{\Sigma'},$$

it follows that $\overrightarrow{T}$ *is not a theory system of* $\mathcal{I}$*.*

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define two operators

$$\begin{array}{rlcl} C: & \mathrm{SenFam}(\mathbf{F}) & \to & \mathrm{ThFam}(\mathcal{I}); \\ \overrightarrow{C}: & \mathrm{SenFam}(\mathbf{F}) & \to & \mathrm{ThSys}(\mathcal{I}); \end{array}$$

as follows. Consider a sentence family $T \in \mathrm{SenFam}(\mathbf{F})$.

- $C(T) = \{C(T)_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$C(T)_\Sigma = C_\Sigma(T_\Sigma);$$
- $\overrightarrow{C}(T) = \{\overrightarrow{C}(T)_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\overrightarrow{C}(T)_\Sigma = C_\Sigma(\overrightarrow{T}_\Sigma).$$

It is clear that $C(T)$ is the smallest theory family of $\mathcal{I}$ containing T. We show in the next proposition that $\overrightarrow{C}(T)$ is the smallest theory system of $\mathcal{I}$ that contains the sentence family T. Note that this implies, in particular, that $\overrightarrow{C}(T)$ is the smallest theory system of $\mathcal{I}$ that contains a given theory family T of $\mathcal{I}$. Note, also, that $\overrightarrow{C}(T) = C(\overrightarrow{T})$ should not be confused with $\overrightarrow{C(T)}$, which, as shown in Example 43, may not be a theory family of $\mathcal{I}$.

Proposition 44 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution, based on $\mathbf{F}$, and $T \in \mathrm{SenFam}(\mathbf{F})$. Then $\overrightarrow{C}(T)$ is the smallest theory system of $\mathcal{I}$ that includes T.*

Proof: It is clear by the definition that $\overrightarrow{C}(T) = C(\overrightarrow{T}) \in \mathrm{ThFam}(\mathcal{I})$. We show that it is a theory system. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\overrightarrow{T}_\Sigma)$. Consider $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then we have

$$\begin{array}{rcll} \mathrm{SEN}^\flat(f)(\phi) & \in & \mathrm{SEN}^\flat(f)(C_\Sigma(\overrightarrow{T}_\Sigma)) & (\text{definition of } \overrightarrow{C}(T)) \\ & \subseteq & C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\overrightarrow{T}_\Sigma)) & (\text{structurality}) \\ & \subseteq & C_{\Sigma'}(\overrightarrow{T}_{\Sigma'}) & (\text{definition of } \overrightarrow{T}) \\ & = & \overrightarrow{C}(T)_{\Sigma'} & (\text{definition of } \overrightarrow{C}(T)). \end{array}$$

It remains to show that $C(\overrightarrow{T})$ is the smallest theory system containing T. To this end, let $T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$. Since, by Proposition 2, $\overrightarrow{T}$ is the least sentence system containing T, we get $\overrightarrow{T} \leq T'$. Therefore, since $C(\overrightarrow{T})$ is the least theory family containing $\overrightarrow{T}$, $C(\overrightarrow{T}) \leq T'$. Thus, we conclude that $\overrightarrow{C}(T) = C(\overrightarrow{T}) \leq T'$ and $\overrightarrow{C}(T)$ is the least theory system of $\mathcal{I}$ that includes T. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is:

- **inconsistent** if $\mathrm{ThFam}(\mathcal{I}) = \{\mathrm{SEN}^\flat\}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$C_\Sigma(\varnothing) = \mathrm{SEN}^\flat(\Sigma);$$
- **almost inconsistent** if
$$\mathrm{ThFam}(\mathcal{I}) = \{T : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma = \varnothing \text{ or } T_\Sigma = \mathrm{SEN}^\flat(\Sigma))\};$$
- **trivial** if it is either inconsistent or almost inconsistent.

Lemma 45 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is trivial if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\psi \in C_\Sigma(\phi)$.*

Proof: Suppose, first, that $\mathcal{I}$ is trivial and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$. Since $\phi \in C_\Sigma(\phi)$, we have $C_\Sigma(\phi) \neq \varnothing$, which implies that $C_\Sigma(\phi) = \mathrm{SEN}^\flat(\Sigma)$. Therefore, $\psi \in C_\Sigma(\phi)$.

Suppose, conversely, that the given condition holds. Let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$, such that $T_\Sigma \neq \varnothing$. Then, there exists $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. But then, by hypothesis, for all $\psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\psi \in C_\Sigma(\phi) \subseteq C_\Sigma(T_\Sigma) = T_\Sigma.$$
Therefore, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = \varnothing$ or $T_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, showing that T is almost inconsistent. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system. We can order π-institutions based on $\mathbf{F}$ by comparing their closure systems. Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and $\mathcal{I}' = \langle \mathbf{F}, C'\rangle$ two π-institutions based on $\mathbf{F}$. We say that $\mathcal{I}'$ is an **extension** of $\mathcal{I}$ and that $\mathcal{I}$ is **weaker** than $\mathcal{I}'$, written $\mathcal{I} \leq \mathcal{I}'$ (or $C \leq C'$) if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,
$$C_\Sigma(\Phi) \subseteq C'_\Sigma(\Phi).$$
Given a collection $\mathcal{I}^i = \langle \mathbf{F}, C^i\rangle$, $i \in I$, of π-institutions based on the same algebraic system $\mathbf{F}$, the **intersection** $\bigcap_{i\in I} \mathcal{I}^i = \langle \mathbf{F}, \bigcap_{i\in I} C^i\rangle$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,
$$(\bigcap_{i\in I} C^i)_\Sigma(\Phi) = \bigcap_{i\in I} C^i_\Sigma(\Phi).$$
It can be shown that $\bigcap_{i\in I} C^i$ is a closure system on $\mathbf{F}$ and that it forms the meet with respect to the $\leq$ order of the closure systems C^i, $i \in I$, on $\mathbf{F}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution. Given a theory system $T \in \mathrm{ThSys}(\mathcal{I})$, we define the family $C^T = \{C^T_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ of operators $C^T_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,
$$C^T_\Sigma(\Phi) = C_\Sigma(T_\Sigma \cup \Phi).$$
We show that C^T is a closure system on $\mathbf{F}$.

Proposition 46 *Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution and $T \in \mathrm{ThSys}(\mathcal{I})$. Then C^T is a closure system on $\mathbf{F}$.*

Proof: We must first show that $C^T_\Sigma : \mathcal{P}(\mathrm{SEN}^\flat(\Sigma)) \to \mathcal{P}(\mathrm{SEN}^\flat(\Sigma))$ is a closure operator. That it is inflationary and monotone follows directly from the corresponding properties of C_Σ. To see that it is idempotent, let $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{rcl} C^T_\Sigma(C^T_\Sigma(\Phi)) & = & C_\Sigma(T_\Sigma \cup C_\Sigma(T_\Sigma \cup \Phi)) \quad \text{(by definition)} \\ & = & C_\Sigma(C_\Sigma(T_\Sigma \cup \Phi)) \quad (\text{since } T_\Sigma \subseteq C_\Sigma(T_\Sigma \cup \Phi)) \\ & = & C_\Sigma(T_\Sigma \cup \Phi) \quad (\text{idempotency of } C) \\ & = & C^T_\Sigma(\Phi) \quad \text{(by definition).} \end{array}$$

Finally, we must show that C^T is structural. To this end, let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$. We have

$$\begin{array}{rcl} \mathrm{SEN}^\flat(f)(C^T_\Sigma(\Phi)) & = & \mathrm{SEN}^\flat(f)(C_\Sigma(T_\Sigma \cup \Phi)) \quad \text{(by definition)} \\ & \subseteq & C_{\Sigma'}(\mathrm{SEN}^\flat(f)(T_\Sigma) \cup \mathrm{SEN}^\flat(f)(\Phi)) \\ & & \qquad\qquad (\text{by the structurality of } C) \\ & \subseteq & C_{\Sigma'}(T_{\Sigma'} \cup \mathrm{SEN}^\flat(f)(\Phi)) \quad (T \in \mathrm{ThSys}(\mathcal{I})) \\ & = & C^T_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \quad \text{(by definition).} \end{array}$$

We conclude that $C^T = \{C^T_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ is a closure system on $\mathbf{F}$. ■

Since C^T is a closure system on $\mathbf{F}$, we get, by definition, that the structure $\langle \mathbf{F}, C^T\rangle$ is a π-institution. We use the notation $\mathcal{I}^T = \langle \mathbf{F}, C^T\rangle$ to denote this π-institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. An $\mathcal{I}$-**logical morphism** (or simply **logical morphism** if $\mathcal{I}$ is clear from context) is a morphism $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{F}$, such that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha_\Sigma(C_\Sigma(\Phi)) \subseteq C_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

More generally, let $\mathbf{F} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and $\mathbf{F}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be two algebraic systems and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ be π-institutions based on $\mathbf{F}$ and $\mathbf{F}'$, respectively. A **logical morphism** $\langle F, \alpha\rangle : \mathcal{I} \to \mathcal{I}'$ is an algebraic system morphism $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{F}'$, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathrm{SEN}(\Sigma)$,

$$\alpha_\Sigma(C_\Sigma(\Phi)) \subseteq C_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

The following lemma characterizes logical morphisms:

Lemma 47 *Let $\mathbf{F} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, $\mathbf{F}' = \langle \mathbf{Sign}', \mathrm{SEN}', N'\rangle$ be two algebraic systems and $\mathcal{I} = \langle \mathbf{F}, C\rangle$, $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ be π-institutions, based on $\mathbf{F}$, $\mathbf{F}'$, respectively. Suppose $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{F}$ is an algebraic system morphism. Then the following conditions are equivalent:*

(a) $\langle F,\alpha\rangle : \mathcal{I} \to \mathcal{I}'$ *is a logical morphism;*

(b) For all $\Sigma \in |\mathbf{Sign}|$ *and all* $\Psi \subseteq \mathrm{SEN}'(F(\Sigma))$,

$$C_\Sigma(\alpha_\Sigma^{-1}(\Psi)) \leq \alpha_\Sigma^{-1}(C'_{F(\Sigma)}(\Psi));$$

(c) For all $T' \in \mathrm{ThFam}(\mathcal{I}')$, $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$.

Proof:

(a)⇒(b) Let $\Sigma \in |\mathbf{Sign}|$ and $\Psi \subseteq \mathrm{SEN}'(F(\Sigma))$. Then, we have

$$\begin{array}{rcll}\alpha_\Sigma(C_\Sigma(\alpha_\Sigma^{-1}(\Psi))) & \subseteq & C_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(\Psi))) & \text{(hypothesis)}\\ & \subseteq & C_{F(\Sigma)}(\Psi). & \text{(set theory)}\end{array}$$

We conclude that $C_\Sigma(\alpha_\Sigma^{-1}(\Psi)) \subseteq \alpha_\Sigma^{-1}(C_{F(\Sigma)}(\Psi))$.

(b)⇒(c) Suppose that $T' \in \mathrm{ThFam}(\mathcal{I}')$. Then we have

$$\begin{array}{rcll}C(\alpha^{-1}(T')) & \leq & \alpha^{-1}(C'(T')) & \text{(hypothesis)}\\ & = & \alpha^{-1}(T'). & (T' \in \mathrm{ThFam}(\mathcal{I}'))\end{array}$$

Therefore, $\alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$.

(c)⇒(a) Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \subseteq \mathrm{SEN}(\Sigma)$. Then, we have, for all $T \in \mathrm{ThFam}(\mathcal{I}')$,

$$\begin{array}{rcll}\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)} & \text{iff} & \Phi \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}) & \text{(set theory)}\\ & \text{implies} & C_\Sigma(\Phi) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}) & \text{(hypothesis)}\\ & \text{iff} & \alpha_\Sigma(C_\Sigma(\Phi)) \subseteq T_{F(\Sigma)}. & \text{(set theory)}\end{array}$$

Since $T \in \mathrm{ThFam}(\mathcal{I}')$ was arbitrary, we get that

$$\alpha_\Sigma(C_\Sigma(\Phi)) \subseteq C'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

So $\langle F,\alpha\rangle$ is a logical morphism.

■

In the special case of $\mathcal{I}$-logical morphisms, we obtain the following

Corollary 48 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution, based on* $\mathbf{F}$*, and* $\langle F,\alpha\rangle : \mathbf{F} \to \mathbf{F}$ *an algebraic system morphism. Then* $\langle F,\alpha\rangle$ *is an* $\mathcal{I}$*-logical morphism if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$.

Proof: Directly from Lemma 47. ■

2.7 Matrix Families and Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. An **F-matrix family** is a pair $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{SenFam}(\mathcal{A})$. The collection of all $\mathbf{F}$-matrix families is denoted by $\mathrm{MatFam}(\mathbf{F})$. An **F-matrix system** is an $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, such that $T \in \mathrm{SenSys}(\mathcal{A})$. The collection of all $\mathbf{F}$-matrix systems is denoted by $\mathrm{MatSys}(\mathbf{F})$.

An $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ defines a closure system $C^\mathfrak{A} = \{C^\mathfrak{A}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ on $\mathbf{F}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{l} \phi \in C^\mathfrak{A}_\Sigma(\Phi) \text{ if and only if, for all } \Sigma' \in |\mathbf{Sign}^\flat| \text{ and all } f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \\ \qquad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')} \text{ imlpies } \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}. \end{array}$$

Let, now, M be a class of $\mathbf{F}$-matrix families. We denote by

$$C^\mathsf{M} = \{C^\mathsf{M}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$$

the closure system on $\mathbf{F}$ that is the signature-wise intersection of the closure systems $C^\mathfrak{A}$, $\mathfrak{A} \in \mathsf{M}$, i.e.,

$$C^\mathsf{M} = \bigcap_{\mathfrak{A} \in \mathsf{M}} C^\mathfrak{A}.$$

We use the notation $\mathcal{I}^\mathsf{M} = \langle \mathbf{F}, C^\mathsf{M} \rangle$ to denote the associated π-institution based on $\mathbf{F}$.

We give a characterization of the closure system C^M on $\mathbf{F}$ generated by a class M of matrix families which shows how that closure system is constructed using the generating matrix families.

Proposition 49 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and M a class of $\mathbf{F}$-matrix families. Then $\mathcal{C}^\mathsf{M}$ is the least closure system on $\mathbf{F}$ containing the family*

$$\mathcal{T} = \{\alpha^{-1}(T) : \mathfrak{A} = \langle \langle \mathbf{A}, \langle F, \alpha \rangle \rangle, T \rangle \in \mathsf{M}\}.$$

Proof: First we show that $\mathcal{T} \subseteq \mathcal{C}^\mathsf{M}$. To this end, let $\mathfrak{A} = \langle \langle \mathbf{A}, \langle F, \alpha \rangle \rangle, T \rangle \in \mathsf{M}$. We must show that $\alpha^{-1}(T) \in \mathcal{C}^\mathsf{M}$. Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C^\mathsf{M}_\Sigma(\alpha^{-1}_\Sigma(T_{F(\Sigma)}))$. Then, by the definition of C^M and the fact that $\mathfrak{A} \in \mathsf{M}$, we get

$$\alpha_\Sigma(\alpha^{-1}_\Sigma(T_{F(\Sigma)})) \subseteq T_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)}.$$

Note, however, that the antecedent of the displayed implication always holds. So the consequent $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ holds. Hence, $\phi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$. Therefore, $C^\mathsf{M}(\alpha^{-1}(T)) \leq \alpha^{-1}(T)$, showing that $\alpha^{-1}(T) \in \mathcal{C}^\mathsf{M}$.

Next, we show that, if $\mathcal{C}$ is a closure system on $\mathbf{F}$, such that $\mathcal{T} \subseteq \mathcal{C}$, then $\mathcal{C}^\mathsf{M} \subseteq \mathcal{C}$. Equivalently, it suffices to show that $C \leq C^\mathsf{M}$. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. Since $\mathcal{C}$ is a closure system on $\mathbf{F}$, we get, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\mathrm{SEN}^\flat(f)(\phi) \in C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$. Thus, since $\mathcal{T} \subseteq \mathcal{C}$, we get, for all $\langle\mathcal{A},T\rangle \in \mathsf{M}$, with $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$,

$$\mathrm{SEN}^\flat(f)(\Phi) \subseteq \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}) \quad \text{implies} \quad \mathrm{SEN}^\flat(f)(\phi) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}),$$

i.e., for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}.$$

Hence, for all $\mathfrak{A} = \langle\mathcal{A},T\rangle \in \mathsf{M}$, $\phi \in C_\Sigma^{\mathfrak{A}}(\Phi)$. We conclude that $\phi \in C_\Sigma^{\mathsf{M}}(\Phi)$. Therefore, $C \leq C^{\mathsf{M}}$, as was to be shown. ∎

Let again $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ be a π-institution based on $\mathbf{F}$. Let $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system, with $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$. A sentence family $T \in \mathrm{SenFam}(\mathcal{A})$ is called an **$\mathcal{I}$-filter family** and the $\mathbf{F}$-matrix family $\mathfrak{A} = \langle\mathcal{A},T\rangle$ an **$\mathcal{I}$-matrix family** if

$$C \leq C^{\mathfrak{A}}.$$

If T happens to be a sentence system, then we refer to T as an **$\mathcal{I}$-filter system** and to $\mathfrak{A} = \langle\mathcal{A},T\rangle$ as an **$\mathcal{I}$-matrix system**.

We have the following simpler characterization of $\mathcal{I}$-filter families, which follows from the structurality of the closure system of a π-institution.

Lemma 50 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system, with $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$, and $T \in \mathrm{SenFam}(\mathcal{A})$. T is an $\mathcal{I}$-filter family if and only if, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$,*

$$\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)} \quad \textit{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)}.$$

Proof: Suppose, first, that T is an $\mathcal{I}$-filter family and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Since T is an $\mathcal{I}$-filter family, $C \leq C^{\langle\mathcal{A},T\rangle}$. Therefore, by taking in the definition of $C^{\langle\mathcal{A},C\rangle}$, $\Sigma' = \Sigma$ and $f : \Sigma \to \Sigma$ to be the identity morphism, we get that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$.

Suppose, conversely, that the given condition holds and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. Consider $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, such that $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}$. Note, that, by structurality, $\mathrm{SEN}^\flat(f)(\phi) \in C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$. Therefore, by the assumption and the hypothesis, $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}$. We conclude that T is an $\mathcal{I}$-filter family. ∎

The next lemma shows that the inverse image under an interpretation of an $\mathcal{I}$-filter family or system is a theory family or system, respectively, of $\mathcal{I}$. Moreover this property also characterizes $\mathcal{I}$-filter families/systems.

Lemma 51 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *be an* $\mathbf{F}$*-algebraic system.*

(a) $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *if and only if* $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$*;*

(b) $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *if and only if* $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$*.*

Proof:

(a) Suppose, first, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We must show that $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. To this end, suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)}))$. Since $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have, by definition,

$$\alpha_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)})) \subseteq T_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)}.$$

But the hypothesis of this implication holds, whence the conclusion is also true and we get $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ or, equivalently, $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Thus $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$.

Suppose, conversely, that $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. To show that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, and assume that $\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)}$. Then, we have $\Phi \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since $\phi \in C_\Sigma(\Phi)$ and $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ or, equivalently, $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$. This proves, by Lemma 50, that $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(b) This follows from Part (a) and from Part (a) of Lemma 6.

■

We denote by $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and by $\mathrm{MatFam}(\mathcal{I})$, respectively, the collection of all $\mathcal{I}$-filter families on $\mathcal{A}$ and the collection of all $\mathcal{I}$-matrix families. Note that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is a complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) = \langle \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$, with the order $\leq$ inherited by the corresponding order on sentence families.

Similarly, we denote by $\mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ and by $\mathrm{MatSys}(\mathcal{I})$, respectively, the collection of all $\mathcal{I}$-filter systems on $\mathcal{A}$ and the collection of all $\mathcal{I}$-matrix systems. Note that $\mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ forms a complete lattice

$$\mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) = \langle \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle,$$

which is a complete sublattice of the complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Moreover, given a $\mathbf{F}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we say that T' is a **sentence family of** $\mathfrak{A}$, written $T' \in \mathrm{SenFam}(\mathfrak{A})$, if $T \leq T'$. Similarly, given an $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we say that $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ is an $\mathcal{I}$-**filter family of** $\mathfrak{A}$, written $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$, if $T \leq T'$.

Since $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathbf{FiSys}^{\mathcal{I}}(\mathcal{A})$ are both complete lattices, it makes sense to define associated closure operators on $\mathrm{SenFam}(\mathcal{A})$.

- Denote by $C^{\mathcal{I},\mathcal{A}} : \mathrm{SenFam}(\mathcal{I}) \to \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ the operator that maps a given sentence family T of $\mathcal{A}$ to the least $\mathcal{I}$-filter family of $\mathcal{A}$ that includes T;

- Denote by $\overrightarrow{C}^{\mathcal{I},\mathcal{A}} : \mathrm{SenFam}(\mathcal{A}) \to \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ the operator that maps a given sentence family T of $\mathcal{A}$ to the least $\mathcal{I}$-theory system of $\mathcal{A}$ that includes T.

We look now at some relations between the pairs of operators $C^{\mathcal{I},\mathcal{A}}$, C on the one hand, and $\overrightarrow{C}^{\mathcal{I},\mathcal{A}}$, $\overrightarrow{C}$ on the other, established via the inverse interpretation α^{-1} of the $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$.

Proposition 52 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *be an* $\mathbf{F}$*-algebraic system. Then, for all* $T \in \mathrm{SenFam}(\mathcal{A})$*, we have:*

(a) $C(\alpha^{-1}(T)) \leq \alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(T))$*;*

(b) $\overrightarrow{C}(\alpha^{-1}(T)) \leq \alpha^{-1}(\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T))$.

Proof:

(a) Suppose $T \in \mathrm{SenFam}(\mathcal{A})$. We have $T \leq C^{\mathcal{I},\mathcal{A}}(T)$, whence $\alpha^{-1}(T) \leq \alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(T))$. By Lemma 51, $\alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(T))$ is a theory family of $\mathcal{I}$ and it includes $\alpha^{-1}(T)$. Therefore, by the definition of C, $C(\alpha^{-1}(T)) \leq \alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(T))$.

(b) We have $T \leq \overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T)$. Therefore, since, by Proposition 2, $\overrightarrow{T}$ is the least sentence system containing T, we get $\overrightarrow{T} \leq \overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T)$. Now, taking into account Lemma 6, we get $\overrightarrow{\alpha^{-1}(T)} = \alpha^{-1}(\overrightarrow{T}) \leq \alpha^{-1}(\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T))$. By Lemma 51, $\alpha^{-1}(\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T))$ is a theory system of $\mathcal{I}$ including $\overrightarrow{\alpha^{-1}(T)}$ and, therefore, $C(\overrightarrow{\alpha^{-1}(T)}) \leq \alpha^{-1}(\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T))$, i.e., $\overrightarrow{C}(\alpha^{-1}(T)) \leq \alpha^{-1}(\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T))$. ■

We now exhibit a relation between the closure operators $C^{\mathcal{I},\mathcal{A}}$ and $\overrightarrow{C}^{\mathcal{I},\mathcal{A}}$ and the arrow operators, as applied to $\mathcal{I}$-filter families on an $\mathbf{F}$-algebraic system $\mathcal{A}$.

Proposition 53 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution, based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*. Consider* $T \in \mathrm{SenFam}(\mathcal{A})$*. Then, we have:*

(a) If $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, then* $\overleftarrow{T} \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and it is the largest* $\mathcal{I}$*-filter system on* $\mathcal{A}$ *included in* T*;*

(b) $\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T) = \overrightarrow{C}^{\mathcal{I},\mathcal{A}}(\overrightarrow{T})$.

Proof:

(a) By Proposition 2, we know that $\overleftarrow{T}$ is a sentence system of $\mathcal{A}$ and that it is the largest one included in T. It suffices, thus, to show that $\overleftarrow{T}$ is an $\mathcal{I}$-filter system. To this end, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that

$$\phi \in C_\Sigma(\Phi) \quad \text{and} \quad \alpha_\Sigma(\Phi) \subseteq \overleftarrow{T}_{F(\Sigma)}.$$

Then, by definition of $\overleftarrow{T}$, we get that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$, $\mathrm{SEN}(F(f))(\alpha_\Sigma(\Phi)) \subseteq T_{F(\Sigma')}$. Since α is a natural transformation, $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \subseteq T_{F(\Sigma')}$. Since $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\phi \in C_\Sigma(\Phi)$, we get that $\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)) \in T_{F(\Sigma')}$. Therefore, $\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)) \in T_{F(\Sigma')}$. Now, noting that this holds for all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and that F is surjective, we conclude that $\alpha_\Sigma(\phi) \in \overleftarrow{T}_{F(\Sigma)}$. Therefore, we get that $\overleftarrow{T} \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$.

(b) The inclusion from left to right is clear, since $T \le \overrightarrow{T}$. On the other hand, since, by Proposition 2, $\overrightarrow{T}$ is the least sentence system including T, we have that every $\mathcal{I}$-filter system including T, also includes $\overrightarrow{T}$. Therefore,

$$\begin{array}{rcl}\overrightarrow{C}^{\mathcal{I},\mathcal{A}}(T) & = & \bigcap\{T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) : T \le T'\} \\ & = & \bigcap\{T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) : \overrightarrow{T} \le T'\} \\ & = & \overrightarrow{C}^{\mathcal{I},\mathcal{A}}(\overrightarrow{T}).\end{array}$$

■

We extend the definition of logical morphism to morphisms between $\mathbf{F}$-algebraic systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. An $\mathcal{I}$-**logical morphism** is a morphism

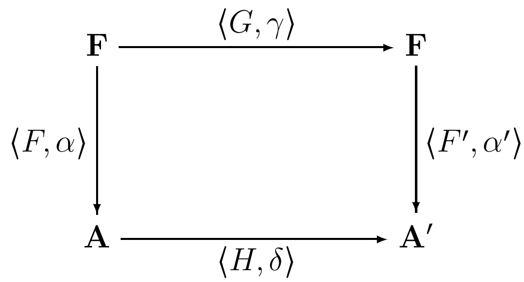
$$\langle\langle G,\gamma\rangle,\langle H,\delta\rangle\rangle : \mathcal{A} \to \mathcal{A}',$$

$$\begin{array}{ccc}\mathbf{F} & \xrightarrow{\langle G,\gamma\rangle} & \mathbf{F} \\ {\scriptstyle\langle F,\alpha\rangle}\downarrow & & \downarrow{\scriptstyle\langle F',\alpha'\rangle} \\ \mathbf{A} & \xrightarrow[\langle H,\delta\rangle]{} & \mathbf{A}'\end{array}$$

such that $\langle G,\gamma\rangle : \mathbf{F} \to \mathbf{F}$ is an $\mathcal{I}$-logical morphism $\langle G,\gamma\rangle : \mathcal{I} \to \mathcal{I}$.

Next, we prove a result relating $\mathcal{I}$-filter families/systems on algebraic systems related by morphisms. This result generalizes Lemma 51.

Proposition 54 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Consider two* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *and a logical morphism* $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$*.*



(a) If $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathbf{A}')$*, then* $\delta^{-1}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(b) If $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$ *is surjective and* $\delta^{-1}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, then* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$*;*

(c) If $\langle \langle G, \gamma \rangle, \langle H, \delta \rangle \rangle : \mathcal{A} \to \mathcal{A}'$ *is surjective, with* G, H *isomorphisms and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *is such that* $\delta^{-1}(\delta(T)) = T$*, then* $\delta(T) \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A}')$*.*

Proof:

(a) Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$. Then, by Lemma 51, $\alpha'^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Thus, by Corollary 48, $\gamma^{-1}(\alpha'^{-1}(T)) \in \mathrm{ThFam}(\mathcal{I})$. Therefore, by the commutativity of the rectangle, $\alpha^{-1}(\delta^{-1}(T)) \in \mathrm{ThFam}(\mathcal{I})$. So, again by Lemma 51, we get that $\delta^{-1}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(b) Because of the surjectivity of $\langle G, \gamma \rangle$ and Lemma 50, it suffices to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, we have

$$\alpha'_{G(\Sigma)}(\gamma_\Sigma(\Phi)) \subseteq T_{F'(G(\Sigma))} \quad \text{implies} \quad \alpha'_{G(\Sigma)}(\gamma_\Sigma(\phi)) \in T_{F'(G(\Sigma))}.$$

We have the following:

$$\begin{array}{ll} & \alpha'_{G(\Sigma)}(\gamma_\Sigma(\Phi)) \subseteq T_{F'(G(\Sigma))} \\ \Rightarrow & \delta_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \subseteq T_{H(F(\Sigma))} \\ \Rightarrow & \alpha_\Sigma(\Phi) \subseteq \delta^{-1}_{F(\Sigma)}(T_{H(F(\Sigma))}) \\ \Rightarrow & \alpha_\Sigma(\phi) \in \delta^{-1}_{F(\Sigma)}(T_{H(F(\Sigma))}) \\ \Rightarrow & \delta_{F(\Sigma)}(\alpha_\Sigma(\phi)) \in T_{H(F(\Sigma'))} \\ \Rightarrow & \alpha'_{G(\Sigma)}(\gamma_\Sigma(\phi)) \in T_{F'(G(\Sigma))}. \end{array}$$

(c) As in Part (b) because of the surjectivity of $\langle G, \gamma \rangle$ and Lemma 50, it suffices to show that for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, we have

$$\alpha'_{G(\Sigma)}(\gamma_\Sigma(\Phi)) \subseteq \delta_{F(\Sigma)}(T_{F(\Sigma)}) \quad \text{implies} \quad \alpha'_{G(\Sigma)}(\gamma_\Sigma(\phi)) \in \delta_{F(\Sigma)}(T_{F(\Sigma)}).$$

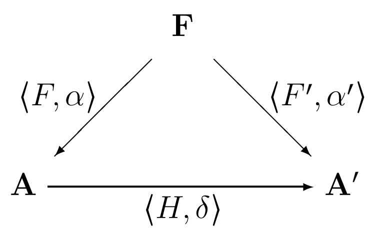
We have

$$
\begin{array}{ll}
& \alpha'_{G(\Sigma)}(\gamma_\Sigma(\Phi)) \subseteq \delta_{F(\Sigma)}(T_{F(\Sigma)}) \\
\Rightarrow & \delta_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \subseteq \delta_{F(\Sigma)}(T_{F(\Sigma)}) \\
\Rightarrow & \alpha_\Sigma(\Phi) \subseteq \delta^{-1}_{F(\Sigma)}(\delta_{F(\Sigma)}(T_{F(\Sigma)})) = T_{F(\Sigma)} \\
\Rightarrow & \alpha_\Sigma(\phi) \in \delta^{-1}_{F(\Sigma)}(\delta_{F(\Sigma)}(T_{F(\Sigma)})) \\
\Rightarrow & \delta_{F(\Sigma)}(\alpha_\Sigma(\phi)) \in \delta_{F(\Sigma)}(T_{F(\Sigma)}) \\
\Rightarrow & \alpha'_{G(\Sigma)}(\gamma_\Sigma(\phi)) \in \delta_{F(\Sigma)}(T_{F(\Sigma)}).
\end{array}
$$

■

This proposition has the following significant consequences.

Corollary 55 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Let, also,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and* $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ *be two* $\mathbf{F}$*-algebraic systems and* $\langle H, \delta \rangle : \mathcal{A} \to \mathcal{A}'$ *a (surjective) morphism (making the following diagram commute):*

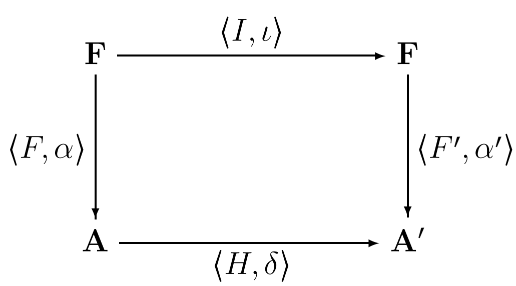


Consider $T \in \mathrm{SenFam}(\mathbf{A}')$.

(a) $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$ *iff* $\delta^{-1}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

(b) $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}')$ *iff* $\delta^{-1}(T) \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*.*

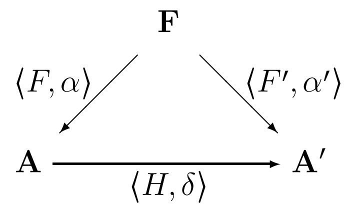
Proof: Follows immediately from Proposition 54 upon considering the commutative square,



where $\langle I, \iota \rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism. ■

Corollary 56 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Let, also,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and* $\mathcal{A}' =$

$\langle \mathbf{A}', \langle F', \alpha' \rangle\rangle$ *be two* $\mathbf{F}$*-algebraic systems and* $\langle H, \delta\rangle : \mathcal{A} \to \mathcal{A}'$ *a morphism, with* H *an isomorphism:*



Suppose $T \in \mathrm{SenFam}(\mathbf{A})$ *and* $\mathrm{Ker}(\langle H, \delta\rangle)$ *is compatible with* T*.*

(a) $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *iff* $\delta(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$*;*

(b) $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *iff* $\delta(T) \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}')$*.*

Proof: First we show that $\delta^{-1}(\delta(T)) = T$: The right to left inclusion is obvious. For the left to right inclusion, consider $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \delta_\Sigma^{-1}(\delta_\Sigma(T_\Sigma))$. Then, we have $\delta_\Sigma(\phi) \in \delta_\Sigma(T_\Sigma)$. Thus, there exists $\psi \in T_\Sigma$, such that $\delta_\Sigma(\phi) = \delta_\Sigma(\psi)$. By hypothesis, $\mathrm{Ker}(\langle H, \delta\rangle)$ is compatible with T. Therefore, $\phi \in T_\Sigma$. Thus, we get $\delta^{-1}(\delta(T)) \leq T$.

Now the conclusion follows from Proposition 54, since $\delta^{-1}(\delta(T)) = T$. ■

Corollary 57 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Let, also,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *be an* $\mathbf{F}$*-algebraic system and* $\theta \in \mathrm{ConSys}(\mathbf{A})$*. Consider* $T \in \mathrm{SenFam}(\mathbf{A}^\theta)$*.*

(a) $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)$ *iff* $\pi^{\theta^{-1}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*;*

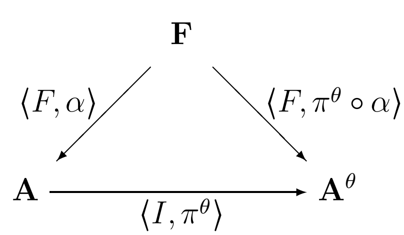
(b) $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}^\theta)$ *iff* $\pi^{\theta^{-1}}(T) \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*.*

On the other hand, if $T \in \mathrm{SenFam}(\mathbf{A})$ *and* θ *is compatible with* T*, then we have:*

(c) $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *iff* $\pi^\theta(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)$*;*

(d) $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *iff* $\pi^\theta(T) \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}^\theta)$*.*

Proof: Parts (a) and (b) follow immediately from Corollary 55 upon considering the commutative diagram



Parts (c) and (d) follow from Corollary 56 upon noticing that $I : \mathbf{Sign} \to \mathbf{Sign}$ is an isomorphism and that, by hypothesis, $\mathrm{Ker}(\langle I, \pi^\theta\rangle) = \theta$ is compatible with T. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$. Consider two $\mathcal{I}$-matrix families $\mathfrak{A} = \langle \mathcal{A}, T\rangle$ and $\mathfrak{A}' = \langle \mathcal{A}', T'\rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$. A morphism $\langle\langle G, \gamma\rangle, \langle H, \delta\rangle\rangle : \mathcal{A} \to \mathcal{A}'$, is called a **matrix family morphism** $\langle\langle G, \gamma\rangle, \langle H, \delta\rangle\rangle : \mathfrak{A} \to \mathfrak{A}'$ if, for all $\Sigma \in |\mathbf{Sign}|$,

$$\delta_\Sigma(T_\Sigma) \subseteq T'_{H(\Sigma)}.$$

This matrix family morphism is said to be **strict** if, for all $\Sigma \in |\mathbf{Sign}|$,

$$\delta_\Sigma(T_\Sigma) \subseteq T'_{H(\Sigma)} \quad \text{and} \quad \delta_\Sigma(\mathrm{SEN}(\Sigma)\backslash T_\Sigma) \subseteq \mathrm{SEN}'(H(\Sigma))\backslash T'_{H(\Sigma)}.$$

These conditions can be equivalently expressed by saying that, for all $\Sigma \in |\mathbf{Sign}|$,

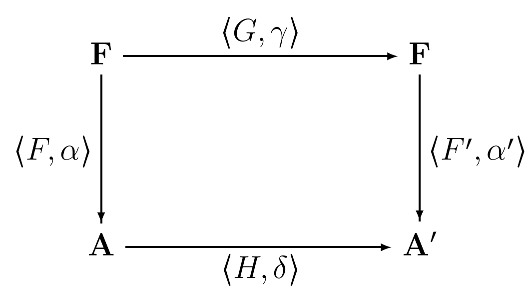
$$\delta_\Sigma^{-1}(T'_{H(\Sigma)}) = T_\Sigma.$$

They are also equivalent to the statement that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{if and only if} \quad \delta_\Sigma(\phi) \in T'_{H(\Sigma)}.$$

We have the following result relating strict morphisms between matrix families with strict morphisms between matrix families based on $\mathcal{F}$.

Lemma 58 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution, based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha'\rangle\rangle$ be two $\mathbf{F}$-algebraic systems and $\mathfrak{A} = \langle \mathcal{A}, T\rangle$ and $\mathfrak{A}' = \langle \mathcal{A}', T'\rangle$ two $\mathcal{I}$-matrix families. A matrix morphism $\langle\langle G, \gamma\rangle, \langle H, \delta\rangle\rangle : \mathfrak{A} \to \mathfrak{A}'$*



is strict if and only if $\langle G, \gamma\rangle : \langle \mathcal{F}, \alpha^{-1}(T)\rangle \to \langle \mathcal{F}, \alpha'^{-1}(T')\rangle$ is strict.

Proof: The statement follows by noticing that

$$\begin{array}{lll} \delta^{-1}(T') = T & \text{iff} & \alpha^{-1}(\delta^{-1}(T')) = \alpha^{-1}(T) \quad (\text{by the surjectivity of } \langle F, \alpha\rangle) \\ & \text{iff} & \gamma^{-1}(\alpha'^{-1}(T')) = \alpha^{-1}(T) \\ & & (\text{by the commutativity of the square}). \end{array}$$

Therefore $\langle\langle G,\gamma\rangle,\langle H,\delta\rangle\rangle : \mathfrak{A} \to \mathfrak{A}'$ is strict if and only if $\langle G,\gamma\rangle : \langle\mathcal{F},\alpha^{-1}(T)\rangle \to \langle\mathcal{F},\alpha'^{-1}(T')\rangle$ is strict. ■

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Given an $\mathbf{F}$-matrix family $\mathfrak{A} = \langle\mathcal{A}, T\rangle$, the **Leibniz reduction** of $\mathfrak{A}$, denoted $\mathfrak{A}^*$, is defined as

$$\mathfrak{A}^* = \langle\mathcal{A}^*, T^*\rangle = \langle\mathcal{A}^{\Omega^{\mathcal{A}}(T)}, T/\Omega^{\mathcal{A}}(T)\rangle,$$

where $\mathcal{A}^{\Omega^{\mathcal{A}}(T)}$ is the quotient $\mathbf{F}$-algebraic system of $\mathcal{A}$ by the congruence system $\Omega^{\mathcal{A}}(T)$ and $T/\Omega^{\mathcal{A}}(T) = \{T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|}$, with

$$T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T) = \{\phi/\Omega^{\mathcal{A}}_\Sigma(T) : \phi \in T_\Sigma\}.$$

An $\mathcal{I}$-matrix family $\mathfrak{A} = \langle\mathcal{A}, T\rangle$ is **Leibniz reduced** if

$$\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}.$$

An $\mathbf{F}$-algebraic system $\mathcal{A}$ is **Leibniz reduced** if it is the algebraic system reduct of a Leibniz reduced $\mathcal{I}$-matrix family.

We denote:

- the class of all Leibniz reduced $\mathcal{I}$-matrix families by $\mathrm{MatFam}^*(\mathcal{I})$;
- the class of all Leibniz reduced $\mathcal{I}$-matrix systems by $\mathrm{MatSys}^*(\mathcal{I})$;
- the class of all reduced $\mathbf{F}$-algebraic systems by $\mathrm{AlgSys}^*(\mathcal{I})$;
- the class of all system reduced $\mathbf{F}$-algebraic systems by $\mathrm{AlgSys}^\bullet(\mathcal{I})$;

i.e., we have:

$$\begin{array}{rcl}
\mathrm{MatFam}^*(\mathcal{I}) & = & \{\langle\mathcal{A},T\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \text{ and } \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}\};\\
\mathrm{MatSys}^*(\mathcal{I}) & = & \{\langle\mathcal{A},T\rangle : T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \text{ and } \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}\};\\
\mathrm{AlgSys}^*(\mathcal{I}) & = & \{\mathcal{A} : (\exists T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\};\\
\mathrm{AlgSys}^\bullet(\mathcal{I}) & = & \{\mathcal{A} : (\exists T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}.
\end{array}$$

2.8 Axiomatic and Filter Extensions

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle\mathbf{A}, \langle F,\alpha\rangle\rangle$ and an $\mathbf{F}$-matrix family $\mathfrak{A} = \langle\mathcal{A}, T\rangle$, we set

$$\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \{T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : T \leq T'\}.$$

$\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ is a complete sublattice of $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and we have $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ if and only if $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We call $\mathfrak{A}' = \langle\mathcal{A}, T'\rangle$ a **filter extension of**

$\mathfrak{A}$ if $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$. Sometimes, by slightly abusing notation, we write $\mathfrak{A}' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$ in this case.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ be two π-institutions based on $\mathbf{F}$. $\mathcal{I}'$ is an **axiomatic extension** (or **axiomatic strengthening**) of $\mathcal{I}$ if there exists $X \in \mathrm{SenSys}(\mathbf{F})$, such that, for all $\Phi \in \mathrm{SenFam}(\mathbf{F})$,

$$C'(\Phi) = C(X \cup \Phi).$$

If this is the case, X is said to be a **system of axioms witnessing** the extension.

We provide now a characterization of axiomatic extensions.

Lemma 59 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *be two* π*-institutions based on* $\mathbf{F}$. $\mathcal{I}'$ *is an axiomatic extension of* $\mathcal{I}$ *if and only if, for all* $\Phi \in \mathrm{SenFam}(\mathbf{F})$,

$$C'(\Phi) = C(\mathrm{Thm}(\mathcal{I}') \cup \Phi).$$

Proof: Assume, first, that $\mathcal{I}'$ is an axiomatic extension of $\mathcal{I}$, with witnessing system of axioms X. Then, we have $\mathrm{Thm}(\mathcal{I}') = C'(\varnothing) = C(X \cup \varnothing) = C(X)$. Therefore, for all $\Phi \in \mathrm{SenFam}(\mathbf{F})$,

$$C'(\Phi) = C(X \cup \Phi) = C(C(X) \cup \Phi) = C(\mathrm{Thm}(\mathcal{I}') \cup \Phi).$$

Assume conversely, that, for all $\Phi \in \mathrm{SenFam}(\mathbf{F})$, $C'(\Phi) = C(\mathrm{Thm}(\mathcal{I}') \cup \Phi)$. Then $X = \mathrm{Thm}(\mathcal{I}')$ is a system of axioms witnessing the fact that $\mathcal{I}'$ is an axiomatic extension of $\mathcal{I}$. ■

We also have the following characterization in terms of $\mathcal{I}$- and $\mathcal{I}'$-filter families and corresponding theory families.

Proposition 60 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *be two* π*-institutions based on* $\mathbf{F}$. *The following statements are equivalent:*

(i) $\mathcal{I}'$ *is an axiomatic extension of* $\mathcal{I}$*;*

(ii) For all $\mathfrak{A} \in \mathrm{MatFam}(\mathcal{I}')$, $\mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \mathrm{FiFam}^{\mathcal{I}'}(\mathfrak{A})$*;*

(iii) For all $T' \in \mathrm{ThFam}(\mathcal{I}')$ *and* $T' \le T \in \mathrm{SenFam}(\mathbf{F})$,

$$T \in \mathrm{ThFam}(\mathcal{I}) \quad \textit{if and only if} \quad T \in \mathrm{ThFam}(\mathcal{I}').$$

Proof:

(i)⇒(ii) Suppose that $\mathcal{I}'$ is an axiomatic extension of $\mathcal{I}$ and let $\mathfrak{A} = \langle \mathcal{A}, T' \rangle \in \mathrm{MatFam}(\mathcal{I}')$. Since $C \leq C'$, we have $\mathrm{FiFam}^{\mathcal{I}'}(\mathfrak{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$. So suppose that $T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$, i.e., $T' \leq T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C'_\Sigma(\Phi)$ and $\alpha_\Sigma(\Phi) \subseteq T''_{F(\Sigma)}$. Since $\phi \in C'_\Sigma(\Phi)$, by Lemma 59, $\phi \in C_\Sigma(\mathrm{Thm}_\Sigma(\mathcal{I}') \cup \Phi)$. Now observe that $\alpha_\Sigma(\mathrm{Thm}_\Sigma(\mathcal{I}')) \subseteq T'_{F(\Sigma)} \subseteq T''_{F(\Sigma)}$, since $T' \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$. Thus, we get

$$\alpha_\Sigma(\mathrm{Thm}_\Sigma(\mathcal{I}') \cup \Phi)) \subseteq T''_{F(\Sigma)}.$$

Hence, since $T'' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that $\alpha_\Sigma(\phi) \in T''_{F(\Sigma)}$. So $T'' \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})$. And, since $T' \leq T''$, $T'' \in \mathrm{FiFam}^{\mathcal{I}'}(\mathfrak{A})$.

(ii)⇒(iii) Let $\mathfrak{A} = \langle \mathcal{F}, T' \rangle \in \mathrm{MatFam}(\mathcal{I}')$. Then, by hypothesis, for all $T' \leq T$, we have $\langle \mathcal{F}, T \rangle \in \mathrm{MatFam}^{\mathcal{I}}(\mathfrak{A})$ iff $\langle \mathcal{F}, T \rangle \in \mathrm{MatFam}^{\mathcal{I}'}(\mathfrak{A})$, i.e., $T \in \mathrm{ThFam}(\mathcal{I})$ iff $T \in \mathrm{ThFam}(\mathcal{I}')$.

(iii)⇒(i) First, note that (iii) implies that $\mathrm{ThFam}(\mathcal{I}') \subseteq \mathrm{ThFam}(\mathcal{I})$ and, therefore, $C \leq C'$. We use this to show that, for all $X \in \mathrm{SenFam}(\mathbf{F})$,

$$C'(X) = C(\mathrm{Thm}(\mathcal{I}') \cup X).$$

From left to right, note that $\mathrm{Thm}(\mathcal{I}') \subseteq C(\mathrm{Thm}(\mathcal{I}')) \subseteq C(\mathrm{Thm}(\mathcal{I}') \cup X)$. So, by hypothesis, $C(\mathrm{Thm}(\mathcal{I}') \cup X) \in \mathrm{ThFam}(\mathcal{I}')$. Thus, we get

$$C'(X) \subseteq C'(C(\mathrm{Thm}(\mathcal{I}') \cup X)) = C(\mathrm{Thm}(\mathcal{I}') \cup X).$$

On the other hand, $C(\mathrm{Thm}(\mathcal{I}') \cup X) \subseteq C'(\mathrm{Thm}(\mathcal{I}') \cup X) = C'(X)$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathrm{MatFam}(\mathcal{I})$. Define, for all $\Phi \in \mathrm{SenFam}(\mathcal{A})$,

$$C^{\mathcal{I},\mathfrak{A}}(\Phi) = C^{\mathcal{I},\mathcal{A}}(T \cup \Phi).$$

$C^{\mathcal{I},\mathfrak{A}}(\Phi)$ is the **$\mathcal{I}$-filter family of $\mathfrak{A}$ generated by** Φ.

We have, for all $\Phi \in \mathrm{SenFam}(\mathcal{A})$, $T \leq C^{\mathcal{I},\mathfrak{A}}(\Phi)$. In the special case where $\mathcal{A} = \mathcal{F}$ and $\mathfrak{A} = \mathfrak{F} = \langle \mathcal{F}, T \rangle \in \mathrm{MatFam}(\mathcal{I})$, we get, for all $\Phi \in \mathrm{SenFam}(\mathbf{F})$,

$$C^{\mathfrak{F}}(\Phi) = C(T \cup \Phi).$$

The following proposition gives many properties governing filter family generation and the interaction with surjective morphisms between $\mathcal{I}$-matrix families.

Proposition 61 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$, $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$ *be* $\mathbf{F}$*-matrix families,* $\langle H, \gamma \rangle : \mathfrak{A} \to \mathfrak{A}'$ *a surjective morphism and* $X \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$, $Y, Y' \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$.

(a) $\gamma^{-1}(Y) \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$*;*

(b) If H *is an isomorphism,* $C^{\mathcal{I},\mathfrak{A}'}(\gamma(X)) \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$*;*

(c) If H *is an isomorphism,* $C^{\mathcal{I},\mathfrak{A}'}(\gamma(\gamma^{-1}(Y))) = \gamma(\gamma^{-1}(Y)) = Y$*;*

(d) If H *is an isomorphism,* $\gamma^{-1}(C^{\mathcal{I},\mathfrak{A}'}(\gamma(X))) = \gamma^{-1}(\gamma(X)) = X$ *if and only if* $\gamma^{-1}(T') \leq X$ *and* $\mathrm{Ker}(\langle H,\gamma\rangle)$ *is compatible with* X*;*

(e) $\gamma^{-1}(Y \cap Y') = \gamma^{-1}(Y) \cap \gamma^{-1}(Y')$*;*

(f) If H *is an isomorphism, for all* $\Phi \in \mathrm{SenFam}(\mathcal{A})$*,* $C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi))) = C^{\mathcal{I},\mathfrak{A}'}(\gamma(\Phi))$*.*

Proof:

(a) We know, by Corollary 55, that $\gamma^{-1}(Y) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. In addition, $T \leq \gamma^{-1}(T') \leq \gamma^{-1}(Y)$. So we get $\gamma^{-1}(Y) \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$.

(b) It is obvious that $C^{\mathcal{I},\mathfrak{A}'}(\gamma(X)) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$. Moreover, by definition, $T' \leq C^{\mathcal{I},\mathfrak{A}'}(\gamma(X))$. So, we get $C^{\mathcal{I},\mathfrak{A}'}(\gamma(X)) \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$.

(c) We have

$$\begin{array}{rcll} C^{\mathcal{I},\mathfrak{A}'}(\gamma(\gamma^{-1}(Y))) & = & C^{\mathcal{I},\mathfrak{A}'}(Y) & (\langle H,\gamma\rangle \text{ surjective}) \\ & = & Y. & (Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')) \end{array}$$

(d) Assume, first, that $\gamma^{-1}(C^{\mathcal{I},\mathfrak{A}'}(\gamma(X))) = \gamma^{-1}(\gamma(X)) = X$. Then, by surjectivity of $\langle H,\gamma\rangle$, $C^{\mathcal{I},\mathfrak{A}'}(\gamma(X)) = \gamma(X)$. This implies that $T' \leq \gamma(X)$, whence $\gamma^{-1}(T') \leq X$. To show compatibility, suppose $\Sigma \in |\mathbf{Sign}|$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$ and $\phi \in X_\Sigma$. Then, we have

$$\psi \in \gamma_\Sigma^{-1}(\gamma_\Sigma(\phi)) \subseteq \gamma_\Sigma^{-1}(\gamma_\Sigma(X_\Sigma)) = X_\Sigma.$$

So $\mathrm{Ker}(\langle H,\gamma\rangle)$ is compatible with X.

Assume, conversely, that $\gamma^{-1}(T') \leq X$ and that $\mathrm{Ker}(\langle H,\gamma\rangle)$ is compatible with X. Then, by compatibility, $\gamma^{-1}(\gamma(X)) = X \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A})$. Thus, by Corollary 55, $\gamma(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}')$. But we also have $T' \leq \gamma(X)$, whence $\gamma(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$. Now we get $\gamma^{-1}(C^{\mathcal{I},\mathfrak{A}'}(\gamma(X))) = \gamma^{-1}(\gamma(X)) = X$.

(e) This follows from set theory.

(f) Let $\Phi \in \mathrm{SenFam}(\mathcal{A})$. Clearly, $C^{\mathcal{I},\mathfrak{A}'}(\gamma(\Phi)) \leq C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi)))$, since $C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi)))$ is an $\mathcal{I}$-filter family of $\mathfrak{A}'$ including $\gamma(\Phi)$.

To show the reverse inclusion, assume $Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$, such that $\gamma(\Phi) \le Y$. Then $\Phi \le \gamma^{-1}(Y)$. Thus, $C^{\mathcal{I},\mathfrak{A}}(\Phi) \le C^{\mathcal{I},\mathfrak{A}}(\gamma^{-1}(Y)) = \gamma^{-1}(Y)$, the equality following by Part (a). Hence, we get

$$C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi))) \le C^{\mathcal{I},\mathfrak{A}'}(\gamma(\gamma^{-1}(Y))) = C^{\mathcal{I},\mathfrak{A}'}(Y) = Y.$$

Since $C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi))) \le Y$ holds, for all $Y \in \mathrm{FiFam}^{\mathcal{I}}(\mathfrak{A}')$, such that $\gamma(\Phi) \le Y$, we get, in particular, $C^{\mathcal{I},\mathfrak{A}'}(\gamma(C^{\mathcal{I},\mathfrak{A}}(\Phi))) \le C^{\mathcal{I},\mathfrak{A}'}(\gamma(\Phi))$. ∎

2.9 Generalized Matrix Families and Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A **generalized F-matrix family**, or **F-gmatrix family** for short, is a pair $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$-algebraic system and $\mathcal{T} \subseteq \mathrm{SenFam}(\mathcal{A})$ is a collection of sentence families of $\mathcal{A}$.

An $\mathbf{F}$-gmatrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ is said to be an **F-gmatrix system** if $\mathcal{T} \subseteq \mathrm{SenSys}(\mathcal{A})$.

Given an $\mathbf{F}$-gmatrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$, the **Tarski congruence system of** $\mathbb{A}$ (or **of** $\mathcal{T}$ **on** $\mathcal{A}$), denoted $\widetilde{\Omega}(\mathbb{A})$ or $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$, is the largest congruence system on $\mathcal{A}$ that is compatible with all sentence families in $\mathcal{T}$.

Lemma 62 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. Then, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \subseteq \mathrm{SenFam}(\mathcal{A})$,*

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T).$$

Proof: Note that, by definition, $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$ is compatible with every $T \in \mathcal{T}$. Therefore, since $\Omega^{\mathcal{A}}(T)$ is the largest congruence system on $\mathcal{A}$ compatible with T, we get that

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \Omega^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T}.$$

Thus, $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \le \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

For the reverse inclusion, note that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$ is a congruence system on $\mathcal{A}$ that is compatible with every $T \in \mathcal{T}$. Therefore, since $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$ is the largest such congruence system, we get that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \le \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. An $\mathbf{F}$-gmatrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ is called a **generalized $\mathcal{I}$-matrix family**, or **$\mathcal{I}$-gmatrix family** for short, if $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

We have a special notation for the Tarski congruence systems, when applied and/or relativized to the collection of all $\mathcal{I}$-filter families:

$$\widetilde{\Omega}^{\mathcal{A}}(\mathcal{I}) := \widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})).$$

Recall that $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism. We set

$$\widetilde{\Omega}(\mathcal{I}) := \widetilde{\Omega}^{\mathcal{F}}(\mathcal{I}) = \widetilde{\Omega}^{\mathcal{F}}(\mathrm{ThFam}(\mathcal{I})).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution, based on $\mathbf{F}$, and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system. Given an $\mathbf{F}$-gmatrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$, the **Tarski reduction** of $\mathbb{A}$, denoted $\mathbb{A}^*$, is defined as

$$\mathbb{A}^* = \langle \mathcal{A}^*, \mathcal{T}^* \rangle = \langle \mathcal{A}^{\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}, \mathcal{T}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) \rangle,$$

where $\mathcal{A}^{\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})}$ is the quotient $\mathbf{F}$-algebraic system of $\mathcal{A}$ by the Tarski congruence system $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T})$ and

$$\mathcal{T}/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \{T/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) : T \in \mathcal{T}\},$$

with $T/\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \{T_\Sigma/\widetilde{\Omega}^{\mathcal{A}}_\Sigma(\mathcal{T})\}_{\Sigma \in |\mathbf{Sign}|}$ such that, for all $\Sigma \in |\mathbf{Sign}|$,

$$T_\Sigma/\widetilde{\Omega}^{\mathcal{A}}_\Sigma(\mathcal{T}) = \{\phi/\widetilde{\Omega}^{\mathcal{A}}_\Sigma(\mathcal{T}) : \phi \in T_\Sigma\}.$$

An $\mathbf{F}$-gmatrix family $\mathbb{A} = \langle \mathcal{A}, \mathcal{T} \rangle$ is **Tarski reduced** if $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. An $\mathbf{F}$-algebraic system $\mathcal{A}$ is **Tarski reduced** if it is the algebraic system reduct of a Tarski reduced $\mathbf{F}$-gmatrix family.

We denote:

- the class of all Tarski reduced $\mathcal{I}$-gmatrix families by $\mathrm{GMatFam}^*(\mathcal{I})$;
- the corresponding class of all Tarski reduced $\mathbf{F}$-algebraic systems by $\mathrm{AlgSys}(\mathcal{I})$,

i.e., we have:

$$\begin{array}{rcl}\mathrm{GMatFam}^*(\mathcal{I}) & = & \{\langle \mathcal{A}, \mathcal{T} \rangle : \mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \text{ and } \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}\};\\ \mathrm{AlgSys}(\mathcal{I}) & = & \{\mathcal{A} : (\exists \mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))(\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}})\}.\end{array}$$

Consider again an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, an $\mathbf{F}$-algebraic system $\mathcal{A}$ and $\mathcal{T} \subseteq \mathrm{SenFam}(\mathcal{A})$. The **Suszko congruence system of** $T \in \mathcal{T}$ (**relative to** $\mathcal{T}$), denoted by $\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T)$, is the largest congruence system on $\mathcal{A}$ that is compatible with all $T' \in \mathcal{T}$, such that $T \leq T'$.

Lemma 63 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then, for all* $\mathbf{F}$-*algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *all* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathcal{A})$ *and all* $T \in \mathcal{T}$,

$$\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T) = \bigcap_{T \leq T' \in \mathcal{T}} \Omega^{\mathcal{A}}(T').$$

Proof: The proof is similar to that of Lemma 62. ■

We note also the following relation between the Suszko congruence system of T relative to $\mathcal{T}$ and the Tarski congruence system of $\mathcal{T}^T = \{T' \in \mathcal{T} : T \leq T'\}$:

$$\widetilde{\Omega}^{\mathcal{A},\mathcal{T}}(T) = \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}^T).$$

We also have some special notations reserved for the Suszko congruence systems, when applied and/or relativized to $\mathrm{ThFam}(\mathcal{I})$ and to all $\mathcal{I}$-filter families.

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I}}(T) & := & \widetilde{\Omega}^{\mathcal{F},\mathrm{ThFam}(\mathcal{I})}(T), \text{ for all } T \in \mathrm{ThFam}(\mathcal{I});\\ \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) & := & \widetilde{\Omega}^{\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})}(T), \text{ for all } T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).\end{array}$$

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Given an $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, the **Suszko reduction** of $\mathfrak{A}$, denoted $\mathfrak{A}^{\mathsf{Su}}$, is defined as

$$\mathfrak{A}^{\mathsf{Su}} = \langle \mathcal{A}^{\mathsf{Su}}, T^{\mathsf{Su}} \rangle = \langle \mathcal{A}^{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}, T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \rangle,$$

where $\mathcal{A}^{\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)}$ is the quotient $\mathbf{F}$-algebraic system of $\mathcal{A}$ by the Suszko congruence system $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T)$ and $T/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \{T_\Sigma/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}|}$, with

$$T_\Sigma/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}_\Sigma(T) = \{\phi/\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}_\Sigma(T) : \phi \in T_\Sigma\}.$$

An $\mathcal{I}$-matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ is **Suszko reduced** if $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. An $\mathbf{F}$-algebraic system $\mathcal{A}$ is **Suszko reduced** if it is the algebraic system reduct of a Suszko reduced $\mathcal{I}$-matrix family.

It turns out that, relative to a given π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, the classes of Tarski reduced $\mathbf{F}$-algebraic systems and of Suszko reduced $\mathbf{F}$-algebraic systems coincide.

Proposition 64 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system.* $\mathcal{A}$ *is Suszko reduced if and only if* $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$*.*

Proof: Suppose, first, that $\mathcal{A}$ is a Suszko reduced $\mathbf{F}$-algebraic system. Then, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. But then we have

$$\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \subseteq \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}.$$

Hence $\langle \mathcal{A}, \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \in \mathrm{GMatFam}^*(\mathcal{I})$ and, consequently, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$.

Suppose, conversely, that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Thus, by definition, there exists $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. Now we get

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(\bigcap \mathcal{T}) & = & \widetilde{\Omega}^{\mathcal{A}}(\{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) : \bigcap \mathcal{T} \leq T\})\\ & \leq & \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}.\end{array}$$

Since $\bigcap\mathcal{T} \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that $\langle\mathcal{A},\bigcap\mathcal{T}\rangle \in \mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$ and, consequently, $\mathcal{A}$ is Suszko reduced. ■

We let $\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I})$ be the class of all Suszko reduced $\mathcal{I}$-matrix families, i.e., we have

$$\mathrm{MatFam}^{\mathsf{Su}}(\mathcal{I}) = \{\langle\mathcal{A},T\rangle : T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \text{ and } \widetilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) = \Delta^{\mathcal{A}}\},$$

whereas, because of Proposition 64, there is no reason for introducing fresh notation for the class of all Suszko reduced **F**-algebraic systems, that class being $\mathrm{AlgSys}(\mathcal{I})$.

2.10 The Algebraic Systems of a π-Institution

We have introduced in Sections 2.7 and 2.9 two of the most important classes of **F**-algebraic systems associated to a π-institution $\mathcal{I} = \langle\mathbf{F},C\rangle$, namely, the classes $\mathrm{AlgSys}^*(\mathcal{I})$ and $\mathrm{AlgSys}(\mathcal{I})$. In this section, we introduce two more classes and consider some of the relationships that hold between them.

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on **F**. The **semantic variety of** $\mathcal{I}$ is the semantic variety generated by the algebraic system $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$, i.e., the class

$$\begin{array}{rcl}\mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) & := & \mathbb{V}^{\mathsf{Sem}}(\mathcal{F}/\widetilde{\Omega}(\mathcal{I}))\\ & = & \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \widetilde{\Omega}(\mathcal{I}) \le \mathrm{Ker}(\mathcal{A})\}.\end{array}$$

The **syntactic variety of** $\mathcal{I}$ is the syntactic variety generated by $\mathcal{F}/\widetilde{\Omega}(\mathcal{I})$, i.e., the class defined by

$$\begin{array}{rcl}\mathbb{V}^{\mathsf{Syn}}(\mathcal{I}) & := & \mathbb{V}^{\mathsf{Syn}}(\mathcal{F}/\widetilde{\Omega}(\mathcal{I}))\\ & = & \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\forall\sigma^\flat \approx \tau^\flat \in \mathrm{NEq}(\mathbf{F}))\\ & & \qquad (\mathcal{F}/\widetilde{\Omega}(\mathcal{I}) \vDash \sigma^\flat \approx \tau^\flat \;\Rightarrow\; \mathcal{A} \vDash \sigma^\flat \approx \tau^\flat)\}.\end{array}$$

We can say a few things about the relationships governing the four classes of **F**-algebraic systems associated with a given π-institution $\mathcal{I} = \langle\mathbf{F},C\rangle$.

Proposition 65 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F},C\rangle$ *a* π*-institution based on* **F**. *Then we have*

$$\mathrm{AlgSys}^*(\mathcal{I}) \subseteq \mathrm{AlgSys}(\mathcal{I}) \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathcal{I}) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathcal{I}).$$

Proof: Suppose, first, that $\mathcal{A} \in \mathrm{AlgSys}^*(\mathcal{I})$. Then there exists an $\mathcal{I}$-filter family $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Hence, we get

$$\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \le \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}.$$

It follows that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$.

Suppose, next, that $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$. Thus, there exists $\mathcal{T} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$. This implies that $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \leq \widetilde{\Omega}^{\mathcal{A}}(\mathcal{T}) = \Delta^{\mathcal{A}}$, i.e., that $\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}$. Applying the inverse of the surjective morphism $\langle F, \alpha \rangle$, we get $\alpha^{-1}(\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) = \alpha^{-1}(\Delta^{\mathcal{A}}) = \mathrm{Ker}(\mathcal{A})$. Therefore, we obtain

$$\begin{array}{rcll}
\widetilde{\Omega}(\mathcal{I}) & = & \bigcap_{T \in \mathrm{ThFam}(\mathcal{I})} \Omega(T) & \text{(by Lemma 62)} \\
& \leq & \bigcap_{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})} \Omega(\alpha^{-1}(T)) & \text{(by Lemma 51)} \\
& = & \bigcap_{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})} \alpha^{-1}(\Omega^{\mathcal{A}}(T)) & \text{(by Proposition 24)} \\
& = & \alpha^{-1}(\bigcap_{T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})} \Omega^{\mathcal{A}}(T)) & \text{(set theory))} \\
& = & \alpha^{-1}(\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}))) & \text{(by Lemma 62)} \\
& = & \mathrm{Ker}(\mathcal{A}). & \text{(as shown above)}
\end{array}$$

Hence $\mathcal{A} \in \mathbb{V}^{\mathsf{Sem}}(\mathcal{I})$.

The last inclusion follows from Theorem 39. ∎

Finally, it can be shown that all four classes generate the same syntactic variety. We first prove a technical lemma that simplifies some algebraic computations.

Lemma 66 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, an* $\mathbf{F}$*-algebraic system,* $\theta \in \mathrm{ConSys}(\mathcal{A})$ *and* $\sigma^\flat \approx \tau^\flat$ *an* $\mathbf{F}$*-equation. Then*

$$\begin{array}{rl}
\mathcal{A}/\theta \vDash \sigma^\flat \approx \tau^\flat \quad \textit{iff} & \textit{for all } \Sigma \in |\mathbf{Sign}^\flat|,\ \vec{\phi} \in \mathrm{SEN}^\flat(\Sigma), \\
& \langle \alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})), \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})) \rangle \in \theta_{F(\Sigma)}.
\end{array}$$

Proof: We have, by definition, $\mathcal{A}/\theta \vDash \sigma^\flat \approx \tau^\flat$ iff, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha^\theta_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) = \alpha^\theta_\Sigma(\tau^\flat_\Sigma(\vec{\phi}))$$

iff, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi}))/\theta_{F(\Sigma)} = \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi}))/\theta_{F(\Sigma)}$$

iff, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})), \alpha_\Sigma(\tau^\flat_\Sigma(\vec{\phi})) \rangle \in \theta_{F(\Sigma)}.$$

∎

Theorem 67 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then*

$$\mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I})) = \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}(\mathcal{I})) = \mathbb{V}^{\mathsf{Syn}}(\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})) = \mathbb{V}^{\mathsf{Syn}}(\mathcal{I}).$$

Proof: By Propositions 65 and 38, we have

$$\mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I})) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}(\mathcal{I})) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathbb{V}^{\mathsf{Sem}}(\mathcal{I})) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathcal{I}).$$

To conclude the proof we need to show that

$$\mathbb{V}^{\mathsf{Syn}}(\mathcal{I}) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I})).$$

To this end, suppose $\mathcal{A} \in \mathbb{V}^{\mathsf{Syn}}(\mathcal{I})$, i.e., that, for every natural $\mathbf{F}$-equation $\sigma^\flat \approx \tau^\flat$,

$$\mathcal{F}/\widetilde{\Omega}(\mathcal{I}) \vDash \sigma^\flat \approx \tau^\flat \quad \text{implies} \quad \mathcal{A} \vDash \sigma^\flat \approx \tau^\flat.$$

To show that $\mathcal{A} \in \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I}))$, suppose that $\sigma^\flat \approx \tau^\flat$ is an $\mathbf{F}$-equation, such that $\mathrm{AlgSys}^*(\mathcal{I}) \vDash \sigma^\flat \approx \tau^\flat$. In particular, for all $T \in \mathrm{ThFam}(\mathcal{I})$, we have that $\mathcal{F}/\Omega(T) \vDash \sigma^\flat \approx \tau^\flat$. This means, by Lemma 66, that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\langle \sigma^\flat_\Sigma(\vec{\phi}), \tau^\flat_\Sigma(\vec{\phi})\rangle \in \Omega_\Sigma(T)$. Since this holds for all $T \in \mathrm{ThFam}(\mathcal{I})$, we get that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \sigma^\flat_\Sigma(\vec{\phi}), \tau^\flat_\Sigma(\vec{\phi})\rangle \in \bigcap_{T \in \mathrm{ThFam}(\mathcal{I})} \Omega_\Sigma(T) = \widetilde{\Omega}_\Sigma(\mathcal{I}).$$

Thus, again by Lemma 66, $\mathcal{F}/\widetilde{\Omega}(\mathcal{I}) \vDash \sigma^\flat \approx \tau^\flat$. Therefore, by hypothesis, $\mathcal{A} \vDash \sigma^\flat \approx \tau^\flat$. We conclude that $\mathcal{A} \in \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I}))$ and, hence, $\mathbb{V}^{\mathsf{Syn}}(\mathcal{I}) \subseteq \mathbb{V}^{\mathsf{Syn}}(\mathrm{AlgSys}^*(\mathcal{I}))$. ■

We close this section by showing that, given a π-institution $\mathcal{I}$, the class of Tarski reduced algebraic systems $\mathrm{AlgSys}(\mathcal{I})$ is closed under the operator $\overset{\triangleleft}{\mathbb{P}}$ and contains a trivial $\mathbf{F}$-algebraic system and, therefore, by Proposition 28, it makes sense, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, to consider the relative congruence system $\Theta^{\mathrm{AlgSys}(\mathcal{I}),\mathcal{A}}(X)$ on $\mathcal{A}$ generated by a relation family $X \in \mathrm{RelFam}(\mathcal{A})$.

Proposition 68 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$. *The class of* $\mathbf{F}$*-algebraic systems* $\mathrm{AlgSys}(\mathcal{I})$ *is closed under subdirect intersections and contains a trivial* $\mathbf{F}$*-algebraic system.*

Proof: It is clear that $\mathrm{AlgSys}(\mathcal{I})$ contains a trivial $\mathbf{F}$-algebraic system $\mathcal{A}$, since $\Delta^{\mathcal{A}} = \nabla^{\mathcal{A}}$ is the only congruence system on $\mathcal{A}$. So it suffices to show that $\mathrm{AlgSys}(\mathcal{I})$ is closed under subdirect intersections. To this end, let

$$\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

be a subdirect intersection, with $\mathcal{A}^i \in \mathrm{AlgSys}(\mathcal{I})$, for all $i \in I$. Thus, by definition, we have, on the one hand, that

$$\bigcap_{i \in I} \mathrm{Ker}(\langle H^i, \gamma^i\rangle) = \Delta^{\mathcal{A}},$$

and on the other, that, for all $i \in I$, there exists $\mathcal{T}^i \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i)$, such that

$$\widetilde{\Omega}^{\mathcal{A}^i}(\mathcal{T}^i) = \Delta^{\mathcal{A}^i}.$$

Now we obtain

$$\begin{array}{rcl}\widetilde{\Omega}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) & \leq & \widetilde{\Omega}^{\mathcal{A}}(\bigcup_{i\in I}(\gamma^i)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i))) \\ & = & \bigcap_{i\in I}\widetilde{\Omega}^{\mathcal{A}}((\gamma^i)^{-1}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i))) \\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\widetilde{\Omega}^{\mathcal{A}^i}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^i))) \\ & \leq & \bigcap_{i\in I}(\gamma^i)^{-1}(\widetilde{\Omega}^{\mathcal{A}^i}(\mathcal{T}^i)) \\ & = & \bigcap_{i\in I}(\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\ & = & \bigcap_{i\in I}\mathrm{Ker}(\langle H^i,\gamma^i\rangle) \\ & = & \Delta^{\mathcal{A}}.\end{array}$$

Therefore, $\mathcal{A} \in \mathrm{AlgSys}(\mathcal{I})$, showing that $\overset{\triangleleft}{\mathbb{P}}(\mathrm{AlgSys}(\mathcal{I})) \subseteq \mathrm{AlgSys}(\mathcal{I})$. ■

Based on Proposition 68 and Proposition 28, we define, for every **F**-algebraic system $\mathcal{A}$, and all $X \in \mathrm{RelFam}(\mathcal{A})$,

$$\Theta^{\mathcal{I},\mathcal{A}}(X) := \Theta^{\mathrm{AlgSys}(\mathcal{I}),\mathcal{A}}(X).$$

2.11 Frege Relations

Let $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ be a sentence functor and $T \in \mathrm{SenFam}(\mathrm{SEN})$. We define:

- The **Frege relation system** $\Lambda(T) = \{\Lambda_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|}$ of T on SEN by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{array}{rcl}\Lambda_\Sigma(T) & = & \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma,\Sigma'), \\ & & \mathrm{SEN}^\flat(f)(\phi) \in T_{\Sigma'} \iff \mathrm{SEN}^\flat(f)(\psi) \in T_{\Sigma'}\};\end{array}$$

- The **Frege relation family** $\lambda(T) = \{\lambda_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|}$ of T on SEN by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\lambda_\Sigma(T) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : (\phi \in T_\Sigma \iff \psi \in T_\Sigma)\}.$$

It turns out that the Frege relation system of T on SEN is an equivalence system, the Frege relation family of T on SEN is an equivalence family and that the former is the largest equivalence system included in the latter.

Proposition 69 *Let* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *be a sentence functor and* $T \in \mathrm{SenFam}(\mathrm{SEN})$.

(a) $\Lambda(T)$ *is an equivalence system on* SEN*;*

(b) $\lambda(T)$ *is an equivalence family on* SEN*;*

(c) $\Lambda(T)$ *is the largest equivalence system included in* $\lambda(T)$*.*

Proof:

(a) That $\Lambda(T)$ is an equivalence family, i.e., that, for all $\Sigma \in |\mathbf{Sign}|$, $\Lambda_\Sigma(T)$ is an equivalence relation, is straightforward. To see that it is a system, i.e., invariant under signature morphisms, let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Lambda_\Sigma(T)$, and $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$. Then, we have, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{\ f\ } \Sigma' \xrightarrow{\ g\ } \Sigma''$$

$\mathrm{SEN}(gf)(\phi) \in T_{\Sigma''}$ iff $\mathrm{SEN}(gf)(\psi) \in T_{\Sigma''}$, whence, we derive that , for all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$,

$$\mathrm{SEN}(g)(\mathrm{SEN}(f)(\phi)) \in T_{\Sigma''} \quad \text{iff} \quad \mathrm{SEN}(g)(\mathrm{SEN}(f)(\psi)) \in T_{\Sigma''}.$$

This shows that $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \rangle \in T_{\Sigma'}$. Thus, $\Lambda(T)$ is an equivalence system.

(b) This part is straightforward.

(c) It is clear that $\Lambda(T) \leq \lambda(T)$, simply by considering, in the definition of $\Lambda(T)$, the particular case where $\Sigma' = \Sigma$ and $f = i_\Sigma : \Sigma \to \Sigma$ is the identity signature morphism. Suppose, next, that θ is an equivalence system, such that $\theta \leq \lambda(T)$. We must show that $\theta \leq \Lambda(T)$. To this end, let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$. Since θ is a system, we get, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\langle \mathrm{SEN}(f)(\phi), \mathrm{SEN}(f)(\psi) \rangle \in \theta_{\Sigma'}$. Hence, since $\theta \leq \lambda(T)$, we conclude that $\mathrm{SEN}(f)(\phi) \in T_{\Sigma'}$ iff $\mathrm{SEN}(f)(\psi) \in T_{\Sigma'}$. Therefore, by definition, $\langle \phi, \psi \rangle \in \Lambda_\Sigma(T)$. Thus, $\theta \leq \Lambda(T)$ and $\Lambda(T)$ is indeed the largest equivalence system included in $\lambda(T)$.

■

There is also a close relationship between the two Frege equivalence families and the Leibniz congruence system of a sentence family. In case SEN is the underlying sentence functor of an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, we sometimes write $\Lambda^{\mathbf{A}}(T)$ and $\lambda^{\mathbf{A}}(T)$ for the relation families $\Lambda(T)$ and $\lambda(T)$, respectively.

Proposition 70 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system and* $T \in \mathrm{SenFam}(\mathbf{A})$*.*

(a) $\Omega^{\mathbf{A}}(T)$ *is the largest congruence system contained in* $\lambda^{\mathbf{A}}(T)$*;*

(b) $\Omega^{\mathbf{A}}(T)$ *is the largest congruence system contained in* $\Lambda^{\mathbf{A}}(T)$.

Proof:

(a) By definition $\Omega^{\mathbf{A}}(T)$ is a congruence system on $\mathbf{A}$. So we must show that $\Omega^{\mathbf{A}}(T) \leq \lambda^{\mathbf{A}}(T)$ and that, moreover, it is the largest congruence system that satisfies this inclusion property.

To see that $\Omega^{\mathbf{A}}(T) \leq \lambda^{\mathbf{A}}(T)$, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega^{\mathbf{A}}_{\Sigma}(T)$. Then, by compatibility of $\Omega^{\mathbf{A}}(T)$ with T, we get that, $\phi \in T_\Sigma$ iff $\psi \in T_\Sigma$. So, by definition $\langle \phi, \psi \rangle \in \lambda^{\mathbf{A}}_{\Sigma}(T)$.

Finally, suppose, that $\theta \in \mathrm{ConSys}(\mathbf{A})$, such that $\theta \leq \lambda^{\mathbf{A}}(T)$. We must show that $\theta \leq \Omega^{\mathbf{A}}(T)$. Since, by definition $\Omega^{\mathbf{A}}(T)$ is the largest congruence system compatible with T, it suffices to show that θ is compatible with T. To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$ and $\phi \in T_\Sigma$. Since $\theta \leq \lambda^{\mathbf{A}}(T)$, we get that $\langle \phi, \psi \rangle \in \lambda^{\mathbf{A}}_{\Sigma}(T)$ and $\phi \in T_\Sigma$. By the definition of $\lambda^{\mathbf{A}}(T)$, we conclude that $\psi \in T_\Sigma$. Therefore, θ is compatible with T and, hence, $\theta \leq \Omega^{\mathbf{A}}(T)$.

(b) Since $\Omega^{\mathbf{A}}(T)$ is, in particular, an equivalence system, we get, by Part (a) and Part (c) of Proposition 69, that $\Omega^{\mathbf{A}}(T) \leq \Lambda^{\mathbf{A}}(T)$. It is the largest congruence system satisfying this property, since $\Lambda^{\mathbf{A}}(T) \leq \lambda^{\mathbf{A}}(T)$ and, by Part (a), it is the largest congruence system in $\lambda^{\mathbf{A}}(T)$.

■

Let $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ be a sentence functor and $\mathcal{T} \subseteq \mathrm{SenFam}(\mathrm{SEN})$ a collection of sentence families of SEN. The following relation systems are also known by the name of Frege in the literature, but we use the name "Carnap" instead to differentiate the two. In the present context, they have the same relation with Frege relation systems as Tarski congruence systems have with Leibniz congruence systems. We define:

- The **Carnap relation system** $\widetilde{\Lambda}(\mathcal{T}) = \{\widetilde{\Lambda}_\Sigma(\mathcal{T})\}_{\Sigma \in |\mathbf{Sign}|}$ of $\mathcal{T}$ on SEN, by
$$\widetilde{\Lambda}(\mathcal{T}) = \bigcap_{T \in \mathcal{T}} \Lambda(T),$$
where the intersection is taken signature-wise;

- The **Carnap relation family** $\widetilde{\lambda}(\mathcal{T}) = \{\widetilde{\lambda}_\Sigma(\mathcal{T})\}_{\Sigma \in |\mathbf{Sign}|}$ of $\mathcal{T}$ on SEN, by
$$\widetilde{\lambda}(\mathcal{T}) = \bigcap_{T \in \mathcal{T}} \lambda(T),$$
where the intersection is taken signature-wise.

That is, we have, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{array}{rcl}\widetilde{\Lambda}_\Sigma(\mathcal{T}) & = & \{\langle \phi, \psi \rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } T \in \mathcal{T}, \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma, \Sigma'), \\ & & \qquad \mathrm{SEN}(f)(\phi) \in T_{\Sigma'} \iff \mathrm{SEN}(f)(\psi) \in T_{\Sigma'}\}\end{array}$$

and, similarly,

$$\widetilde{\lambda}_\Sigma(\mathcal{T}) = \{\langle\phi,\psi\rangle \in \mathrm{SEN}(\Sigma)^2 : \text{for all } T \in \mathcal{T}, \quad \phi \in T_\Sigma \iff \psi \in T_\Sigma\}$$

We have analogs of Propositions 69 and 1420 for the case of $\widetilde{\Lambda}$ and $\widetilde{\lambda}$. The analog of Proposition 69 asserts that $\widetilde{\Lambda}(\mathcal{T})$ is an equivalence system on SEN, $\widetilde{\lambda}(\mathcal{T})$ is an equivalence family on SEN and that $\widetilde{\Lambda}(\mathcal{T})$ is the largest equivalence system included in $\widetilde{\lambda}(\mathcal{T})$.

Corollary 71 *Let* SEN : **Sign** → **Set** *be a sentence functor and consider* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathrm{SEN})$.

- *(a)* $\widetilde{\Lambda}(\mathcal{T})$ *is an equivalence system on* SEN;
- *(b)* $\widetilde{\lambda}(\mathcal{T})$ *is an equivalence family on* SEN;
- *(c)* $\widetilde{\Lambda}(\mathcal{T})$ *is the largest equivalence system on* SEN *included in* $\widetilde{\lambda}(T)$.

Proof:

- (a) Since the intersection of equivalence relations is an equivalence relation, we get, by definition, that $\widetilde{\Lambda}(\mathcal{T})$ is an *equivalence* family. Moreover, since the intersection of relation systems is a relation system, we get, by Proposition 69, that $\widetilde{\Lambda}(\mathcal{T})$ is an equivalence *system*.
- (b) As in Part (a), Part (b) follows from the fact that $\lambda(T)$ is an equivalence family, for all $T \in \mathcal{T}$.
- (c) By Proposition 69, we get $\widetilde{\Lambda}(\mathcal{T}) = \bigcap_{T\in\mathcal{T}} \Lambda(T) \le \bigcap_{T\in\mathcal{T}} \lambda(T) = \widetilde{\lambda}(\mathcal{T})$. Let, now, θ be an equivalence system on SEN, such that $\theta \le \widetilde{\lambda}(\mathcal{T})$. We must show that $\theta \le \widetilde{\Lambda}(\mathcal{T})$. By hypothesis, $\theta \le \lambda(T)$, for all $T \in \mathcal{T}$. Therefore, by Proposition 69, $\theta \le \Lambda(T)$, for all $T \in \mathcal{T}$. Hence, $\theta \le \bigcap_{T\in\mathcal{T}} \Lambda(T) = \widetilde{\Lambda}(\mathcal{T})$. Thus, $\widetilde{\Lambda}(\mathcal{T})$ is indeed the largest equivalence system included in $\widetilde{\lambda}(\mathcal{T})$.

■

Once more, if SEN happens to be the underlying sentence functor of an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, we sometimes write $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$ and $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$ for $\widetilde{\Lambda}(\mathcal{T})$ and $\widetilde{\lambda}(\mathcal{T})$, respectively.

The analog of Proposition 1420 asserts that both $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$ and $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$ are in the same relation with $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ as $\Lambda^{\mathbf{A}}(T)$ and $\lambda^{\mathbf{A}}(T)$ are with $\Omega^{\mathbf{A}}(T)$, i.e., that the Tarski congruence system of a collection of sentence families is the largest congruence system included in either the Carnap equivalence system or the Carnap equivalence family of the collection.

Proposition 72 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system and* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathbf{A})$.

(a) $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$*;*

(b) $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$*.*

Proof:

(a) To see that $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T}) \leq \widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$, let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathbf{A}}_{\Sigma}(\mathcal{T})$. Since $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ is compatible with every $T \in \mathcal{T}$, we get that, for all $T \in \mathcal{T}$, $\phi \in T_\Sigma$ if and only if $\psi \in T_\Sigma$. Thus, $\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathbf{A}}_{\Sigma}(\mathcal{T})$.

Suppose, next, that θ is a congruence system on $\mathbf{A}$, such that $\theta \leq \widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$. We must show that $\theta \leq \widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$. For this it suffices to show that θ is compatible with every $T \in \mathcal{T}$. Let $T \in \mathcal{T}$, $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathrm{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$ and $\phi \in T_\Sigma$. By hypothesis, $\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathbf{A}}_{\Sigma}(\mathcal{T})$. By definition, $\langle \phi, \psi \rangle \in \lambda^{\mathbf{A}}_{\Sigma}(T)$. Therefore, since $\phi \in T_\Sigma$ we get $\psi \in T_\Sigma$ and, hence, θ is compatible with T.

(b) Since $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ is an equivalence system and, by Part (a), $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T}) \leq \widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$, we get, by Corollary 71, $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T}) \leq \widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$. Moreover, since, by Corollary 71, $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T}) \leq \widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$ and, by Part (a), $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$ is the largest congruence system in $\widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$, it must also be the largest one in $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T})$. ∎

Finally, consider a sentence functor $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$, a collection $\mathcal{T}$ of sentence families of SEN and a sentence family $X \in \mathcal{T}$. The following is sometimes also termed Frege relation family, but, once more, to differentiate it from the preceding notions, we use the term “Lindenbaum” instead. we define:

- The **Lindenbaum relation system** $\widetilde{\Lambda}^{\mathcal{T}}(X) = \{\widetilde{\Lambda}^{\mathcal{T}}_{\Sigma}(X)\}_{\Sigma \in |\mathbf{Sign}|}$ **of** X **relative to** $\mathcal{T}$ by instantiating the definition of $\widetilde{\Lambda}$, given above, to the collection $\mathcal{T}^X$ of sentence families in $\mathcal{T}$ that include X, i.e.,

$$\widetilde{\Lambda}^{\mathcal{T}}(X) := \widetilde{\Lambda}(\mathcal{T}^X) = \bigcap \{\Lambda(T) : T \in \mathcal{T}, X \leq T\}.$$

- The **Lindenbaum relation family** $\widetilde{\lambda}^{\mathcal{T}}(X) = \{\widetilde{\lambda}^{\mathcal{T}}_{\Sigma}(X)\}_{\Sigma \in |\mathbf{Sign}|}$ **of** X **relative to** $\mathcal{T}$ by instantiating the definition of $\widetilde{\lambda}$ to the collection $\mathcal{T}^X$ of sentence families in $\mathcal{T}$ that include X, i.e.,

$$\widetilde{\lambda}^{\mathcal{T}}(X) := \widetilde{\lambda}(\mathcal{T}^X) = \bigcap \{\lambda(T) : T \in \mathcal{T}, X \leq T\}.$$

Using Corollary 71, we get immediately

Corollary 73 *Let* $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *be a sentence functor,* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathrm{SEN})$ *and* $X \in \mathcal{T}$*.*

(a) $\widetilde{\Lambda}^{\mathcal{T}}(X)$ *is an equivalence system on* SEN*;*

(b) $\widetilde{\lambda}^{\mathcal{T}}(X)$ *is an equivalence family on* SEN*;*

(c) $\widetilde{\Lambda}^{\mathcal{T}}(X)$ *is the largest equivalence system on* SEN *included in* $\widetilde{\lambda}^{\mathcal{T}}(X)$.

Proof: Directly by Corollary 71. ∎

When SEN happens to be the underlying sentence functor of an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, we sometimes write $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(X)$ and $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(X)$ for the equivalence system $\widetilde{\Lambda}^{\mathcal{T}}(X)$ and the equivalence family $\widetilde{\lambda}^{\mathcal{T}}(X)$, respectively. Proposition 72 allows us to derive a relation between the Lindenbaum equivalence system $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(X)$ or the Lindenbaum equivalence family $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(X)$ of a sentence family X relative to the collection $\mathcal{T}$ of sentence families and the Suszko congruence system $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(X)$ of the family relative to the same collection.

Corollary 74 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *be an algebraic system, consider* $\mathcal{T} \subseteq \mathrm{SenFam}(\mathbf{A})$ *and* $X \in \mathcal{T}$.

(a) $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(X)$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\lambda}^{\mathcal{T}}(X)$*;*

(b) $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(X)$ *is the largest congruence system on* $\mathbf{A}$ *included in* $\widetilde{\Lambda}^{\mathcal{T}}(X)$.

Proof: We apply Proposition 72 to the collection $\mathcal{T}^X$. We get that $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T}^X)$ is the largest congruence system on $\mathbf{A}$ that is included in either $\widetilde{\lambda}(\mathcal{T}^X)$ or $\widetilde{\Lambda}(\mathcal{T}^X)$. The former is, by definition, equal to $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(X)$ and the latter ones to $\widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(X)$ and $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(X)$, respectively. So we get the conclusion. ∎

Consider now a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, with $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$, and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system. The most common application of the Carnap operator will be to the collection $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ of all $\mathcal{I}$-filter families and that of the Lindenbaum operator to an $\mathcal{I}$-filter family T of $\mathcal{A}$ relative to $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. So we set the following notation:

$$\widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}) \coloneqq \widetilde{\Lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})) \quad \text{and} \quad \widetilde{\lambda}^{\mathcal{A}}(\mathcal{I}) \coloneqq \widetilde{\lambda}^{\mathcal{A}}(\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})).$$

Moreover, given $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we set

$$\widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}(T) \coloneqq \widetilde{\Lambda}^{\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})}(T) \quad \text{and} \quad \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \coloneqq \widetilde{\lambda}^{\mathcal{A},\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})}(T).$$

When those notions specialize to the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$, the superscript referring to the algebraic system is often omitted. Thus, we have

$$\widetilde{\Lambda}(\mathcal{I}) = \widetilde{\Lambda}^{\mathcal{F}}(\mathcal{I}) \quad \text{and} \quad \widetilde{\lambda}(\mathcal{I}) = \widetilde{\lambda}^{\mathcal{F}}(\mathcal{I})$$

and, for $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\Lambda}^{\mathcal{I}}(T) = \widetilde{\Lambda}^{\mathcal{I},\mathcal{F}}(T) \quad \text{and} \quad \widetilde{\lambda}^{\mathcal{I}}(T) = \widetilde{\lambda}^{\mathcal{I},\mathcal{F}}(T).$$

We have the following characterizations of Lindenbaum equivalence systems and Lindenbaum equivalence families. We use those to derive characterizations of other relation families/systems as corollaries.

Theorem 75 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

(a) $\langle \phi, \psi \rangle \in \widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$ *if and only if, for all* $\Sigma' \in |\mathbf{Sign}|$*,* $f \in \mathbf{Sign}(\Sigma, \Sigma')$*,*

$$C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}(f)(\phi)) = C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}(f)(\psi));$$

(b) $\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$ *if and only if* $C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, \phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, \psi)$*.*

In particular, if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, then* $\widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}(T) = \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T)$*.*

Proof:

(a) We have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\langle \phi, \psi \rangle \in \widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$ iff, for all $T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\phi) \in T'_{\Sigma'} \quad \text{iff} \quad \mathrm{SEN}(f)(\psi) \in T'_{\Sigma'}$$

iff, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$T_\Sigma \cup \{\mathrm{SEN}(f)(\phi)\} \subseteq T'_{\Sigma'} \quad \text{iff} \quad T_\Sigma \cup \{\mathrm{SEN}(f)(\psi)\} \subseteq T'_{\Sigma'}$$

iff, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(T_\Sigma, \mathrm{SEN}(f)(\phi)) = C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(T_\Sigma, \mathrm{SEN}(f)(\psi)).$$

(b) We have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, $\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T)$ iff, for all $T \le T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\phi \in T'_\Sigma \Leftrightarrow \psi \in T'_\Sigma$ iff, for all $T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T_\Sigma \cup \{\phi\} \subseteq T'_\Sigma \Leftrightarrow T_\Sigma \cup \{\psi\} \subseteq T'_\Sigma$ iff $C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, \phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(T_\Sigma, \psi)$.

The last statement follows from Parts (a) and (b) and the structurality property of $C^{\mathcal{I},\mathcal{A}}$. ∎

Specializing to the least $\mathcal{I}$-filter family on $\mathcal{A}$, which happens to be a theory system, we get

Corollary 76 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. Then* $\widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}) = \widetilde{\lambda}^{\mathcal{A}}(\mathcal{I})$ *and, for all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{A}}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad C^{\mathcal{I},\mathcal{A}}_\Sigma(\phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(\psi).$$

Proof: Directly by Theorem 75, by taking $T = C^{\mathcal{I},\mathcal{A}}(\varnothing)$. ∎

Specializing to theory families, we get the following

Theorem 77 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$ *and* $T \in \mathrm{ThFam}(\mathcal{I})$*. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

(a) $\langle \phi, \psi \rangle \in \widetilde{\Lambda}^{\mathcal{I}}_\Sigma(T)$ *if and only if, for all* $\Sigma' \in |\mathbf{Sign}^\flat|$*,* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$*,*

$$C_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}^\flat(f)(\phi)) = C_{\Sigma'}(T_{\Sigma'}, \mathrm{SEN}^\flat(f)(\psi));$$

(b) $\langle \phi, \psi \rangle \in \widetilde{\lambda}^{\mathcal{I}}_\Sigma(T)$ *if and only if* $C_\Sigma(T_\Sigma, \phi) = C_\Sigma(T_\Sigma, \psi)$*.*

In particular, if $T \in \mathrm{ThSys}(\mathcal{I})$*, then* $\widetilde{\Lambda}^{\mathcal{I}}(T) = \widetilde{\lambda}^{\mathcal{I}}(T)$*.*

Proof: We apply Theorem 75 to the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. ∎

As a corollary, we also get

Corollary 78 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Then* $\widetilde{\Lambda}(\mathcal{I}) = \widetilde{\lambda}(\mathcal{I})$ *and, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \widetilde{\lambda}_\Sigma(\mathcal{I}) \quad \text{iff} \quad C_\Sigma(\phi) = C_\Sigma(\psi).$$

Proof: Apply Theorem 77 to $T = \mathrm{Thm}(\mathcal{I})$, which happens to be a theory system. ∎

We record, finally, a couple of relatively straightforward monotonicity properties of the Carnap and Lindenbaum operators. The following theorem refers to collections of filter families and individual filter families and the subsequent corollary specializes this to theory families.

Theorem 79 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$*,* $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ π*-institutions based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*.*

(a) *If* $\mathcal{I} \le \mathcal{I}'$*, then* $\widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}) \le \widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}')$ *and* $\widetilde{\lambda}^{\mathcal{A}}(\mathcal{I}) \le \widetilde{\lambda}^{\mathcal{A}}(\mathcal{I}')$*;*

(b) *If* $T \le T'$*, then* $\widetilde{\Lambda}^{\mathcal{A},\mathcal{I}}(T) \le \widetilde{\Lambda}^{\mathcal{A},\mathcal{I}}(T')$ *and* $\widetilde{\lambda}^{\mathcal{A},\mathcal{I}}(T) \le \widetilde{\lambda}^{\mathcal{A},\mathcal{I}}(T')$*.*

Proof:

(a) Since $\mathcal{I} \le \mathcal{I}'$, we have $\mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A}) \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence,

$$\begin{array}{rcl}\widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}) & = & \bigcap\{\Lambda^{\mathcal{A}}(X) : X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & \le & \bigcap\{\Lambda^{\mathcal{A}}(X) : X \in \mathrm{FiFam}^{\mathcal{I}'}(\mathcal{A})\} \\ & = & \widetilde{\Lambda}^{\mathcal{A}}(\mathcal{I}').\end{array}$$

An almost identical reasoning yields the second inclusion.

(b) Since $T \leq T'$, we get

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})^{T},$$

whence we have

$$\begin{array}{rcl}\widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}(T) & = & \bigcap\{\Lambda^{\mathcal{A}}(X) : T \leq X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & \leq & \bigcap\{\Lambda^{\mathcal{A}}(X) : T' \leq X \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ & = & \widetilde{\Lambda}^{\mathcal{I},\mathcal{A}}(T')\end{array}$$

and, similarly, $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T')$.

■

Corollary 80 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *π-institutions, based on* $\mathbf{F}$*, and* $T, T' \in \mathrm{ThFam}(\mathcal{I})$.

(a) If $\mathcal{I} \leq \mathcal{I}'$*, then* $\widetilde{\Lambda}(\mathcal{I}) \leq \widetilde{\Lambda}(\mathcal{I}')$ *and* $\widetilde{\lambda}(\mathcal{I}) \leq \widetilde{\lambda}(\mathcal{I}')$*;*

(b) If $T \leq T'$*, then* $\widetilde{\Lambda}^{\mathcal{I}}(T) \leq \widetilde{\Lambda}^{\mathcal{I}}(T')$ *and* $\widetilde{\lambda}^{\mathcal{I}}(T) \leq \widetilde{\lambda}^{\mathcal{I}}(T')$*.*

Proof: Apply Theorem 79 to $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. ■

In closing, we provide the following table summarizing the correspondences between notions giving rise to congruence systems and notions giving rise to equivalence families and systems:

	$T \in \mathrm{SenFam}(\mathbf{A})$	$\mathcal{T} \subseteq \mathrm{SenFam}(\mathbf{A})$	$T \in \mathcal{T} \subseteq \mathrm{SenFam}(\mathbf{A})$
Congrunece Systems	Leibniz $\Omega^{\mathbf{A}}(T)$	Tarski $\widetilde{\Omega}^{\mathbf{A}}(\mathcal{T})$	Suszko $\widetilde{\Omega}^{\mathbf{A},\mathcal{T}}(T)$
Equivalence Families/Systems	Frege $\Lambda^{\mathbf{A}}(T), \lambda^{\mathbf{A}}(T)$	Carnap $\widetilde{\Lambda}^{\mathbf{A}}(\mathcal{T}), \widetilde{\lambda}^{\mathbf{A}}(\mathcal{T})$	Lindenbaum $\widetilde{\Lambda}^{\mathbf{A},\mathcal{T}}(T), \widetilde{\lambda}^{\mathbf{A},\mathcal{T}}(T)$

2.12 Subsystems and π-Subinstitutions

In this section, we look at $N^\flat$-algebraic subsystems. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system and let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an $N^\flat$-algebraic system. A **universe** U **of** $\mathbf{A}$ is a sentence system of $\mathbf{A}$ that is closed under the operations in N, i.e., such that, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in U_\Sigma$,

$$\sigma_\Sigma(\vec{\phi}) \in U_\Sigma.$$

We denote by $\mathrm{Unv}(\mathbf{A})$ the collection of all universes of $\mathbf{A}$.

Given a universe $U \in \mathrm{Unv}(\mathbf{A})$, we may define a functor $\mathrm{SEN}' : \mathbf{Sign} \to \mathbf{Set}$, as follows:

- For all $\Sigma \in |\mathbf{Sign}|$, $\mathrm{SEN}'(\Sigma) = U_\Sigma$;

- For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathrm{SEN}'(\Sigma)$,

$$\mathrm{SEN}'(f)(\phi) = \mathrm{SEN}(f)(\phi).$$

Moreover, given a natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, we may define the natural transformation $\sigma' : \mathrm{SEN}'^k \to \mathrm{SEN}'$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}'(\Sigma)$,

$$\sigma'_\Sigma(\vec{\phi}) = \sigma_\Sigma(\vec{\phi}).$$

In other words $\sigma' = \sigma \restriction_U = \sigma \restriction_{\mathrm{SEN}'}$.

We denote by N' the category of natural transformations on SEN' consisting of the restrictions $\sigma' = \sigma \restriction_{\mathrm{SEN}'}$, with the composition operation inherited by that of N, i.e., such that

$$\sigma' \circ \tau' = \sigma \restriction_{\mathrm{SEN}'} \circ \tau \restriction_{\mathrm{SEN}'} = (\sigma \circ \tau) \restriction_{\mathrm{SEN}'} = (\sigma \circ \tau)'.$$

Finally, we set $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N' \rangle$ and call $\mathbf{A}'$ the **algebraic subsystem of $\mathbf{A}$** on the universe U or on the functor SEN'. We write $\mathbf{A}' \le \mathbf{A}$ to signify that $\mathbf{A}'$ is an algebraic subsystem of $\mathbf{A}$.

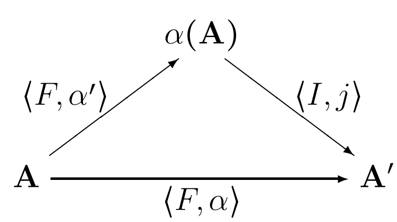
Note that the pair $\langle I, j \rangle : \mathbf{A}' \to \mathbf{A}$, where $I : \mathbf{Sign} \to \mathbf{Sign}$ and $j : \mathrm{SEN}' \to \mathrm{SEN}$, defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}'(\Sigma)$, by

$$j_\Sigma(\phi) = \phi,$$

becomes a morphism of $N^\flat$-algebraic systems, called the **injection morphism of $\mathbf{A}'$ into $\mathbf{A}$**.

Now we relate injection morphisms with the construction of the image algebraic system outlined in Lemma 13.

Proposition 81 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *and* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ $N^\flat$*-algebraic systems and* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ *an algebraic system morphism, with* $F : \mathbf{Sign} \to \mathbf{Sign}'$ *an isomorphism. Then, we have* $\langle F, \alpha \rangle = \langle I, j \rangle \circ \langle F, \alpha' \rangle$*,*



where $\langle F, \alpha' \rangle : \mathbf{A} \to \alpha(\mathbf{A})$ *is the surjective morphism defined in Lemma 14 and* $\langle I, j \rangle : \alpha(\mathbf{A}) \to \mathbf{A}'$ *is the injection morphism.*

Proof: We have, using the definitions, that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$,

$$j_{F(\Sigma)}(\alpha'_\Sigma(\phi)) = j_{F(\Sigma)}(\alpha_\Sigma(\phi)) = \alpha_\Sigma(\phi).$$

This proves the commutativity of the triangle. ∎

We call the decomposition of $\langle F, \alpha\rangle : \mathbf{A} \to \mathbf{A}'$ established in Proposition 81, the **(natural) epi-mono factorization of** $\langle F, \alpha\rangle$.

Of particular interest are the subuniverses of an algebraic system that are generated by a given sentence family X of the algebraic system. We detail this construction here and introduce some relevant notation.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be a base algebraic system and let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an $N^\flat$-algebraic system. Consider a sentence family

$$X \in \mathrm{SenFam}(\mathbf{A}).$$

Of course, it is very likely that X is neither a system (i.e., invariant under signature morphisms) nor closed under the operations in N. But we have pertinent constructions that can be employed to obtain a closure of X with respect to those operations.

Recall, first, that, by Proposition 2, $\overrightarrow{X}$ is the least sentence system of $\mathbf{A}$ containing X.

Second, define $\nu^{\mathbf{A}}(X) = \{\nu^{\mathbf{A}}_\Sigma(X)\}_{\Sigma\in|\mathbf{Sign}|}$, by letting, for all $\Sigma \in |\mathbf{Sign}|$, $\nu^{\mathbf{A}}_\Sigma(X)$ be given by

$$\nu^{\mathbf{A}}_\Sigma(X) = \{\sigma^{\mathbf{A}}_\Sigma(\vec{\phi}) : \sigma \in N, \vec{\phi} \in X_\Sigma\}.$$

We can show that $\nu^{\mathbf{A}}(X)$ is the least sentence family of $\mathbf{A}$ containing X and closed under the operations in N and that, moreover, it happens to be a sentence system in case X is a sentence system. As a consequence, we obtain that $\nu^{\mathbf{A}}(\overrightarrow{X})$ is the least universe of $\mathbf{A}$ including X. These results are detailed in the following proposition and theorem.

Proposition 82 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $X \in \mathrm{SenFam}(\mathbf{A})$.*

(a) $\nu^{\mathbf{A}}(X)$ is the least sentence family of $\mathbf{A}$ including X and closed under the operations in N;

(b) If $X \in \mathrm{SenSys}(\mathbf{A})$, the $\nu^{\mathbf{A}}(X)$ is also a sentence system.

Proof: Note, first, that, since the identity $\iota : \mathrm{SEN} \to \mathrm{SEN}$ is a natural transformation in N, we have, by definition, that $X \le \nu^{\mathbf{A}}(X)$. Suppose, next, that $\sigma : \mathrm{SEN}^k \to \mathrm{SEN}$ is in N, $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi} \in \nu^{\mathbf{A}}_\Sigma(X)$. Thus, for all $i < k$, there exists $\tau^i : \mathrm{SEN}^{n_i} \to \mathrm{SEN}$ and $\vec{\chi}^i \in X_\Sigma$, such that

$$\phi_i = \tau^i_\Sigma(\vec{\chi}^i).$$

Let $n = n_0 + n_1 + \cdots + n_{k-1}$ and $\vec{\chi} = \langle \vec{\chi}^0, \vec{\chi}^1, \dots, \vec{\chi}^{k-1} \rangle$ be the vector of length n resulting from the concatenation of the elements of the $\vec{\chi}^i$'s. Then we get that

$$\begin{array}{rcl}\sigma_\Sigma(\vec{\phi}) & = & \sigma_\Sigma(\tau^0_\Sigma(\vec{\chi}^0), \dots, \tau^{k-1}_\Sigma(\vec{\chi}^{k-1})) \\ & = & [\sigma \circ \langle \tau^0 \circ \langle p^{n,0}, \dots, p^{n,n_0-1} \rangle, \tau^1 \circ \langle p^{n,n_0}, \dots, p^{n,n_0+n_1-1} \rangle, \dots, \\ & & \qquad \tau^{k-1} \circ \langle p^{n,n_0+\cdots+n_{k-1}}, \dots, p^{n,n_0+\cdots+n_k-1} \rangle \rangle](\vec{\chi}).\end{array}$$

Since the natural transformation above is in N and $\vec{\chi} \in X_\Sigma$, we conclude that $\sigma_\Sigma(\vec{\phi}) \in \nu^{\mathbf{A}}_\Sigma(X)$, whence $\nu^{\mathbf{A}}(\Sigma)$ is closed under the operations in N.

To show minimality, suppose that $Y \in \mathrm{SenFam}(\mathbf{A})$, such that $X \leq Y$ and Y is closed under the operations in N. Consider $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \nu^{\mathbf{A}}_\Sigma(X)$. By definition, there exists σ in N and $\vec{\phi} \in X_\Sigma$, such that $\phi = \sigma_\Sigma(\vec{\phi})$. But, then, since $\vec{\phi} \in X_\Sigma \subseteq Y_\Sigma$ and Y is closed under the operations in N, we get that $\phi = \sigma_\Sigma(\vec{\phi}) \in Y_\Sigma$. Since this holds for all $\Sigma \in |\mathbf{Sign}|$, we get that $\nu^{\mathbf{A}}(X) \leq Y$ and, hence, $\nu^{\mathbf{A}}(X)$ is the least sentence family of $\mathbf{A}$ including X and closed under the operations in N.

Finally, let $X \in \mathrm{SenSys}(\mathbf{A})$. Suppose $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \nu^{\mathbf{A}}_\Sigma(X)$. Then, there exists σ in N and $\vec{\phi} \in X_\Sigma$, such that $\phi = \sigma_\Sigma(\vec{\phi})$. We now get

$$\begin{array}{rcll}\mathrm{SEN}(f)(\phi) & = & \mathrm{SEN}(f)(\sigma_\Sigma(\vec{\phi})) & \\ & = & \sigma_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi})) & (\sigma \text{ in } N) \\ & \in & \nu^{\mathbf{A}}_{\Sigma'}(X). & (\sigma \text{ in } N,\ \phi \in X_\Sigma,\ X \in \mathrm{SenSys}(\mathbf{A}))\end{array}$$

Therefore $\nu^{\mathbf{A}}(X) \in \mathrm{SenSys}(\mathbf{A})$. ■

Theorem 83 *Let* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be an algebraic system and consider* $X \in \mathrm{SenFam}(\mathbf{A})$. *Then* $\nu^{\mathbf{A}}(\overrightarrow{X})$ *is the least universe of* $\mathbf{A}$ *including* X.

Proof: By Proposition 2, $\overrightarrow{X} \in \mathrm{SenSys}(\mathbf{A})$. Therefore, by Proposition 82, $\nu^{\mathbf{A}}(\overrightarrow{X}) \in \mathrm{Unv}(\mathbf{A})$. Suppose, that $U \in \mathrm{Unv}(\mathbf{A})$, such that $X \leq U$. Since U is a universe, it is a sentence system. Thus, by Proposition 2, $\overrightarrow{X} \leq U$. Moreover, since U is a universe, it is closed under the operations in N, whence, by Proposition 82, $\nu^{\mathbf{A}}(\overrightarrow{X}) \leq U$. We conclude that $\nu^{\mathbf{A}}(\overrightarrow{X})$ is the least universe of $\mathbf{A}$ containing X. ■

Based on Theorem 83, given $X \in \mathrm{SenFam}(\mathbf{A})$, we call $\nu^{\mathbf{A}}(\overrightarrow{X})$ the **universe of A generated by** X and sometimes denote it by

$$\langle X \rangle = \{\langle X \rangle_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}.$$

We adopt many simplifying notations such as writing $\langle \Phi \rangle$, $\Phi \subseteq \mathrm{SEN}(\Sigma)$, for the universe $\langle T \rangle$, generated by $T \in \mathrm{SenFam}(\mathbf{A})$, with

$$T_{\Sigma'} = \begin{cases} \Phi, & \text{if } \Sigma' = \Sigma \\ \varnothing, & \text{if } \Sigma' \neq \Sigma \end{cases}$$

and $\langle\phi,\psi\rangle$ for $\langle\{\phi,\psi\}\rangle$, $\phi,\psi \in \mathrm{SEN}(\Sigma)$, if such overloading is unlikely to result into major mayhem.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system. Consider an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ and let $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle$ be an algebraic subsystem of $\mathbf{A}$. Define $\alpha^{-1}(\mathrm{SEN}') = \{\alpha_\Sigma^{-1}(\mathrm{SEN}')\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ by letting $\alpha_\Sigma^{-1}(\mathrm{SEN}')$ be given, for all $\Sigma \in |\mathbf{Sign}^\flat|$, by

$$\alpha_\Sigma^{-1}(\mathrm{SEN}') = \alpha_\Sigma^{-1}(\mathrm{SEN}'(F(\Sigma))).$$

Lemma 84 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system. If $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle \le \mathbf{A}$ is an algebraic subsystem of $\mathbf{A}$, then $\alpha^{-1}(\mathrm{SEN}')$ is a universe of $\mathbf{F}$.*

Proof: Since SEN' is a sentence system of $\mathcal{A}$, by Lemma 6, we get that $\alpha^{-1}(\mathrm{SEN}')$ is a sentence system of $\mathbf{F}$. So it suffices to show that $\alpha^{-1}(\mathrm{SEN}')$ is closed under the operations in $N^\flat$. To this end, let $\sigma^\flat \in N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \alpha^{-1}(\mathrm{SEN}'(F(\Sigma))$. Then we have

$$\begin{array}{rcl}\alpha_\Sigma(\sigma^\flat_\Sigma(\vec{\phi})) & = & \sigma^{\mathcal{A}}_{F(\Sigma)}(\alpha_\Sigma(\vec{\phi}))\\ & \in & \mathrm{SEN}'(F(\Sigma)),\end{array}$$

since $\alpha_\Sigma(\vec{\phi}) \in \mathrm{SEN}'(F(\Sigma))$, by hypothesis, and $\mathrm{SEN}'(F(\Sigma))$ is a universe of $\mathbf{A}$. Thus $\alpha^{-1}(\mathrm{SEN}')$ is indeed a universe of $\mathbf{F}$. ■

We define the triple $\alpha^{-1}(\mathbf{A}') = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat\rangle$ as the algebraic subsystem of $\mathbf{F}$ determined by the universe $\alpha^{-1}(\mathrm{SEN}')$ of $\mathbf{F}$.

Let, again, $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ an $\mathbf{F}$-algebraic system, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, and $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle$ be an algebraic subsystem of $\mathbf{A}$. We define the pair $\langle F,\alpha'\rangle : \alpha^{-1}(\mathbf{A}') \to \mathbf{A}'$ by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \alpha_\Sigma^{-1}(\mathrm{SEN}'(F(\Sigma))$,

$$\alpha'_\Sigma(\phi) = \alpha_\Sigma(\phi).$$

Then $\langle F,\alpha'\rangle$ turns out to be a surjective morphism from $\alpha^{-1}(\mathbf{A}')$ to $\mathbf{A}'$.

Lemma 85 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system. If $\mathbf{A}' = \langle \mathbf{Sign}, \mathrm{SEN}', N'\rangle \le \mathbf{A}$ is an algebraic subsystem of $\mathbf{A}$, then $\langle F,\alpha'\rangle : \alpha^{-1}(\mathbf{A}') \to \mathbf{A}'$ is a surjective morphism.*

Proof: Since $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ is surjective and full, by hypothesis, it suffices to show that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\alpha'_\Sigma : \alpha^{-1}(\mathrm{SEN}'(F(\Sigma))) \to \mathrm{SEN}'(F(\Sigma))$ is also surjective. But this follows by the definition of $\alpha^{-1}(\mathrm{SEN}')$ and the surjectivity of $\langle F,\alpha\rangle : \mathbf{F} \to \mathbf{A}$. ■

Lemma 85 shows that $\mathcal{A}' = \langle \mathbf{A}', \langle F, \alpha' \rangle \rangle$ may be viewed as an $\alpha^{-1}(\mathbf{A}')$-algebraic system.

Consider now an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$. Given an algebraic subsystem $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle$ of $\mathbf{F}$, we define the **π-subinstitution induced by**, or **associated with $\mathbf{F}'$**, to be the pair $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$, where $C' : \mathcal{P}\mathrm{SEN}'^\flat \to \mathcal{P}\mathrm{SEN}'^\flat$ is defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}'^\flat(\Sigma)$, by

$$C'_\Sigma(\Phi) = C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma).$$

Proposition 86 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle$ *an algebraic subsystem of* $\mathbf{F}$*. Then* $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ *is a* π*-institution.*

Proof: We must show that $C' : \mathcal{P}\mathrm{SEN}'^\flat \to \mathcal{P}\mathrm{SEN}'^\flat$ is a closure system on $\mathbf{F}'$. The inflation property is clear, since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}'^\flat(\Sigma)$,

$$\Phi \subseteq C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma) = C'_\Sigma(\Phi).$$

Monotonicity is also clear, since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi, \Psi \subseteq \mathrm{SEN}'^\flat(\Sigma)$, such that $\Phi \subseteq \Psi$,

$$C'_\Sigma(\Phi) = C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma) \subseteq C_\Sigma(\Psi) \cap \mathrm{SEN}'^\flat(\Sigma) = C'_\Sigma(\Psi).$$

For idempotency, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}'^\flat(\Sigma)$, such that $\phi \in C'_\Sigma(C'_\Sigma(\Phi))$. Then we have

$$\begin{array}{rcl}
\phi & \in & C_\Sigma(C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma)) \cap \mathrm{SEN}'^\flat(\Sigma) \\
& \subseteq & C_\Sigma(C_\Sigma(\Phi)) \cap \mathrm{SEN}'^\flat(\Sigma) \\
& = & C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma) \\
& = & C'_\Sigma(\Phi).
\end{array}$$

It now only remains to show that C' is also structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\Phi \subseteq \mathrm{SEN}'^\flat(\Sigma)$. Then, we have

$$\begin{array}{rcl}
\mathrm{SEN}'^\flat(f)(C'_\Sigma(\Phi)) & = & \mathrm{SEN}'^\flat(f)(C_\Sigma(\Phi) \cap \mathrm{SEN}'^\flat(\Sigma)) \\
& \subseteq & \mathrm{SEN}^\flat(f)(C_\Sigma(\Phi)) \cap \mathrm{SEN}'^\flat(\Sigma') \\
& \subseteq & C_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi)) \cap \mathrm{SEN}'^\flat(\Sigma') \\
& = & C_{\Sigma'}(\mathrm{SEN}'^\flat(f)(\Phi)) \cap \mathrm{SEN}'^\flat(\Sigma') \\
& = & C'_{\Sigma'}(\mathrm{SEN}'^\flat(f)(\Phi)).
\end{array}$$

We conclude that C' is a closure system on $\mathbf{F}'$ and, therefore, $\mathcal{I}'$ is a π-institution. ■

We also give a characterization of the theory families and the theory systems of the induced subinstitution in terms of those of its parent.

Proposition 87 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle$ *an algebraic subsystem of* $\mathbf{F}$*. Then*

$$\mathrm{ThFam}(\mathcal{I}') = \{T \cap \mathrm{SEN}'^\flat : T \in \mathrm{ThFam}(\mathcal{I})\} \quad \textit{and} \quad \mathrm{ThSys}(\mathcal{I}') = \{T \cap \mathrm{SEN}'^\flat : T \in \mathrm{ThSys}(\mathcal{I})\}.$$

Proof: We show the first equality. The second may be proved similarly.

Suppose, first, that $T' \in \mathrm{ThFam}(\mathcal{I}')$. Then we have $C'(T') = T'$. By definition, $C'(T') = C(T') \cap \mathrm{SEN}'^\flat$. Thus, we get $T' = C(T') \cap \mathrm{SEN}'^\flat$. Since $C(T') \in \mathrm{ThFam}(\mathcal{I})$, we get that $\mathrm{ThFam}(\mathcal{I}') \subseteq \{T \cap \mathrm{SEN}'^\flat : T \in \mathrm{ThFam}(\mathcal{I})\}$.

Suppose, conversely, that $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have

$$\begin{array}{rcl} C'(T \cap \mathrm{SEN}'^\flat) & = & C(T \cap \mathrm{SEN}'^\flat) \cap \mathrm{SEN}'^\flat \\ & \subseteq & C(T) \cap \mathrm{SEN}'^\flat \\ & = & T \cap \mathrm{SEN}'^\flat. \end{array}$$

So $T \cap \mathrm{SEN}'^\flat \in \mathrm{ThFam}(\mathcal{I}')$ and we conclude that

$$\{T \cap \mathrm{SEN}'^\flat : T \in \mathrm{ThFam}(\mathcal{I})\} \subseteq \mathrm{ThFam}(\mathcal{I}').$$

Equality now follows. ∎

Proposition 87 implies that the property of all theory families being theory systems (which shall be used in the next chapter as the defining property of a *systemic* π*-institution*) is inherited by all π-subinstitutions of a π-institution:

Corollary 88 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution, based on* $\mathbf{F}$*, and* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat \rangle$ *an algebraic subsystem of* $\mathbf{F}$*. If* $\mathcal{I}$ *is such that* $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$*, then* $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ *satisfies the same property.*

Proof: If $T' \in \mathrm{ThFam}(\mathcal{I}')$, then, by Proposition 87, there exists a theory family $T \in \mathrm{ThFam}(\mathcal{I})$, such that $T' = T \cap \mathrm{SEN}'^\flat$. By hypothesis, we have $T \in \mathrm{ThSys}(\mathcal{I})$, whence $T' = T \cap \mathrm{SEN}'^\flat \in \mathrm{ThSys}(\mathcal{I}')$. It follows that $\mathrm{ThFam}(\mathcal{I}') = \mathrm{ThSys}(\mathcal{I}')$. ∎

We now look at a relationship between Leibniz congruence systems of theory families in institutions and of Leibniz congruence systems of corresponding theory families in subinstitutions associated with given universes.

Proposition 89 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution, based on* $\mathbf{F}$*, and* $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ *a* π*-subinstitution of* $\mathcal{I}$*, associated with* $\mathbf{F}' = \langle \mathbf{Sign}, \mathrm{SEN}'^\flat, N'^\flat \rangle \leq \mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^\flat)^2 \leq \Omega^{\mathbf{F}'}(T \cap \mathrm{SEN}'^\flat).$$

Proof: By the maximality property of $\Omega^{\mathbf{F}'}(T \cap \mathrm{SEN}'^{\flat})$, it suffices to show that $\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^{\flat})^2$ is a congruence system on $\mathbf{F}'$ that is compatible with the theory family $T \cap \mathrm{SEN}'^{\flat}$.

The reflexivity, symmetry, transitivity and congruence properties of

$$\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^{\flat})^2$$

are inherited by those of $\Omega^{\mathbf{F}}(T)$. Moreover, we have, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^{\flat}|$ and all $f \in \mathbf{Sign}^{\flat}(\Sigma, \Sigma')$,

$$\begin{aligned} \mathrm{SEN}'^{\flat}(f)(\Omega^{\mathbf{F}}_{\Sigma}(T) \cap \mathrm{SEN}'^{\flat}(\Sigma)^2) &\subseteq \mathrm{SEN}^{\flat}(f)(\Omega^{\mathbf{F}}_{\Sigma}(T)) \cap \mathrm{SEN}'^{\flat}(\Sigma')^2 \\ &\subseteq \Omega^{\mathbf{F}}_{\Sigma'}(T) \cap \mathrm{SEN}'^{\flat}(\Sigma')^2. \end{aligned}$$

So $\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^{\flat})^2$ is indeed a congruence system on $\mathbf{F}'$. Finally, assume that $\Sigma \in |\mathbf{Sign}^{\flat}|$ and $\phi, \psi \in \mathrm{SEN}'^{\flat}(\Sigma)$, such that

$$\langle \phi, \psi \rangle \in \Omega^{\mathbf{F}}_{\Sigma}(T) \cap \mathrm{SEN}'^{\flat}(\Sigma)^2 \quad \text{and} \quad \phi \in T_{\Sigma} \cap \mathrm{SEN}'^{\flat}(\Sigma).$$

Then, by the compatibility of $\Omega^{\mathbf{F}}(T)$ with T, we get that $\psi \in T_{\Sigma} \cap \mathrm{SEN}'^{\flat}(\Sigma)$. We conclude that $\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^{\flat})^2$ is indeed compatible with $T \cap \mathrm{SEN}'^{\flat}$ and, therefore, $\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^{\flat})^2 \leq \Omega^{\mathbf{F}'}(T \cap \mathrm{SEN}'^{\flat})$. ∎

In particular, we have the following, where, recall that $\langle \phi, \psi \rangle$ denotes the universe of $\mathbf{F}$ generated by $\{\phi, \psi\} \subseteq \mathrm{SEN}^{\flat}(\Sigma)$.

Corollary 90 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Then, for all $\Sigma \in |\mathbf{Sign}^{\flat}|$ and all $\phi, \psi \in \mathrm{SEN}^{\flat}(\Sigma)$,*

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T) \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega^{\langle \phi, \psi \rangle}_{\Sigma}(T \cap \langle \phi, \psi \rangle).$$

Proof: This follows directly by Proposition 89 by considering the universe $\langle \phi, \psi \rangle$ of $\mathbf{F}$ generated by the sentence family T, with $T_{\Sigma} = \{\phi, \psi\}$ and $T_{\Sigma'} = \varnothing$, for all $\Sigma' \neq \Sigma$. ∎

We turn now to the examination of the relation between π-institutions and their models, on the one hand, and π-subinstitutions and their models, on the other.

We show first that, for every π-institution $\mathcal{I}$, every $\mathcal{I}$-filter family on an $\mathbf{F}$-algebraic system $\mathcal{A}$ gives rise naturally to an $\mathcal{I}'$-filter family on an $\mathbf{F}'$-algebraic subsystem of $\mathcal{A}$.

Proposition 91 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let, also $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle \leq \mathbf{A}$ be an algebraic subsystem of $\mathbf{A}$. Then $T \cap \mathrm{SEN}' \in \mathrm{FiFam}^{\mathcal{I}'}(\langle \mathbf{A}', \langle F, \alpha' \rangle \rangle)$, where $\mathcal{I}' = \langle \alpha^{-1}(\mathbf{A}'), C' \rangle$ is the π-subinstitution of $\mathcal{I}$ induced by $\alpha^{-1}(\mathbf{A}')$.*

Proof: By Lemma 84, $\alpha^{-1}(\mathbf{A}')$ is an algebraic subsystem of $\mathbf{F}$. Therefore, the pair $\mathcal{I}' = \langle \alpha^{-1}(\mathbf{A}'), C' \rangle$ is a well defined π-subinstitution of $\mathcal{I}$. So it suffices to show, by Lemma 51, that $\alpha^{-1}(T \cap \mathrm{SEN}') \in \mathrm{ThFam}(\mathcal{I}')$. But this is easy, since we have

$$\alpha^{-1}(T \cap \mathrm{SEN}') = \alpha^{-1}(T) \cap \alpha^{-1}(\mathrm{SEN}') \in \mathrm{ThFam}(\mathcal{I}'),$$

membership following by Lemma 51 and Proposition 87. ∎

As a corollary, we obtain the fact that inverse images of Leibniz congruence systems of filter families on algebraic subsystems equal Leibniz congruence systems of the corresponding theory families of π-subinstitutions.

Corollary 92 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Let, also* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle \leq \mathbf{A}$ *be an algebraic subsystem of* $\mathbf{A}$*. Then*

$$\alpha^{-1}(\Omega^{\mathbf{A}'}(T \cap \mathrm{SEN}')) = \Omega^{\alpha^{-1}(\mathbf{A}')}(\alpha^{-1}(T) \cap \alpha^{-1}(\mathrm{SEN}')).$$

Proof: This follows by Proposition 91 and Proposition 24. ∎

2.13 Syntax

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ be an algebraic system and consider a set $E \subseteq N$ of natural transformations in N. All natural transformations in E are, therefore, finitary. Since, however, there may be an infinite number of them, they may be collectively of unbounded arity. As a consequence, we write, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)^\omega$,

$$E_\Sigma(\vec{\phi}) = \{\sigma_\Sigma(\phi_0, \dots, \phi_{k-1}) : \sigma \in E\}$$

to denote the values of E on the tuple $\vec{\phi}$, where, for each $\sigma \in E$ k-ary, only the first k components of $\vec{\phi}$ are actually used.

In certain contexts, we will view the first k positions of each natural transformation in E as **distinguished**, while treating all remaining positions as **parametric**. In that case we have to exercise meticulous care when we employ the following notation. Given $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi} \in \mathrm{SEN}(\Sigma)^k$, we write

$$E_\Sigma[\vec{\phi}] = \{E_{\Sigma,\Sigma'}[\vec{\phi}]\}_{\Sigma' \in |\mathbf{Sign}|},$$

where, for all $\Sigma' \in |\mathbf{Sign}|$, we define

$$E_{\Sigma,\Sigma'}[\vec{\phi}] \quad = \quad \{\sigma_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}), \vec{\chi}) : \sigma \in E, f \in \mathbf{Sign}(\Sigma, \Sigma'), \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')\}.$$

Let, again, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $E \subseteq N$. For $T \in \mathrm{SenFam}(\mathbf{A})$, we set

$$\overleftarrow{E}(T) = \{\overleftarrow{E}_\Sigma(T)\}_{\Sigma\in|\mathbf{Sign}|},$$

where, for all $\Sigma \in |\mathbf{Sign}|$,

$$\overleftarrow{E}_\Sigma(T) = \{\vec{\phi} \in \mathrm{SEN}(\Sigma) : E_\Sigma[\vec{\phi}] \leq T\}.$$

We show that $\overleftarrow{E}(T)$ is a relation system on $\mathbf{A}$.

Lemma 93 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system, $E \subseteq N$ and $T \in \mathrm{SenFam}(\mathbf{A})$. Then $\overleftarrow{E}(T)$ is a relation system on $\mathbf{A}$.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi} \in \mathrm{SEN}(\Sigma)$, such that $\vec{\phi} \in \overleftarrow{E}_\Sigma(T)$. Our goal is to show that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\mathrm{SEN}(f)(\vec{\phi}) \in \overleftarrow{E}_{\Sigma'}(T).$$

So we fix $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$. By hypothesis, we have that, $E_\Sigma[\vec{\phi}] \leq T$. Thus, for all $\Sigma'' \in |\mathbf{Sign}|$, $g \in \mathbf{Sign}(\Sigma', \Sigma'')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma'')$,

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

$$E_{\Sigma''}(\mathrm{SEN}(gf)(\vec{\phi}), \vec{\chi}) \subseteq T_{\Sigma''},$$

or, equivalently,

$$E_{\Sigma''}(\mathrm{SEN}(g)(\mathrm{SEN}(f)(\vec{\phi})), \vec{\chi}) \subseteq T_{\Sigma''}.$$

By definition, this means that $E_{\Sigma'}[\mathrm{SEN}(f)(\vec{\phi})] \leq T$, i.e., that $\mathrm{SEN}(f)(\vec{\phi}) \in \overleftarrow{E}_{\Sigma'}(T)$. Therefore $\overleftarrow{E}(T)$ is a relation system. ■

We show, next, that $\overleftarrow{E}$ is a monotone operator on $\mathrm{SenFam}(\mathbf{A})$.

Lemma 94 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be an algebraic system and $E \subseteq N$. Then, for all $T, T' \in \mathrm{SenFam}(\mathbf{A})$,*

$$T \leq T' \quad \textit{implies} \quad \overleftarrow{E}(T) \leq \overleftarrow{E}(T').$$

Proof: Suppose that $T, T' \in \mathrm{SenFam}(\mathcal{I})$, with $T \leq T'$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \mathrm{SEN}(\Sigma)$, we have

$$\begin{array}{rcl} \vec{\phi} \in \overleftarrow{E}_\Sigma(T) & \text{iff} & E_\Sigma[\vec{\phi}] \leq T \\ & \text{implies} & E_\Sigma[\vec{\phi}] \leq T' \\ & \text{iff} & \vec{\phi} \in \overleftarrow{E}_\Sigma(T'). \end{array}$$

So $\overleftarrow{E}(T) \leq \overleftarrow{E}(T')$. ■

A very useful property of the $\overleftarrow{E}$ operator on sentence families is that it commutes with inverse surjective morphisms.

Lemma 95 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems and* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ *be a surjective morphism. Then, for all* $E \subseteq N^\flat$*, we have*

$$\alpha^{-1}(\overleftarrow{E^{\mathbf{A}'}}(T)) = \overleftarrow{E^{\mathbf{A}}}(\alpha^{-1}(T)), \quad \text{for all } T \in \mathrm{SenFam}(\mathbf{A}').$$

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi} \in \mathrm{SEN}(\Sigma)$. Then we have $\vec{\phi} \in \alpha_\Sigma^{-1}(\overleftarrow{E^{\mathbf{A}'}_{F(\Sigma)}}(T))$ iff $\alpha_\Sigma(\vec{\phi}) \in \overleftarrow{E^{\mathbf{A}'}_{F(\Sigma)}}(T)$ iff $E^{\mathbf{A}'}_{F(\Sigma)}[\alpha_\Sigma(\vec{\phi})] \leq T$ iff, by surjectivity, for all $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$E^{\mathbf{A}'}_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\vec{\phi})), \alpha_{\Sigma'}(\vec{\chi})) \subseteq T_{F(\Sigma')}$$

iff for all $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$E^{\mathbf{A}'}_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi})), \alpha_{\Sigma'}(\vec{\chi})) \subseteq T_{F(\Sigma')}$$

iff for all $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$\alpha_{\Sigma'}(E^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}), \vec{\chi})) \subseteq T_{F(\Sigma')}$$

iff for all $\Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}(\Sigma')$,

$$E^{\mathbf{A}}_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}), \vec{\chi}) \subseteq \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')})$$

iff $E^{\mathbf{A}}_\Sigma[\vec{\phi}] \leq \alpha^{-1}(T)$ iff $\vec{\phi} \in \overleftarrow{E^{\mathbf{A}}_\Sigma}(\alpha^{-1}(T))$. ■

On the other hand, there is also a relationship between the operator $\overleftarrow{E}$ and images under morphisms.

Lemma 96 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a a base algebraic system,* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* $\mathbf{A}' = \langle \mathbf{Sign}', \mathrm{SEN}', N' \rangle$ *be* $N^\flat$*-algebraic systems,* $\langle F, \alpha \rangle : \mathbf{A} \to \mathbf{A}'$ *be a morphism and* $E \subseteq N$*. Then, for all* $\Sigma \in |\mathbf{Sign}|$*, all* $\vec{\phi} \in \mathrm{SEN}(\Sigma)$ *and all* $\Sigma' \in |\mathbf{Sign}|$*, we have*

$$\alpha_{\Sigma'}(E_{\Sigma,\Sigma'}[\vec{\phi}]) \subseteq E'_{F(\Sigma),F(\Sigma')}[\alpha_\Sigma(\vec{\phi})],$$

with equality holding in case $\langle F, \alpha \rangle$ *is surjective.*

Proof: Let $\varepsilon \in E$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\vec{\chi} \in \mathrm{SEN}(\Sigma')$. Then, we have

$$\begin{aligned}
&\alpha_{\Sigma'}(\varepsilon_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi}), \vec{\chi})) \\
&\quad = \varepsilon'_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}(f)(\vec{\phi})), \alpha_{\Sigma'}(\vec{\chi})) \\
&\quad = \varepsilon'_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\vec{\phi})), \alpha_{\Sigma'}(\vec{\chi})) \\
&\quad \in E'_{F(\Sigma),F(\Sigma')}[\alpha_\Sigma(\vec{\phi})].
\end{aligned}$$

If $\langle F,\alpha\rangle$ is surjective, then every element in $E'_{F(\Sigma),F(\Sigma')}[\alpha_\Sigma(\vec{\phi})]$ is of the form $\varepsilon'_{F(\Sigma')}(\mathrm{SEN}'(F(f))(\alpha_\Sigma(\vec{\phi})),\alpha_{\Sigma'}(\vec{\chi}))$, for some $\varepsilon\in E$, $\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and $\vec{\chi}\in\mathrm{SEN}(\Sigma')$. Thus, by following the preceding equalities bottom-up, we get the reverse inclusion. ∎

Finally, we prove a close relationship between $\overleftarrow{E^{\mathbf{A}}}$, where E is a collection of natural transformations, with two distinguished arguments, and the Leibniz operator on the algebraic system $\mathbf{A}$.

Proposition 97 *Let $\mathbf{A}=\langle\mathbf{Sign},\mathrm{SEN},N\rangle$ be an algebraic system, $E\subseteq N$, with two distinguished arguments, and $T\in\mathrm{SenFam}(\mathbf{A})$. If $\overleftarrow{E}(T)$ is a reflexive relation system on $\mathbf{A}$, then*

$$\Omega^{\mathbf{A}}(T)\leq\overleftarrow{E}(T).$$

Proof: Suppose that $\Sigma\in|\mathbf{Sign}|$ and $\phi,\psi\in\mathrm{SEN}(\Sigma)$, such that $\langle\phi,\psi\rangle\in\Omega^{\mathbf{A}}_\Sigma(T)$. Since $\Omega^{\mathbf{A}}(T)$ is a congruence system, we have, for all $\sigma\in E\subseteq N$ and all $\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$, $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\begin{aligned}&\langle\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi),\vec{\chi}),\\&\qquad\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\phi),\vec{\chi})\rangle\in\Omega^{\mathbf{A}}_{\Sigma'}(T).\end{aligned}$$

By the assumption of reflexivity, we get that, for all $\sigma\in E$, all $\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and $\vec{\chi}\in\mathrm{SEN}(\Sigma')$, $\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\phi),\vec{\chi})\in T_{\Sigma'}$. Therefore, by the compatibility of $\Omega^{\mathbf{A}}(T)$ with T, we conclude that, for all $\sigma\in E$, all $\Sigma'\in|\mathbf{Sign}|$, $f\in\mathbf{Sign}(\Sigma,\Sigma')$ and $\vec{\chi}\in\mathrm{SEN}(\Sigma')$,

$$\sigma_{\Sigma'}(\mathrm{SEN}(f)(\phi),\mathrm{SEN}(f)(\psi),\vec{\chi})\in T_{\Sigma'}.$$

This means that $E_\Sigma[\phi,\psi]\leq T$, or equivalently, $\langle\phi,\psi\rangle\in\overleftarrow{E_\Sigma}(T)$. Therefore, $\Omega^{\mathbf{A}}(T)\leq\overleftarrow{E}(T)$. ∎

Proposition 97 allows us to conclude that in cases where $\overleftarrow{E}(T)$ is actually a congruence system compatible with the sentence family T, it coincides with the Leibniz congruence system of T on $\mathbf{A}$.

Corollary 98 *Let $\mathbf{A}=\langle\mathbf{Sign},\mathrm{SEN},N\rangle$ be an algebraic system, $E\subseteq N$, with two distinguished arguments, and $T\in\mathrm{SenFam}(\mathbf{A})$. If $\overleftarrow{E}(T)$ is a congruence system on $\mathbf{A}$ compatible with T, then*

$$\overleftarrow{E}(T)=\Omega^{\mathbf{A}}(T).$$

Proof: Since, by hypothesis, $\overleftarrow{E}(T)$ is a congruence system on $\mathbf{A}$, it is reflexive. So, by Proposition 97, we have $\Omega^{\mathbf{A}}(T)\leq\overleftarrow{E}(T)$. On the other hand, since it is a congruence system on $\mathbf{A}$ compatible with T and, by definition, $\Omega^{\mathbf{A}}(T)$ is the largest such, we get that $\overleftarrow{E}(T)\leq\Omega^{\mathbf{A}}(T)$. We conclude that $\overleftarrow{E}(T)=\Omega^{\mathbf{A}}(T)$. ∎

2.14 Global versus Local Membership

We turn now to exploring some syntactic conditions with respect to morphisms, parameters and theory families in a π-institution. We consider the following setting: Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $E \subseteq N^\flat$ a collection of natural transformations in $N^\flat$, with k distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$.

- We say $\vec{\phi}$ is E-**locally in** T if, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

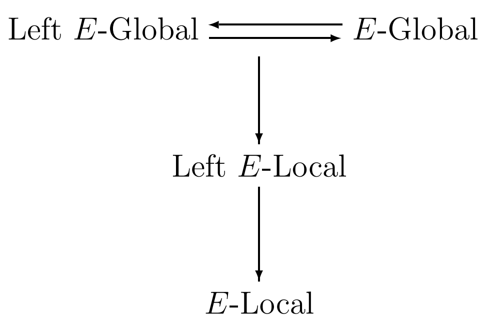
$$E_\Sigma(\vec{\phi}, \vec{\chi}) \subseteq T_\Sigma.$$

- We say that $\vec{\phi}$ is E-**globally in** T if

$$E_\Sigma[\vec{\phi}] \leq T.$$

- We say $\vec{\phi}$ is **left** E-**locally in** T if it is E-locally in $\overleftarrow{T}$.
- Similarly, $\vec{\phi}$ is **left** E-**globally in** T if it is E-globally in $\overleftarrow{T}$.

We show next that these properties satisfy the following diagram, where arrows are implications pointing from the stronger to the weaker property. After the lemma proving this result, we construct some examples showing that all implications are proper (i.e., none of them are equivalences in general for arbitrary π-institutions).



Proposition 99 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $E \subseteq N^\flat$, with k distinguished variables, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$, $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$.*

(a) $\vec{\phi}$ is left E-globally in T if and only if it is E-globally in T.

(b) If $\vec{\phi}$ is E-globally in T, then it is left E-locally in T. The implication becomes an equivalence if all arguments in E are distinguished (i.e., there are no parameters).

(c) *If $\vec{\phi}$ is left E-locally in T, then it is E-locally in T. The implication becomes an equivalence if $T \in \mathrm{ThSys}(\mathcal{I})$.*

Proof:

(a) If $\vec{\phi}$ is left E-globally in T, then $E_\Sigma[\vec{\phi}] \leq \overleftarrow{T}$. But, by Proposition 2, $\overleftarrow{T} \leq T$, whence $E_\Sigma[\vec{\phi}] \leq T$. Thus, $\vec{\phi}$ is E-globally in T.

Suppose, conversely, that $\vec{\phi}$ is E-globally in T. Then, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) \subseteq T_{\Sigma'}.$$

As a special case, we get that, for all $\Sigma', \Sigma'' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\begin{array}{ccccc} \Sigma & \xrightarrow{\quad f \quad} & \Sigma' & \xrightarrow{\quad g \quad} & \Sigma'' \\ \vec{\phi} & \longmapsto & \mathrm{SEN}^\flat(f)(\vec{\phi}) & \longmapsto & \mathrm{SEN}^\flat(g \circ f)(\vec{\phi}) \\ & & \vec{\chi} & \longmapsto & \mathrm{SEN}^\flat(g)(\vec{\chi}) \end{array}$$

$$E_{\Sigma''}(\mathrm{SEN}^\flat(g \circ f)(\vec{\phi}), \mathrm{SEN}^\flat(g)(\vec{\chi})) \subseteq T_{\Sigma''}.$$

So $\mathrm{SEN}^\flat(g)(E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi})) \subseteq T_{\Sigma''}$. Since this holds for all $\Sigma'' \in |\mathbf{Sign}^\flat|$ and all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$, we get $E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) \subseteq \overleftarrow{T}_{\Sigma'}$. Since this holds for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, we get $E_\Sigma[\vec{\phi}] \leq \overleftarrow{T}$. We now conclude that $\vec{\phi}$ is left E-globally in T.

(b) Suppose $\vec{\phi}$ is E-globally in T. Then, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) \subseteq T_{\Sigma'}.$$

Thus, in particular, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \mathrm{SEN}^\flat(f)(\vec{\chi})) \subseteq T_{\Sigma'}$. Therefore,

$$\mathrm{SEN}^\flat(f)(E_\Sigma(\vec{\phi}, \vec{\chi})) \subseteq T_{\Sigma'},$$

which shows that $E_\Sigma(\vec{\phi}, \vec{\chi}) \subseteq \overleftarrow{T}_\Sigma$. So $\vec{\phi}$ is left E-locally in T.

Finally, assume all arguments in E are distinguished. Then, if $\vec{\phi}$ is left E-locally in T, we have $E_\Sigma(\vec{\phi}) \subseteq \overleftarrow{T}_\Sigma$, whence, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi})) = \mathrm{SEN}^\flat(f)(E_\Sigma(\vec{\phi})) \subseteq T_{\Sigma'}.$$

Hence $E_\Sigma[\vec{\phi}] \leq T$ and $\vec{\phi}$ is E-globally in T.

(c) The implication holds, exactly as the left to right implication in Part (a), because $\overleftarrow{T} \leq T$, for all $T \in \mathrm{ThFam}(\mathcal{I})$. The equivalence statement holds because, by Proposition 2, $\overleftarrow{T} = T$, whenever $T \in \mathrm{ThSys}(\mathcal{I})$. ■

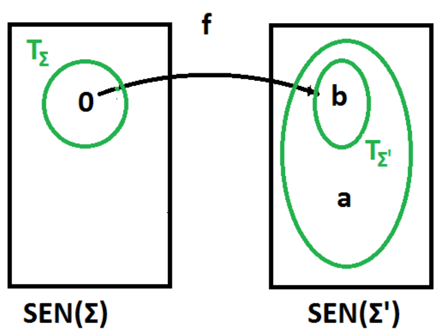
We provide examples to show that the implications in Proposition 99 are proper in general, i.e., they are not equivalences for arbitrary π-institutions, arbitrary sets of natural transformations E and arbitrary theory families T.

Example 100 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two objects* Σ, Σ' *and a single non-identity morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is determined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma')$*, given by* $\mathrm{SEN}^\flat(f)(0) = b$*;*
- $N^\flat$ *is the category of natural transformations generated by the binary transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, determined by the following tables:*

$\sigma^\flat_\Sigma$	
0	0

$\sigma^\flat_{\Sigma'}$	a	b
a	b	b
b	a	b



Consider the closure system C *on* $\mathbf{F}$ *defined by setting*

$$\mathcal{C}_\Sigma = \{\{0\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}$$

and let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the associated* π*-institution.*

Finally, take $T = \{T_\Sigma, T_{\Sigma'}\} \in \mathrm{ThFam}(\mathcal{I})$ *to be the theory family specified by*

$$T_\Sigma = \{0\} \quad \textit{and} \quad T_{\Sigma'} = \{b\}$$

and consider $E = \{\sigma^\flat\} \subseteq N^\flat$*, with one distinguished argument. Notice that* $\overleftarrow{T} = T$*.*

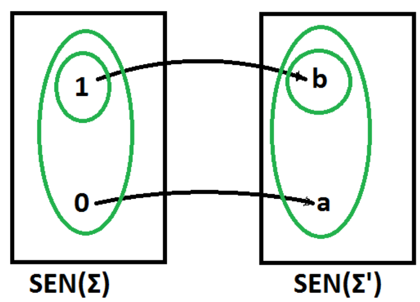
We now have $\sigma^\flat_\Sigma(0, 0) \in T_\Sigma = \overleftarrow{T}_\Sigma$*. Thus, 0 is* E*-left locally in* T*. On the other hand* $\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(0), a) = \sigma^\flat_{\Sigma'}(b, a) = a \notin T_{\Sigma'}$*. Therefore 0 is not* E*-globally in* T*.*

Example 101 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two objects* Σ, Σ' *and a single non-identity morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is determined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma')$*, given by* $\mathrm{SEN}^\flat(f)(0) = a$ *and* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the category of natural transformations generated by the binary transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, determined by the following tables:*

$\sigma^\flat_\Sigma$	0	1
0	1	1
1	0	1

$\sigma^\flat_{\Sigma'}$	a	b
a	b	b
b	a	b



Consider the closure system C *on* $\mathbf{F}$ *defined by setting*

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}$$

and let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the associated* π*-institution.*

Finally, take $T = \{T_\Sigma, T_{\Sigma'}\} \in \mathrm{ThFam}(\mathcal{I})$ *to be the theory family specified by*

$$T_\Sigma = \{0,1\} \quad \text{and} \quad T_{\Sigma'} = \{b\}$$

and consider $E = \{\sigma^\flat\} \subseteq N^\flat$*, with one distinguished argument. Notice that we have* $\overleftarrow{T} = \{\{1\},\{b\}\}$*.*

Since $\sigma^\flat_\Sigma(1,0) = 0$ *and* $\sigma^\flat_\Sigma(1,1) = 1$ *are both in* T_Σ*, we conclude that* 1 *is* E*-locally in* T*. On the other hand,* $\sigma^\flat_\Sigma(1,0) = 0 \notin \overleftarrow{T}_\Sigma$*. Thus* 1 *is not left* E*-locally in* T*.*

Let again $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $E \subseteq N^\flat$ a set of natural transformations, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$ and $T \in \mathrm{ThFam}(\mathcal{I})$. Quantifying over all signatures and all sentences, we get the following definitions:

- We say E is **locally in** T if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$E_\Sigma(\vec{\phi}, \vec{\chi}) \subseteq T_\Sigma.$$
- We say E is **left locally in** T if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$E_\Sigma(\vec{\phi}, \vec{\chi}) \subseteq \overleftarrow{T}_\Sigma.$$
- We say E is **globally in** T if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$E_\Sigma[\vec{\phi}] \leq T.$$

Of course, we have, taking into account Proposition 99:

Corollary 102 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $E \subseteq N^\flat$, *with* k *distinguished arguments,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution, based on* $\mathbf{F}$, *and* $T \in \mathrm{ThFam}(\mathcal{I})$.

(a) If E *is globally in* T, *then it is left locally in* T;

(b) If E *is left locally in* T, *then it is locally in* T.

Proof: Directly by Proposition 99. ∎

But Corollary 102 gives only half the true story. It turns out all three universal properties are equivalent.

Proposition 103 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $E \subseteq N^\flat$, *with* k *distinguished arguments,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution, based on* $\mathbf{F}$, *and* $T \in \mathrm{ThFam}(\mathcal{I})$. E *is globally in* T *if and only if it is locally in* T.

Proof: By Corollary 102, it suffices to show that, if E is locally in T, then it is also globally in T. To this end, suppose E is locally in T, i.e., that for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$,
$$E_\Sigma(\vec{\phi}, \vec{\psi}) \subseteq T_\Sigma.$$
Thus, in particular, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,
$$\begin{array}{ccc} \Sigma & \xrightarrow{\quad f \quad} & \Sigma' \\ \vec{\phi} & \longmapsto & \mathrm{SEN}^\flat(f)(\vec{\phi}) \\ & & \vec{\chi} \end{array}$$
$$E_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) \subseteq T_{\Sigma'}.$$
But this is equivalent to $E_\Sigma[\vec{\phi}] \leq T$, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$. Thus, E is globally in T. ∎

2.15 Global Properties and Parameters

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. Every $\sigma^\flat \in N^\flat$ has finite arity, but, when the exact arity is unimportant, we will write

$$\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell.$$

As already mentioned at the beginning of Section 2.13, this is also convenient in case we are dealing with a set $S^\flat \subseteq N^\flat$. In that case the set of arities of the natural transformations in $S^\flat$ may be unbounded and we write

$$S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell,$$

even though, again, the arity of each member of $S^\flat$ is finite. Finally, we denote

$$p^k := \langle p^{k,0}, p^{k,1}, \ldots, p^{k,k-1} \rangle : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^k$$

the identity natural transformation, being a tuple of the appropriate k-ary projections.

For all $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments, we denote by

$$\dot{\sigma}^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$$

the collection of k-ary natural transformations in $N^\flat$, defined by

$$\dot{\sigma}^\flat = \{\sigma^\flat \circ \langle p^k, \tau^\flat \rangle : \tau^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\omega \in N^\flat\}.$$

More generally, given a collection $S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments, we denote by

$$\dot{S}^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$$

the collection of all k-ary natural transformations in $N^\flat$ defined by

$$\dot{S}^\flat = \bigcup \{\dot{\sigma}^\flat : \sigma^\flat \in S^\flat\}.$$

Concerning these definitions, we adopt the following conventions:

1. If $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$ is k-ary, with k distinguished arguments, i.e., is thought of as parameter free, then $\dot{\sigma}^\flat = \{\sigma^\flat\}$. In this case, we identify the singleton $\dot{\sigma}^\flat$ with $\sigma^\flat$, the unique element that it contains. Similarly, for a parameterless collection $S^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, we identify $\dot{S}^\flat$ with $S^\flat$.

2. If $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ has 2 distinguished arguments, we write $\ddot{\sigma}^\flat : (\mathrm{SEN}^\flat)^2 \to (\mathrm{SEN}^\flat)^\ell$ for the collection $\dot{\sigma}^\flat$ to emphasize the binary character of $\ddot{\sigma}^\flat$. More generally, $\ddot{S}^\flat : (\mathrm{SEN}^\flat)^2 \to (\mathrm{SEN}^\flat)^\ell$ stands for the collection $\dot{S}^\flat$, when $S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ has 2 distinguished arguments.

We have the following relation concerning global membership based on a set of natural transformations and membership based on the corresponding parameter free counterpart.

Lemma 104 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and consider a collection* $S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ *of natural transformations in* $N^\flat$*, with* k *distinguished arguments. Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$*,*

$$\dot{S}^\flat_\Sigma[\vec{\phi}] \leq S^\flat_\Sigma[\vec{\phi}].$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$. Then, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, we have

$$\begin{array}{rcl} \dot{S}^\flat_{\Sigma,\Sigma'}[\vec{\phi}] & = & \bigcup_{f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')} \{\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \tau^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}))) : \\ & & \qquad \sigma^\flat \in S^\flat, \tau^\flat \in N^\flat\} \quad \text{(by definition)} \\ & \subseteq & \bigcup_{f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')} \{\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) : \sigma^\flat \in S^\flat, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')\} \\ & & \text{(set theoretic)} \\ & = & S^\flat_{\Sigma,\Sigma'}[\vec{\phi}]. \quad \text{(by definition)} \end{array}$$

Since $\Sigma' \in |\mathbf{Sign}^\flat|$ was arbitrary, we conclude that $\dot{S}^\flat_\Sigma[\vec{\phi}] \leq S^\flat_\Sigma[\vec{\phi}]$. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ a collection of natural transformations in $N^\flat$, with k distinguished arguments, and $T \in \mathrm{SenFam}(\mathbf{F}^\ell)$. Recall that by $\overleftarrow{S^\flat}(T)$ is denoted the k-ary relation system $\overleftarrow{S^\flat}(T) = \{\overleftarrow{S^\flat_\Sigma}(T)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ on $\mathbf{F}$, given, for all $\Sigma \in |\mathbf{Sign}^\flat|$, by

$$\overleftarrow{S^\flat_\Sigma}(T) = \{\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k : S^\flat_\Sigma[\vec{\phi}] \leq T\}.$$

Then we obtain

Corollary 105 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and consider a collection* $S^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ *of natural transformations in* $N^\flat$*, with* k *distinguished arguments. Then, for all* $T \in \mathrm{SenFam}(\mathbf{F}^\ell)$*,*

$$\overleftarrow{S^\flat}(T) \leq \overleftarrow{\dot{S}^\flat}(T).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\begin{array}{rcl} \overleftarrow{S^\flat_\Sigma}(T) & = & \{\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k : S^\flat_\Sigma[\vec{\phi}] \leq T\} \quad \text{(definition)} \\ & \subseteq & \{\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k : \dot{S}^\flat_\Sigma[\vec{\phi}] \leq T\} \quad \text{(Lemma 104)} \\ & = & \overleftarrow{\dot{S}^\flat_\Sigma}(T). \quad \text{(definition)} \end{array}$$

We conclude that $\overleftarrow{S^\flat}(T) \leq \overleftarrow{\dot{S}^\flat}(T)$. ∎

We now turn to collections of natural transformations satisfying certain properties globally.

For fixed k, we assume P is a **(antimonotone) global property** of natural transformations $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments. That is:

(a) For $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments, $\sigma^\flat$ either does or does not satisfy P;

(b) For every $\sigma^\flat, \tau^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments, if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k$, $\sigma^\flat_\Sigma[\vec{\phi}] \leq \tau^\flat_\Sigma[\vec{\phi}]$, then, if $\tau^\flat$ satisfies P, then $\sigma^\flat$ also satisfies P.

For instance, given $T \in \mathrm{SenFam}(\mathbf{F}^\ell)$,

$$P^T(\sigma): \quad \text{for all } \Sigma \in |\mathbf{Sign}^\flat| \text{ and all } \vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k, \quad \sigma_\Sigma[\vec{\phi}] \leq T$$

is a global property of natural transformations in $N^\flat$, with k distinguished arguments.

Given such a global property P, we denote by $P^\flat \subseteq N^\flat$ the collection of all $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ in $N^\flat$, with k distinguished arguments, that satisfy property P:

$$P^\flat = \{\sigma^\flat \in N^\flat : P(\sigma^\flat)\}.$$

We call $P^\flat$ the P-**core** of $N^\flat$.

As an example, for the property P^T introduced above, based on a fixed sentence family $T \in \mathrm{SenFam}(\mathbf{F}^\ell)$, we have

$$P^{T\flat} = \{\sigma^\flat \in N^\flat : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\forall \vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^k)(\sigma^\flat_\Sigma[\vec{\phi}] \leq T)\}.$$

Along the same lines, given a global property P of natural transformations in $N^\flat$, with k distinguished arguments, we may consider the restriction $\hat{P}$ of P to the collection of parameter free k-ary natural transformations in $N^\flat$:

$$\hat{P}: \quad \sigma : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell \in N^\flat \text{ and } P(\sigma).$$

Then we define

$$\hat{P}^\flat = \{\sigma^\flat \in N^\flat : \hat{P}(\sigma^\flat)\}.$$

We call $\hat{P}^\flat$ the k-**ary** P-**core** of $N^\flat$ or the **parameter free** P-**core** of $N^\flat$. The following inclusion is straightforward:

Lemma 106 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and consider a global property* P *of natural transformations* $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ *in* $N^\flat$*, with* k *distinguished arguments. Then*

$$\hat{P}^\flat \subseteq P^\flat.$$

Proof: Straightforward by the definition of $\hat{P}$, since any parameter free k-ary natural transformation is a natural transformation with k distinguished arguments and no parameters. ■

Let P be a global property of natural transformations in $N^\flat$, with k distinguished arguments. We have now defined two sets of k-ary natural transformations in $N^\flat$ associated with P:

- The first set is $\dot{P}^\flat$, obtained by $P^\flat$ by applying the dot operator;
- The second is the set $\hat{P}^\flat$ obtained by restricting the property P on the subfamily of parameter free k-ary natural transformations in $N^\flat$.

In the main theorem of the section we show that, for any global property P of natural transformations in $N^\flat$, with k distinguished arguments, these two sets are identical, i.e., $\hat{P}^\flat = \dot{P}^\flat$.

Theorem 107 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and consider a global property* P *of natural transformations* $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$ *in* $N^\flat$*, with* k *distinguished arguments. Then*

$$\hat{P}^\flat = \dot{P}^\flat.$$

Proof: Suppose, first, that $\sigma^\flat \in \hat{P}^\flat$. Then, by definition, $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$ is parameter free and satisfies P. Thus, we have $\sigma^\flat \in P^\flat$ and $\sigma^\flat = \dot{\sigma}^\flat \in \dot{P}^\flat$. Therefore, $\hat{P}^\flat \subseteq \dot{P}^\flat$.

Suppose, conversely, that $\rho^\flat \in \dot{P}^\flat$. Then, by definition, there exists $\sigma^\flat : (\mathrm{SEN}^\flat)^\omega \to (\mathrm{SEN}^\flat)^\ell$, with k distinguished arguments, in $P^\flat$ and $\tau^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\omega$ in $N^\flat$, such that

$$\rho^\flat = \sigma^\flat \circ \langle p^k, \tau^\flat \rangle : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell.$$

Noting that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)$, $\rho^\flat_\Sigma[\vec{\phi}] \le \sigma^\flat_\Sigma[\vec{\phi}]$, and taking into account that P is global and that $\sigma^\flat \in P^\flat$, we obtain that $\rho^\flat \in P^\flat$. But $\rho^\flat : (\mathrm{SEN}^\flat)^k \to (\mathrm{SEN}^\flat)^\ell$ is also parameter free. Therefore $\rho^\flat \in \hat{P}^\flat$. We conclude that $\dot{P}^\flat \subseteq \hat{P}^\flat$. ■

2.16 Finitarity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.

$\mathcal{I}$ is **finitary** if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$, if $\phi \in C_\Sigma(\Phi)$, then, there exists finite $\Psi \subseteq \Phi$, such that $\phi \in C_\Sigma(\Psi)$.

Equivalently, $\mathcal{I}$ is finitary if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$C_\Sigma(\Phi) = \bigcup \{ C_\Sigma(\Psi) : \Psi \subseteq_\omega \Phi \},$$

where $\Psi \subseteq_\omega \Phi$ denotes the finite subset relation.

Yet another well-known equivalent characterization of finitarity asserts that $\mathcal{I}$ is finitary if and only if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and every upward directed collection $\{T^i_\Sigma : i \in I\}$ of Σ-theories, i.e., a collection, such that:

- $C_\Sigma(T^i_\Sigma) = T^i_\Sigma$, for all $i \in I$;
- for every $i, j \in I$, there exists $k \in I$, such that $T^i_\Sigma, T^j_\Sigma \subseteq T^k_\Sigma$,

the union $\bigcup_{i \in I} T^i_\Sigma$ is also a Σ-theory.

We formulate next some versions of these properties with reference to theory families.

Let **Sign** be a category and SEN : **Sign** → **Set** a functor. A sentence family $X \in \mathrm{SenFam}(\mathrm{SEN})$ is called **locally finite** if, for all $\Sigma \in |\mathbf{Sign}|$, X_Σ is finite. In this case we write $|X| <_l \omega$. Given sentence families $X, Y \in \mathrm{SenFam}(\mathrm{SEN})$, we use the notation $X \leq_{lf} Y$ to suggest that X is a locally finite subfamily of Y.

We say that a collection $\{X^i : i \in I\} \subseteq \mathrm{SenFam}(\mathrm{SEN})$ is:

- **locally directed** if, for all $\Sigma \in |\mathbf{Sign}|$ and all finite $J \subseteq I$, there exists $k \in I$, such that $X^j_\Sigma \leq X^k_\Sigma$, for all $j \in J$;
- **directed** if, for all finite $J \subseteq I$, there exists $k \in I$, such that $X^j \leq X^k$, for all $j \in J$.

Directedness is a stronger property than local directedness.

Lemma 108 *Let* **Sign** *be a category,* SEN : **Sign** → **Set** *a sentence functor and* $\{T^i : i \in I\} \subseteq \mathrm{SenFam}(\mathrm{SEN})$*. If* $\{T^i\}$ *is directed, then it is locally directed.*

Proof: Suppose $\{T^i\}$ is directed. Let $\Sigma \in |\mathbf{Sign}|$ and $i, j \in I$. Since $\{T^i\}$ is directed, there exists a $k \in I$, such that $T^i, T^j \leq T^k$. In particular, $T^i_\Sigma, T^j_\Sigma \subseteq T^k_\Sigma$. Therefore, $\{T^i\}$ is also locally directed. ∎

The opposite implication patently fails, i.e., in general, local directedness does not imply directedness.

Example 109 *Let* **Sign** *be the discrete category with objects* Σ *and* Σ'*. Let* $\mathrm{SEN}^\flat : \mathbf{Sign} \to \mathbf{Set}$ *be defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$*.*

Consider the sentence families $T = \{\{1\}, \{a, b\}\}$ *and* $T' = \{\{0, 1\}, \{b\}\}$ *and the collection* $\mathcal{T} = \{T, T'\}$*.*

$\mathcal{T}$ *is locally directed, since* $T_\Sigma \subseteq T'_\Sigma$ *and* $T'_{\Sigma'} \subseteq T_{\Sigma'}$*.*

On the other hand, $\mathcal{T}$ *is not directed since there does not exist* $X \in \mathcal{T}$*, such that* $T, T' \leq X$*.*

Given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on $\mathbf{F}$, we say that $\mathcal{I}$ is:

- **locally continuous** if, for every locally directed family $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I});$$
- **continuous** if, for every directed family $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I}).$$

Since, by Lemma 108, directedness implies local directedness, we get the following straightforward relationship between local continuity and continuity.

Corollary 110 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is locally continuous, then it is continuous.*

Proof: Assume $\mathcal{I}$ is locally continuous and let $\mathcal{T} \subseteq \mathrm{ThFam}(\mathcal{I})$ be directed. By Lemma 108, $\mathcal{T}$ is locally directed. Thus, by local continuity, $\bigcup \mathcal{T} \in \mathrm{ThFam}(\mathcal{I})$. Hence, $\mathcal{I}$ is continuous. ■

However, more is true. In fact, continuity turns out to be equivalent to the seemingly stronger notion of local continuity.

Theorem 111 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is locally continuous if and only if it is continuous.*

Proof: The "only if" is by Corollary 110. Suppose, conversely, that $\mathcal{I}$ is continuous. Let $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ be locally directed. We construct the collection

$$\mathcal{T} = \{T' \in \mathrm{ThFam}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(\exists i \in I)(T'_\Sigma = T^i_\Sigma)\}.$$

First, note that $\mathcal{T}$ is directed. In fact, let $T, T' \in \mathcal{T}$ and $\Sigma \in |\mathbf{Sign}^\flat|$. By the definition of $\mathcal{T}$, there exist $i(\Sigma), j(\Sigma) \in I$, such that $T_\Sigma = T^{i(\Sigma)}_\Sigma$ and $T'_\Sigma = T^{j(\Sigma)}_\Sigma$. Since $\{T^i : i \in I\}$ is locally directed, there exists $k(\Sigma) \in I$, such that $T^{i(\Sigma)}_\Sigma, T^{j(\Sigma)}_\Sigma \subseteq T^{k(\Sigma)}_\Sigma$. Consider $T'' = \{T''_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$, where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$T''_\Sigma = T^{k(\Sigma)}_\Sigma.$$

Then $T'' \in \mathcal{T}$ and, moreover, $T, T' \leq T''$. Thus, $\mathcal{T}$ is indeed directed. Second, notice that $\bigcup \mathcal{T} = \bigcup_{i\in I} T^i$. Thus, taking into account the continuity of $\mathcal{I}$, we get

$$\bigcup_{i\in I} T^i = \bigcup \mathcal{T} \in \mathrm{ThFam}(\mathcal{I}).$$

Therefore, $\mathcal{I}$ is locally continuous. ■

Now we get the following characterizations of finitarity.

Proposition 112 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then the following conditions are equivalent:*

(i) $\mathcal{I}$ *is finitary;*

(ii) For every $X \in \mathrm{SenFam}(\mathbf{F})$*,*

$$C(X) = \bigcup \{C(Y) : Y \leq_{lf} X\};$$

(iii) $\mathcal{I}$ *is locally continuous.*

(iv) $\mathcal{I}$ *is continuous.*

Proof:

(i)⇒(ii) Suppose $\mathcal{I}$ is finitary and let $X \in \mathrm{SenFam}(\mathbf{F})$. Clearly, by the monotonicity of C, $\bigcup\{C(Y) : Y \leq_{lf} X\} \leq C(X)$. To prove the converse, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(X_\Sigma)$. By finitarity, there exists $Y_\Sigma \subseteq_f X_\Sigma$, such that $\phi \in C_\Sigma(Y_\Sigma)$. Now set $Y = \{Y_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}^\flat|}$, where, for all $\Sigma' \in |\mathbf{Sign}^\flat|$,

$$Y_{\Sigma'} = \begin{cases} Y_\Sigma, & \text{if } \Sigma' = \Sigma \\ \varnothing, & \text{if } \Sigma' \neq \Sigma \end{cases}$$

Clearly, $Y \leq_{lf} X$ and, moreover, $\phi \in C_\Sigma(Y)$. Thus, we get $C(X) \leq \bigcup\{C(Y) : Y \leq_{lf} X\}$.

(ii)⇒(iii) Suppose that, for every $X \in \mathrm{SenFam}(\mathbf{F})$, $C(X) = \bigcup\{C(Y) : Y \leq_{lf} X\}$ and let $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ be locally directed. Consider $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\bigcup_{i \in I} T^i_\Sigma)$. By hypothesis, there exists locally finite $Y \leq \bigcup_{i \in I} T^i$, such that $\phi \in C_\Sigma(Y_\Sigma)$. Since $\{T^i : i \in I\}$ is locally directed, there exists $i \in I$, such $Y_\Sigma \subseteq T^i_\Sigma$. Now we get $\phi \in C_\Sigma(T^i_\Sigma) = T^i_\Sigma \subseteq \bigcup_{i \in I} T^i_\Sigma$. We conclude that $\bigcup_{i \in I} T^i$ is a theory family and, therefore, $\mathcal{I}$ is locally continuous.

(iii)⇒(i) Assume that $\mathcal{I}$ is locally continuous and let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. We define a collection of theory families of $\mathcal{I}$ as follows: For every finite subset $\Psi \subseteq_f \Phi$, let $T^\Psi = \{T^\Psi_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}^\flat|}$ be given, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, by setting

$$T^\Psi_{\Sigma'} = \begin{cases} C_\Sigma(\Psi), & \text{if } \Sigma' = \Sigma \\ C_{\Sigma'}(\varnothing), & \text{if } \Sigma' \neq \Sigma \end{cases}$$

Clearly, $\{T^\Psi : \Psi \subseteq_f \Phi\}$ is a locally directed. Therefore, by hypothesis

$$C(\bigcup\{T^\Psi : \Psi \subseteq_f \Phi\}) = \bigcup\{T^\Psi : \Psi \subseteq_f \Phi\}.$$

Now we get
$$\phi \in C_\Sigma(\Phi) = C_\Sigma(\bigcup_{\Psi \subseteq_f \Phi} T_\Sigma^\Psi) = \bigcup_{\Psi \subseteq_f \Phi} T_\Sigma^\Psi,$$
whence $\phi \in T_\Sigma^\Psi = C_\Sigma(\Psi)$, for some $\Psi \subseteq_f \Phi$. We conclude that $\mathcal{I}$ is finitary.

(iii)⇔(iv) This is the content of Theorem 111.

■

We now prove a lemma concerning $\mathcal{I}$-filter generation to the effect that, for a finitary π-institution, the $\mathcal{I}$-filter generated by a certain sentence family can be built inductively by "closing under consequences" in a structured way.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π-institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $X \in \mathrm{SenFam}(\mathcal{A})$, we define
$$\Xi^{\mathcal{I},\mathcal{A},n}(X) = \{\Xi_\Sigma^{\mathcal{I},\mathcal{A},n}(X)\}_{\Sigma \in |\mathbf{Sign}|}, \quad n < \omega,$$
by induction on n, as follows:

- If $n = 0$, $\Xi^{\mathcal{I},\mathcal{A},0}(X) = X$;
- Assume $\Xi^{\mathcal{I},\mathcal{A},i}(X)$ has been defined, for all $i < n$. We define
$$\Xi^{\mathcal{I},\mathcal{A},n}(X) = \{\Xi_\Sigma^{\mathcal{I},\mathcal{A},n}(X)\}_{\Sigma \in |\mathbf{Sign}|},$$
by setting, for all $\Sigma' \in |\mathbf{Sign}|$,
$$\begin{aligned}\Xi_{\Sigma'}^{\mathcal{I},\mathcal{A},n}(X) \quad = \quad & \{\alpha_\Sigma(\phi) : \Sigma \in |\mathbf{Sign}^\flat|, \text{ such that } F(\Sigma) = \Sigma', \\ & \text{and } \Phi \cup \{\phi\} \subseteq_\omega \mathrm{SEN}^\flat(\Sigma), \text{ such that} \\ & \phi \in C_\Sigma(\Phi) \text{ and } \alpha_\Sigma(\Phi) \subseteq \Xi_{\Sigma'}^{\mathcal{I},\mathcal{A},n-1}(X)\}.\end{aligned}$$

We may write the latter set more concisely as
$$\Xi_{\Sigma'}^{\mathcal{I},\mathcal{A},n}(X) = \bigcup_{\Sigma : F(\Sigma) = \Sigma'} \{\alpha_\Sigma(\phi) : \phi \in C_\Sigma(\Phi), \alpha_\Sigma(\Phi) \subseteq \Xi_{\Sigma'}^{\mathcal{I},\mathcal{A},n-1}(X)\}.$$

We prove some basic properties of this set.

Lemma 113 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a finitary* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $X \in \mathrm{SenFam}(\mathcal{A})$.

(a) For all $n < \omega$, $\Xi^{\mathcal{I},\mathcal{A},n}(X) \leq \Xi^{\mathcal{I},\mathcal{A},n+1}(X)$;

(b) $\bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$;

(c) $\bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}(X) \leq C^{\mathcal{I},\mathcal{A}}(X)$.

Proof:

(a) Let $\Sigma' \in |\mathbf{Sign}|$, $\phi' \in \mathrm{SEN}(\Sigma)$, such that $\phi' \in \Xi^{\mathcal{I},\mathcal{A},n}_{\Sigma'}(X)$. By surjectivity of $\langle F,\alpha\rangle$, there exists $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $F(\Sigma) = \Sigma'$ and $\alpha_\Sigma(\phi) = \phi'$. But $\phi \in C_\Sigma(\phi)$ and $\alpha_\Sigma(\phi) = \phi' \in \Xi^{\mathcal{I},\mathcal{A},n}_{\Sigma'}(X)$ imply that $\phi' \in \alpha_\Sigma(\phi) \in \Xi^{\mathcal{I},\mathcal{A},n+1}_{\Sigma'}(X)$. So, we get $\Xi^{\mathcal{I},\mathcal{A},n}(X) \le \Xi^{\mathcal{I},\mathcal{A},n+1}(X)$.

(b) Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq_\omega \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$ and assume that $\alpha_\Sigma(\Phi) \subseteq \bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}_{F(\Sigma)}(X)$. Then, since $\Phi \subseteq_\omega \mathrm{SEN}^\flat(\Sigma)$, there exists $n < \omega$, such that $\alpha_\Sigma(\Phi) \subseteq \Xi^{\mathcal{I},\mathcal{A},n}_{F(\Sigma)}(X)$. Since $\phi \in C_\Sigma(\Phi)$, we get, by the definition of $\Xi^{\mathcal{I},\mathcal{A},n+1}(X)$,

$$\alpha_\Sigma(\phi) \in \Xi^{\mathcal{I},\mathcal{A},n+1}_{F(\Sigma)}(X) \subseteq \bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}_{F(\Sigma')}(X).$$

We conclude that $\bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

(c) We prove this by induction on $n < \omega$.

For $n = 0$, $\Xi^{\mathcal{I},\mathcal{A},0}(X) = X \le C^{\mathcal{I},\mathcal{A}}(X)$.

Suppose that $\Xi^{\mathcal{I},\mathcal{A},i}(X) \le C^{\mathcal{I},\mathcal{A}}(X)$, for all $i < n$.

Let $\Sigma' \in |\mathbf{Sign}|$, $\phi' \in \Xi^{\mathcal{I},\mathcal{A},n}_{\Sigma'}(X)$. Thus, there exists $\Sigma \in |\mathbf{Sign}^\flat|$, such that $F(\Sigma) = \Sigma'$, and $\Phi \cup \{\phi\} \subseteq_\omega \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, $\alpha_\Sigma(\Phi) \subseteq \Xi^{\mathcal{I},\mathcal{A},n-1}_{\Sigma'}(X)$ and $\alpha_\Sigma(\phi) = \phi'$. By the induction hypothesis, $\alpha_\Sigma(\Phi) \subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(X)$. Hence, since $\phi \in C_\Sigma(\Phi)$ and $C^{\mathcal{I},\mathcal{A}}(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, it follows that $\phi' = \alpha_\Sigma(\phi) \in C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(X)$. We conclude that $\Xi^{\mathcal{I},\mathcal{A},n}_{\Sigma'}(X) \subseteq C^{\mathcal{I},\mathcal{A}}_{\Sigma'}(X)$.

It now follows that $\bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}(X) \le C^{\mathcal{I},\mathcal{A}}(X)$.

■

We set

$$\Xi^{\mathcal{I},\mathcal{A}}(X) := \bigcup_{n<\omega} \Xi^{\mathcal{I},\mathcal{A},n}(X).$$

Proposition 114 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a finitary* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *an* $\mathbf{F}$*-algebraic system and* $X \in \mathrm{SenFam}(\mathcal{A})$*. Then*

$$C^{\mathcal{I},\mathcal{A}}(X) = \Xi^{\mathcal{I},\mathcal{A}}(X).$$

Proof: Since by Lemma 113, $\Xi^{\mathcal{I},\mathcal{A}}(X) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $X \le \Xi^{\mathcal{I},\mathcal{A}}(X)$, we get, by the minimality of $C^{\mathcal{I},\mathcal{A}}(X)$, that $C^{\mathcal{I},\mathcal{A}}(X) \le \Xi^{\mathcal{I},\mathcal{A}}(X)$. On the other hand, by Lemma 113, $\Xi^{\mathcal{I},\mathcal{A}}(X) \le C^{\mathcal{I},\mathcal{A}}(X)$. Thus, we conclude that $C^{\mathcal{I},\mathcal{A}}(X) = \Xi^{\mathcal{I},\mathcal{A}}(X)$. ■

2.17 Equational π-Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K be a class of $\mathbf{F}$-algebraic systems. Denote by $\mathrm{Eq}(\mathbf{F}) = \{\mathrm{Eq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ the family of **$\mathbf{F}$-equations**, i.e., for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Eq}_\Sigma(\mathbf{F}) = \mathrm{SEN}^\flat(\Sigma)^2.$$

The **equational consequence relative to K** or **K-equational consequence** is the closure family $D^{\mathsf{K}} : \mathcal{P}\mathrm{Eq}(\mathbf{F}) \to \mathcal{P}\mathrm{Eq}(\mathbf{F})$, defined by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$D^{\mathsf{K}}_\Sigma : \mathcal{P}(\mathrm{Eq}_\Sigma(\mathbf{F})) \to \mathcal{P}(\mathrm{Eq}_\Sigma(\mathbf{F}))$$

be given, for all $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, by

$$\begin{array}{lll}\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E) & \text{iff} & \text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathsf{K}, \\ & & \alpha_\Sigma(E) \subseteq \Delta^{\mathcal{A}}_{F(\Sigma)} \text{ implies } \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).\end{array}$$

This closure operator appeared, for the first time, in Section 2.4 as a means to characterize the relative congruence system generated by a family of equations, with respect to the class K of $\mathbf{F}$-algebraic systems. In Proposition 29, it was shown that, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a class K of $\mathbf{F}$-algebraic systems, $D^{\mathsf{K}} : \mathcal{P}\mathrm{Eq}(\mathbf{F}) \to \mathcal{P}\mathrm{Eq}(\mathbf{F})$ is a (not necessarily structural) closure family on $\mathrm{Eq}(\mathbf{F})$.

Moreover, it turns out that the closure family D^{K} satisfies the properties of reflexivity, symmetry, transitivity, congruence and invariance, detailed in the following

Proposition 115 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and let K be a class of $\mathbf{F}$-algebraic systems. For all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, all $\sigma^\flat$ in $N^\flat$, all $\vec{\phi}, \vec{\psi} \in \mathrm{SEN}^\flat(\Sigma)$, all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,*

(Reflexivity) $\phi \approx \phi \in D^{\mathsf{K}}_\Sigma(\varnothing)$;

(Symmetry) $\psi \approx \phi \in D^{\mathsf{K}}_\Sigma(\phi \approx \psi)$;

(Transitivity) $\phi \approx \chi \in D^{\mathsf{K}}_\Sigma(\phi \approx \psi, \psi \approx \chi)$;

(Congruence) $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in D^{\mathsf{K}}_\Sigma(\{\phi_i \approx \psi_i : i \in I\})$;

(Invariance) $\mathrm{SEN}^\flat(f)(\phi) \approx \mathrm{SEN}^\flat(f)(\psi) \in D^{\mathsf{K}}_{\Sigma'}(\phi \approx \psi)$.

Proof: All properties follow directly by applying Proposition 30. ■

Corollary 116 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic systems. Then $\mathrm{ThFam}(D^{\mathsf{K}}) = \mathrm{ThSys}(D^{\mathsf{K}}) = \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$.*

Proof: The first equality is a direct consequence of Invariance, given in Proposition 115, while the second follows directly from Theorem 32. ■

Assume, next, that $Q = \{Q_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|} \leq \mathrm{Eq}(\mathbf{F})$ is an $\mathbf{F}$-equation system, i.e., a family of $\mathbf{F}$-equations that is invariant under signature morphisms in the sense that, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\mathrm{SEN}^\flat(f)(Q_\Sigma) \subseteq Q_{\Sigma'}.$$

Let, also $E = \{E_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|} \leq \mathrm{Eq}(\mathbf{F})$ be an $\mathbf{F}$-equation family (not necessarily invariant under signature morphisms). We define, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $n < \omega$,

$$\Xi^{Q,n}_\Sigma(E) : \mathcal{P}(\mathrm{Eq}_\Sigma(\mathbf{F})) \to \mathcal{P}(\mathrm{Eq}_\Sigma(\mathbf{F})),$$

by induction on $n < \omega$, as follows:

- $\Xi^{Q,0}_\Sigma(E) = \{\phi \approx \phi : \phi \in \mathrm{SEN}^\flat(\Sigma)\} \cup Q_\Sigma \cup E_\Sigma$;
- Assuming that $\Xi^{Q,n}_\Sigma(E)$ has been defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$, we set

$$\begin{array}{rcl}\Xi^{Q,n+1}_\Sigma(E) & = & \{\psi \approx \phi : \phi \approx \psi \in \Xi^{Q,n}_\Sigma(E)\}\\ & & \cup\{\phi \approx \chi : \phi \approx \psi, \psi \approx \chi \in \Xi^{Q,n}_\Sigma(E)\}\\ & & \cup\{\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) : \phi_i \approx \psi_i \in \Xi^{Q,n}_\Sigma(E), i < k\}\\ & & \cup\{\mathrm{SEN}^\flat(f)(\phi \approx \psi) : \phi \approx \psi \in \Xi^{Q,n}_{\Sigma'}(E),\\ & & \qquad \Sigma' \in |\mathbf{Sign}^\flat|, f \in \mathbf{Sign}^\flat(\Sigma', \Sigma)\}.\end{array}$$

Now, set, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\Xi^Q_\Sigma(E) = \bigcup_{n<\omega} \Xi^{Q,n}_\Sigma(E)$$

and, finally,

$$\Xi^Q(E) = \{\Xi^Q_\Sigma(E)\}_{\Sigma\in|\mathbf{Sign}^\flat|}.$$

We show that $\Xi^Q : \mathcal{P}(\mathrm{Eq}(\mathbf{F})) \to \mathcal{P}(\mathrm{Eq}(\mathbf{F}))$ is a closure family on $\mathrm{Eq}(\mathbf{F})$ that satisfies Reflexivity, Symmetry, Transitivity, Congruence and Invariance.

Proposition 117 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $Q \leq \mathrm{Eq}(\mathbf{F})$ an $\mathbf{F}$-equation system. Then $\Xi^Q : \mathcal{P}\mathrm{Eq}(\mathbf{F}) \to \mathcal{P}\mathrm{Eq}(\mathbf{F})$ is a closure family on $\mathrm{Eq}(\mathbf{F})$, that satisfies Reflexivity, Symmetry, Transitivity, Congruence and Invariance.*

Proof: We start by showing that Ξ^Q is a closure family.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in E$. Then, by definition, $\phi \approx \psi \in \Xi^{Q,0}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$. So Ξ^Q is inflationary.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $E \cup F \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi^Q_\Sigma(E)$ and $E \subseteq F$. Then, for some $n < \omega$, $\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E)$. We show by induction on $n < \omega$ that, for all $n < \omega$,

$$\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E) \quad \text{implies} \quad \phi \approx \psi \in \Xi^{Q,n}_\Sigma(F).$$

  - For $n = 0$, we have $\phi = \psi$ or $\phi \approx \psi \in Q_\Sigma$ or $\phi \approx \psi \in E$. In the first two cases, $\phi \approx \psi \in \Xi^{Q,0}_\Sigma(F)$ by definition, and, in the last case, $\phi \approx \psi \in \Xi^{Q,0}_\Sigma(F)$, since $E \subseteq F$, by hypothesis.
  - Assume, next, that the statement holds for $n > 0$. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi \in \Xi^{Q,n+1}_\Sigma(E)$.

    If $\psi \approx \phi \in \Xi^{Q,n}_\Sigma(E)$, then, by the induction hypothesis, $\psi \approx \phi \in \Xi^{Q,n}_\Sigma(F)$, whence, by definition, $\phi \approx \psi \in \Xi^{Q,n+1}_\Sigma(F)$.

    If $\phi \approx \chi, \chi \approx \psi \in \Xi^{Q,n}_\Sigma(E)$, then, by the induction hypothesis, $\phi \approx \chi, \chi \approx \psi \in \Xi^{Q,n}_\Sigma(F)$, whence, by definition, $\phi \approx \psi \in \Xi^{Q,n+1}_\Sigma(F)$.

    If $\phi \approx \psi$ is of the form $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi})$, with $\phi_i \approx \psi_i \in \Xi^{Q,n}_\Sigma(E)$, $i < k$, then, by the induction hypothesis, $\phi_i \approx \psi_i \in \Xi^{Q,n}_\Sigma(F)$, whence, by definition, $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in \Xi^{Q,n+1}_\Sigma(F)$.

    Finally, if $\phi \approx \psi$ is of form $\mathrm{SEN}^\flat(f)(\phi' \approx \psi')$, with $\phi' \approx \psi' \in \Xi^{Q,n}_{\Sigma'}(E)$, then, by the induction hypothesis, $\phi' \approx \psi' \in \Xi^{Q,n}_{\Sigma'}(F)$, and, therefore, by definition, $\mathrm{SEN}^\flat(f)(\phi' \approx \psi') \in \Xi^{Q,n+1}_\Sigma(F)$.

  Thus, if $\phi \approx \psi \in \Xi^Q_\Sigma(E)$, then $\phi \approx \psi \in \Xi^Q_\Sigma(F)$ and Ξ^Q is monotone.

- Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi^Q_\Sigma(\Xi^Q_\Sigma(E))$. Then, for some $n < \omega$, $\phi \approx \psi \in \Xi^{Q,n}_\Sigma(\Xi^Q_\Sigma(E))$. We show by induction on $n < \omega$ that, for all $n < \omega$,

$$\phi \approx \psi \in \Xi^{Q,n}_\Sigma(\Xi^Q_\Sigma(E)) \quad \text{implies} \quad \phi \approx \psi \in \Xi^Q_\Sigma(E).$$

  - For $n = 0$, $\phi = \psi$ or $\phi \approx \psi \in Q_\Sigma$ or $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. In the first two cases $\phi \approx \psi \in \Xi^{Q,0}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$, by definition, and in the last the implication is trivial.
  - Suppose that the statement holds for $n > 0$ and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \approx \psi \in \Xi^{Q,n+1}_\Sigma(\Xi^Q_\Sigma(E))$.

    If $\psi \approx \phi \in \Xi^{Q,n}_\Sigma(\Xi^Q_\Sigma(E))$, then, by the induction hypothesis, $\psi \approx \phi \in \Xi^Q_\Sigma(E)$, i.e., $\psi \approx \phi \in \Xi^{Q,m}_\Sigma(E)$, for some $m < \omega$. Thus, by definition, $\phi \approx \psi \in \Xi^{Q,m+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$.

    If $\phi \approx \chi, \chi \approx \psi \in \Xi^{Q,n}_\Sigma(\Xi^Q_\Sigma(E))$, then, by the induction hypothesis, $\phi \approx \chi, \chi \approx \psi \in \Xi^Q_\Sigma(E)$, i.e., for some $m < \omega$, $\phi \approx \chi, \chi \approx \psi \in \Xi^{Q,m}_\Sigma(E)$. Thus, by definition, $\phi \approx \psi \in \Xi^{Q,m+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$.

If $\phi \approx \psi$ is of the form $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi})$, with $\phi_i \approx \psi_i \in \Xi^{Q,n}_\Sigma(\Xi^Q_\Sigma(E))$, $i < k$, then, by the induction hypothesis, $\phi_i \approx \psi_i \in \Xi^Q_\Sigma(E)$, for all $i < k$. Thus, there exists $m < \omega$, such that $\phi_i \approx \psi_i \in \Xi^{Q,m}_\Sigma(E)$, for all $i < k$, and, consequently, by definition, $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in \Xi^{Q,m+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$.

Finally, suppose that $\phi \approx \psi$ is of the form $\mathrm{SEN}^\flat(f)(\phi' \approx \psi')$, where $\phi' \approx \psi' \in \Xi^{Q,n}_{\Sigma'}(E)$. Then, by the induction hypothesis, $\phi' \approx \psi' \in \Xi^Q_{\Sigma'}(E)$, whence, there exists $m < \omega$, such that $\phi' \approx \psi' \in \Xi^{Q,m}_{\Sigma'}(E)$. But, then, by definition, $\mathrm{SEN}^\flat(f)(\phi' \approx \psi') \in \Xi^{Q,m+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$.

So Ξ^Q is a closure family. Finally, we show that it satisfies the five extra rules.

- For Reflexivity, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then, by definition, $\phi \approx \phi \in \Xi^{Q,0}_\Sigma(\varnothing) \subseteq \Xi^Q_\Sigma(\varnothing)$, whence Ξ^Q is Reflexive.

- For Symmetry, let $E \le \mathrm{Eq}(\mathbf{F})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. Then, there exists $n < \omega$, such that $\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E)$. By definition, $\psi \approx \phi \in \Xi^{Q,n+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$. We conclude that $\psi \approx \phi \in \Xi^Q_\Sigma(\phi \approx \psi)$ and, hence Ξ^Q is Symmetric.

- For Transitivity, let $E \le \mathrm{Eq}(\mathbf{F})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi, \psi \approx \chi \in \Xi^Q_\Sigma(E)$. Then, there exists $n < \omega$, such that $\phi \approx \psi, \psi \approx \chi \in \Xi^{Q,n}_\Sigma(E)$. By definition, $\phi \approx \chi \in \Xi^{Q,n+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$. So Ξ^Q is Transitive.

- For Congruence, let $E \le \mathrm{Eq}(\mathbf{F})$, $\sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$ in $N^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi_i, \psi_i \in \mathrm{SEN}^\flat(\Sigma)$, $i < k$, such that $\phi_i \approx \psi_i \in \Xi^Q_\Sigma(E)$. Then, there exists $n < \omega$, such that $\phi_i \approx \psi_i \in \Xi^{Q,n}_\Sigma(E)$, for all $i < k$, whence, by definition, $\sigma^\flat_\Sigma(\vec{\phi}) \approx \sigma^\flat_\Sigma(\vec{\psi}) \in \Xi^{Q,n+1}_\Sigma(E) \subseteq \Xi^Q_\Sigma(E)$. Thus Ξ^Q satisfies Congruence.

- Finally, for Invariance, let $E \le \mathrm{Eq}(\mathbf{F})$, $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. Then, there exists $n < \omega$, such that $\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E)$, and, hence, by definition,

  $$\mathrm{SEN}^\flat(f)(\phi \approx \psi) \in \Xi^{Q,n+1}_{\Sigma'}(E) \subseteq \Xi^Q_{\Sigma'}(E).$$

  We conclude that Ξ^Q satisfies Invariance as well.

This shows that $\Xi^Q : \mathcal{P}\mathrm{Eq}(\mathbf{F}) \to \mathcal{P}\mathrm{Eq}(\mathbf{F})$ is a closure family that satisfies Reflexivity, Symmetry, Transitivity, Congruence and Invariance. ■

We show that, given a semantic variety, i.e., a class K of $\mathbf{F}$-algebraic systems, such that $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$, we have $D^{\mathsf{K}} = \Xi^{\mathrm{Ker}(\mathsf{K})}$.

We prove first a lemma.

Lemma 118 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a semantic variety of* $\mathbf{F}$*-algebraic systems, i.e., a class of* $\mathbf{F}$*-algebraic systems, such that* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$*. Then, for all* $E \subseteq \mathrm{Eq}(\mathbf{F})$*,* $\Xi^{\mathrm{Ker}(\mathsf{K})}(E) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$*.*

Proof: By Proposition 117, $\Xi^{\mathrm{Ker}(\mathsf{K})}(E)$ is a congruence system on $\mathbf{F}$. Moreover, by definition, $\mathrm{Ker}(\mathsf{K}) \leq \Xi^{\mathrm{Ker}(\mathsf{K})}(E)$. But, note that

$$\mathrm{Ker}(\mathcal{F}/\Xi^{\mathrm{Ker}(\mathsf{K})}(E)) = \Xi^{\mathrm{Ker}(\mathsf{K})}(E).$$

Thus, we have $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{F}/\Xi^{\mathrm{Ker}(\mathsf{K})}(E))$. Thus, by definition and the hypothesis,

$$\mathcal{F}/\Xi^{\mathrm{Ker}(\mathsf{K})}(E) \in \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}.$$

We conclude that $\Xi^{\mathrm{Ker}(\mathsf{K})}(E) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$. ■

Theorem 119 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems, such that* $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$*. Then* $D^{\mathsf{K}} = \Xi^Q$*, where* $Q = \mathrm{Ker}(\mathsf{K})$*.*

Proof: Assume, first, that $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E)$. Thus, by definition, for all $\mathcal{A} \in \mathsf{K}$,

$$E \subseteq \mathrm{Ker}_\Sigma(\mathcal{A}) \quad \text{implies} \quad \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathcal{A}).$$

In particular, by Lemma 118,

$$E \subseteq \mathrm{Ker}_\Sigma(\mathcal{F}/\Xi^Q(E)) \quad \text{implies} \quad \langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathcal{F}/\Xi^Q(E)).$$

Equivalently, we have $E \subseteq \Xi^Q_\Sigma(E)$ implies $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. Since the first inclusion holds by the definition of Ξ^Q, we have $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. We conclude that $D^{\mathsf{K}} \leq \Xi^Q$.

Assume, conversely, that $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi^Q_\Sigma(E)$. Then, by definition, there exists an $n < \omega$, such that $\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E)$. We show, by induction on $n < \omega$, that, for all $n < \omega$,

$$\phi \approx \psi \in \Xi^{Q,n}_\Sigma(E) \quad \text{implies} \quad \phi \approx \psi \in D^{\mathsf{K}}_\Sigma(E).$$

- If $n = 0$, then $\phi = \psi$ or $\phi \approx \psi \in \mathrm{Ker}_\Sigma(\mathsf{K})$ or $\phi \approx \psi \in E$.

  In the first case, the conclusion follows by Proposition 115, and in the last, by Proposition 29.

  In the second case, we have, for all $\mathcal{A} \in \mathsf{K}$, $\mathrm{Ker}(\mathsf{K}) \leq \mathrm{Ker}(\mathcal{A})$, whence $\phi \approx \psi \in \mathrm{Ker}_\Sigma(\mathcal{A})$. So $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(\varnothing) \subseteq D^{\mathsf{K}}_\Sigma(E)$.

- Assume, now, that the conclusion holds for $n > 0$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $E \cup \{\phi \approx \psi\} \subseteq \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi_\Sigma^{Q,n+1}(E)$.

  If $\psi \approx \phi \in \Xi_\Sigma^{Q,n}(E)$, then, by the induction hypothesis, $\psi \approx \phi \in D_\Sigma^{\mathsf{K}}(E)$, whence, by Proposition 115, $\phi \approx \psi \in D_\Sigma^{\mathsf{K}}(E)$.

  If $\phi \approx \chi, \chi \approx \psi \in \Xi_\Sigma^{Q,n}(E)$, then , by the induction hypothesis, $\phi \approx \chi, \chi \approx \psi \in D_\Sigma^{\mathsf{K}}(E)$. So, by Proposition 115, we have $\phi \approx \psi \in D_\Sigma^{\mathsf{K}}(E)$.

  If $\phi \approx \psi$ is of the form $\sigma_\Sigma^\flat(\vec{\phi}) \approx \sigma_\Sigma^\flat(\vec{\psi})$, for some $\sigma^\flat$ in $N^\flat$ and $\phi_i \approx \psi_i \in \Xi_\Sigma^{Q,n}(E)$, $i < k$, then, by the induction hypothesis, $\phi_i \approx \psi_i \in D_\Sigma^{\mathsf{K}}(E)$, for all $i < k$, whence, once more by Proposition 115, $\sigma_\Sigma^\flat(\vec{\phi}) \approx \sigma_\Sigma^\flat(\vec{\psi}) \in D_\Sigma^{\mathsf{K}}(E)$.

  Finally, if $\phi \approx \psi$ is of the form $\mathrm{SEN}^\flat(f)(\phi' \approx \psi')$, for some $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma', \Sigma)$ and $\phi' \approx \psi' \in \Xi_{\Sigma'}^{Q,n}(E)$, then, by the induction hypothesis, $\phi' \approx \psi' \in D_{\Sigma'}^{\mathsf{K}}(E)$, whence, by Proposition 115, $\mathrm{SEN}^\flat(f)(\phi' \approx \psi') \in D_\Sigma^{\mathsf{K}}(E)$.

Thus, we get $\Xi^Q \leq D^{\mathsf{K}}$ and, therefore, $D^{\mathsf{K}} = \Xi^Q$. ■

2.18 Categorical Universal Algebra

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. We define **F**-equations, **F**-quasiequations and **F**-guasiequations (standing for generalized **F**-quasiequations). Recall that **F**-equations have already been introduced in Section 2.17, but the definition is repeated here for the sake of completeness.

- The family $\mathrm{Eq}(\mathbf{F}) = \{\mathrm{Eq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F-equations** is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Eq}_\Sigma(\mathbf{F}) = \mathrm{SEN}^\flat(\Sigma)^2 = \{\phi \approx \psi : \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\};$$

- The family $\mathrm{QEq}(\mathbf{F}) = \{\mathrm{QEq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F-quasiequations** is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{QEq}_\Sigma(\mathbf{F}) = \{\langle \{\phi_i \approx \psi_i : i < k\}, \phi \approx \psi \rangle : k \in \omega, \vec{\phi}, \vec{\psi}, \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\};$$

- The family $\mathrm{GEq}(\mathbf{F}) = \{\mathrm{GEq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F-guasiequations** is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{GEq}_\Sigma(\mathbf{F}) = \{\langle \{\phi_i \approx \psi_i : i \in I\}, \phi \approx \psi \rangle : \vec{\phi}, \vec{\psi}, \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)\}.$$

Sometimes we write $\langle \phi, \psi \rangle$ in place of $\phi \approx \psi$. Moreover, we use the notation
$$\vec{\phi} \approx \vec{\psi} := \{\phi_i \approx \psi_i : i \in I\}.$$

Thus, the **F**-guasiequation $\langle\{\phi_i \approx \psi_i : i \in I\}, \phi \approx \psi\rangle$ may be written more compactly $\langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle$ and, sometimes, also $\vec{\phi} \approx \vec{\psi} \to \phi \approx \psi$. Note that

$$\mathrm{Eq}(\mathbf{F}) \leq \mathrm{QEq}(\mathbf{F}) \leq \mathrm{GEq}(\mathbf{F}).$$

Let $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\Sigma \in |\mathbf{Sign}^\flat|$, $\langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle \in \mathrm{GEq}_\Sigma(\mathbf{F})$ and $\mathcal{A} = \langle\mathbf{A}, \langle F, \alpha\rangle\rangle$ an **F**-algebraic system. We say that $\mathcal{A}$ **satisfies** $\langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle$ or that the guasiequation $\langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle$ **is true in**, or **is satisfied in**, or **holds in** $\mathcal{A}$, written

$$\mathcal{A} \vDash_\Sigma \langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle,$$

if

$$\alpha_\Sigma(\phi_i) = \alpha_\Sigma(\psi_i),\ i \in I,\ \text{imply}\ \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi).$$

Since **F**-quasiequations and **F**-equations are special cases of **F**-guasiequations, the definition covers them as well. Thus, we have

- $\mathcal{A}$ satisfies the **F**-quasiequation $\langle\vec{\phi} \approx \vec{\psi}, \phi \approx \psi\rangle$ if $\alpha_\Sigma(\phi_i) = \alpha_\Sigma(\psi_i)$, for all $i < k$, imply $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$;
- $\mathcal{A}$ satisfies the **F**-equation $\phi \approx \psi$ if $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$.

Now we define the following families:

- The family $\mathrm{Eq}(\mathcal{A}) = \{\mathrm{Eq}_\Sigma(\mathcal{A})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F**-equations satisfied by $\mathcal{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Eq}_\Sigma(\mathcal{A}) = \{e \in \mathrm{Eq}_\Sigma(\mathbf{F}) : \mathcal{A} \vDash_\Sigma e\};$$
- The family $\mathrm{QEq}(\mathcal{A}) = \{\mathrm{QEq}_\Sigma(\mathcal{A})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F**-quasiequations satisfied by $\mathcal{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{QEq}_\Sigma(\mathcal{A}) = \{q \in \mathrm{QEq}_\Sigma(\mathbf{F}) : \mathcal{A} \vDash_\Sigma q\};$$
- The family $\mathrm{GEq}(\mathcal{A}) = \{\mathrm{GEq}_\Sigma(\mathcal{A})\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ of **F**-guasiequations satisfied by $\mathcal{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{GEq}_\Sigma(\mathcal{A}) = \{g \in \mathrm{GEq}_\Sigma(\mathbf{F}) : \mathcal{A} \vDash_\Sigma g\}.$$

Finally, given a class K of **F**-algebraic systems, we define:

- $\mathrm{Eq}(\mathsf{K}) = \bigcap\{\mathrm{Eq}(\mathcal{A}) : \mathcal{A} \in \mathsf{K}\}$;
- $\mathrm{QEq}(\mathsf{K}) = \bigcap\{\mathrm{QEq}(\mathcal{A}) : \mathcal{A} \in \mathsf{K}\}$;
- $\mathrm{GEq}(\mathsf{K}) = \bigcap\{\mathrm{GEq}(\mathcal{A}) : \mathcal{A} \in \mathsf{K}\}$.

Note, again, that

$$\mathrm{Eq}(\mathcal{A}) \leq \mathrm{QEq}(\mathcal{A}) \leq \mathrm{GEq}(\mathcal{A}) \quad \text{and} \quad \mathrm{Eq}(\mathsf{K}) \leq \mathrm{QEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathsf{K}).$$

Given a class $G \leq \mathrm{GEq}(\mathbf{F})$ of $\mathbf{F}$-guasiequations (which includes the case of quasiequations or equations), we define $\mathrm{AlgSys}(G)$ or, sometimes, $\mathrm{Mod}(G)$, to be the collection of all $\mathbf{F}$-algebraic systems that satisfy all the $\mathbf{F}$-guasiequations in G:

$$\mathrm{AlgSys}(G) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \mathcal{A} \vDash G\}.$$

As is well-known, based on an underlying Galois connection, we get the following, for all $G, G' \leq \mathrm{GEq}(\mathbf{F})$ and all $\mathsf{K}, \mathsf{K}' \subseteq \mathrm{AlgSys}(\mathbf{F})$,

- If $\mathsf{K} \subseteq \mathsf{K}'$, then $\mathrm{GEq}(\mathsf{K}') \leq \mathrm{GEq}(\mathsf{K})$;
- If $G \leq G'$, then $\mathrm{AlgSys}(G') \subseteq \mathrm{AlgSys}(G)$;
- $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathrm{GEq}(\mathsf{K}))$ and $\mathrm{GEq}(\mathsf{K}) = \mathrm{GEq}(\mathrm{AlgSys}(\mathrm{GEq}(\mathsf{K})))$;
- $G \subseteq \mathrm{GEq}(\mathrm{AlgSys}(G))$ and $\mathrm{AlgSys}(G) = \mathrm{AlgSys}(\mathrm{GEq}(\mathrm{AlgSys}(G)))$.

Similar relations hold with the GEq operator replaced by either the Eq or the QEq operator. We may apply some of these either without providing explicit justification or, simply, by saying "by the Galois connection".

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic systems.

- K is called an **equational class** if there exists $E \leq \mathrm{Eq}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{AlgSys}(E)$;
- K is called a **quasiequational class** if there exists $Q \leq \mathrm{QEq}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{AlgSys}(Q)$;
- K is called a **guasiequational class** if there exists $G \leq \mathrm{GEq}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{AlgSys}(G)$.

Clearly, by definition, if K is an equational class, then it is a quasiequational class and, if it is a quasiequational class, then it is a guasiequational class.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and K a class of $\mathbf{F}$-algebraic systems. We define:

- The **semantic variety generated by K**

$$\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \mathrm{Eq}(\mathsf{K}) \leq \mathrm{Eq}(\mathcal{A})\};$$

- The **semantic quasivariety generated by K**

$$\mathbb{Q}^{\mathsf{Sem}}(\mathsf{K}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \mathrm{QEq}(\mathsf{K}) \leq \mathrm{QEq}(\mathcal{A})\};$$

- The **semantic guasivariety generated by** K

$$\mathbb{G}^{\mathsf{Sem}}(\mathsf{K}) = \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : \mathrm{GEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathcal{A})\}.$$

We have the following straightforward relationships between these classes.

Lemma 120 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. Then*

$$\mathsf{K} \subseteq \mathbb{G}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{Q}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}).$$

Proof: The essential observation we use, which has been discussed before, is that

$$\mathrm{Eq}(\mathsf{K}) \leq \mathrm{QEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathsf{K}).$$

Thus, we get

$$\begin{array}{l}\{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\forall g \in \mathrm{GEq}(\mathsf{K}))(\mathcal{A} \vDash g)\}\\ \qquad \subseteq \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\forall q \in \mathrm{QEq}(\mathsf{K}))(\mathcal{A} \vDash q)\}\\ \qquad \subseteq \{\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F}) : (\forall e \in \mathrm{Eq}(\mathsf{K}))(\mathcal{A} \vDash e)\}.\end{array}$$

In other words, $\mathsf{K} \subseteq \mathbb{G}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{Q}^{\mathsf{Sem}}(\mathsf{K}) \subseteq \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. ■

Given a class K of $\mathbf{F}$-algebraic systems

- K is a **semantic variety** if $\mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$;
- K is a **semantic quasivariety** if $\mathbb{Q}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$;
- K is a **semantic guasivariety** if $\mathbb{G}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$.

We have the following result identifying equational classes with semantic varieties, quasiequational classes with semantic quasivarieties and guasiequational classes with semantic guasivarieties.

Proposition 121 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.*

(a) K *is an equational class iff it is a semantic variety;*

(b) K *is a quasiequational class iff it is a semantic quasivariety;*

(c) K *is a guasiequational class iff it is a semantic guasivariety.*

Proof:

(a) Suppose, first, that K is an equational class. Then, there exists $E \leq \mathrm{Eq}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{AlgSys}(E)$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, such that $\mathrm{Eq}(\mathsf{K}) \leq \mathrm{Eq}(\mathcal{A})$. Then we have

$$\begin{array}{rcl} \mathcal{A} & \in & \mathrm{AlgSys}(\mathrm{Eq}(\mathcal{A})) \\ & \subseteq & \mathrm{AlgSys}(\mathrm{Eq}(\mathsf{K})) \\ & = & \mathrm{AlgSys}(\mathrm{Eq}(\mathrm{AlgSys}(E))) \\ & = & \mathrm{AlgSys}(E) = \mathsf{K}. \end{array}$$

Therefore, K is a semantic variety.

Suppose, conversely, that K is a semantic variety. Set $E = \mathrm{Eq}(\mathsf{K})$. Then $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathrm{Eq}(\mathsf{K})) = \mathrm{AlgSys}(E)$. On the other hand, if $\mathcal{A} \in \mathrm{AlgSys}(E)$, then

$$\mathrm{Eq}(\mathsf{K}) = \mathrm{Eq}(\mathrm{AlgSys}(\mathrm{Eq}(\mathsf{K}))) = \mathrm{Eq}(\mathrm{AlgSys}(E)) \leq \mathrm{Eq}(\mathcal{A}),$$

whence, by hypothesis, $\mathcal{A} \in \mathsf{K}$. Therefore, $\mathsf{K} = \mathrm{AlgSys}(E)$ and K is an equational class.

(b) Suppose, first, that K is a quasiequational class. Then, there exists $Q \leq \mathrm{QEq}(\mathbf{F})$, such that $\mathsf{K} = \mathrm{AlgSys}(Q)$. Let $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, such that $\mathrm{QEq}(\mathsf{K}) \leq \mathrm{QEq}(\mathcal{A})$. Then we have

$$\begin{array}{rcl} \mathcal{A} & \in & \mathrm{AlgSys}(\mathrm{QEq}(\mathcal{A})) \\ & \subseteq & \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K})) \\ & = & \mathrm{AlgSys}(\mathrm{QEq}(\mathrm{AlgSys}(Q))) \\ & = & \mathrm{AlgSys}(Q) = \mathsf{K}. \end{array}$$

Therefore, K is a semantic quasivariety.

Suppose, conversely, that K is a semantic quasivariety. Set $Q = \mathrm{QEq}(\mathsf{K})$. Then $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K})) = \mathrm{AlgSys}(Q)$. On the other hand, if $\mathcal{A} \in \mathrm{AlgSys}(Q)$, then

$$\mathrm{QEq}(\mathsf{K}) = \mathrm{QEq}(\mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K}))) = \mathrm{QEq}(\mathrm{AlgSys}(Q)) \leq \mathrm{QEq}(\mathcal{A}),$$

whence, by hypothesis, $\mathcal{A} \in \mathsf{K}$. Therefore, $\mathsf{K} = \mathrm{AlgSys}(Q)$ and K is a quasiequational class.

(c) Very similar to Part (b).

■

We define or revisit, next, some operators on classes of $\mathbf{F}$-algebraic systems that will serve to provide different characterizations to the equational, quasi-equational and guasiequational classes of $\mathbf{F}$-algebraic systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, K a class of $\mathbf{F}$-algebraic systems and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system.

- Given $\Sigma \in |\mathbf{Sign}^\flat|$, we say that $\mathcal{A}$ is Σ-K-**certified** if there exists $\mathcal{A}^\Sigma \in \mathsf{K}$, such that $\mathrm{Eq}_\Sigma(\mathcal{A}) = \mathrm{Eq}_\Sigma(\mathcal{A}^\Sigma)$. In this case $\mathcal{A}^\Sigma$ is called the Σ-K-**certificate** of $\mathcal{A}$.

- We say that $\mathcal{A}$ is K-**certified** if it is Σ-K-certified, for all $\Sigma \in |\mathbf{Sign}^\flat|$. This, of course, means that

$$(\forall \Sigma \in |\mathbf{Sign}^\flat|)(\exists \mathcal{A}^\Sigma \in \mathsf{K})(\mathrm{Eq}_\Sigma(\mathcal{A}) = \mathrm{Eq}_\Sigma(\mathcal{A}^\Sigma)).$$

We write $\mathbb{C}(\mathsf{K})$ for the class of all $\mathbf{F}$-algebraic systems that are K-certified. We say that K is an **abstract class** whenever every K-certified $\mathbf{F}$-algebraic system belongs to K, i.e., when $\mathbb{C}(\mathsf{K}) = \mathsf{K}$.

It is not difficult to show that $\mathbb{C}$ is a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 122 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then the operator* $\mathbb{C}$ *on classes of* $\mathbf{F}$*-algebraic systems is a closure operator.*

Proof: Suppose K is a class of $\mathbf{F}$-algebraic systems.

- Let $\mathcal{A} \in \mathsf{K}$. Then, since for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathcal{A}^\Sigma = \mathcal{A} \in \mathsf{K}$ is a Σ-K-certificate for $\mathcal{A}$, we get that $\mathcal{A} \in \mathbb{C}(\mathsf{K})$. Thus, $\mathsf{K} \subseteq \mathbb{C}(\mathsf{K})$ and $\mathbb{C}$ is inflationary.

- If $\mathsf{K} \subseteq \mathsf{K}'$ and $\mathcal{A} \in \mathbb{C}(\mathsf{K})$, then, by definition, for every $\Sigma \in |\mathbf{Sign}^\flat|$, there exists a Σ-K-certificate $\mathcal{A}^\Sigma$. Since $\mathsf{K} \subseteq \mathsf{K}'$, $\mathcal{A}^\Sigma \in \mathsf{K}'$ is also a Σ-K'-certificate. Thus, $\mathcal{A} \in \mathbb{C}(\mathsf{K}')$ and $\mathbb{C}$ is also monotone.

- Finally, suppose that $\mathcal{A} \in \mathbb{C}(\mathbb{C}(\mathsf{K}))$. Then, there exists, for all $\Sigma \in |\mathbf{Sign}^\flat|$, a Σ-$\mathbb{C}(\mathsf{K})$-certificate $\mathcal{A}^\Sigma$ for $\mathcal{A}$. Therefore, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\Sigma' \in |\mathbf{Sign}^\flat|$, there exists a Σ'-K-certificate $\mathcal{A}^{\langle \Sigma, \Sigma' \rangle}$ for $\mathcal{A}^\Sigma$. But, then, for every $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Eq}_\Sigma(\mathcal{A}) = \mathrm{Eq}_\Sigma(\mathcal{A}^\Sigma) = \mathrm{Eq}_\Sigma(\mathcal{A}^{\langle \Sigma, \Sigma \rangle}).$$

  Thus, for every $\Sigma \in |\mathbf{Sign}^\flat|$, there exists a Σ-K-certificate $\mathcal{A}^{\langle \Sigma, \Sigma \rangle}$ for $\mathcal{A}$, i.e., $\mathcal{A} \in \mathbb{C}(\mathsf{K})$ and $\mathbb{C}$ is also idempotent.

Thus $\mathbb{C}$ is a closure operator on classes of $\mathbf{F}$-algebraic systems. ∎

The importance of abstract classes of $\mathbf{F}$-algebraic systems here, and the reason why they will be our exclusive focus in this section, rests on the following observation to the effect that the validity of a guasiequation transfers from K-certificates of an $\mathbf{F}$-algebraic system to the $\mathbf{F}$-algebraic system itself.

Lemma 123 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* K *a class of* $\mathbf{F}$*-algebraic systems and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. If* $\mathcal{A} \in \mathbb{C}(\mathsf{K})$*, then* $\mathrm{GEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathcal{A})$.

Proof: Suppose $\mathcal{A} \in \mathbb{C}(\mathsf{K})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$, such that $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A})$. Let $\mathcal{A}^\Sigma \in \mathsf{K}$ be a Σ-K-certificate for $\mathcal{A}$. Then, by definition $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A}^\Sigma)$. Since $\mathcal{A}^\Sigma \in \mathsf{K}$ and $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$, we get $\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}^\Sigma) = \mathrm{Eq}_\Sigma(\mathcal{A})$. Therefore, $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathcal{A})$. We conclude that $\mathrm{GEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathcal{A})$. ■

Using Lemma 123, we get the following corollary to the effect that all semantically defined classes of algebraic systems are abstract.

Corollary 124 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. If* K *is a guasiequational class (and, hence, a fortiori, if it is a quasiequational class or an equational class), then it is abstract.*

Proof: Suppose K is a guasiequational class defined by the family of $\mathbf{F}$-guasiequations $G \leq \mathrm{GEq}(\mathbf{F})$ and let $\mathcal{A} \in \mathbb{C}(\mathsf{K})$. Then, by Lemma 123, $\mathrm{GEq}(\mathsf{K}) \leq \mathrm{GEq}(\mathcal{A})$, whence

$$\begin{array}{rcl}
\mathcal{A} & \in & \mathrm{AlgSys}(\mathrm{GEq}(\mathcal{A})) \\
 & \subseteq & \mathrm{AlgSys}(\mathrm{GEq}(\mathsf{K})) \\
 & = & \mathrm{AlgSys}(\mathrm{GEq}(\mathrm{AlgSys}(G))) \\
 & = & \mathrm{AlgSys}(G) \\
 & = & \mathsf{K}.
\end{array}$$

Thus, K is an abstract class. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, K a class of $\mathbf{F}$-algebraic systems and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$-algebraic system.

- Given $\Sigma \in |\mathbf{Sign}^\flat|$, we say that $\mathcal{A}$ is **directedly** Σ-K-**certified** if there exists a collection of $\mathbf{F}$-algebraic systems $\{\mathcal{A}^{\Sigma,i} : i \in I\} \subseteq \mathsf{K}$, such that:
  - $\bigcup_{i \in I} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ is directed, where, for all $i \in I$, $\mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ denotes the collection of all finite subsets of $\mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i})$, and
  - $\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{i \in I} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i})$.

  We call $\{\mathcal{A}^{\Sigma,i} : i \in I\}$ the **directed** Σ-K-**certificate** of $\mathcal{A}$.

- We say that $\mathcal{A}$ is **directedly** K-**certified** if it is directedly Σ-K-certified, for all $\Sigma \in |\mathbf{Sign}^\flat|$.

We write $\mathbb{C}^*(\mathsf{K})$ for the class of all $\mathbf{F}$-algebraic systems that are directedly K-certified. We say that K is a **directedly abstract class** whenever every directedly K-certified $\mathbf{F}$-algebraic system belongs to K, i.e., when $\mathbb{C}^*(\mathsf{K}) = \mathsf{K}$.

We show that, like $\mathbb{C}$, $\mathbb{C}^*$ is a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 125 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then the operator* $\mathbb{C}^*$ *on classes of* $\mathbf{F}$*-algebraic systems is a closure operator.*

Proof: Suppose K is a class of $\mathbf{F}$-algebraic systems.

- Let $\mathcal{A} \in \mathsf{K}$. Then, since, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\{\mathcal{A}\} \subseteq \mathsf{K}$ is a directed Σ-K-certificate for $\mathcal{A}$, we get that $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$. Thus, $\mathsf{K} \subseteq \mathbb{C}^*(\mathsf{K})$ and $\mathbb{C}^*$ is inflationary.

- If $\mathsf{K} \subseteq \mathsf{K}'$ and $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$, then, by definition, for every $\Sigma \in |\mathbf{Sign}^\flat|$, there exists a directed Σ-K-certificate $\{\mathcal{A}^{\Sigma,i} : i \in I_\Sigma\} \subseteq \mathsf{K}$. Since $\mathsf{K} \subseteq \mathsf{K}'$, $\{\mathcal{A}^{\Sigma,i} : i \in I_\Sigma\} \subseteq \mathsf{K}'$ is also a directed Σ-K'-certificate. Thus, $\mathcal{A} \in \mathbb{C}^*(\mathsf{K}')$ and $\mathbb{C}^*$ is also monotone.

- Finally, suppose that $\mathcal{A} \in \mathbb{C}^*(\mathbb{C}^*(\mathsf{K}))$. Then, for all $\Sigma \in |\mathbf{Sign}^\flat|$, there exists $\{\mathcal{A}^{\Sigma,i} : i \in I_\Sigma\} \subseteq \mathbb{C}^*(\mathsf{K})$, such that $\bigcup_{i \in I_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ is directed and $\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{i \in I_\Sigma} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i})$. Thus, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$ and all $i \in I_\Sigma$, there exists $\{\mathcal{A}^{\Sigma,i,\Sigma',j} : j \in J^{\Sigma,i}_{\Sigma'}\} \subseteq \mathsf{K}$, such that $\bigcup_{j \in J^{\Sigma,i}_{\Sigma'}} \mathrm{Eq}^\omega_{\Sigma'}(\mathcal{A}^{\Sigma,i,\Sigma',j})$ is directed and, moreover, $\mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma,i}) = \bigcup_{j \in J^{\Sigma,i}_{\Sigma'}} \mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma,i,\Sigma',j})$. Now notice that, for all $\Sigma \in |\mathbf{Sign}^\flat|$, the collection
$$\{\mathcal{A}^{\Sigma,i,\Sigma,j} : i \in I_\Sigma, j \in J^{\Sigma,i}_\Sigma\} \subseteq \mathsf{K}$$
satisfies
$$\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{i \in I_\Sigma} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i}) = \bigcup_{i \in I_\Sigma} \bigcup_{j \in J^{\Sigma,i}_\Sigma} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i,\Sigma,j}).$$
Thus, to see that $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$, it suffices to show that the collection
$$\bigcup_{i \in I_\Sigma} \bigcup_{j \in J^{\Sigma,i}_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i,\Sigma,j})$$
is directed. Consider $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i,\Sigma,j})$ and $X' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i',\Sigma,j'})$. Then, as
$$\begin{array}{rcl}\mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i}) & = & \bigcup_{j \in J^{\Sigma,i}_\Sigma} \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i,\Sigma,j}),\\ \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i'}) & = & \bigcup_{j \in J^{\Sigma,i'}_\Sigma} \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i',\Sigma,j}),\end{array}$$
we get that $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ and $X' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i'})$. As $\bigcup_{i \in I_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ is directed, there exists $k \in I_\Sigma$ and $Y \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,k})$, such that $X, X' \subseteq Y$. Now, from $\mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,k}) = \bigcup_{j \in J^{\Sigma,k}_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,k,\Sigma,j})$, the finiteness of Y and the fact that the union is directed, there must exist $\ell \in J^{\Sigma,k}_\Sigma$, such that $Y \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,k,\Sigma,\ell})$. This establishes the directedness of the collection $\bigcup_{i \in I_\Sigma} \bigcup_{j \in J^{\Sigma,i}_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i,\Sigma,j})$.

Thus $\mathbb{C}^*$ is a closure operator on classes of $\mathbf{F}$-algebraic systems. ∎

The importance of directedly abstract classes of $\mathbf{F}$-algebraic systems stems from the fact that the validity of a quasiequation transfers from directed K-certificates of an $\mathbf{F}$-algebraic system to the $\mathbf{F}$-algebraic system itself.

Lemma 126 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* K *a class of* $\mathbf{F}$*-algebraic systems and* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system. If* $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$*, then* $\mathrm{QEq}(\mathsf{K}) \leq \mathrm{QEq}(\mathcal{A})$.

Proof: Suppose $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{QEq}_\Sigma(\mathsf{K})$, such that $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A})$. Let $\{\mathcal{A}^{\Sigma,i} : i \in I\} \subseteq \mathsf{K}$ be a directed Σ-K-certificate for $\mathcal{A}$. Then, by definition $\vec{\phi} \approx \vec{\psi} \subseteq \bigcup_{i \in I} \mathrm{Eq}_\Sigma^\omega(\mathcal{A}^{\Sigma,i})$. Since $\vec{\phi} \approx \vec{\psi}$ is finite and the union is directed, there exists $i \in I$, such that $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i})$. But $\mathcal{A}^{\Sigma,i} \in \mathsf{K}$ and $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{QEq}_\Sigma(\mathsf{K})$, whence

$$\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i}) \subseteq \bigcup_{i \in I} \mathrm{Eq}_\Sigma(\mathcal{A}^{\Sigma,i}) = \mathrm{Eq}_\Sigma(\mathcal{A}).$$

Therefore, $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{QEq}_\Sigma(\mathcal{A})$ and $\mathrm{QEq}(\mathsf{K}) \leq \mathrm{QEq}(\mathcal{A})$. ∎

Using Lemma 126, we get that all semantic quasivarieties of algebraic systems are directedly abstract.

Corollary 127 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. If* K *is a quasiequational class (and, hence, a fortiori, if it is an equational class), then it is directedly abstract.*

Proof: Suppose K is a quasiequational class defined by the family of $\mathbf{F}$-quasiequations $Q \leq \mathrm{QEq}(\mathbf{F})$ and let $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$. Then, by Lemma 126, $\mathrm{QEq}(\mathsf{K}) \leq \mathrm{QEq}(\mathcal{A})$, whence

$$\begin{array}{rcl}\mathcal{A} & \in & \mathrm{AlgSys}(\mathrm{QEq}(\mathcal{A})) \\ & \subseteq & \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K})) \\ & = & \mathrm{AlgSys}(\mathrm{QEq}(\mathrm{AlgSys}(Q))) \\ & = & \mathrm{AlgSys}(Q) \\ & = & \mathsf{K}.\end{array}$$

Thus, K is a directedly abstract class. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i \rangle \rangle$, $i \in I$, $\mathbf{F}$-algebraic systems and $\langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^i$, $i \in I$, surjective morphisms. Recall from Section 2.4 that we say that the collection

$$\langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

is a **subdirect intersection** if

$$\bigcap_{i \in I} \mathrm{Ker}(\langle H^i, \gamma^i \rangle) = \Delta^{\mathcal{A}}.$$

Given a class K of $\mathbf{F}$-algebraic systems, we write $\mathcal{A} \in \overset{\triangleleft}{\mathbb{IP}}(\mathsf{K})$ in case there exists a subdirect intersection $\{\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, i \in I\}$, with $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$. If $\overset{\triangleleft}{\mathbb{IP}}(\mathsf{K}) = \mathsf{K}$, we say that K is **closed under subdirect intersections**.

The following lemma provides an alternative characterization of the concept of subdirect intersection.

Lemma 128 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*,* $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i\rangle\rangle$*,* $i \in I$*,* $\mathbf{F}$*-algebraic systems and* $\{\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i : i \in I\}$ *a collection of morphisms. The collection* $\{\langle H^i, \gamma^i\rangle : i \in I\}$ *is a subdirect intersection if and only if* $\mathrm{Ker}(\langle F, \alpha\rangle) = \bigcap_{i\in I} \mathrm{Ker}(\langle F^i, \alpha^i\rangle)$.

Proof: Suppose, first, that $\{\langle H^i, \gamma^i\rangle : i \in I\}$ is a subdirect intersection and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then

$$\begin{array}{lll}
\langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha\rangle) & \text{iff} & \alpha_\Sigma(\phi) = \alpha_\Sigma(\psi) \\
& \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \Delta^{\mathcal{A}}_{F(\Sigma)} \\
& \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \bigcap_{i\in I} \mathrm{Ker}_\Sigma(\langle H^i, \gamma^i\rangle) \\
& \text{iff} & \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\phi)) = \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\psi)), i \in I \\
& \text{iff} & \alpha^i_\Sigma(\phi) = \alpha^i_\Sigma(\psi), i \in I \\
& \text{iff} & \langle \phi, \psi\rangle \in \bigcap_{i\in I} \mathrm{Ker}_\Sigma(\langle F^i, \alpha^i\rangle).
\end{array}$$

The reverse relies on the surjectivity of $\langle F, \alpha\rangle$. Suppose $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then we get

$$\begin{array}{lll}
\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \Delta^{\mathcal{A}}_{F(\Sigma)} & \text{iff} & \langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha\rangle) \\
& \text{iff} & \langle \phi, \psi\rangle \in \bigcap_{i\in I} \mathrm{Ker}_\Sigma(\langle F^i, \alpha^i\rangle) \\
& \text{iff} & \alpha^i_\Sigma(\phi) = \alpha^i_\Sigma(\psi), i \in I \\
& \text{iff} & \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\phi)) = \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\psi)), i \in I \\
& \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \bigcap_{i\in I} \mathrm{Ker}_{F(\Sigma)}(\langle H^i, \gamma^i\rangle).
\end{array}$$

Thus, by the surjectivity of $\langle F, \alpha\rangle$ we get that $\Delta^{\mathcal{A}} = \bigcap_{i\in I} \mathrm{Ker}(\langle H^i, \gamma^i\rangle)$. ■

It is not difficult to verify that the subdirect intersection operator is also a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 129 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system. Then the operator* $\overset{\triangleleft}{\mathbb{IP}}$ *on classes of* $\mathbf{F}$*-algebraic systems is a closure operator.*

Proof: Suppose K is a class of $\mathbf{F}$-algebraic systems.

- If $\mathcal{A} \in \mathsf{K}$, then $\{\langle I, \iota\rangle : \mathcal{A} \to \mathcal{A}\}$, where $\langle I, \iota\rangle : \mathcal{A} \to \mathcal{A}$ is the identity morphism, is a subdirect intersection family. Thus, we get that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{IP}}(\mathsf{K})$. Hence $\mathsf{K} \subseteq \overset{\triangleleft}{\mathbb{IP}}(\mathsf{K})$ and $\overset{\triangleleft}{\mathbb{IP}}$ is inflationary;

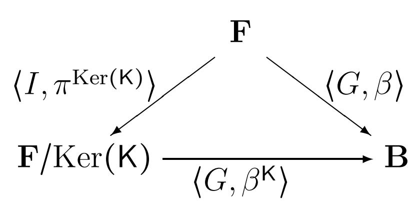
- It is obvious that $\overset{\triangleleft}{\mathbb{I}\Pi}$ is monotonic;
- Suppose that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{I}\Pi}(\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K}))$. Then, there exists a subdirect intersection family $\{\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, i \in I\}$, with $\mathcal{A}^i \in \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$, for all $i \in I$. Therefore, for each $i \in I$, there exists a sibdirect intersection family $\{\langle H^{ij}, \gamma^{ij}\rangle : \mathcal{A}^i \to \mathcal{A}^{ij}, j \in J_i\}$, with $\mathcal{A}^{ij} \in \mathsf{K}$, for all $i \in I$ and all $j \in J_i$. Consider
$$\{\langle H^{ij}, \gamma^{ij}\rangle \circ \langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^{ij}, i \in I, j \in J_i\}.$$
It is a subdirect intersection family, since
$$\begin{aligned}\textstyle\bigcap_{i\in I, j\in J_i} \mathrm{Ker}(\langle H^{ij}, \gamma^{ij}\rangle \circ \langle H^i, \gamma^i\rangle) & \\ &= \textstyle\bigcap_{i\in I, j\in J_i} (\gamma^{ij} \circ \gamma^i)^{-1}(\Delta^{\mathcal{A}^{ij}}) \\ &= \textstyle\bigcap_{i\in I, j\in J_i} (\gamma^i)^{-1}((\gamma^{ij})^{-1}(\Delta^{\mathcal{A}^{ij}})) \\ &= \textstyle\bigcap_{i\in I} (\gamma^i)^{-1}(\bigcap_{j\in J_i} (\gamma^{ij})^{-1}(\Delta^{\mathcal{A}^{ij}})) \\ &= \textstyle\bigcap_{i\in I} (\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\ &= \Delta^{\mathcal{A}}.\end{aligned}$$
Since $\mathcal{A}^{ij} \in \mathsf{K}$, for all $i \in I$, $j \in J_i$, we get that $\overset{\triangleleft}{\mathbb{I}\Pi}(\overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})) \subseteq \overset{\triangleleft}{\mathbb{I}\Pi}(\mathsf{K})$ and $\overset{\triangleleft}{\mathbb{I}\Pi}$ is idempotent.

Thus, $\overset{\triangleleft}{\mathbb{I}\Pi}$ is a closure operator. ∎

A key property concerning subdirect intersections, which is very useful in applying the concept, is given in the following

Lemma 130 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and consider a class* $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$. *The class of morphisms*
$$\langle G, \beta^{\mathsf{K}}\rangle : \mathcal{F}/\bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}(\langle G, \beta\rangle) \to \mathcal{B}, \quad \mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle \in \mathsf{K},$$
where, for all $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\beta^{\mathsf{K}}_\Sigma(\phi/\bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}_\Sigma(\langle G, \beta\rangle)) = \beta_\Sigma(\phi),$$
forms a subdirect intersection.

Proof: It is not difficult to see that β^{K} is well defined and forms a natural transformation. Moreover, $\langle G, \beta^{\mathsf{K}}\rangle$ is an $\mathbf{F}$-morphism. Letting $\mathrm{Ker}(\mathsf{K}) = \bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}(\langle G, \beta\rangle)$, we have, by definition, the following commutative triangle.



To show that the displayed family forms a subdirect intersection, let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we get

$$\begin{array}{ll}\langle \phi/\mathrm{Ker}_\Sigma(\mathsf{K}), \psi/\mathrm{Ker}_\Sigma(\mathsf{K})\rangle \in \bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}_\Sigma(\langle G, \beta^{\mathsf{K}}\rangle) & \\ \quad \text{iff} \quad \beta^{\mathsf{K}}_\Sigma(\phi/\mathrm{Ker}_\Sigma(\mathsf{K})) = \beta^{\mathsf{K}}_\Sigma(\psi/\mathrm{Ker}_\Sigma(\mathsf{K})), \quad \mathcal{B} \in \mathsf{K}, & \\ \quad \text{iff} \quad \beta_\Sigma(\phi) = \beta_\Sigma(\psi), \quad \mathcal{B} \in \mathsf{K}, & \\ \quad \text{iff} \quad \phi/\mathrm{Ker}_\Sigma(\mathsf{K}) = \psi/\mathrm{Ker}_\Sigma(\mathsf{K}). & \end{array}$$

Thus, $\bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}(\langle G, \beta^{\mathsf{K}}\rangle) = \Delta^{\mathcal{F}/\mathrm{Ker}(\mathsf{K})}$, showing that

$$\langle G, \beta^{\mathsf{K}}\rangle : \mathcal{F}/\bigcap_{\mathcal{B}\in\mathsf{K}} \mathrm{Ker}(\langle G, \beta\rangle) \to \mathcal{B}, \quad \mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle \in \mathsf{K},$$

constitutes indeed a subdirect intersection. ■

Finally, we show that every semantic guasivariety of $\mathbf{F}$-algebraic systems is closed under subdirect intersections.

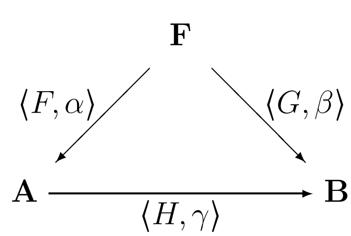
Proposition 131 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$. *If* $\mathsf{K} = \mathbb{G}^{\mathsf{Sem}}(\mathsf{K})$, *then* $\overset{\triangleleft}{\mathbb{\Pi}}(\mathsf{K}) \subseteq \mathsf{K}$.

Proof: Assume that $\mathsf{K} = \mathbb{G}^{\mathsf{Sem}}(\mathsf{K})$. Let $X = \mathrm{GEq}(\mathsf{K})$. Assume that $\mathcal{A} \in \overset{\triangleleft}{\mathbb{\Pi}}(\mathsf{K})$ and $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi} \approx \vec{\psi} \to \phi \approx \psi \in X_\Sigma$, such that $\mathcal{A} \vDash_\Sigma \vec{\phi} \approx \vec{\psi}$, i.e., $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A})$. Since $\mathcal{A} \in \overset{\triangleleft}{\mathbb{\Pi}}(\mathsf{K})$, there exists a subdirect intersection

$$\langle H^i, \gamma^i\rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

such that $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$. Hence, we get $\vec{\phi} \approx \vec{\psi} \subseteq \mathrm{Eq}_\Sigma(\mathcal{A}^i)$, $i \in I$. Now, since $\mathcal{A}^i \in \mathsf{K}$ and $\vec{\phi} \approx \vec{\psi} \to \phi \approx \psi \in X_\Sigma = \mathrm{GEq}_\Sigma(\mathsf{K})$, we conclude that $\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}^i)$, for all $i \in I$. Therefore, $\phi \approx \psi \in \bigcap_{i\in I} \mathrm{Eq}_\Sigma(\mathcal{A}^i) = \mathrm{Eq}_\Sigma(\mathcal{A})$, the latter by the definition of subdirect intersection and Lemma 128. Therefore, $\mathcal{A} \vDash_\Sigma \vec{\phi} \approx \vec{\psi} \to \phi \approx \psi$. This shows that $\mathcal{A} \in \mathrm{AlgSys}(X) = \mathrm{AlgSys}(\mathrm{GEq}(\mathsf{K})) = \mathbb{G}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$. We conclude that $\overset{\triangleleft}{\mathbb{\Pi}}(\mathsf{K}) \subseteq \mathsf{K}$, i.e., K is closed under subdirect intersections. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta\rangle\rangle$ $\mathbf{F}$-algebraic systems and $\langle H, \gamma\rangle : \mathcal{A} \to \mathcal{B}$ a surjective morphism.



In this case we say $\mathcal{B}$ is a **morphic image** of $\mathcal{A}$. Given a class K of $\mathbf{F}$-algebraic systems, we write $\mathcal{B} \in \mathbb{H}(\mathsf{K})$ in case there exists a surjective morphism $\langle H, \gamma\rangle$:

$\mathcal{A} \to \mathcal{B}$, with $\mathcal{A} \in \mathsf{K}$. If $\mathbb{H}(\mathsf{K}) = \mathsf{K}$, we say that K is **closed under morphic images**.

It is straightforward to verify that $\mathbb{H}$ is a closure operator on classes of $\mathbf{F}$-algebraic systems.

Proposition 132 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system. Then the operator* $\mathbb{H}$ *on classes of* $\mathbf{F}$*-algebraic systems is a closure operator.*

Proof: Let K be a class of $\mathbf{F}$-algebraic systems. If $\mathcal{A} \in \mathsf{K}$, then, using again the identity $\langle I, \iota \rangle : \mathcal{A} \to \mathcal{A}$, we see that $\mathcal{A} \in \mathbb{H}(\mathsf{K})$, and, hence, $\mathbb{H}$ is inflationary. It is again obvious that it is monotonic. Finally, if $\mathcal{A} \in \mathbb{H}(\mathbb{H}(\mathsf{K}))$, then, there exists a surjective morphism $\langle G, \beta \rangle : \mathcal{A}' \to \mathcal{A}$, with $\mathcal{A}' \in \mathbb{H}(\mathsf{K})$, whence, there also exists a surjective morphism $\langle H, \gamma \rangle : \mathcal{A}'' \to \mathcal{A}'$, with $\mathcal{A}'' \in \mathsf{K}$. Now the surjective morphism $\langle G, \beta \rangle \circ \langle H, \gamma \rangle : \mathcal{A}'' \to \mathcal{A}$ witnesses the fact that $\mathcal{A} \in \mathbb{H}(\mathsf{K})$. Therefore, $\mathbb{H}(\mathbb{H}(\mathsf{K})) \subseteq \mathbb{H}(\mathsf{K})$, and $\mathbb{H}$ is idempotent. Thus, $\mathbb{H}$ is a closure operator. ■

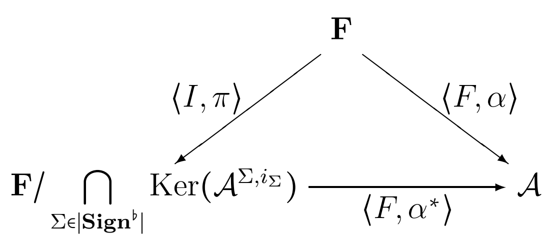
We show, next, that, if a class K of $\mathbf{F}$-algebraic systems is closed under subdirect intersections and morphic images, then it is also closed under directed K-certifications.

Proposition 133 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *be a class of* $\mathbf{F}$*-algebraic systems. Then* $\mathbb{C}^*(\mathsf{K}) \subseteq \mathbb{H}(\overset{\triangleleft}{\mathbb{II}}(\mathsf{K}))$.

Proof: Suppose $\mathcal{A} \in \mathbb{C}^*(\mathsf{K})$. Then, by definition, for all $\Sigma \in |\mathbf{Sign}^\flat|$, there exists a collection $\{\mathcal{A}^{\Sigma,i} : i \in I_\Sigma\} \subseteq \mathsf{K}$, such that $\bigcup_{i \in I_\Sigma} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,i})$ is directed and $\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{i \in I_\Sigma} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,i})$. Fix, for every $\Sigma \in |\mathbf{Sign}^\flat|$, an $i_\Sigma \in I_\Sigma$ and consider the family of morphisms

$$\langle H^{\Sigma,i_\Sigma}, \gamma^{\Sigma,i_\Sigma} \rangle : \mathcal{F}/\bigcap_{\Sigma \in |\mathbf{Sign}^\flat|} \mathrm{Ker}(\mathcal{A}^{\Sigma,i_\Sigma}) \to \mathcal{A}^{\Sigma,i_\Sigma}, \quad \Sigma \in |\mathbf{Sign}^\flat|.$$

By Lemma 130, it constitutes a subdirect intersection, whence, since $\mathcal{A}^{\Sigma,i_\Sigma} \in \mathsf{K}$, for all $\Sigma \in |\mathbf{Sign}^\flat|$, we get $\mathcal{F}/\bigcap_{\Sigma \in |\mathbf{Sign}^\flat|} \mathrm{Ker}(\mathcal{A}^{\Sigma,i_\Sigma}) \in \overset{\triangleleft}{\mathbb{II}}(\mathsf{K})$. Now it is not difficult to see that there exists a morphism $\langle F, \alpha^* \rangle : \mathcal{F}/\bigcap_{\Sigma \in |\mathbf{Sign}^\flat|} \mathrm{Ker}(\mathcal{A}^{\Sigma,i_\Sigma}) \to \mathcal{A}$, such that the following diagram commutes



The natural transformation α^* is defined, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma')$, by

$$\alpha^*_{\Sigma'}(\phi/\bigcap_{\Sigma \in |\mathbf{Sign}^\flat|} \mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma,i_\Sigma})) = \alpha_{\Sigma'}(\phi).$$

It is well-defined, since, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma')$, we have

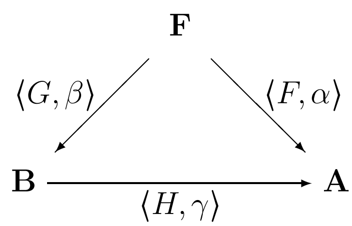
$$\begin{array}{lll}\langle \phi, \psi \rangle \in \bigcap_{\Sigma \in |\mathbf{Sign}^\flat|} \mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma, i_\Sigma}) & \text{implies} & \langle \phi, \psi \rangle \in \mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma', i_{\Sigma'}}) \\ & \text{implies} & \langle \phi, \psi \rangle \in \bigcup_{i \in I_{\Sigma'}} \mathrm{Ker}_{\Sigma'}(\mathcal{A}^{\Sigma', i}) \\ & \text{implies} & \langle \phi, \psi \rangle \in \mathrm{Ker}_{\Sigma'}(\mathcal{A}).\end{array}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathcal{A} \in \mathbb{H}(\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}))$. Therefore, $\mathbb{C}^*(\mathsf{K}) \subseteq \mathbb{H}(\overset{\triangleleft}{\mathbb{P}}(\mathsf{K}))$. ■

Finally, it is not difficult to see that semantic varieties are closed under morphic images.

Proposition 134 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$. *If* $\mathsf{K} = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$, *then* $\mathbb{H}(\mathsf{K}) \subseteq \mathsf{K}$.

Proof: Assume that $\mathsf{K} = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K})$. Let $X = \mathrm{Eq}(\mathsf{K})$. Assume that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathbb{H}(\mathsf{K})$ and $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \approx \psi \in X_\Sigma$. Since $\mathcal{A} \in \mathbb{H}(\mathsf{K})$, there exists $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle \in K$ and $\langle H, \gamma \rangle : \mathcal{B} \to \mathcal{A}$:



Since $\mathcal{B} \in \mathsf{K}$ and $\phi \approx \psi \in X_\Sigma = \mathrm{Eq}_\Sigma(\mathsf{K})$, we conclude that $\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{B})$. Therefore, $\beta_\Sigma(\phi) = \beta_\Sigma(\psi)$. But this gives $\gamma_{G(\Sigma)}(\beta_\Sigma(\phi)) = \gamma_{G(\Sigma)}(\beta_\Sigma(\psi))$ or, equivalently, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Therefore, $\mathcal{A} \vDash_\Sigma \phi \approx \psi$. This shows that $\mathcal{A} \in \mathrm{AlgSys}(X) = \mathrm{AlgSys}(\mathrm{Eq}(\mathsf{K})) = \mathbb{V}^{\mathsf{Sem}}(\mathsf{K}) = \mathsf{K}$. We conclude that $\mathbb{H}(\mathsf{K}) \subseteq \mathsf{K}$, i.e., K is closed under morphic images. ■

We are now ready to provide alternative characterizations of equational, quasiequational and guasiequational classes of $\mathbf{F}$-algebraic systems. Namely, we show that a class of $\mathbf{F}$-algebraic systems is:

- a guasiequational class if and only if it is abstract and closed under subdirect intersections;
- a quasiequational class if and only if it is directedly abstract and closed under subdirect intersections;
- an equational class if and only if it is closed under subdirect intersections and morphic images.

Theorem 135 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is a guasiequational class if and only if it is abstract and closed under subdirect intersections.*

Proof: If K is a guasiequational class, then it is abstract by Corollary 124 and it is closed under subdirect intersections by Proposition 131.

Assume, conversely, that K is abstract and closed under subdirect intersections and set $G = \mathrm{GEq}(\mathsf{K})$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathrm{AlgSys}(\mathbf{F})$, such that $G \leq \mathrm{GEq}(\mathcal{A})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, and $\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})$, i.e., such that $\alpha_\Sigma(\phi) \neq \alpha_\Sigma(\psi)$. Thus, by definition, the guasiequation

$$\langle \mathrm{Eq}_\Sigma(\mathcal{A}), \phi \approx \psi\rangle \notin \mathrm{GEq}_\Sigma(\mathcal{A}).$$

Therefore, since $G \leq \mathrm{GEq}(\mathcal{A})$, $\langle \mathrm{Eq}_\Sigma(\mathcal{A}), \phi \approx \psi\rangle \notin \mathrm{GEq}_\Sigma(\mathsf{K})$. Hence, for every $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})$, there exists $\mathcal{K}^{\langle\Sigma,\phi\approx\psi\rangle} \in \mathsf{K}$, such that $\mathrm{Eq}_\Sigma(\mathcal{A}) \subseteq \mathrm{Eq}_\Sigma(\mathcal{K}^{\langle\Sigma,\phi\approx\psi\rangle})$, but $\phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{K}^{\langle\Sigma,\phi\approx\psi\rangle})$. We conclude that

$$\mathrm{Eq}_\Sigma(\mathcal{A}) = \bigcap\{\mathrm{Eq}_\Sigma(\mathcal{K}^{\langle\Sigma,\phi\approx\psi\rangle}) : \phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})\}.$$

Let, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathsf{K}^\Sigma = \{\mathcal{K}^{\langle\Sigma,\phi\approx\psi\rangle} : \phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})\}.$$

- Since, by hypothesis, K is closed under subdirect intersections, and, by Lemma 130,
$$\{\langle F^\mathcal{K}, \alpha^\mathcal{K}\rangle : \mathcal{F}/\mathrm{Ker}(\mathsf{K}^\Sigma) \to \mathcal{K}, \mathcal{K} \in \mathsf{K}^\Sigma\}$$
is a subdirect intersection, we get that $\mathcal{F}/\mathrm{Ker}(\mathsf{K}^\Sigma) \in \mathsf{K}$.
- Since, for all $\Sigma \in |\mathbf{Sign}^\flat|$,
$$\mathrm{Ker}_\Sigma(\mathcal{A}) = \mathrm{Ker}_\Sigma(\mathsf{K}^\Sigma) = \mathrm{Ker}_\Sigma(\mathcal{F}/\mathrm{Ker}(\mathsf{K}^\Sigma))$$
and $\mathcal{F}/\mathrm{Ker}(\mathsf{K}^\Sigma) \in \mathsf{K}$, $\mathcal{A} \in \mathbb{C}(\mathsf{K})$. Since K is abstract, we conclude that $\mathcal{A} \in \mathsf{K}$.

Therefore, K is a guasiequational class of $\mathbf{F}$-algebraic systems. ∎

Theorem 136 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is a quasiequational class if and only if it is directedly abstract and closed under subdirect intersections.*

Proof: If K is a quasiequational class, then it is directedly abstract by Corollary 127 and it is closed under subdirect intersections by Proposition 131.

Conversely, suppose that $\mathsf{K} \subseteq \mathrm{AlgSys}(\mathbf{F})$, such that $\mathbb{C}^*(\mathsf{K}) \subseteq \mathsf{K}$ and $\overset{\triangleleft}{\mathbb{IP}}(\mathsf{K}) \subseteq \mathsf{K}$. It suffices to show that $\mathsf{K} = \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K}))$. The left to right inclusion always holds. For the converse, consider $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle \in \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K}))$. For all $\Sigma \in |\mathbf{Sign}^\flat|$, all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$ and all $\phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})$, we consider the $\mathbf{F}$-quasiequation

$$q^{\Sigma,X,\phi\approx\psi} := X \to \phi \approx \psi.$$

Since $\mathcal{A} \vDash_\Sigma \mathrm{Eq}_\Sigma(\mathcal{A})$ and $\mathcal{A} \nvDash_\Sigma \phi \approx \psi$, we get that $q^{\Sigma,X,\phi\approx\psi} \notin \mathrm{QEq}_\Sigma(\mathcal{A})$. Thus, since $\mathcal{A} \in \mathrm{AlgSys}(\mathrm{QEq}(\mathsf{K}))$, we infer that $q^{\Sigma,X,\phi\approx\psi} \notin \mathrm{QEq}_\Sigma(\mathsf{K})$. Therefore, there exists $\mathcal{A}^{\Sigma,X,\phi\approx\psi} \in \mathsf{K}$, such that $\mathcal{A}^{\Sigma,X,\phi\approx\psi} \nvDash_\Sigma q^{\Sigma,X,\phi\approx\psi}$, i.e.,

$$\mathcal{A}^{\Sigma,X,\phi\approx\psi} \vDash_\Sigma X \quad \text{and} \quad \mathcal{A}^{\Sigma,X,\phi\approx\psi} \nvDash_\Sigma \phi \approx \psi.$$

Let, for all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$,

$$\mathsf{A}^{\Sigma,X} = \{\mathcal{A}^{\Sigma,X,\phi\approx\psi} : \phi \approx \psi \notin \mathrm{Eq}_\Sigma(\mathcal{A})\}.$$

Define, for all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$,

$$\mathcal{A}^{\Sigma,X} := \mathcal{F}/\mathrm{Ker}(\mathsf{A}^{\Sigma,X}) = \mathcal{F}/\bigcap_{\phi\approx\psi\notin\mathrm{Eq}_\Sigma(\mathcal{A})} \mathrm{Ker}(\mathcal{A}^{\Sigma,X,\phi\approx\psi}).$$

By Proposition 130, for all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$, $\mathcal{A}^{\Sigma,X} \in \overset{\triangleleft}{\mathbb{P}}(\mathsf{K}) = \mathsf{K}$. Consequently, it suffices to show the following:

- $\bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,X})$ is directed;
- $\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,X})$.

Suppose, first, that $E \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,X})$ and $E' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,X'})$, for some $X, X' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$. Then, by construction of $\mathcal{A}^{\Sigma,X}$ and $\mathcal{A}^{\Sigma,X'}$, we get that $E, E' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$. Therefore, $E \cup E' \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,E\cup E'})$ and, hence, $\bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Eq}^\omega_\Sigma(\mathcal{A}^{\Sigma,X})$ is indeed directed.

Finally, note that, by construction, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\mathrm{Ker}_\Sigma(\mathcal{A}) = \bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,X}).$$

Indeed, for all $\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathbf{F})$,

- if $\phi \approx \psi \in \mathrm{Ker}_\Sigma(\mathcal{A})$, then, $\phi \approx \psi \in \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,\{\phi\approx\psi\}})$, whence $\phi \approx \psi \in \bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,X})$.
- if $\phi \approx \psi \notin \mathrm{Ker}_\Sigma(\mathcal{A})$, then, by construction, for all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$, $\phi \approx \psi \notin \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,X})$. Therefore, $\phi \approx \psi \notin \bigcup_{X\in\mathrm{Eq}^\omega_\Sigma(\mathcal{A})} \mathrm{Ker}_\Sigma(\mathcal{A}^{\Sigma,X})$.

Since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $X \in \mathrm{Eq}^\omega_\Sigma(\mathcal{A})$, $\mathcal{A}^{\Sigma,X} \in \mathsf{K}$, we get, by the definition of $\mathbb{C}^*$ and the two properties just proven, that $\mathcal{A} \in \mathbb{C}^*(\mathsf{K}) = \mathsf{K}$. Thus, K is a quasiequational class of $\mathbf{F}$-algebraic systems. ∎

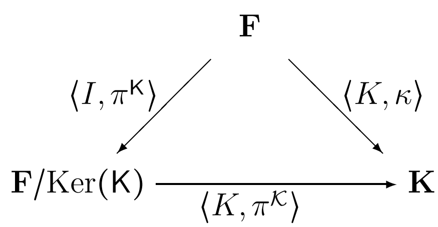
Theorem 137 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is an equational class if and only if it is closed under subdirect intersections and morphic images.*

Proof: If K is an equational class, then it is closed under subdirect intersections by Proposition 131 and under morphic images by Proposition 134.

Suppose, conversely, that K is a class of $\mathbf{F}$-algebraic systems that is closed under subdirect intersections and morphic images. Set $E = \mathrm{Eq}(\mathsf{K})$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, such that $E \leq \mathrm{Eq}(\mathcal{A})$. Consider, for all $\mathcal{K} = \langle \mathbf{K}, \langle K, \kappa \rangle \rangle \in \mathsf{K}$, the mapping

$$\langle K, \pi^{\mathcal{K}} \rangle : \mathbf{F}/\mathrm{Ker}(\mathsf{K}) \to \mathbf{K}$$

defined by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,



$$\pi^{\mathcal{K}}_\Sigma(\phi/\mathrm{Ker}_\Sigma(\mathsf{K})) = \kappa_\Sigma(\phi).$$

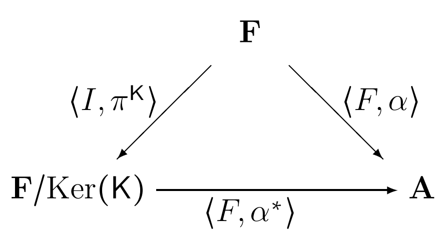
By Lemma 130, the collection

$$\{\langle K, \pi^{\mathcal{K}} \rangle : \mathcal{F}/\mathrm{Ker}(\mathsf{K}) \to \mathcal{K}, \mathcal{K} = \langle \mathbf{K}, \langle K, \kappa \rangle \rangle \in \mathsf{K}\}$$

forms a subdirect intersection. Since all codomains are in K and K is closed under subdirect intersections, we get $\mathcal{F}/\mathrm{Ker}(\mathsf{K}) \in \mathsf{K}$. Now consider the morphism

$$\langle F, \alpha^* \rangle : \mathcal{F}/\mathrm{Ker}(\mathsf{K}) \to \mathcal{A},$$

given, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, by



$$\alpha^*_\Sigma(\phi/\mathrm{Ker}_\Sigma(\mathsf{K})) = \alpha_\Sigma(\phi).$$

It is well defined, since, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, if $\langle \phi, \psi \rangle \in \mathrm{Ker}_\Sigma(\mathsf{K})$, then, by hypothesis, $\langle \phi, \psi \rangle \in \mathrm{Eq}_\Sigma(\mathcal{A})$ and, hence, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Moreover, since $\langle F, \alpha \rangle$ is surjective, so is $\langle F, \alpha^* \rangle$. Since $\mathcal{F}/\mathrm{Ker}(\mathsf{K}) \in \mathsf{K}$ and K is closed under morphic images, we conclude that $\mathcal{A} \in \mathsf{K}$. Therefore, K is an equational class of $\mathbf{F}$-algebraic systems. ■

We prove, next, the following result to the effect that, for any guasiequational class K of $\mathbf{F}$-algebraic systems, the theory families of the equational structure $\mathcal{Q}^{\mathsf{K}} = \langle \mathbf{F}, D^{\mathsf{K}} \rangle$ coincide with the K-congruence systems on $\mathcal{F}$.

Corollary 138 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems. If* K *is a guasiequational class, then*

$$\mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}}) = \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F}).$$

Proof: We can rely on preceding results, but we also give a direct proof.

Since K is a guasiequational class, by Theorem 135, it is abstract and closed under subdirect intersections. Since any guasiequational class also contains a trivial $\mathbf{F}$-algebraic system, we conclude, by Theorem 32, that $\mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}}) = \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$.

Next, we provide a direct proof of the same result. Suppose K is a guasiequational class of $\mathbf{F}$-algebraic systems.

Let $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ and $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(\theta_\Sigma)$. Then $\langle \theta_\Sigma, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$. Thus, since, by hypothesis, $\mathcal{F}/\theta \in \mathsf{K}$, $\mathcal{F}/\theta \vDash_\Sigma \langle \theta_\Sigma, \phi \approx \psi \rangle$. But, obviously, $\mathcal{F}/\theta \vDash_\Sigma \theta_\Sigma$. Therefore, we get $\mathcal{F}/\theta \vDash_\Sigma \phi \approx \psi$, or, equivalently, $\langle \phi, \psi \rangle \in \theta_\Sigma$. We conclude that $D^{\mathsf{K}}(\theta) = \theta$ and, hence, $\theta \in \mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}})$.

Assume, conversely, that $\theta \in \mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}})$ and consider $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi}$, $\vec{\psi}$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$ and $\mathcal{F}/\theta \vDash_\Sigma \vec{\phi} \approx \vec{\psi}$. Then, $\langle \phi_i, \psi_i \rangle \in \theta_\Sigma$, for all $i \in I$. Since $\langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle \in \mathrm{GEq}_\Sigma(\mathsf{K})$ and $\theta \in \mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}})$, we get $\langle \phi, \psi \rangle \in \theta_\Sigma$. Hence, $\mathcal{F}/\theta \vDash_\Sigma \phi \approx \psi$. We conclude, taking into account the fact that K is a guasiequational class, that $\mathcal{F}/\theta \in \mathrm{AlgSys}(\mathrm{GEq}(\mathsf{K})) = \mathsf{K}$. Thus, $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$. ■

We obtain, as a corollary, that, if the relative equational consequences of two semantic guasivarieties are identical, then the two guasivarieties coincide.

Proposition 139 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *and* K' *semantic guasivarieties of* $\mathbf{F}$*-algebraic systems, such that* $D^{\mathsf{K}} = D^{\mathsf{K}'}$. *Then* $\mathsf{K} = \mathsf{K}'$.

Proof: Let $\mathcal{A} \in \mathsf{K}$ and consider $\Sigma \in |\mathbf{Sign}^\flat|$, $\vec{\phi}, \vec{\psi}, \phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\mathsf{K}' \vDash_\Sigma \langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle.$$

This is equivalent to $\phi \approx \psi \in D^{\mathsf{K}'}_\Sigma(\vec{\phi} \approx \vec{\psi})$. By hypothesis, we get $\phi \approx \psi \in D^{\mathsf{K}}_\Sigma(\vec{\phi} \approx \vec{\psi})$, i.e., $\mathsf{K} \vDash_\Sigma \langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle$. Since $\mathcal{A} \in \mathsf{K}$, $\mathcal{A} \vDash_\Sigma \langle \vec{\phi} \approx \vec{\psi}, \phi \approx \psi \rangle$. This shows that $\mathrm{GEq}(\mathsf{K}') \leq \mathrm{GEq}(\mathcal{A})$ and, hence $\mathcal{A} \in \mathbb{G}^{\mathsf{Sem}}(\mathsf{K}') = \mathsf{K}'$, the latter equation by the assumption that K' is a semantic guasivariety. We conclude that $\mathsf{K} \subseteq \mathsf{K}'$. By symmetry, we get $\mathsf{K} = \mathsf{K}'$. ■

These results allow us to obtain another round of different characterizations of equational, quasiequational and guasiequational classes of $\mathbf{F}$-algebraic systems.

To provide the characterization of guasiequational classes, we need, first, some technical lemmas.

Lemma 140 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system and* K *an abstract class of* $\mathbf{F}$*-algebraic systems.* K *is closed under subdirect intersections if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is closed under intersection.*

Proof: Let K be an abstract class of $\mathbf{F}$-algebraic systems. Suppose, first, that K is closed under subdirect intersections and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Then, by definition, $\mathcal{A}/\theta^i \in \mathsf{K}$, for all $i \in I$. Let, for all $i \in I$,

$$\langle I, \rho^i \rangle : \mathcal{A}/\bigcap_{i \in I} \theta^i \to \mathcal{A}/\theta^i$$

be defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \pi \circ \alpha \rangle \swarrow & & \searrow \langle F, \pi^i \circ \alpha \rangle \\ \mathcal{A}/\bigcap_{i \in I} \theta^i & \xrightarrow[\langle I, \rho^i \rangle]{} & \mathcal{A}/\theta^i \end{array}$$

$$\rho^i_\Sigma(\phi/\bigcap_{i \in I} \theta^i_\Sigma) = \phi/\theta^i_\Sigma.$$

Then, we have $\bigcap_{i \in I} \mathrm{Ker}(\langle I, \rho^i \rangle) = \Delta^{\mathcal{A}/\bigcap_{i \in I} \theta^i}$. Hence, the family $\{\langle I, \rho^i \rangle : i \in I\}$ forms a subdirect intersection. Thus, by hypothesis, since $\mathcal{A}/\theta^i \in \mathsf{K}$, for all $i \in I$, $\mathcal{A}/\bigcap_{i \in I} \theta^i \in \mathsf{K}$ and, therefore, $\bigcap_{i \in I} \theta^i \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. We conclude that $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is closed under intersections.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is closed under intersection and let

$$\langle H^i, \gamma^i \rangle : \mathcal{A} \to \mathcal{A}^i, \quad i \in I,$$

be a subdirect intersection, such that $\mathcal{A}^i \in \mathsf{K}$, for all $i \in I$. For every $i \in I$, consider the morphism

$$\langle H^i, \delta^i \rangle : \mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) \to \mathcal{A}^i,$$

defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \pi^i \circ \alpha \rangle \swarrow & & \searrow \langle F^i, \alpha^i \rangle \\ \mathbf{A}/\mathrm{Ker}(\langle H^i, \gamma^i \rangle) & \xrightarrow[\langle H^i, \delta^i \rangle]{} & \mathbf{A}^i \end{array}$$

$$\delta^i_\Sigma(\phi/\mathrm{Ker}_\Sigma(\langle H^i, \gamma^i \rangle)) = \gamma^i_\Sigma(\phi).$$

It is clearly well-defined and, moreover, we have, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i\rangle)) & \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \mathrm{Ker}_{F(\Sigma)}(\langle H^i, \gamma^i\rangle)\\ & \text{iff} & \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\phi)) = \gamma^i_{F(\Sigma)}(\alpha_\Sigma(\psi))\\ & \text{iff} & \alpha^i_\Sigma(\phi) = \alpha^i_\Sigma(\psi)\\ & \text{iff} & \phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}^i).\end{array}$$

Thus, $\mathcal{A}^i$ is a Σ-K-certificate for $\mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i\rangle)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$. Since K is abstract, we get that $\mathcal{A}/\mathrm{Ker}(\langle H^i, \gamma^i\rangle) \in \mathsf{K}$ and, hence, $\mathrm{Ker}(\langle H^i, \gamma^i\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Thus, by hypothesis, $\Delta^{\mathcal{A}} = \bigcap_{i\in I}\mathrm{Ker}(\langle H^i, \gamma^i\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, showing that $\mathcal{A} \in \mathsf{K}$. We conclude that K is closed under subdirect intersections. ∎

Lemma 141 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system,* K *be an abstract class of* $\mathbf{F}$*-algebraic systems,* $\mathcal{A}$ *an* $\mathbf{F}$*-algebraic system and* $\theta \in \mathrm{ConSys}(\mathcal{A})$*. Then* $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *if and only if* $\mathrm{Ker}(\langle F, \alpha^\theta\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$*,*

$$\mathbf{F} \xrightarrow{\langle F, \alpha\rangle} \mathbf{A} \xrightarrow{\langle I, \pi^\theta\rangle} \mathbf{A}/\theta$$

where $\langle F, \alpha^\theta\rangle = \langle I, \pi^\theta\rangle \circ \langle F, \alpha\rangle$.

Proof: Consider the diagram,

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle I,\pi\rangle \swarrow & & \searrow \langle F,\alpha^\theta\rangle \\ \mathbf{F}/\mathrm{Ker}(\langle F,\alpha^\theta\rangle) & \xrightarrow[\langle F,\rho\rangle]{} & \mathcal{A}/\theta\end{array}$$

where $\langle F, \rho\rangle : \mathbf{F}/\mathrm{Ker}(\langle F, \alpha^\theta\rangle) \to \mathcal{A}/\theta$ is defined, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, by

$$\rho_\Sigma(\phi/\mathrm{Ker}_\Sigma(\langle F, \alpha^\theta\rangle)) = \alpha_\Sigma(\phi)/\theta_{F(\Sigma)}.$$

This is well-defined, since, if $\langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha^\theta\rangle)$, then $\alpha^\theta_\Sigma(\phi) = \alpha^\theta_\Sigma(\psi)$, i.e., by definition, $\alpha_\Sigma(\phi)/\theta_{F(\Sigma)} = \alpha_\Sigma(\psi)/\theta_{F(\Sigma)}$. Moreover, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, we have

$$\begin{array}{rll}\phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{F}/\mathrm{Ker}(\langle F, \alpha^\theta\rangle)) & \text{iff} & \langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle I, \pi\rangle)\\ & \text{iff} & \langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha^\theta\rangle)\\ & \text{iff} & \phi \approx \psi \in \mathrm{Eq}_\Sigma(\mathcal{A}/\theta).\end{array}$$

Thus, $\mathrm{Eq}(\mathcal{F}/\mathrm{Ker}(\langle F, \alpha^\theta\rangle)) = \mathrm{Eq}(\mathcal{A}/\theta)$. Since K is abstract, we conclude that $\mathbf{F}/\mathrm{Ker}(\langle F, \alpha^\theta\rangle) \in \mathsf{K}$ if and only if $\mathcal{A}/\theta \in \mathsf{K}$. Therefore, $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ if and only if $\mathrm{Ker}(\langle F, \alpha^\theta\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$. ∎

Lemma 142 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be a base algebraic system and* K *an abstract class of* $\mathbf{F}$*-algebraic systems.* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ *is closed under intersection if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is closed under intersection.*

Proof: The "if" direction is obvious. For the only if, suppose $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is closed under intersection and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Note that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\begin{array}{rll}\langle \phi, \psi\rangle \in \mathrm{Ker}_\Sigma(\langle F, \alpha^{\bigcap_{i\in I}\theta^i}\rangle) & \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \bigcap_{i\in I}\theta^i_{F(\Sigma)}\\ & \text{iff} & \langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi)\rangle \in \theta^i_{F(\Sigma)},\ \text{all } i \in I,\\ & \text{iff} & \langle \phi, \psi\rangle \in \bigcap_{i\in I}\mathrm{Ker}_\Sigma(\langle F, \alpha^{\theta^i}\rangle).\end{array}$$

Thus, $\mathrm{Ker}(\langle F, \alpha^{\bigcap_{i\in I}\theta^i}\rangle) = \bigcap_{i\in I}\mathrm{Ker}(\langle F, \alpha^{\theta^i}\rangle)$. Using Lemma 141, we now get

$$\begin{array}{rcl}\theta^i \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}), i \in I, & \text{iff} & \mathrm{Ker}(\langle F, \alpha^{\theta^i}\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F}), i \in I,\\ & \text{implies} & \bigcap_{i\in I}\mathrm{Ker}(\langle F, \alpha^{\theta^i}\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})\\ & \text{iff} & \mathrm{Ker}(\langle F, \alpha^{\bigcap_{i\in I}\theta^i}\rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})\\ & \text{iff} & \bigcap_{i\in I}\theta^i \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}).\end{array}$$

Therefore, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is closed under intersection. ■

Now we formulate our first characterization theorem.

Theorem 143 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is a guasiequational class if and only if it is abstract and* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ *is closed under intersection.*

Proof: We have K is a guasiequational class if and only if, by Theorem 135, it is abstract and closed under subdirect intersections, if and only if, by Lemma 140, it is abstract and, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is closed under intersection, if and only if, by Lemma 142, it is abstract and $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is closed under intersection. ■

A similar characterization can be obtained for quasiequational classes.

Theorem 144 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is a quasiequational class if and only if it is directedly abstract and* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ *is closed under intersection.*

Proof: We have K is a quasiequational class if and only if, by Theorem 136, it is directedly abstract and closed under subdirect intersections, if and only if, by Lemma 140 (taking into account that directed abstraction implies abstraction), it is directedly abstract and, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is closed under intersections, if and only if, by Lemma 142, it is directedly abstract and $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is closed under intersection. ■

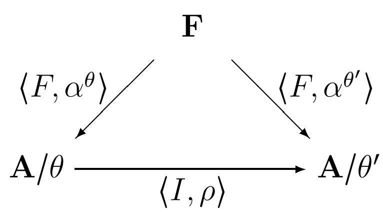
Finally, we work with equational classes. Again, to provide an analogous characterization, we go through a couple of technical lemmas.

The first is an analog of Lemma 140, but instead of addressing subdirect intersections and intersections of relative congruence systems, it addresses morphic images and shows that closure of an abstract class under morphic images amounts to the collection of all relative congruence systems on every algebraic system being an up-set in the lattice of congruence systems.

Lemma 145 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system and* K *an abstract class of* $\mathbf{F}$*-algebraic systems.* K *is closed under morphic images if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is an up-set in* $\mathrm{ConSys}(\mathcal{A})$*.*

Proof: Let K be an abstract class of $\mathbf{F}$-algebraic systems.

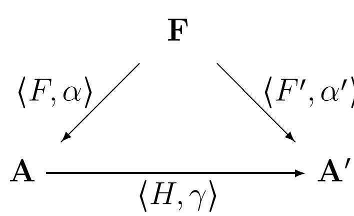
Assume, first, that K is closed under morphic images and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\theta, \theta' \in \mathrm{ConSys}(\mathcal{A})$, such that $\theta \leq \theta'$ and $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. We consider the morphism $\langle I, \rho \rangle : \mathcal{A}/\theta \to \mathcal{A}/\theta'$, given, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathrm{SEN}(\Sigma)$, by



$$\rho_\Sigma(\phi/\theta_\Sigma) = \phi/\theta'_\Sigma.$$

It is clearly, well-defined, since $\theta \leq \theta'$. Since $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$, $\mathcal{A}/\theta \in \mathsf{K}$, whence, since K is closed under morphic images, $\mathcal{A}/\theta' \in \mathsf{K}$, giving $\theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Therefore, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is an up-set in $\mathrm{ConSys}(\mathcal{A})$.

Suppose, conversely, that $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is an up-set in $\mathrm{ConSys}(\mathcal{A})$, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. Consider $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ and a surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \to \mathcal{A}'$



and assume that $\mathcal{A} \in \mathsf{K}$. Then, we have $\Delta^{\mathcal{A}} \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ iff, by Lemma 141, $\mathrm{Ker}(\langle F, \alpha \rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ implies, by the hypothesis and the commutativity of the triangle, $\mathrm{Ker}(\langle F', \alpha' \rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ iff, again by Lemma 141, $\Delta^{\mathcal{A}'} \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}')$ iff $\mathcal{A}' \in \mathsf{K}$. Therefore, K is closed under morphic images. ■

The second is an analog of Lemma 142, but instead of addressing closure of the collections of relative congruence systems under intersection, it deals with their upward closure under the signature-wise ordering in the lattices of congruence systems.

Lemma 146 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be a base algebraic system and* K *an abstract class of* $\mathbf{F}$*-algebraic systems.* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ *is an upset in* $\mathrm{ConSys}(\mathcal{F})$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*,* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ *is an upset in* $\mathrm{ConSys}(\mathcal{A})$*.*

Proof: The "if" direction is obvious.

For the "only if" assume that $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is an up-set in $\mathrm{ConSys}(\mathcal{F})$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\theta, \theta' \in \mathrm{ConSys}(\mathcal{A})$, such that $\theta \leq \theta'$ and $\theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$. Then, taking into account the fact that $\mathrm{Ker}(\langle F, \alpha^\theta \rangle) \leq \mathrm{Ker}(\langle F, \alpha^{\theta'} \rangle)$ and that $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is an upset and using Lemma 141, we have

$$\begin{array}{lcl} \theta \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}) & \text{iff} & \mathrm{Ker}(\langle F, \alpha^\theta \rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F}) \\ & \text{implies} & \mathrm{Ker}(\langle F, \alpha^{\theta'} \rangle) \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{F}) \\ & \text{iff} & \theta' \in \mathrm{ConSys}^{\mathsf{K}}(\mathcal{A}). \end{array}$$

Therefore, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is an up-set in $\mathrm{ConSys}(\mathcal{A})$. ■

Now we get the following theorem characterizing equational classes of $\mathbf{F}$-algebraic systems.

Theorem 147 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* K *a class of* $\mathbf{F}$*-algebraic systems.* K *is an equational class if and only if it is abstract and* $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ *is an upset in* $\mathrm{ConSys}(\mathcal{F})$*, closed under intersections.*

Proof: We have K is an equational class if and only if, by Theorem 137, it is closed under subdirect intersections and morphic images, if and only if, by Proposition 133 and Lemmas 140 and 145, it is abstract and, for all $\mathcal{A} \in \mathrm{AlgSys}(\mathbf{F})$, $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{A})$ is an upset in $\mathrm{ConSys}(\mathcal{A})$, closed under intersections, if and only if, by Lemmas 142 and 146, it is abstract and $\mathrm{ConSys}^{\mathsf{K}}(\mathcal{F})$ is an upset in $\mathrm{ConSys}(\mathcal{F})$, closed under intersections. ■

Chapter 3

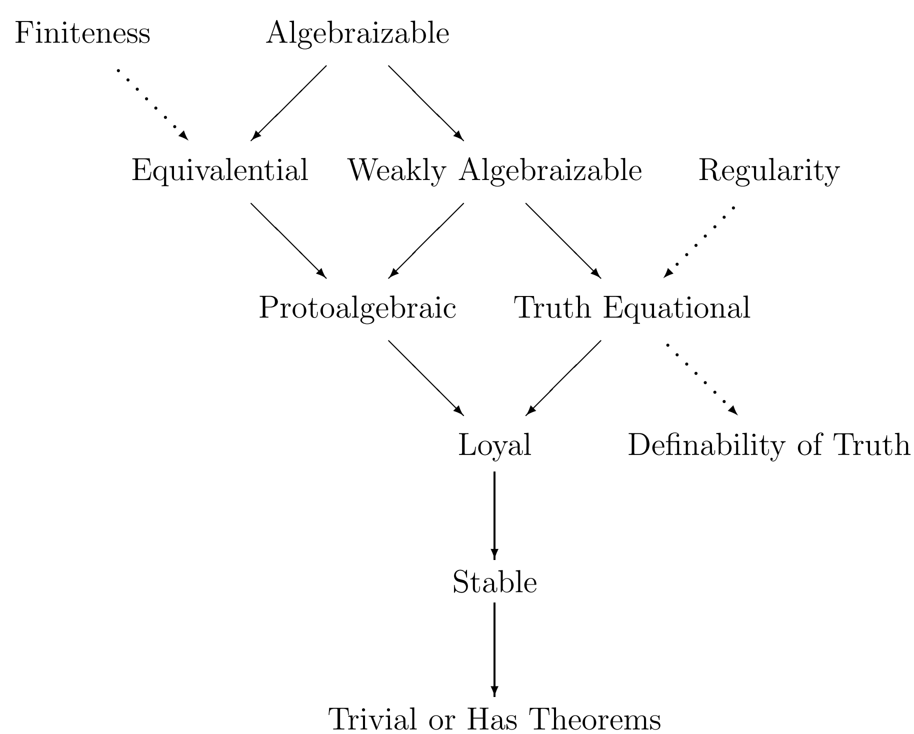
The Semantic Leibniz Hierarchy: Bottom Half

3.1 Introduction

In this chapter we give the main definitions and some key properties of the main classes of the *semantic Leibniz hierarchy*. The term *Leibniz hierarchy* refers to the classification of logical systems according to the strength of their relation to classes of algebraic systems. The term *semantic* refers to the definition of those classes by means of the *Leibniz operator* as applied to the theory families/systems of the corresponding π-institution or, via available so called *transfer theorems*, to the filter families/systems of their Leibniz reduced matrix systems.

As we will see later, there is also a *syntactic Leibniz hierarchy* whose classes do not coincide with those of the semantic hierarchy in general. However, we will show that under certain conditions, there is a correspondence between the classes in the two hierarchies.

A *very rough idea* of the main classes of the semantic Leibniz hierarchy, with the inclusion relations between them, is given in the following diagram. The hierarchy parallels that of sentential logics, established in the classical theory (see, e.g., Figure 9 on Page 316 of [86]). However, as we will see in this and subsequent chapters, in the case of logics formalized as π-institutions, various refinements of these classes are possible. One of the main goals of the monograph is to study those refinements and their interrelations. In the diagram we also give an idea of how this hierarchy is extended with other classes that are "attached" via dotted links to the main classes. Some of these extensions will also be studied later.



In Section 3.2, we introduce three fundamental classes of π-institutions, namely *systemic*, *stable* and *loyal* π-institutions. *Systemicity* and *stability* play a very important role throughout the monograph and facilitate discussions about the refinements of the various classes alluded to previously. *Loyalty* does not play a comparable role, but it constitutes at the same time a relaxation of *order preservation* and of *order reflectivity* and, as such, defines an important class close to the bottom of the hierarchy.

A π-institution is called *systemic* if all of its theory families are theory systems, i.e., invariant under the action of signature morphisms. In the context of π-institutions, the importance of systemicity was brought to the fore in the study of protoalgebraicity [105, 104]. Generally speaking, however, preservation of relations or, more concretely, of distinguished sets, is an important property in the model theory of first-order logics (see, e.g., page 71 of [17], page 5 of [43] or page 8 of [66]) and, hence, also in the theory of logical matrices serving as models of sentential logics (see, e.g., page 31 of [64] or page 200 of [86]). Systemicity is characterized by asserting that the closure family generated by any sentence of the given π-institution includes all translates of that sentence via signature morphisms. Systemicity also affords the chance to introduce the first of a host of so-called *transfer theorems*. This term refers to a property holding on the lattice of theory families of a π-institution *transferring* to the lattice of its filter families on arbitrary algebraic systems. This paradigm follows an oft-encountered situation in the theory of sentential logics (see, e.g., Section 3.6 of [86]). In this specific instance, it is shown that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is systemic if and only if every filter family on every $\mathbf{F}$-algebraic system is actually a filter system.

Recall from Chapter 2 that, given a π-institution $\mathcal{I}$ and a theory family T of $\mathcal{I}$, $\overleftarrow{T}$ is the largest theory system of $\mathcal{I}$ included in T. In Section 2.3 it was shown (Proposition 20) that the Leibniz congruence system associated with T is included in the one associated with $\overleftarrow{T}$. We call the π-institution $\mathcal{I}$ *stable* if, for all theory families T of $\mathcal{I}$, these two Leibniz congruence systems coincide. Since systemicity directly yields that, for all T, $\overleftarrow{T} = T$, it clearly implies stability. Moreover, this implication is proper. As was the case with systemicity, stability also transfers.

The last concept introduced in Section 3.2 is that of *loyalty*. There are four possible flavors, analogs of which also arise and are pursued for many other properties considered in the monograph. The general idea of the property is, perhaps, best conveyed by *family loyalty*. The property holds for a π-institution $\mathcal{I}$ if, for no pair T and T' of theory families of $\mathcal{I}$ is it the case that $T < T'$ and $\Omega(T) > \Omega(T')$, i.e., $\mathcal{I}$ is *family loyal* if proper inclusion between theory families is never reversed when passing to corresponding Leibniz congruence systems. As in most other properties that we study, the other three versions are obtained from the family version as follows:

- *left loyalty* by replacing on the theory family side T and T' by their arrow counterparts $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively;

- *right loyalty* by replacing on the congruence system side T and T' by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively, i.e., by considering the inequality $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$ in place of $\Omega(T) \leq \Omega(T')$;

- *system loyalty* by applying the defining condition only on the collection of theory systems of $\mathcal{I}$, instead of considering arbitrary pairs of theory families.

It turns out that family loyalty implies stability. Moreover, family loyalty is the strongest of the four properties, followed by left loyalty, which, in turn, implies system loyalty, which is equivalent to right loyalty. Both implications are proper. Another feature of family loyalty is that, apart from trivial π-institutions, all family loyal ones must possess theorems. In closing the section, it is shown that all flavors of loyalty also transfer from theory families/systems to filter families/systems over arbitrary algebraic systems.

In Section 3.3, we introduce versions of the *monotonicity property*. This property is very important historically, since one of the first major classes of sentential logics to be studied in detail in the context of abstract algebraic logic was that of protoalgebraic logics [28] (see, also, Chapter 1 of [64] and Section 6.2 of [86]). They are characterized by the monotonicity of the Leibniz operator on their theory lattices. In the context of π-institutions, *family monotonicity* asserts that, for every pair T, T' of theory families, if T is included in T', then the Leibniz congruence system of T is also dominated by that of T'. *Left monotonicity* results by replacing, on the theory family side (hypothesis), T and T' by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively. Similarly, *right monotonicity* ensues when the same is done on the congruence system side (conclusion). Finally, *system monotonicity* is monotonicity restricted to the collection of theory systems. It is shown that family and left monotonicity coincide, as do right and system monotonicity. In agreement with the terminology inherited by the sentential framework, we call a π-institution satisfying family monotonicity *protoalgebraic*, whereas one satisfying system monotonicity is termed *prealgebraic* [105, 104]. Since prealgebraicity is defined by the same monotonicity condition as protoalgebraicity, but restricted to theory systems, protoalgebraic π-institutions form a subclass of the class of prealgebraic ones. Moreover, it turns out that a π-institution is protoalgebraic if and only if it is prealgebraic and stable. Protoalgebraicity actually implies family loyalty, a condition stronger than stability, and similarly, prealgebraicity implies system loyalty. Finally, it is shown that both monotonicity properties transfer.

In Sections 3.4 and 3.5, we undertake the study of properties that may be referred to, collectively, as *complete monotonicity* properties. The reason for studying these properties can be traced back to the work of Raftery

[77] in an indirect way, but they are also loosely related, especially in the study of finitary deductive systems, to the property of continuity, whose importance was already apparent in [35]. Raftery used a property termed complete order reflectivity to characterize truth equationality of sentential logics. The property asserts that, given a sentential logic $\mathcal{S}$, for all collections $\mathcal{T} \cup \{T'\}$ of theories of $\mathcal{S}$, $\bigcap_{T\in\mathcal{T}} \Omega(T) \subseteq \Omega(T')$ implies $\bigcap \mathcal{T} \subseteq T'$. Noting that in both the lattice of theories and the lattice of congruences on the formula algebra intersection coincides with meet, this property may be rewritten as $\bigwedge_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigwedge \mathcal{T} \leq T'$. Since, however, join and union of both theories and congruences differ, depending on whether one adopts a set-theoretic or a lattice-theoretic point of view, the dual property of complete order reflectivity may take one of two possible forms. The first asserts that, for all $\mathcal{T} \cup \{T'\}$, $T' \subseteq \bigcup \mathcal{T}$ implies $\Omega(T') \subseteq \bigcup_{T\in\mathcal{T}} \Omega(T)$. The second stipulates that, for all $\mathcal{T} \cup \{T'\}$, $T' \leq \bigvee \mathcal{T}$ implies $\Omega(T') \leq \bigvee_{T\in\mathcal{T}} \Omega(T)$. The translation of complete order reflectivity in the categorical context was first introduced in [107]. Various flavors of it are studied in detail in Section 3.8. In Sections 3.4 and 3.5, we study the properties corresponding to the two aforementioned duals.

In Section 3.4, we look at the various flavors of *complete* $\bigcup$*-monotonicity*. Again, the simplest one is *family complete* $\bigcup$*-monotonicity*. A π-institution is *family completely* $\bigcup$*-monotone* if, for all collections $\mathcal{T} \cup \{T'\}$ of theory families, $T' \leq \bigcup_{T\in\mathcal{T}} T$ implies $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$. *Left complete* $\bigcup$*-monotonicity* results by replacing all theory families appearing in the hypothesis by their arrow counterparts. Similarly, *right complete* $\bigcup$*-monotonicity* arises by performing the same replacement in the conclusion. Finally, *system complete* $\bigcup$*-monotonicity* is the property resulting by applying the same condition defining the family version to collections of theory systems only. We use the abbreviation *c*$^\cup$*-monotonicity* to refer to complete $\bigcup$-monotonicity. Moreover, when we drop the $\bigcup$ (or $^\cup$) from the notation, it is to this version of complete monotonicity that we refer to. Family or left c$^\cup$-monotonicity are strong enough to imply stability. Moreover, family c$^\cup$-monotonicity is equivalent to possessing both left and right c$^\cup$-monotonicity. Either left or right c$^\cup$-monotonicity on its own implies system c$^\cup$-monotonicity. For these four properties, it is also the case that they transfer from theory families/systems to filter families/systems on arbitrary algebraic systems. In closing, it is established that left c$^\cup$-monotonicity implies protoalgebraicity, whereas system c$^\cup$-monotonicity is sufficient for prealgebraicity.

In Section 3.5, we undertake a similar study of the complete monotonicity properties involving the join instead of the union operation. We say that a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is *family completely* $\bigvee$*-monotone*, abbreviated *family c*$^\vee$*-monotone*, if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families, $T' \leq \bigvee^{\mathcal{I}} \mathcal{T}$ implies $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T\in\mathcal{T}} \Omega(T)$, where $\bigvee^{\mathcal{I}}$ denotes the join in the complete lattice of theory families of $\mathcal{I}$ and $\bigvee^{\mathbf{F}}$ the join in the complete lattice of congruence systems on $\mathbf{F}$. As in Section 3.4, *left c*$^\vee$*-monotonicity* results by replacing in the hypothesis every theory family by its arrow counterpart, *right* $c^\vee$*-monotonicity* by doing the same in the conclusion and *system* $c^\vee$*-monotonicity* by restricting the defining implication to all collections of theory systems, instead of insisting that it hold for arbitrary collections of theory families. Working with join instead of union leaves most of our conclusions intact. It is still the case that family $c^\vee$-monotonicity and left $c^\vee$-monotonicity are each sufficient for stability. Family $c^\vee$ monotonicity is equivalent to the combination of left and right $c^\vee$-monotonicities and each of the latter implies system $c^\vee$-monotonicity. And it is still the case that left $c^\vee$-monotonicity implies protoalgebraicity and system $c^\vee$-monotonicity implies prealgebraicity. There are, however, some differences between $c^\vee$-monotonicity properties and their counterparts using union. One example is that $c^\vee$-monotonicity properties, unlike $c^\cup$-monotonicity properties, do not transfer in general. This is due to the fact that, unlike union, the join operation does not commute with inverse surjective morphisms between algebraic systems. Another difference, which may also be viewed as a partial justification for considering both properties, is that the corresponding classes in the two hierarchies are incomparable. For instance, there exists a family $c^\cup$-monotone π-institution which is not family $c^\vee$-monotone and vice-versa.

In Section 3.6 we switch from the study of monotonicity properties to the study of *injectivity properties*. The importance of injectivity in the context of sentential logics was already apparent in the work of Blok and Pigozzi [35], but it was brought more in focus following its generalizations, first by Herrmann [43] and, ultimately, with the work of Czelakowski and Jansana [62] on weakly algebraizable logics. A π-institution is *family injective* if, for all theory families T and T', $\Omega(T) = \Omega(T')$ implies $T = T'$, i.e., when the Leibniz operator on theory families is injective. *Left injectivity* is obtained by replacing T and T' on the theory family side (conclusion) by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively, while *right injectivity* by doing the same on the congruence system side (hypothesis). Finally, *system injectivity* imposes injectivity of the Leibniz operator on theory systems only. Here, right injectivity turns out to be the most potent of the four properties and it implies systemicity. Then comes family injectivity, followed by left injectivity, which, in turn, implies system injectivity. Right injectivity is equivalent to system injectivity coupled with systemicity, whereas, if system injectivity is combined with stability, they imply left injectivity. All injectivity properties transfer.

In the last two sections of the chapter, Sections 3.7 and 3.8, we study *reflectivity properties*, which are dual to the monotonicity properties delved into in Sections 3.3, 3.4 and 3.5.

In Section 3.7, we study the various flavors of *reflectivity*. In the context of algebraizable sentential logics the importance of this property was at least implicit, if not apparent, in the work of Blok and Pigozzi [35]. And, as was the case with injectivity, it kept its central role in the generalizations to infinitary algebraizable [43] and weakly algebraizable logics [62]. A π-institution $\mathcal{I}$ is *family reflective* if, for all theory families T and T', $\Omega(T) \leq \Omega(T')$ implies $T \leq T'$, i.e., if the Leibniz operator is order reflecting on the theory families of $\mathcal{I}$. *Left reflectivity* replaces T and T' on the theory family side (conclusion) by their arrow counterparts, while *right reflectivity* applies the same replacement on the congruence system side (hypothesis). Finally, *system reflectivity* imposes order reflectivity of the Leibniz operator on theory systems only. Each of family and right reflectivity implies systemicity. This allows proving that these two versions of reflectivity are actually equivalent. They imply left reflectivity, which dominates system reflectivity. System reflectivity together with stability imply left reflectivity. System reflectivity, coupled with systemicity, is equivalent to family reflectivity. All these properties transfer. Section 3.7 ends by establishing some relations between reflectivity and properties introduced in preceding sections. More precisely, it is shown that family, left and system reflectivity imply, respectively, right, left and system injectivity. Additionally, family, left and system reflectivity imply, respectively, family, left and system loyalty.

In Section 3.8, we study versions of *complete reflectivity*. As was mentioned previously, in the context of sentential logics, the property was introduced by Raftery in [77], where it was used to characterize truth equationality of sentential logics. A logic is truth equational if the filters of its Leibniz reduced matrix models are equationally definable. This is equivalent to the assertion that the filters of arbitrary matrix models are definable using equations via the corresponding Leibniz congruences. Raftery showed that truth equationality is equivalent to the complete order reflectivity of the Leibniz operator on the theories of the logic, i.e., the property that, for every collection $\mathcal{T} \cup \{T'\}$ of theories, $\bigcap_{T\in\mathcal{T}} \Omega(T) \subseteq \Omega(T')$ implies $\bigcap \mathcal{T} \subseteq T'$ (see, e.g., pages 371-382 of [86]; in particular, Theorem 6.101). Given a π-institution $\mathcal{I}$, *family complete reflectivity* asserts that, for every collection $\mathcal{T} \cup \{T'\}$ of theory families of $\mathcal{I}$, $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap \mathcal{T} \leq T'$. *Left complete reflectivity* is obtained by replacing on the theory family side (conclusion) each theory appearing by its arrow version. Similarly, *right complete reflectivity* results by performing the same replacement on the congruence system side (hypothesis). *System complete reflectivity* is the restriction of the condition defining family complete reflectivity on collections of theory systems. We abbreviate complete reflectivity by *c-reflectivity*. On their own, family and right c-reflectivity each implies systemicity, and this allows showing that they are equivalent properties. They imply left c-reflectivity, which, in turn, implies system c-reflectivity. System c-reflectivity, coupled with stability implies left c-reflectivity. Moreover, together with systemicity, it turns out to be equivalent to family c-reflectivity. All three different properties transfer and it is fairly obvious that they generalize the corresponding reflectivity properties, since the latter are special cases of the former in which the collection $\mathcal{T}$ is a singleton.

The properties of systemicity, stability, loyalty, monotonicity, $c^{\cup}$-monotonicity, $c^{\vee}$-monotonicity, injectivity, reflectivity and c-reflectivity constitute the building blocks of the hierarchies of π-institutions that will be presented and studied in subsequent chapters of the monograph.

3.2 Systemicity, Stability and Loyalty

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system. Recall that, by Proposition 42, for every theory family $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T}$ is the largest theory system included in T. Moreover, recall that, by Proposition 20, $\Omega(T) \leq \Omega(\overleftarrow{T})$.

Definition 148 (Systemicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is called* **systemic** *if* $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$*, or, equivalently, if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T} = T.$$

Another interesting characterization is the following. Recall that, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on $\mathbf{F}$, and a sentence family $X \in \mathrm{SenFam}(\mathbf{F})$, we denote by

$$C(X) = \{C_\Sigma(X)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$$

the least theory family of $\mathcal{I}$ including X. Moreover if $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, we use $C(\Phi)$ and $C(\phi) \coloneqq C(\{\phi\})$ to denote $C(X)$, where $X = \{X_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}^\flat|}$ is such that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$, $X_{\Sigma'} = \begin{cases} \Phi, & \text{if } \Sigma' = \Sigma \\ \varnothing, & \text{if } \Sigma' \neq \Sigma \end{cases}$.

Proposition 149 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is systemic if and only if, for all* $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$*, all* $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\mathrm{SEN}^\flat(f)(\phi) \in C_{\Sigma'}(\phi).$$

Proof: Suppose, first, that $\mathcal{I}$ is systemic. Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Since, by hypothesis, for all $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\phi \in T_\Sigma$, we have, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\mathrm{SEN}^\flat(f)(\phi) \in T_{\Sigma'}$, we conclude that for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\mathrm{SEN}^\flat(f)(\phi) \in C_{\Sigma'}(\phi)$.

Assume, conversely, that the displayed condition in the statement holds and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Consider $\Sigma' \in |\mathbf{Sign}^\flat|$ and $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$. Then, by hypothesis,

$$\begin{array}{rcl}\mathrm{SEN}^\flat(f)(\phi) & \in & C_{\Sigma'}(\phi) \\ & = & \bigcap\{T'_{\Sigma'} : T' \in \mathrm{ThFam}(\mathcal{I}), \phi \in T'_\Sigma\} \\ & \subseteq & T_{\Sigma'}.\end{array}$$

Thus, $T \in \mathrm{ThSys}(\mathcal{I})$ and $\mathcal{I}$ is systemic. ∎

The following is one of many typical transfer theorems that we will encounter for various properties regarding π-institutions.

Theorem 150 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is systemic if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$.*

Proof: The right to left implication follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism, and taking into account the fact that, by Lemma 51, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$ and $\mathrm{FiSys}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThSys}(\mathcal{I})$.

For the left to right implication, suppose that $\mathcal{I}$ is systemic and assume that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Thus, by hypothesis, $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$. Hence, using again Lemma 51, $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$. Therefore $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$. ∎

Now we introduce another important class of π-institutions in the semantic Leibniz hierarchy.

Definition 151 (Stability) *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is called* **stable** *if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,*

$$\Omega(\overleftarrow{T}) = \Omega(T).$$

Since, by Proposition 20, it always holds that $\Omega(T) \leq \Omega(\overleftarrow{T})$, we have that

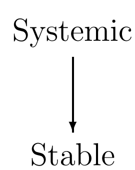
$$\mathcal{I} \text{ is stable if and only if, for all } T \in \mathrm{ThFam}(\mathcal{I}),\ \Omega(\overleftarrow{T}) \leq \Omega(T).$$

The following obvious relation holds between these two classes.

Proposition 152 *Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution. If $\mathcal{I}$ is systemic, then it is stable.*

Proof: If $\mathcal{I}$ is systemic, then, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = T$, whence $\Omega(\overleftarrow{T}) = \Omega(T)$. Thus, $\mathcal{I}$ is stable. ∎

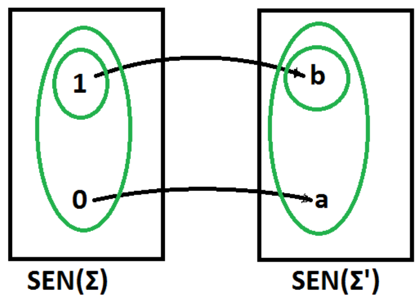
We denote this relation by the following diagram, where the arrow represents inclusion.



We show that this is a proper inclusion, i.e., there are stable π-institutions that are not systemic.

Example 153 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is a category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone (consisting only of the projection natural transformations).*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

There is a single theory family which is not a theory system, namely $T = \{\{0, 1\}, \{b\}\}$*. So* $\mathcal{I}$ *is not systemic. On the other hand, we have* $\Omega(\overleftarrow{T}) = \Omega(\{\{1\}, \{b\}\}) = \Delta^{\mathbf{F}} = \Omega(T)$*. Therefore,* $\mathcal{I}$ *is stable.*

The stability property transfers from the theory families of a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ to all $\mathcal{I}$-filter families on all $\mathbf{F}$-algebraic systems.

Theorem 154 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is stable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(T)$*.*

Proof: The "if" part is trivial, since stability is defined by the given condition on all theory families of the π-institution, which, by Lemma 51, are exactly the $\mathcal{I}$-filter families on $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$.

For the "only if" assume that $\mathcal{I}$ is stable and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have:

$$\begin{array}{rcl}
\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) & = & \Omega(\alpha^{-1}(\overleftarrow{T})) \quad \text{(by Proposition 24)} \\
& = & \Omega(\overleftarrow{\alpha^{-1}(T)}) \quad \text{(by Lemma 6)} \\
& = & \Omega(\alpha^{-1}(T)) \\
& & \text{(by Lemma 51, Proposition 42 and stability)} \\
& = & \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad \text{(by Proposition 24).}
\end{array}$$

By surjectivity of $\langle F,\alpha\rangle$, we get that $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(T)$. ■

Next, we introduce various versions of the loyalty property and the corresponding classes in the loyalty hierarchy of π-institutions.

Definition 155 (Loyalty) *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

- *$\mathcal{I}$ is called* **family loyal** *if, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$,*
$$T \nleq T' \quad or \quad \Omega(T) \ngeq \Omega(T').$$
- *$\mathcal{I}$ is called* **left loyal** *if, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$,*
$$\overleftarrow{T} \nleq \overleftarrow{T'} \quad or \quad \Omega(T) \ngeq \Omega(T').$$
- *$\mathcal{I}$ is called* **right loyal** *if, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$,*
$$T \nleq T' \quad or \quad \Omega(\overleftarrow{T}) \ngeq \Omega(\overleftarrow{T'}).$$
- *$\mathcal{I}$ is called* **system loyal** *if, for all $T,T' \in \mathrm{ThSys}(\mathcal{I})$,*
$$T \nleq T' \quad or \quad \Omega(T) \ngeq \Omega(T').$$

We establish relationships between these properties that lead to a loyalty hierarchy of π-institutions.

We show, first, that family loyalty implies stability.

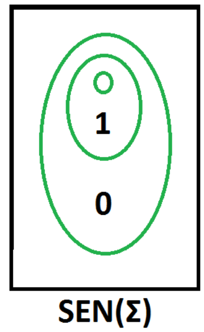
Lemma 156 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is family loyal, then it is stable.*

Proof: Suppose $\mathcal{I}$ is family loyal and let $T \in \mathrm{ThFam}(\mathcal{I})$. We must show that $\Omega(\overleftarrow{T}) = \Omega(T)$. If $\overleftarrow{T} = T$, then the conclusion is obvious. So suppose $\overleftarrow{T} \neq T$. Then, by Proposition 42, we have $\overleftarrow{T} < T$. Using family loyalty, we get $\Omega(\overleftarrow{T}) \ngeq \Omega(T)$. Hence, by Proposition 20, we have $\Omega(\overleftarrow{T}) = \Omega(T)$. We conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\overleftarrow{T}) = \Omega(T)$, whence $\mathcal{I}$ is stable. ■

There are π-institutions that are stable but not family loyal. The following example shows that family loyal π-institutions form a proper subclass of the class of stable π-institutions.

Example 157 *Consider the algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category, with object Σ;*

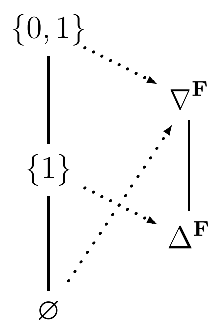


- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$;
- $N^\flat$ *is the trivial clone (consisting only of the projections).*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting*

$$C_\Sigma = \{\varnothing, \{1\}, \{1,0\}\}.$$

The lattice of theory families (which are all systems) and the corresponding Leibniz congruence systems are given in the diagram.



Since all theory families are theory systems, $\mathcal{I}$ *is clearly stable. On the other hand, letting* $T = \{\varnothing\}$ *and* $T' = \{\{1\}\}$*, we have* $T < T'$ *and* $\Omega(T) > \Omega(T')$*. Therefore,* $\mathcal{I}$ *is not family loyal.*

Now we can establish the following relationships between the four loyalty properties.

Proposition 158 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family loyal then it is left loyal;*

(b) If $\mathcal{I}$ *is left loyal, then it is system loyal;*

(c) $\mathcal{I}$ *is system loyal if and only if it is right loyal;*

(b) $\mathcal{I}$ *is family loyal if and only if it is system loyal and stable.*

Proof:

(a) Suppose $\mathcal{I}$ is family loyal. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T} < \overleftarrow{T'}$. Then, by family loyalty $\Omega(\overleftarrow{T}) \not> \Omega(\overleftarrow{T'})$. But, by Lemma 156, $\mathcal{I}$ is stable. So we get $\Omega(T) \not> \Omega(T')$. We conclude that $\mathcal{I}$ is left loyal.

(b) Suppose that $\mathcal{I}$ is left loyal and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) > \Omega(T')$. Then, by left loyalty, $\overleftarrow{T} \not< \overleftarrow{T'}$. But, since T, T' are theory systems, $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Hence $T \not< T'$. Therefore $\mathcal{I}$ is system loyal.

(c) Suppose, now, that $\mathcal{I}$ is right loyal and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T < T'$. Then, by right loyalty, $\Omega(\overleftarrow{T}) \not> \Omega(\overleftarrow{T'})$. Thus, since T, T' are theory systems, $\Omega(T) \not> \Omega(T')$. We conclude that $\mathcal{I}$ is system loyal.

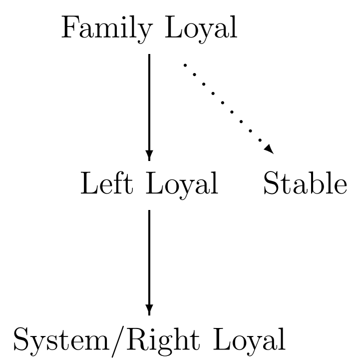
Suppose, conversely, that $\mathcal{I}$ is system loyal and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T < T'$. Then, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$. If $\overleftarrow{T} = \overleftarrow{T'}$, then $\Omega(\overleftarrow{T}) \not> \Omega(\overleftarrow{T'})$. On the other hand, if $\overleftarrow{T} < \overleftarrow{T'}$, then, by system loyalty, $\Omega(\overleftarrow{T}) \not> \Omega(\overleftarrow{T'})$. We conclude that $\mathcal{I}$ is right loyal.

(d) Suppose, first, that $\mathcal{I}$ is family loyal. Then, by Lemma 156, it is stable and it is, a fortiori, system loyal.

Suppose, conversely, that $\mathcal{I}$ is system loyal and stable. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) > \Omega(T')$. By stability, $\Omega(\overleftarrow{T}) > \Omega(\overleftarrow{T'})$. Therefore, by system loyalty, $\overleftarrow{T} \not< \overleftarrow{T'}$. Since $\Omega(\overleftarrow{T}) \neq \Omega(\overleftarrow{T'})$, we also have, $\overleftarrow{T} \not\leq \overleftarrow{T'}$. Therefore, by Lemma 1, $T \not< T'$. We conclude that $\mathcal{I}$ is family loyal.

■

By Proposition 158, the following **loyalty hierarchy** arises.



Example 157 brings to the fore another interesting point, namely, that family loyal π-institutions must have theorems, unless they are trivial.

Proposition 159 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ is trivial, then it is family loyal.

(b) If $\mathcal{I}$ is family loyal and non-trivial, then it has theorems.

Proof:

(a) If $\mathcal{I}$ is trivial, then the only Leibniz congruence system is $\nabla^{\mathbf{F}}$. So $\mathcal{I}$ is family loyal.

(b) Suppose $\mathcal{I}$ is family loyal and non-trivial. By non-triviality, it has a theory family T, such that, for some $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma \neq \varnothing$ and $T_\Sigma \neq \mathrm{SEN}(\Sigma)$. Therefore, we have $\overline{\varnothing} < T$. So, by loyalty, $\Omega(\overline{\varnothing}) \not> \Omega(T)$. But $\Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}}$. So $\nabla^{\mathbf{F}} \not> \Omega(T)$. This shows that $\Omega(T) = \nabla^{\mathbf{F}}$, which is a contradiction, since $\nabla^{\mathbf{F}}$ cannot be compatible with any theory family T, with a component $T_\Sigma \neq \varnothing, \mathrm{SEN}(\Sigma)$.

■

We also have the following straightforward relationship.

Proposition 160 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is systemic and system loyal, then it is family loyal.*

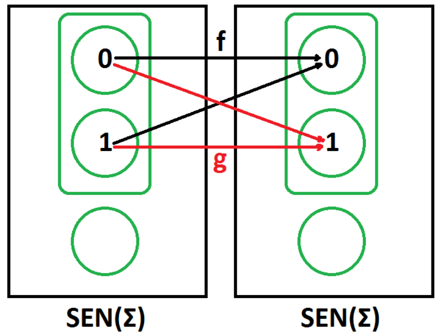
Proof: If $\mathcal{I}$ is systemic, then $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ and, as a result, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = T$. Thus, under this hypothesis, all loyalty properties coincide. ■

The next example serves many purposes:

- It shows a π-institution that is left loyal, but not family loyal.
- It shows a π-institution that is system loyal, but not stable, and, hence, by Proposition 158, not family loyal.
- It shows an example of a nontrivial π-institution without theorems that is system loyal, but not family loyal, illustrating Proposition 159.

Example 161 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and two non-identity morphisms $f, g : \Sigma \to \Sigma$, such that $f \circ f = f$, $g \circ g = g$, $g \circ f = g$ and $f \circ g = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(g)(0) = \mathrm{SEN}^\flat(g)(1) = 1$;
- $N^\flat$ *is the trivial clone.*



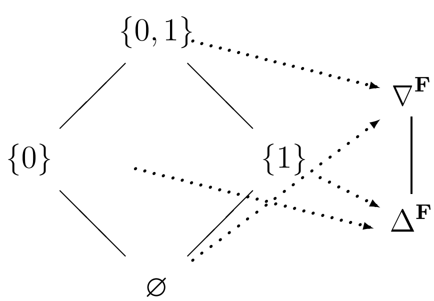
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{1\}, \{0,1\}\}.$$

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\varnothing$	$\varnothing$
$\{0\}$	$\varnothing$
$\{1\}$	$\varnothing$
$\{0,1\}$	$\{0,1\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.

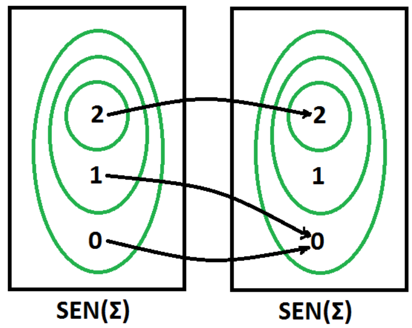


Note that, since $\overleftarrow{\{\{0\}\}} = \{\varnothing\}$ and these theory families map to different congruence systems, $\mathcal{I}$ is not stable. $\mathcal{I}$ is not family loyal, since $\{\varnothing\} < \{\{0\}\}$ and $\Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} > \Delta^{\mathbf{F}} = \Omega(\{\{0\}\})$. However, $\mathcal{I}$ is left loyal, since, if $\overleftarrow{T} < \overleftarrow{T'}$, then $T' = \{\{0,1\}\}$ and, therefore, since $\Omega(T') = \nabla^{\mathbf{F}}$, $\Omega(T) \not> \Omega(T')$.

Now we provide a variety of additional examples, all showcasing π-institutions that are left loyal (and, hence, also system loyal), but fail to be family loyal.

Example 162 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

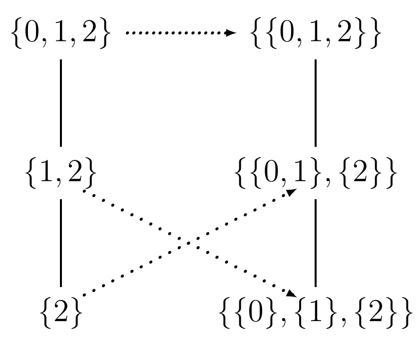


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$*.*

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



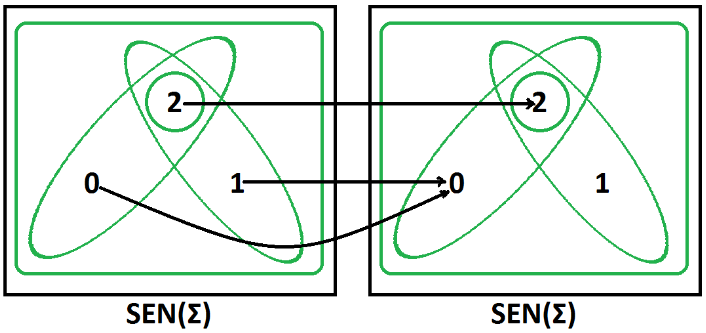
Taking into account the fact that $\{\{1,2\}\}$ *is a theory family that is not a theory system, it is easy to see that this* π*-institution is left loyal (and, hence, system loyal), but fails to be family loyal.*

Example 163 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*

- $N^\flat$ *is the trivial clone.*

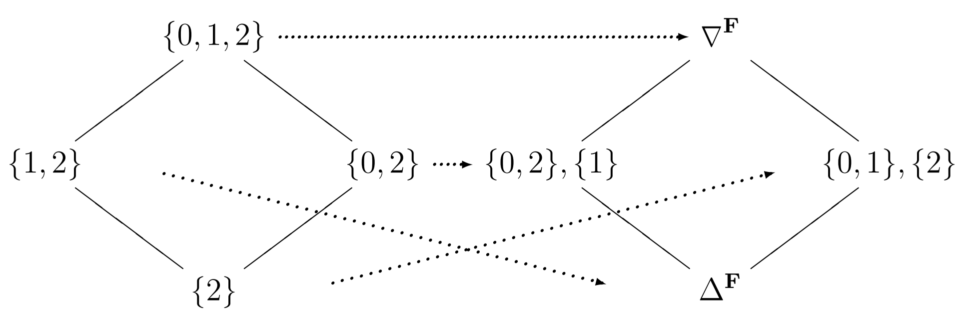


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

Note that $\{\{1,2\}\}$ *is the only theory family that is not a theory system.*

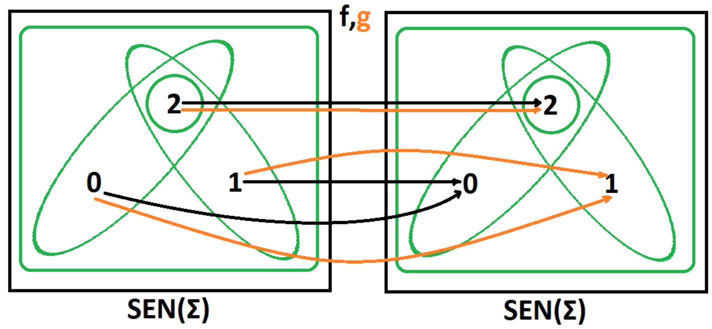
The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Again it is not difficult to see that $\mathcal{I}$ *is left and right loyal, but fails to be family loyal.*

Example 164 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and two non-identity morphisms* $f, g : \Sigma \to \Sigma$*, such that* $f \circ f = f$*,* $g \circ g = g$*,* $g \circ f = g$ *and* $f \circ g = f$*;*



- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(f)(2) = 2$ *and* $\mathrm{SEN}^\flat(g)(0) = 1$, $\mathrm{SEN}^\flat(g)(1) = 1$, $\mathrm{SEN}^\flat(g)(2) = 2$;
- $N^\flat$ *is the trivial clone.*

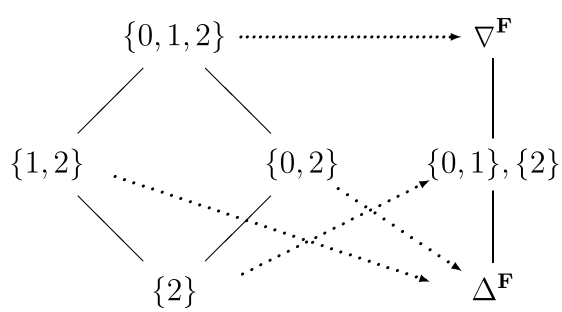
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{0,2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



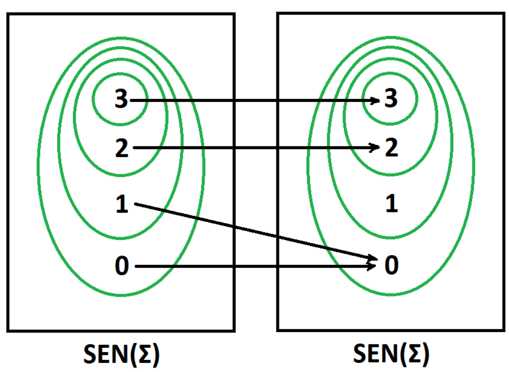
Again it is easy to check, keeping in mind that $\{\{2\}\}$ and $\{\{0,1,2\}\}$ are the only theory systems, that $\mathcal{I}$ is left loyal (and, hence, system loyal), but not family loyal.

Finally, an example of a system loyal π-institution that is not left loyal.

Example 165 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2, 3\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(f)(2) = 2$ *and* $\mathrm{SEN}^\flat(f)(3) = 3$;
- $N^\flat$ *is the clone generated by the following two unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$:

x	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	0	0
1	1	1
2	0	3
3	3	3



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

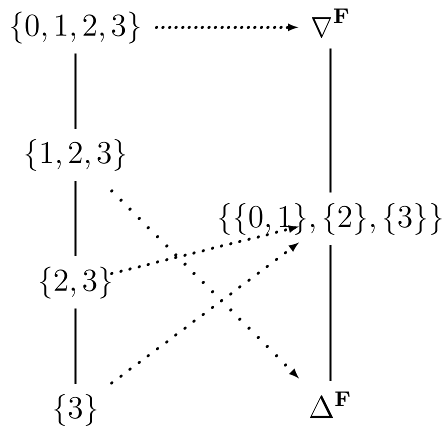
$$\mathcal{C}_\Sigma = \{\{3\}, \{2, 3\}, \{1, 2, 3\}, \{0, 1, 2, 3\}\}.$$

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{3\}$	$\{3\}$
$\{2, 3\}$	$\{2, 3\}$
$\{1, 2, 3\}$	$\{2, 3\}$
$\{0, 1, 2, 3\}$	$\{0, 1, 2, 3\}$

The lattice of theory families and the corresponding Leibniz congruence sys-

tems are shown in the diagram.



$\mathcal{I}$ has three theory systems, $\mathrm{Thm}(\mathcal{I}) = \{\{3\}\}$, $T = \{\{2,3\}\}$ *and* $\mathrm{SEN} = \{\{0,1,2,3\}\}$. *An inspection of the diagram shows that $\mathcal{I}$ is system loyal. On the other hand, setting $T' = \{\{1,2,3\}\}$, we get that*

$$\overleftarrow{T'} = \overleftarrow{\{\{1,2,3\}\}} = \{\{2,3\}\} > \{\{3\}\} = \overleftarrow{\{\{3\}\}} = \overleftarrow{\mathrm{Thm}(\mathcal{I})},$$

whereas

$$\Omega(T') = \Delta^{\mathbf{F}} < \{\{0,1\},\{2\},\{3\}\} = \Omega(\mathrm{Thm}(\mathcal{I})).$$

Therefore, $\mathcal{I}$ is not left loyal.

For all loyalty properties, we have transfer theorems, detailed in the various parts of the following result.

Theorem 166 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be a π-institution based on $\mathbf{F}$.*

(a) *$\mathcal{I}$ is family loyal if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T \nless T' \quad \text{or} \quad \Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T');$$

(b) *$\mathcal{I}$ is left loyal if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\overleftarrow{T} \nless \overleftarrow{T'} \quad \text{or} \quad \Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T');$$

(c) *$\mathcal{I}$ is system loyal if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$,*

$$T \nless T' \quad \text{or} \quad \Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T').$$

Proof:

(a) For the "if", suppose that the loyalty condition holds for the $\mathcal{I}$-filter families of every $\mathbf{F}$-algebraic system. Then it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism. The fact that, by Lemma 51, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$, concludes the proof.

Suppose, conversely, that $\mathcal{I}$ is family loyal. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T < T'$. We must show that $\Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T')$. Since $T < T'$, we must have $\alpha^{-1}(T) \leq \alpha^{-1}(T')$. However, by surjectivity of $\langle F, \alpha \rangle$, if $\alpha^{-1}(T) = \alpha^{-1}(T')$, we get $T = T'$. Thus, we must have $\alpha^{-1}(T) < \alpha^{-1}(T')$. By Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$. Thus, by loyalty, we get $\Omega(\alpha^{-1}(T)) \ngtr \Omega(\alpha^{-1}(T'))$. Thus, by Proposition 24,

$$\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \ngtr \alpha^{-1}(\Omega^{\mathcal{A}}(T')).$$

The following claim now completes the proof:

Claim: $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \ngtr \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$ implies $\Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T')$.

We work by contraposition. Assume $\Omega^{\mathcal{A}}(T) > \Omega^{\mathcal{A}}(T')$. Then, clearly, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \geq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Moreover, by surjectivity, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \neq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Thus, we conclude that $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) > \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$.

(b) If the left loyalty condition holds for the $\mathcal{I}$-filter families of every $\mathbf{F}$-algebraic system, it holds, in particular, for the $\mathbf{F}$-algebraic system $\mathcal{F}$. Since, by Lemma 51, $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$, $\mathcal{I}$ is left loyal.

Suppose, conversely, that $\mathcal{I}$ is left loyal. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\overleftarrow{T} < \overleftarrow{T'}$. We must show that $\Omega^{\mathcal{A}}(T) \ngtr \Omega^{\mathcal{A}}(T')$. Since $\overleftarrow{T} < \overleftarrow{T'}$, we must have $\alpha^{-1}(\overleftarrow{T}) \leq \alpha^{-1}(\overleftarrow{T'})$. However, by surjectivity of $\langle F, \alpha \rangle$, if $\alpha^{-1}(\overleftarrow{T}) = \alpha^{-1}(\overleftarrow{T'})$, we get $\overleftarrow{T} = \overleftarrow{T'}$. Thus, we must have $\alpha^{-1}(\overleftarrow{T}) < \alpha^{-1}(\overleftarrow{T'})$. By Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$. By Lemma 6, $\overleftarrow{\alpha^{-1}(T)} < \overleftarrow{\alpha^{-1}(T')}$. Thus, by left loyalty, we get $\Omega(\alpha^{-1}(T)) \ngtr \Omega(\alpha^{-1}(T'))$. Thus, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \ngtr \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. The claim used in Part (a) is used once more to complete the proof of Part (b).

(c) The proof follows along the lines of that of Part (a). ∎

As a concluding remark, we rephrase the definitions of family and of system loyalty in terms of mappings between partially ordered sets.

Given two posets $\mathbf{P} = \langle P, \leq \rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq \rangle$, we call a mapping $f : P \to Q$ **loyal** if, for all $p_1, p_2 \in P$,

$$p_1 < p_2 \quad \text{implies} \quad f(p_1) \not\succ f(p_2).$$

Then we have the following easy consequence (or, rather, reformulation) of the definition, combined with Theorem 166.

For a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and an $\mathbf{F}$-algebraic system $\mathcal{A}$, we define

$$\begin{array}{rcl}\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}) & := & \mathrm{ConSys}^{\mathrm{AlgSys}^*(\mathcal{I})}(\mathcal{A});\\ \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) & := & \mathrm{ConSys}^{\mathrm{AlgSys}(\mathcal{I})}(\mathcal{A}).\end{array}$$

Moreover, we set

$$\begin{array}{rcl}\mathrm{ConSys}^*(\mathcal{I}) & := & \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F}) = \mathrm{ConSys}^{\mathrm{AlgSys}^*(\mathcal{I})}(\mathcal{F});\\ \mathrm{ConSys}(\mathcal{I}) & := & \mathrm{ConSys}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ConSys}^{\mathrm{AlgSys}(\mathcal{I})}(\mathcal{F}).\end{array}$$

Proposition 167 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is family loyal;*

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is loyal;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is loyal, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, we get

Proposition 168 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is system loyal;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is loyal;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is loyal, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

3.3 Monotonicity

In this section we define and study classes of π-institutions that are defined using monotonicity properties of the Leibniz operator.

Definition 169 (Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **family monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T \leq T' \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$

- $\mathcal{I}$ *is called* **left monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\overleftarrow{T} \leq \overleftarrow{T'} \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$

- $\mathcal{I}$ *is called* **right monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \textit{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$

- $\mathcal{I}$ *is called* **system monotone** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$T \leq T' \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$

First, we show a very useful lemma to the effect that family monotonicity implies stability.

Lemma 170 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family monotone, then* $\mathcal{I}$ *is stable.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then we have, by Proposition 42, that $T, \overleftarrow{T} \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T} \leq T$. Therefore, by family monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(T)$. However, by Proposition 20, $\Omega(T) \leq \Omega(\overleftarrow{T})$. Therefore, we get that $\Omega(\overleftarrow{T}) = \Omega(T)$. So $\mathcal{I}$ is stable. ■

Using Lemma 170, we can now show that family and left monotonicity are equivalent properties.

Proposition 171 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family monotone if and only if it is left monotone.*

Proof: Suppose, first, that $\mathcal{I}$ is left monotone. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$. Therefore, by hypothesis, $\Omega(T) \leq \Omega(T')$. Hence $\mathcal{I}$ is family monotone.

Suppose, conversely, that $\mathcal{I}$ is family monotone. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T} \leq \overleftarrow{T'}$. Then, by hypothesis, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. But, by Lemma 170, $\mathcal{I}$ is stable, whence $\Omega(\overleftarrow{T}) = \Omega(T)$ and $\Omega(\overleftarrow{T'}) = \Omega(T')$. Thus, we conclude that $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is left monotone. ■

An interesting observation is that system monotonicity may also be defined by using arbitrary theory families, but modifying the application of monotonicy to that of "arrow monotonicity". Formally speaking, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, we say that $\mathcal{I}$ is **arrow monotone** if, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\overleftarrow{T} \leq \overleftarrow{T'} \quad \text{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$

Lemma 172 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system monotone if and only if it is arrow monotone.*

Proof: Suppose, first, that $\mathcal{I}$ is system monotone and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T} \le \overleftarrow{T'}$. Since, by Proposition 42, $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, we get, by system monotonicity, that $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. Thus, $\mathcal{I}$ is arrow monotone.

Suppose, conversely, that $\mathcal{I}$ is arrow monotone and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \le T'$. Then, again by Proposition 42, we get that $\overleftarrow{T} = T \le T' = \overleftarrow{T'}$. Therefore, by arrow monotonicity, $\Omega(T) = \Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'}) = \Omega(T')$. So $\mathcal{I}$ is system monotone. ■

Next, we show that the two properties of right monotonicity and system monotonicity also coincide.

Proposition 173 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system monotone if and only if it is right monotone.*

Proof: Suppose, first, that $\mathcal{I}$ is right monotone and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \le T'$. Then, by right monotonicity, $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. But, since T, T' are theory systems, we have $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Hence, $\Omega(T) \le \Omega(T')$. Therefore, $\mathcal{I}$ is system monotone.

Suppose, conversely, that $\mathcal{I}$ is system monotone and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \le T'$. Then by Lemma 1, $\overleftarrow{T} \le \overleftarrow{T'}$. Since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, we can apply system monotonicity to get $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. Thus, $\mathcal{I}$ is right monotone. ■

Because of Propositions 171 and 173, we make the following definitions:

Definition 174 (Pre- and Protoalgebraicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **protoalgebraic** *if it is family monotone;*
- $\mathcal{I}$ *is called* **prealgebraic** *if it is system monotone.*

We show now that stability is exactly the separating property between prealgebraicity and protoalgebraicity.

Theorem 175 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if it is prealgebraic and stable.*

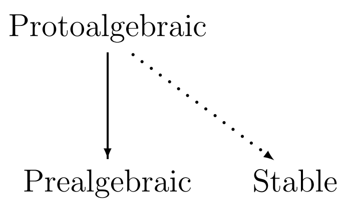
Proof: Suppose, first, that $\mathcal{I}$ is protoalgebraic. Then it is clearly prealgebraic and, by Lemma 170, it is stable.

Suppose, conversely, that $\mathcal{I}$ is stable and prealgebraic and consider $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, using stability, Proposition 42 and prealgebraicity, we get

$$\begin{array}{rcll} \Omega(T) & = & \Omega(\overleftarrow{T}) & \text{(stability)} \\ & \leq & \Omega(\overleftarrow{T'}) & \text{(Proposition 42 and prealgebraicity)} \\ & = & \Omega(T') & \text{(stability).} \end{array}$$

So Ω is monotone on theory families and $\mathcal{I}$ is protoalgebraic. ∎

In terms of monotonicity, we have established the following **monotonicity hierarchy**:



Now we give examples of π-institutions to show that the two inclusions depicted in this diagram are proper. Moreover, we show that there are π-institutions that are neither prealgebraic nor stable. In other words, we show the following

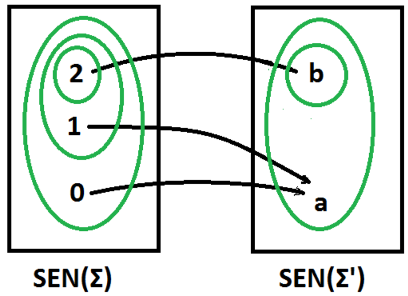
- There exist π-institutions that are neither prealgebraic nor stable.
- There exist π-institutions that are prealgebraic but not stable and, hence, not protoalgebraic.
- There exist π-institutions that are stable but not prealgebraic and, hence, not protoalgebraic.

Example 176 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = a$ *and* $\mathrm{SEN}^\flat(f)(2) = b$*;*
- $N^\flat$ *is the trivial clone.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$



It is easy to see that $\mathcal{I}$ is not stable: Consider the theory family $T = \{\{1,2\},\{b\}\}$. *Then we have* $\overleftarrow{T} = \{\{2\},\{b\}\}$ *and*

$$\Omega(\overleftarrow{T}) = \{\{\{0,1\},\{2\}\},\{\{a\},\{b\}\}\} \neq \Delta^{\mathbf{F}} = \Omega(T).$$

As a consequence, we get that $\mathcal{I}$ is not protoalgebraic.

We now show that it is not prealgebraic either. We use the two theory systems

$$T = \{\{2\},\{a,b\}\} \leq \{\{1,2\},\{a,b\}\} = T'.$$

We have

$$\Omega_\Sigma(T) = \{\{0,1\},\{2\}\}, \quad \Omega_{\Sigma'}(T) = \{\{a,b\}\};$$
$$\Omega_\Sigma(T') = \{\{0\},\{1,2\}\}, \quad \Omega_{\Sigma'}(T') = \{\{a,b\}\}.$$

Since $T \leq T'$ *but* $\Omega(T) \nleq \Omega(T')$, *we conclude that $\mathcal{I}$ is not prealgebraic.*

Example 177 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

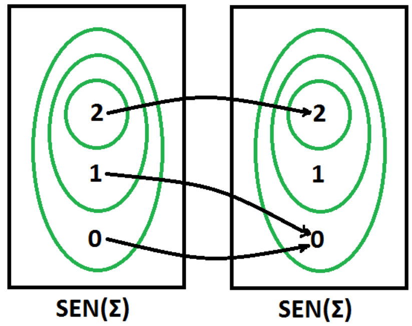
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

First, observe that the only two theory systems are $T = \{\{2\}\}$ *and* $T' = \{\{0,1,2\}\}$. *Further, we have* $\Omega_\Sigma(T) = \{\{0,1\},\{2\}\}$ *and* $\Omega_\Sigma(T') = \{\{0,1,2\}\}$. *So $\mathcal{I}$ is prealgebraic.*



On the other hand, for $T'' = \{\{1,2\}\} \in \mathrm{ThFam}(\mathcal{I})$, *we have* $\overleftarrow{T''} = \{\{2\}\}$. *Moreover* $\Omega_\Sigma(T'') = \{\{0\},\{1\},\{2\}\} \not\subseteq \{\{0,1\},\{2\}\} = \Omega_\Sigma(\overleftarrow{T''})$. *Therefore, we conclude that* $\mathcal{I}$ *is not stable. As a consequence, it is not protoalgebraic either.*

Example 178 *Take any non-protoalgebraic deductive system* $\mathcal{S} = \langle \mathcal{L}, \vdash_{\mathcal{S}} \rangle$ *or, in closure system notation,* $\mathcal{S} = \langle \mathcal{L}, C_{\mathcal{S}} \rangle$. *Consider the discrete* π*-institution* $\mathcal{I}^{\mathcal{S}} = \langle \mathbf{F}^{\mathcal{L}}, C^{\mathcal{S}} \rangle$ *corresponding to the deductive system* $\mathcal{S}$ *(see Section 1.1 for details). This* π*-institution is not protoalgebraic (since the deductive system is not), but it is certainly stable (since its only signature morphism is the identity). Therefore, we conclude that it is not prealgebraic either.*

The monotonicity property transfers from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ to all $\mathcal{I}$-filter families/systems on an arbitrary $\mathbf{F}$-algebraic system.

Theorem 179 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is prealgebraic if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$,

$$T \leq T' \quad \text{implies} \quad \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T');$$

(b) $\mathcal{I}$ *is protoalgebraic if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \leq T' \quad \text{implies} \quad \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T').$$

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{ThSys}(\mathcal{I}) = \mathrm{FiSys}^{\mathcal{I}}(\mathcal{F})$, by Lemma 51.

For the "only if", suppose that $\mathcal{I}$ is prealgebraic and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$.

Then, clearly, $\alpha^{-1}(T) \le \alpha^{-1}(T')$. Since, by Lemma 51, we have $\alpha^{-1}(T)$, $\alpha^{-1}(T') \in \mathrm{ThSys}(\mathcal{I})$, we get, by applying prealgebraicity, $\Omega(\alpha^{-1}(T)) \le \Omega(\alpha^{-1}(T'))$. But, then, by Proposition 24, we get that $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Finally, surjectivity yields that $\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$.

(b) The "if" is obtained by considering the **F**-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$ and taking into account that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$, by Lemma 51.

For the "only if", assume $\mathcal{I}$ is protoalgebraic and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an **F**-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \le T'$. Then, clearly, $\alpha^{-1}(T) \le \alpha^{-1}(T')$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by protoalgebraicity, $\Omega(\alpha^{-1}(T)) \le \Omega(\alpha^{-1}(T'))$. By Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$ and, hence, using surjectivity of $\langle F, \alpha\rangle$, $\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$.

■

As we did for loyalty, we may recast the two monotonicity classes in terms of the monotonicity of mappings from posets of theory or filter families/systems into posets of congruence systems.

Given two posets $\mathbf{P} = \langle P, \le\rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq\rangle$, we call a mapping $f : P \to Q$ **monotone** or **order preserving** if, for all $p_1, p_2 \in P$,

$$p_1 \le p_2 \quad \text{implies} \quad f(p_1) \preccurlyeq f(p_2).$$

Proposition 180 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is protoalgebraic;*

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* **F***-algebraic system* $\mathcal{A}$*.*

Similarly, for prealgebraicity, we get

Proposition 181 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is prealgebraic;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* **F***-algebraic system* $\mathcal{A}$*.*

Now we turn into exploring some of the relationships that hold between protoalgebraicity and prealgebraicity, on the one hand, and the various loyalty properties, on the other. Namely, we show that protoalgebraicity implies family loyalty and that prealgebraicity implies system loyalty. Note that, since family loyalty implies stability, the first part of the following theorem is a strengthening of Lemma 170.

Theorem 182 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is protoalgebraic, then it is family loyal;*

(b) If $\mathcal{I}$ *is prealgebraic, then it is system loyal.*

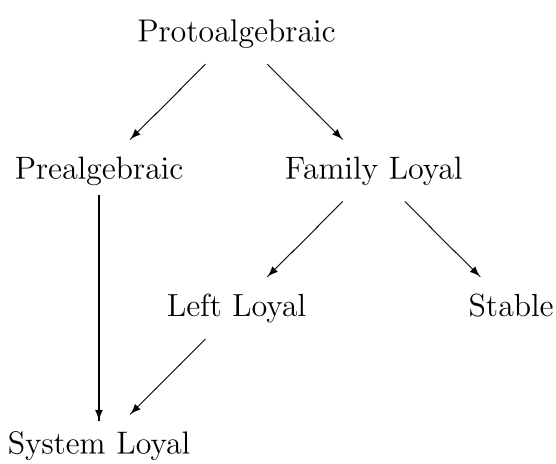
Proof:

(a) Suppose $\mathcal{I}$ is protoalgebraic and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T < T'$. Then, we have $T \leq T'$, whence, by protoalgebraicity, $\Omega(T) \leq \Omega(T')$. But this implies that $\Omega(T) \not\geq \Omega(T')$. We conclude that $\mathcal{I}$ is family loyal.

(b) Suppose that $\mathcal{I}$ is prealgebraic and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T < T'$. Then, by prealgebraicity, $\Omega(T) \leq \Omega(T')$. This implies that $\Omega(T) \not\geq \Omega(T')$. We conclude that $\mathcal{I}$ is system loyal.

■

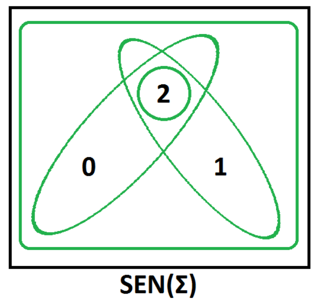
We have now established the following hierarchies:



Finally, we provide an example to show that the loyalty classes are proper subclasses of the classes defined using monotonicity.

Example 183 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be defined as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial one object category, with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*

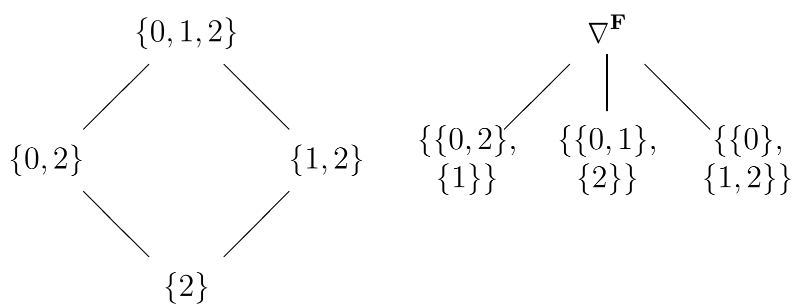


- *$N^\flat$ is the trivial clone, consisting of the projections only.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{\{0,1,2\}\}.$$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



First, note that, since the category $\mathbf{Sign}^\flat$ is trivial, $\mathcal{I}$ is systemic, i.e., every theory family is also a theory system.

By considering, for instance, $T = \{\{2\}\}$ and $T' = \{\{0,2\}\}$, we see that $T \leq T'$, but $\Omega(T) \nleq \Omega(T')$. Thus, $\mathcal{I}$ is not prealgebraic.

On the other hand, it is clear that there do not exist $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T < T'$ and $\Omega(T) > \Omega(T')$. Hence $\mathcal{I}$ is family loyal.

3.4 Complete $\bigcup$-Monotonicity

We now define classes of π-institutions that are based on various versions of a property called *complete monotonicity*. These properties are strengthened versions of the monotonicity properties and the purpose for introducing them is that they are, in some sense, the dual properties of complete order reflectivity, which strengthens order reflectivity, which, in turn, is, in this same sense, the property dual to monotonicity. This property is somehow related to a property known as *continuity* in the context of sentential logics.

In the case of sentential logics, the property of complete reflectivity asserts that, given a sentential logic $\mathcal{S}$ and a collection of theories $\mathcal{T} \cup \{T'\}$ of $\mathcal{S}$,

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \subseteq \Omega(T') \quad \text{implies} \quad \bigcap \mathcal{T} \subseteq T.$$

Note that meet and intersection coincide both in the lattice of theories of $\mathcal{S}$ and in the lattice of congruences on the formula algebra. Since, however, join and union differ, depending on the point of view, either lattice- or set-theoretic, one may perceive two different properties as dual properties of complete reflectivity. One, which we refer to as complete $\cup$-monotonicity, asserts that, for every collection $\mathcal{T} \cup \{T'\}$ of theories,

$$T' \subseteq \bigcup \mathcal{T} \quad \text{implies} \quad \Omega(T') \subseteq \bigcup_{T\in\mathcal{T}} \Omega(T).$$

The other, which may be termed complete $\vee$-monotonicity, asserts that, for every collection $\mathcal{T} \cup \{T'\}$ of theories,

$$T' \subseteq \bigvee \mathcal{T} \quad \text{implies} \quad \Omega(T') \subseteq \bigvee_{T\in\mathcal{T}} \Omega(T).$$

In this section, we deal with an analog of the first property for π-institutions. In the next section, we look at the second property.

Definition 184 (Complete $\bigcup$-Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **family completely $\bigcup$-monotone** *or, simply,* **family completely monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$T' \leq \bigcup_{T\in\mathcal{T}} T \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is* **left completely $\bigcup$-monotone** *or, simply,* **left completely monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T} \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is* **right completely $\bigcup$-monotone** *or, simply,* **right completely monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$T' \leq \bigcup_{T\in\mathcal{T}} T \quad \textit{implies} \quad \Omega(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T}).$$
- $\mathcal{I}$ *is* **system completely $\bigcup$-monotone** *or, simply,* **system completely monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,
$$T' \leq \bigcup_{T\in\mathcal{T}} T \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$

Sometimes we will use the abbreviated form **c$^\cup$-monotonicity** or **c-monotonicity** to refer to complete $\bigcup$-monotonicity.

We have seen in Lemma 170 that family monotonicity (protoalgebraicity) implies stability. Since family complete monotonicity is a stronger property than family monotonicity, we get Part (a) of the following:

Lemma 185 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family completely monotone, then it is stable.*

(b) If $\mathcal{I}$ *is left completely monotone, it is stable.*

Proof:

(a) If $\mathcal{I}$ is family completely monotone, then it is, a fortiori, family monotone. Thus, the result follows from Lemma 170.

(b) Suppose that $\mathcal{I}$ is left c-monotone and let $T \in \mathrm{ThFam}(\mathcal{I})$. By Proposition 42, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Applying left c-monotonicity, we get that $\Omega(\overleftarrow{T}) = \Omega(T)$. Hence $\mathcal{I}$ is stable.

■

Family completely monotone π-institutions are both left and right completely monotone. And, conversely, if a π-institution is both left and right c-monotone, then it is family c-monotone.

Proposition 186 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family completely monotone if and only if it is both left and right completely monotone.*

Proof: Suppose, first, that $\mathcal{I}$ is family completely monotone.

- Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T'} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$. Applying family c-monotonicity, we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. However, by Lemma 185, $\mathcal{I}$ is stable. Hence we get $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. We conclude that $\mathcal{I}$ is left completely monotone.
- Next, let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. Applying family c-monotonicity, we get $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. Once more, by Lemma 185, $\mathcal{I}$ is stable. Hence we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. We conclude that $\mathcal{I}$ is right completely monotone.

Suppose, conversely, that $\mathcal{I}$ is both left and right completely monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. Then, by right c-monotonicity, we get that $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. But since $\mathcal{I}$ is left completely monotone, by Lemma 185, it is stable, whence we get $\Omega(T') \leq \bigcup_{T\in\mathcal{T}}\Omega(T)$. Therefore, $\mathcal{I}$ is family completely monotone. ■

If a π-institution $\mathcal{I}$ is left or right completely monotone, then it is also system completely monotone.

Proposition 187 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is left c-monotone, then it is system c-monotone;*

(b) If $\mathcal{I}$ *is right c-monotone, then it is system c-monotone.*

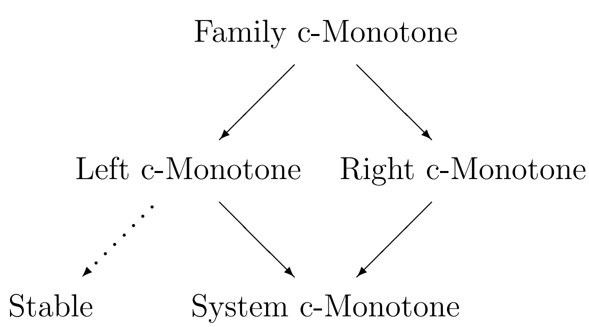
Proof:

(a) Suppose $\mathcal{I}$ is left c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. Since $\mathcal{T}\cup\{T'\}$ is a collection of theory systems, we get $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$. Hence, applying left c-monotonicity, we get $\Omega(T') \leq \bigcup_{T\in\mathcal{T}}\Omega(T)$. Thus, $\mathcal{I}$ is system c-monotone.

(b) Suppose $\mathcal{I}$ is right c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. Applying right c-monotonicity, we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}}\Omega(\overleftarrow{T})$. Since $\mathcal{T}\cup\{T'\}$ is a collection of theory systems, we now get $\Omega(T') \leq \bigcup_{T\in\mathcal{T}}\Omega(T)$. Thus, $\mathcal{I}$ is system c-monotone.

■

In terms of complete monotonicity, we have established the following hierarchy:



Now we give examples of π-institution to show that the inclusions depicted in this diagram are proper. We first give an example of a π-institution that is left c-monotone but not right c-monotone. This shows that:

- The class of family c-monotone π-institutions is properly contained in the class of all left c-monotone π-institutions;

- The class of all system c-monotone π-institutions properly includes the class of all right c-monotone π-institutions.

Example 188 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

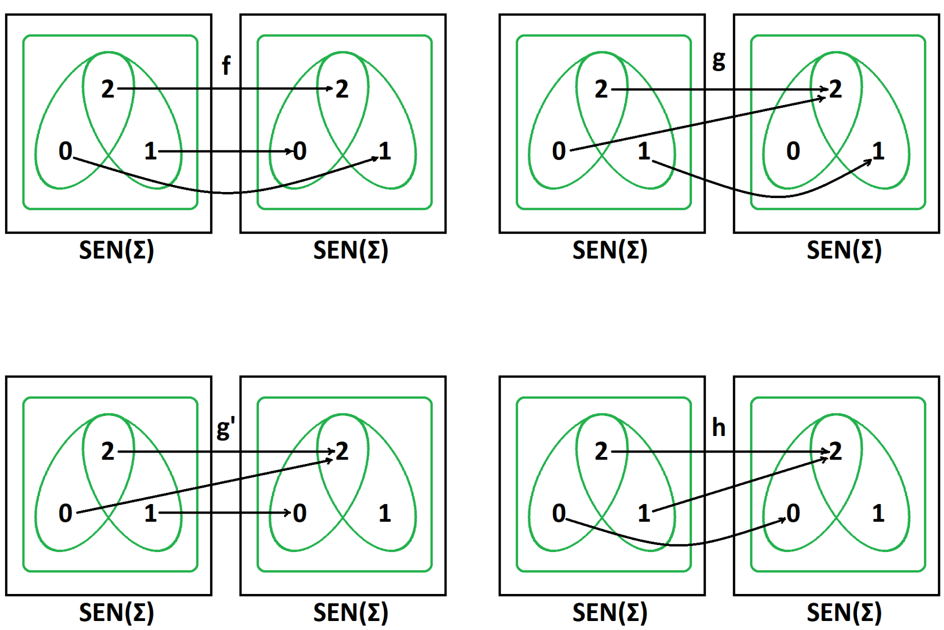
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and six non-identity morphisms* $f, g, g', h, h', t : \Sigma \to \Sigma$*, in which composition is defined by the following table, whose entry in row* k *and column* ℓ *is the result of the composition* $\ell \circ k$*:*

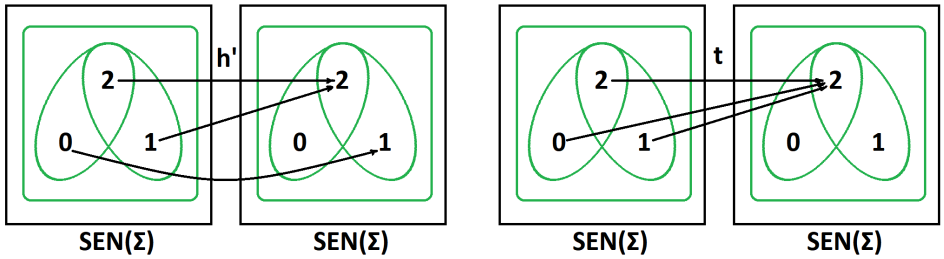
$\circ$	f	g	g'	h	h'	t
f	f	h'	h	g'	g	t
g	g'	g	g'	t	t	t
g'	g	t	t	g'	g	t
h	h'	t	t	h	h'	t
h'	h	h'	h	t	t	t
t	t	t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given, on objects, by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and, on morphisms, by the following table, whose entries in column* k *give the values of the function* $\mathrm{SEN}^\flat(k) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma)$*:*

x	f	g	g'	h	h'	t
0	1	2	2	0	1	2
1	0	1	0	2	2	2
2	2	2	2	2	2	2

- $N^\flat$ *is the trivial clone.*





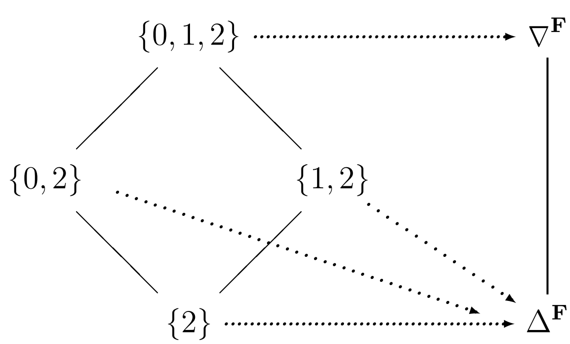
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{0,2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ has only two theory systems, $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$*, and* $\mathrm{SEN} = \{\{0,1,2\}\}$.

To show that $\mathcal{I}$ is left completely monotone, assume that, for some $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$.

- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{0,1,2\}\}$, then $\{\{0,1,2\}\} \in \mathcal{T}$ and, hence,*

$$\Omega(T') \leq \nabla^{\mathbf{F}} = \Omega(\{\{0,1,2\}\}) \leq \bigcup_{T\in\mathcal{T}} \Omega(T);$$

- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{2\}\}$, then $T' \neq \{\{0,1,2\}\}$, whence*

$$\Omega(T') = \Delta^{\mathbf{F}} \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$

Thus, in any case, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$ *and* $\mathcal{I}$ *is left completely monotone.*

On the other hand, we have

$$\{\{0,1,2\}\} \leq \{\{0,2\}\} \cup \{\{1,2\}\},$$

whereas

$$\begin{array}{rcl}\Omega(\overleftarrow{\{\{0,1,2\}\}}) & = & \Omega(\{\{0,1,2\}\}) = \nabla^{\mathbf{F}} \\ & \nleq & \Delta^{\mathbf{F}} \\ & = & \Omega(\{\{2\}\}) \cup \Omega(\{\{2\}\}) \\ & = & \Omega(\overleftarrow{\{\{0,2\}\}}) \cup \Omega(\overleftarrow{\{\{1,2\}\}}).\end{array}$$

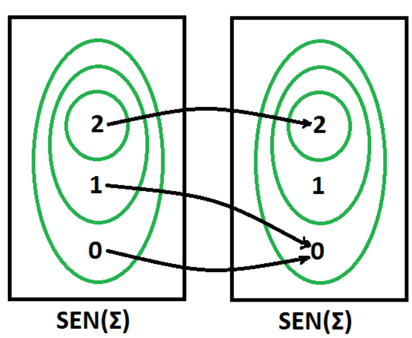
Therefore, $\mathcal{I}$ *is not right completely monotone.*

We now give an example of a right c-monotone π-institution that fails to be left c-monotone. This will show that:

- The class of family c-monotone π-institutions is properly contained in the class of right c-monotone π-institutions;
- The class of left c-monotone π-institutions is a proper subclass of the class of system c-monotone π-institutions.

Example 189 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

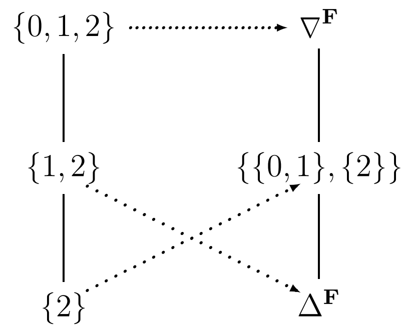


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The structure of the lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Taking into account that $\overleftarrow{\{\{1,2\}\}} = \{\{2\}\}$*, we can see that* $\mathcal{I}$ *is right c-monotone.*

On the other hand, for $T = \{\{1,2\}\}$ *and* $T' = \{\{2\}\}$*, we have* $\overleftarrow{T'} = \{\{2\}\} \leq \overleftarrow{T}$*, but* $\Omega(T') = \{\{\{0,1\},\{2\}\}\} \nleq \Delta^{\mathbf{F}} = \Omega(T)$*. Hence* $\mathcal{I}$ *is not left c-monotone.*

As we saw in Theorem 179 for the various monotonicity properties, all versions of complete monotonicity transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to the $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 190 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is family c-monotone if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T' \leq \bigcup_{T\in\mathcal{T}} T$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T)$*.*

(b) $\mathcal{I}$ *is left c-monotone if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T}\cup\{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T)$*.*

(c) $\mathcal{I}$ *is right c-monotone if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T}\cup\{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T' \leq \bigcup_{T\in\mathcal{T}} T$ *implies* $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})$*.*

(d) $\mathcal{I}$ *is system c-monotone if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*,* $T' \leq \bigcup_{T\in\mathcal{T}} T$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T)$*.*

Proof: We shall prove Parts (b) and (c). Parts (a) and (d) follow along the same lines and are slightly easier.

(b) The "if" follows by considering the **F**-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$, by Lemma 51.

For the "only if", suppose that $\mathcal{I}$ is left c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\overleftarrow{T'} \le \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$. Apply the inverse morphism $\langle F, \alpha \rangle$ to get $\alpha^{-1}(\overleftarrow{T'}) \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \overleftarrow{T})$, or, equivalently, $\alpha^{-1}(\overleftarrow{T'}) \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\overleftarrow{T})$. Now apply Lemma 6 to get $\overleftarrow{\alpha^{-1}(T')} \le \bigcup_{T \in \mathcal{T}} \overleftarrow{\alpha^{-1}(T)}$. But, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$. Therefore, applying left c-monotonicity, we get $\Omega(\alpha^{-1}(T')) \le \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T))$. Hence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T))$, i.e.,

$$\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)).$$

Finally, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(T') \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

(c) The "if" is obtained by considering the **F**-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$, by Lemma 51.

For the "only if", suppose that $\mathcal{I}$ is right c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T' \le \bigcup_{T \in \mathcal{T}} T$. Apply the inverse morphism $\langle F, \alpha \rangle$ to get $\alpha^{-1}(T') \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} T)$, or, equivalently, $\alpha^{-1}(T') \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(T)$. By Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$. Therefore, applying right c-monotonicity, we get $\Omega(\overleftarrow{\alpha^{-1}(T')}) \le \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{\alpha^{-1}(T)})$. By Lemma 6, $\Omega(\alpha^{-1}(\overleftarrow{T'})) \le \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(\overleftarrow{T}))$. Hence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T}))$. This is equivalent to $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}))$. Finally, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})$.

■

Next we look at the relationships that hold between protoalgebraicity and prealgebraicity, on the one hand, and the various c-monotonicity properties, on the other. More precisely, we show that left complete monotonicity implies protoalgebraicity and that system complete monotonicity implies prealgebraicity.

Theorem 191 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* **F**.

(a) If $\mathcal{I}$ *is left c-monotone, then it is protoalgebraic;*

(b) If $\mathcal{I}$ is system c-monotone, then it is prealgebraic.

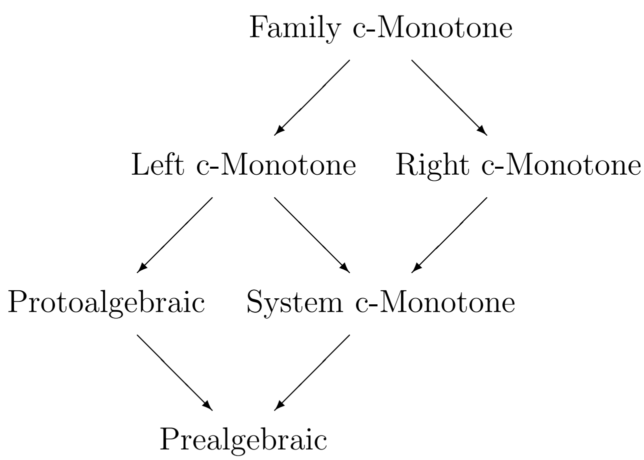
Proof:

(a) Suppose $\mathcal{I}$ is left c-monotone and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. Thus, by left c-monotonicity, $\Omega(T) \leq \Omega(T')$. Hence $\mathcal{I}$ is protoalgebraic.

(b) Suppose that $\mathcal{I}$ is system c-monotone and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$. Then we get right away from system c-monotonicity that $\Omega(T) \leq \Omega(T')$ and, therefore, $\mathcal{I}$ is prealgebraic.

■

We have now established the following hierarchy of **monotonicity** and **complete monotonicity** properties:

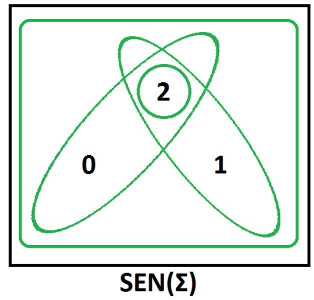


Finally, we provide an example to show that the c-monotonicity classes are proper subclasses of the monotonicity classes. Namely, we construct a protoalgebraic π-institution that fails to be system c-monotone.

Example 192 *Define the algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object Σ;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by*

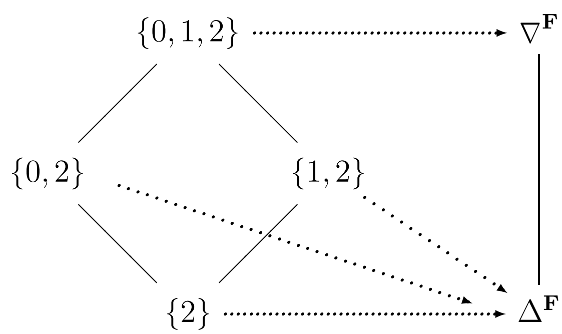
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	1
1	2
2	0



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

It is easy to see that the lattices of theory families and corresponding Leibniz congruence systems are as given in the diagram.



From the diagram one can verify immediately that $\mathcal{I}$ is protoalgebraic, On the other hand, we have $\{\{0,1,2\}\} \leq \{\{0,2\}\} \cup \{\{1,2\}\}$, but, obviously, $\Omega(\{\{0,1,2\}\}) \nleq \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\})$. Taking into account that $\mathcal{I}$ is systemic, we conclude that $\mathcal{I}$ fails to be system c-monotone.

3.5 Complete $\bigvee$-Monotonicity

We now define classes of π-institutions that are based on the corresponding versions of the property of *complete monotonicity* using the join operation. These properties are also strengthened versions of the monotonicity properties.

To define these complete monotonicity properties, let us introduce the following notation. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be a base algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Denote by $\bigvee^{\mathcal{I}} \mathcal{T} = \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} T$ the join of a collection $\mathcal{T}$ of theory families of $\mathcal{I}$ in the complete lattice $\mathbf{ThFam}(\mathcal{I})$ of theory families of $\mathcal{I}$. Analogously, denote by $\bigvee^{\mathbf{F}} \Theta = \bigvee^{\mathbf{F}}_{\theta \in \Theta} \theta$ the join of a collection Θ of congruence systems on $\mathbf{F}$ in the complete lattice $\mathbf{ConSys}(\mathbf{F})$ of congruence systems on $\mathbf{F}$.

Definition 193 (Complete $\bigvee$-Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **family completely $\bigvee$-monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,*

$$T' \leq \bigvee_{T \in \mathcal{T}}^{\mathcal{I}} T \quad \textit{implies} \quad \Omega(T') \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(T).$$

- $\mathcal{I}$ *is* **left completely $\bigvee$-monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,*

$$\overleftarrow{T'} \leq \bigvee_{T \in \mathcal{T}}^{\mathcal{I}} \overleftarrow{T} \quad \textit{implies} \quad \Omega(T') \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(T).$$

- $\mathcal{I}$ *is* **right completely $\bigvee$-monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,*

$$T' \leq \bigvee_{T \in \mathcal{T}}^{\mathcal{I}} T \quad \textit{implies} \quad \Omega(\overleftarrow{T'}) \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(\overleftarrow{T}).$$

- $\mathcal{I}$ *is* **system completely $\bigvee$-monotone** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$*,*

$$T' \leq \bigvee_{T \in \mathcal{T}}^{\mathcal{I}} T \quad \textit{implies} \quad \Omega(T') \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(T).$$

Sometimes we will use the abbreviated form **c$^\vee$-monotonicity** to refer to complete $\bigvee$-monotonicity.

We have seen in Lemma 170 that family monotonicity (protoalgebraicity) implies stability. Since family complete monotonicity is a stronger property than family monotonicity, we get Part (a) of the following:

Lemma 194 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family completely* $\bigvee$*-monotone, then it is stable.*

(b) If $\mathcal{I}$ *is left completely* $\bigvee$*-monotone, it is stable.*

Proof:

(a) If $\mathcal{I}$ is family completely $\bigvee$-monotone, then it is, a fortiori, family monotone. Thus, the result follows from Lemma 170.

(b) Suppose that $\mathcal{I}$ is left c$^\vee$-monotone and let $T \in \mathrm{ThFam}(\mathcal{I})$. By Proposition 42, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Applying left c$^\vee$-monotonicity, we get that $\Omega(\overleftarrow{T}) = \Omega(T)$. Hence $\mathcal{I}$ is stable.

■

Family completely $\bigvee$-monotone π-institutions are both left and right completely $\bigvee$-monotone. And, conversely, if a π-institution is both left and right $c^\vee$-monotone, then it is family $c^\vee$-monotone. This parallels Proposition 186, which concerned the case of $c^\cup$-monotonicity properties.

Proposition 195 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family completely* $\bigvee$*-monotone if and only if it is both left and right completely* $\bigvee$*-monotone.*

Proof: Suppose, first, that $\mathcal{I}$ is family completely $\bigvee$-monotone.

- Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T'} \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T}$. Applying family $c^\vee$-monotonicity, we get $\Omega(\overleftarrow{T'}) \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. However, by Lemma 185, $\mathcal{I}$ is stable. Hence we get $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$. We conclude that $\mathcal{I}$ is left completely $\bigvee$-monotone.
- Next, let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T' \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} T$. Applying family $c^\vee$-monotonicity, we get $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$. Once more, by Lemma 185, $\mathcal{I}$ is stable. Hence we get $\Omega(\overleftarrow{T'}) \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. We conclude that $\mathcal{I}$ is right completely $\bigvee$-monotone.

Suppose, conversely, that $\mathcal{I}$ is both left and right completely $\bigvee$-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T' \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} T$. Then, by right $c^\vee$-monotonicity, we get that $\Omega(\overleftarrow{T'}) \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. But since $\mathcal{I}$ is left completely $\bigvee$-monotone, by Lemma 185, it is stable, whence we get $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$. Therefore, $\mathcal{I}$ is family completely $\bigvee$-monotone. ■

If a π-institution $\mathcal{I}$ is left or right completely $\bigvee$-monotone, then it is also system completely $\bigvee$-monotone. This is an analog of Proposition 187, which addressed the case of $c^\cup$-monotonicity.

Proposition 196 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is left* $c^\vee$*-monotone, then it is system* $c^\vee$*-monotone;*

(b) If $\mathcal{I}$ *is right* $c^\vee$*-monotone, then it is system* $c^\vee$*-monotone.*

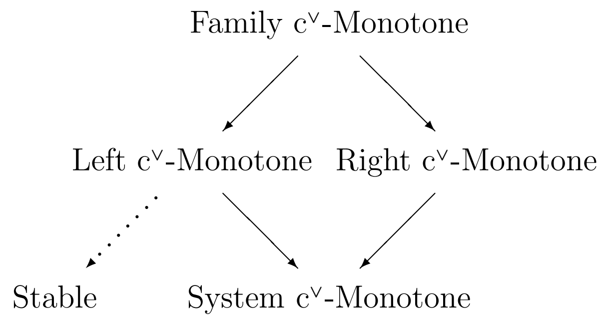
Proof:

(a) Suppose $\mathcal{I}$ is left $c^\vee$-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $T' \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} T$. Since $\mathcal{T} \cup \{T'\}$ is a collection of theory systems, we get $\overleftarrow{T'} \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T}$. Hence, applying left $c^\vee$-monotonicity, we get $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$. Thus, $\mathcal{I}$ is system $c^\vee$-monotone.

(b) Suppose $\mathcal{I}$ is right $c^\vee$-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $T' \leq \bigvee^{\mathcal{I}}_{T\in\mathcal{T}} T$. Applying right $c^\vee$-monotonicity, we get $\Omega(\overleftarrow{T'}) \leq \bigvee^{\mathbf{F}}_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$. Since $\mathcal{T} \cup \{T'\}$ is a collection of theory systems, we now get $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T\in\mathcal{T}} \Omega(T)$. Thus, $\mathcal{I}$ is system $c^\vee$-monotone.

■

In terms of complete $\bigvee$-monotonicity, we have established the following hierarchy, which exactly mirrors the hierarchy of $c^\cup$-monotonicity classes:



Now we give examples of π-institutions to show that the inclusions depicted in this diagram are proper. We first give an example of a π-institution that is left $c^\vee$-monotone but not right $c^\vee$-monotone. This shows that:

- The class of family $c^\vee$-monotone π-institutions is properly contained in the class of all left $c^\vee$-monotone π-institutions;

- The class of all system $c^\vee$-monotone π-institutions properly includes the class of all right $c^\vee$-monotone π-institutions.

Example 197 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

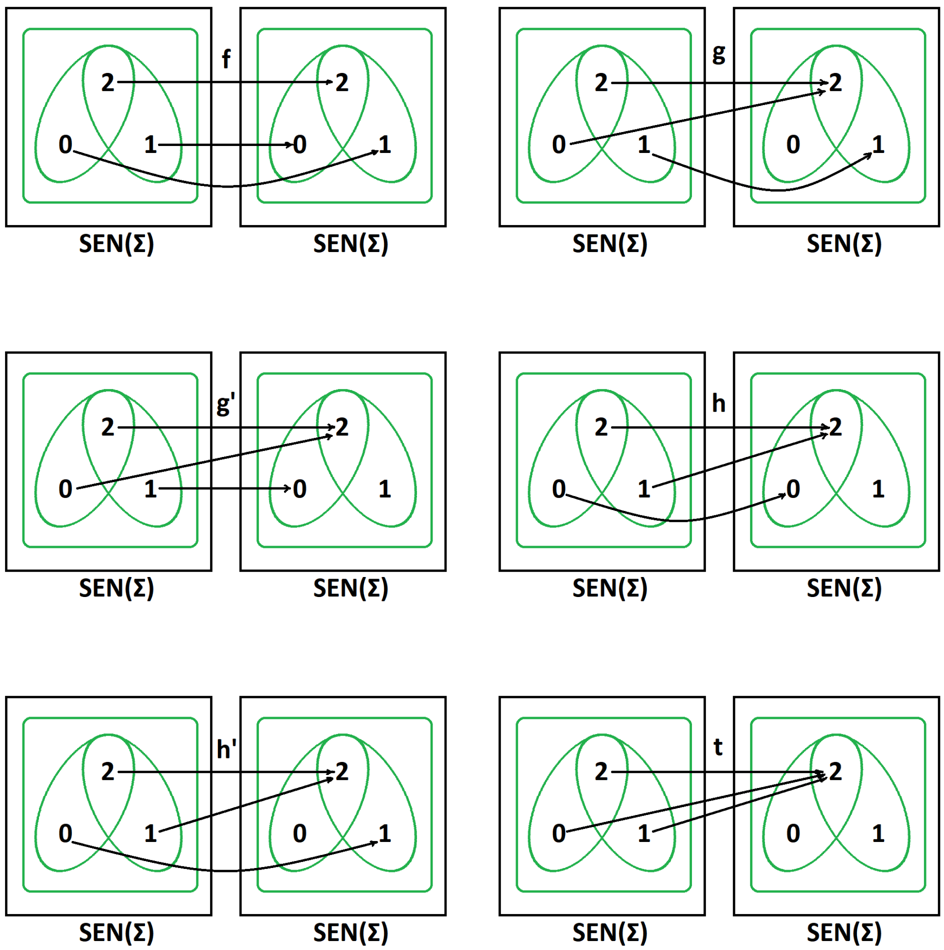
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and six non-identity morphisms* $f, g, g', h, h', t : \Sigma \to \Sigma$, *in which composition is defined by the following table, whose entry in row* k *and column* ℓ *is the result of the composition* $\ell \circ k$*:*

$\circ$	f	g	g'	h	h'	t
f	f	h'	h	g'	g	t
g	g'	g	g'	t	t	t
g'	g	t	t	g'	g	t
h	h'	t	t	h	h'	t
h'	h	h'	h	t	t	t
t	t	t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given, on objects, by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and, on morphisms, by the following table, whose entries in column* k *give* *the values of the function* $\mathrm{SEN}^\flat(k) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma)$*:*

x	f	g	g'	h	h'	t
0	1	2	2	0	1	2
1	0	1	0	2	2	2
2	2	2	2	2	2	2

- $N^\flat$ *is the trivial clone.*



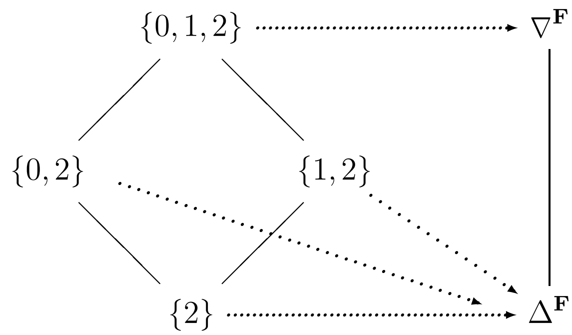
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{0,2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ has only two theory systems, $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$, *and* $\mathrm{SEN} = \{\{0,1,2\}\}$.

To show that $\mathcal{I}$ is left completely monotone, assume that, for some $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T'} \leq \bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T}$.

- *If $\bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T} = \{\{0,1,2\}\}$, then $\{\{0,1,2\}\} \in \mathcal{T}$ and, hence,*

$$\Omega(T') \leq \nabla^{\mathbf{F}} = \Omega(\{\{0,1,2\}\}) \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(T);$$

- *If $\bigvee^{\mathcal{I}}_{T \in \mathcal{T}} \overleftarrow{T} = \{\{2\}\}$, then $T' \neq \{\{0,1,2\}\}$, whence*

$$\Omega(T') = \Delta^{\mathbf{F}} \leq \bigvee_{T \in \mathcal{T}}^{\mathbf{F}} \Omega(T).$$

Thus, in any case, $\Omega(T') \leq \bigvee^{\mathbf{F}}_{T \in \mathcal{T}} \Omega(T)$ and $\mathcal{I}$ is left completely $\bigvee$-monotone.

On the other hand, we have

$$\{\{0,1,2\}\} \leq \{\{0,2\}\} \vee^{\mathcal{I}} \{\{1,2\}\},$$

whereas

$$\begin{array}{rcl}\Omega(\overleftarrow{\{\{0,1,2\}\}}) & = & \Omega(\{\{0,1,2\}\}) = \nabla^{\mathbf{F}} \\ & \nleq & \Delta^{\mathbf{F}} \\ & = & \Omega(\{\{2\}\}) \vee^{\mathbf{F}} \Omega(\{\{2\}\}) \\ & = & \Omega(\overleftarrow{\{\{0,2\}\}}) \vee^{\mathbf{F}} \Omega(\overleftarrow{\{\{1,2\}\}}).\end{array}$$

Therefore, $\mathcal{I}$ is not right completely $\bigvee$-monotone.

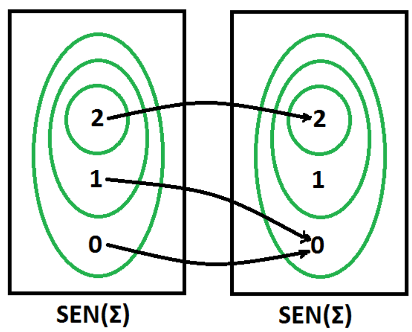
We now give an example of a right $\mathrm{c}^{\vee}$-monotone π-institution that fails to be left $\mathrm{c}^{\vee}$-monotone. This will show that:

- The class of family $\mathrm{c}^{\vee}$-monotone π-institutions is properly contained in the class of right $\mathrm{c}^{\vee}$-monotone π-institutions;

- The class of left $c^{\vee}$-monotone π-institutions is a proper subclass of the class of system $c^{\vee}$-monotone π-institutions.

Example 198 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

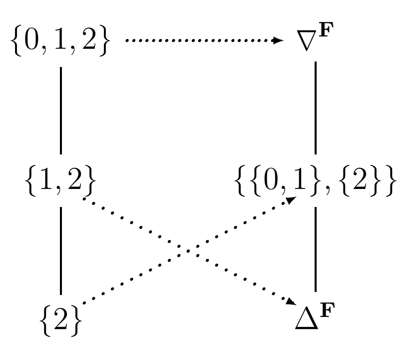


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$*.*

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The structure of the lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Taking into account that $\overleftarrow{\{\{1,2\}\}} = \{\{2\}\}$*, we can see that* $\mathcal{I}$ *is right* $c^{\vee}$*-monotone.*

On the other hand, for $T = \{\{1,2\}\}$ *and* $T' = \{\{2\}\}$, *we have* $\overleftarrow{T'} = \{\{2\}\} \leq \overleftarrow{T}$, *but* $\Omega(T') = \{\{\{0,1\},\{2\}\}\} \nleq \Delta^{\mathbf{F}} = \Omega(T)$. *Hence* $\mathcal{I}$ *is not left* $c^{\vee}$*-monotone.*

As we saw in Theorem 190, the various complete $\bigcup$-monotonicity properties defined based on the union operation transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to the $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems. On the other hand, the $\bigvee$-monotonicity versions introduced in this section do not transfer in general. The problem appears to be that the commutativity of unions with inverse surjective morphisms, i.e., $\bigcup_{T\in\mathcal{T}} \alpha^{-1}(T) = \alpha^{-1}(\bigcup_{T\in\mathcal{T}} T)$, ceases to hold when unions are replaced by joins. In that case, one has, in general, a proper inclusion instead of an equality. To describe it, let us again introduce some notation. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. Let, also $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system. Denote by $\bigvee^{\mathcal{I},\mathcal{A}} \mathcal{T} = \bigvee^{\mathcal{I},\mathcal{A}}_{T\in\mathcal{T}} T$ the join of a collection $\mathcal{T}$ of $\mathcal{I}$-filter families of $\mathcal{A}$ in the complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ of $\mathcal{I}$-filter families of $\mathcal{A}$. Analogously, denote by $\bigvee^{\mathcal{A}} \Theta = \bigvee^{\mathcal{A}}_{\theta\in\Theta} \theta$ the join of a collection Θ of congruence systems on $\mathcal{A}$ in the complete lattice $\mathbf{ConSys}(\mathcal{A})$ of congruence systems on $\mathcal{A}$. According to this notation, we get, in general, that

$$\bigvee_{T\in\mathcal{T}}^{\mathcal{I}} \alpha^{-1}(T) \subsetneqq \alpha^{-1}\left(\bigvee_{T\in\mathcal{T}}^{\mathcal{I},\mathcal{A}} T\right).$$

The following example showcases this proper inclusion.

Example 199 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

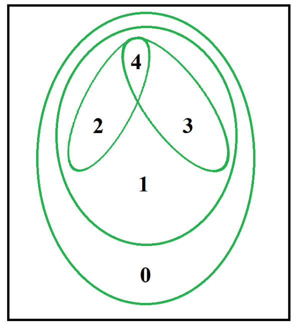
- $\mathbf{Sign}^\flat$ *is the trivial category, with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4\}$*;*
- $N^\flat$ *is the trivial clone.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{4\},\{2,4\},\{3,4\},\{1,2,3,4\},\{0,1,2,3,4\}\}.$$

Next, consider the $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, *defined as follows:*

- *The algebraic system* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ *is specified by the following data:*
  - $\mathbf{Sign}$ *is the trivial category, with object* Σ'*;*

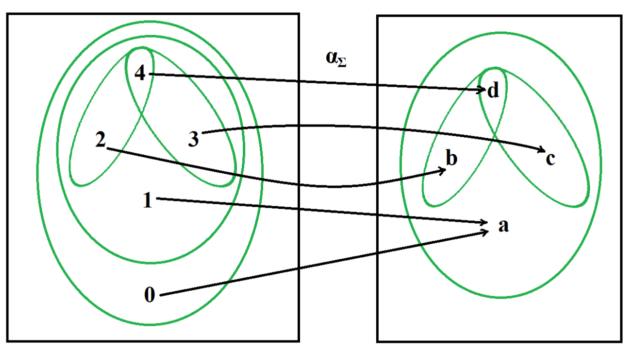


SEN(Σ)

- $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *is given by* $\mathrm{SEN}(\Sigma') = \{a, b, c, d\}$*;*
- N *is the trivial clone.*

- $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ *is the trivial functor taking* Σ *to* Σ'*;*
- $\alpha : \mathrm{SEN}^\flat \to \mathrm{SEN} \circ F$ *is determined by letting* $\alpha_\Sigma : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}(\Sigma')$ *be given by*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\alpha_\Sigma(x)$
0	a
1	a
2	b
3	c
4	d



$\mathrm{SEN}^\flat(\Sigma)$ SEN(Σ')

Based on Lemma 51, we get that

$$\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) = \{\{\{d\}\}, \{\{b, d\}\}, \{\{c, d\}\}, \{\{a, b, c, d\}\}\}.$$

Now we can easily verify that

$$\alpha^{-1}(\{\{b, d\}\}) \vee^{\mathcal{I}} \alpha^{-1}(\{\{c, d\}\}) = \{\{2, 4\}\} \vee^{\mathcal{I}} \{\{3, 4\}\} = \{\{1, 2, 3, 4\}\},$$

whereas

$$\alpha^{-1}(\{\{b,d\}\} \vee^{\mathcal{I},\mathcal{A}} \{\{c,d\}\}) = \alpha^{-1}(\{\{a,b,c,d\}\}) = \{\{0,1,2,3,4\}\}.$$

Thus, for $\mathcal{T} = \{\{\{b,d\}\},\{\{c,d\}\}\}$, *we get* $\bigvee^{\mathcal{I}}_{T\in\mathcal{T}} \alpha^{-1}(T) \not\geq \alpha^{-1}(\bigvee^{\mathcal{I},\mathcal{A}}_{T\in\mathcal{T}} T)$.

We may characterize family and system c$^\vee$-monotonicity in terms of the complete order preservation of mappings from posets of theory families/ systems into posets of congruence systems. Given complete lattices $\mathbf{P} = \langle P, \leq\rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq\rangle$, call a mapping $f : P \to Q$ **completely order preserving** if, for all $\{x\} \cup Y \subseteq P$,

$$x \leq \bigvee_{y\in Y}^{\mathbf{P}} y \quad \text{implies} \quad f(x) \preccurlyeq \bigvee_{y\in Y}^{\mathbf{Q}} f(y).$$

Proposition 200 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is family completely* $\bigvee$*-monotone;*

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}(\mathcal{I})$ *is completely order preserving.*

Similarly, for system c-monotonicity, we have

Proposition 201 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is system completely* $\bigvee$*-monotone;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}(\mathcal{I})$ *is completely order preserving.*

Next we look at the relationships that hold between protoalgebraicity and prealgebraicity, on the one hand, and the various c$^\vee$-monotonicity properties, on the other. More precisely, we show that left complete $\bigvee$-monotonicity implies protoalgebraicity and that system complete $\bigvee$-monotonicity implies prealgebraicity. Once more, this theorem parallels Theorem 191, which dealt with $\bigcup$-monotonicity.

Theorem 202 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is left* c$^\vee$*-monotone, then it is protoalgebraic;*

(b) If $\mathcal{I}$ *is system* c$^\vee$*-monotone, then it is prealgebraic.*

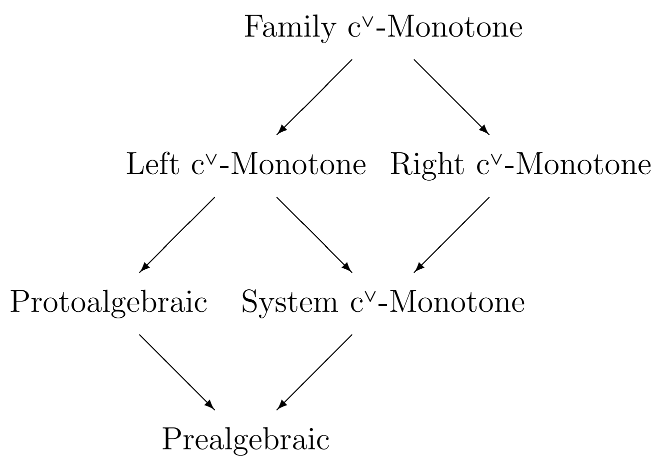
Proof:

(a) Suppose $\mathcal{I}$ is left c$^\vee$-monotone and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. Thus, by left c$^\vee$-monotonicity, $\Omega(T) \leq \Omega(T')$. Hence $\mathcal{I}$ is protoalgebraic.

(b) Suppose that $\mathcal{I}$ is system c$^\vee$-monotone and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$. Then we get right away from system c$^\vee$-monotonicity that $\Omega(T) \leq \Omega(T')$ and, therefore, $\mathcal{I}$ is prealgebraic.

■

We have now established the following hierarchy of **monotonicity** and **complete $\bigvee$-monotonicity** properties, which also mirrors the combined hierarchy of monotonicity and complete $\bigcup$-monotonicity properties:



We now provide an example to show that the c$^\vee$-monotonicity classes are proper subclasses of the monotonicity classes. Namely, we construct a protoalgebraic π-institution that fails to be system c$^\vee$-monotone.

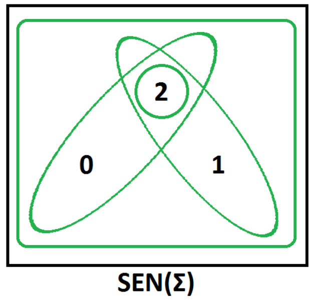
Example 203 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by*

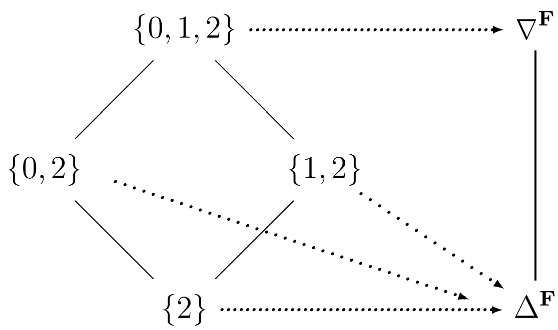
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	1
1	2
2	0

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$



It is easy to see that the lattices of theory families and corresponding Leibniz congruence systems are as given in the diagram.



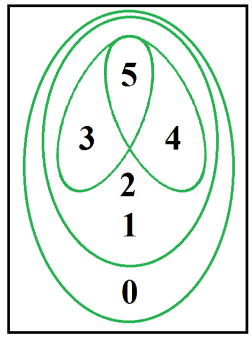
From the diagram one can verify immediately that $\mathcal{I}$ *is protoalgebraic, On the other hand, we have* $\{\{0,1,2\}\} \leq \{\{0,2\}\} \vee^{\mathcal{I}} \{\{1,2\}\}$, *but, obviously,* $\Omega(\{\{0,1,2\}\}) \nleq \Omega(\{\{0,2\}\}) \vee^{\mathbf{F}} \Omega(\{\{1,2\}\})$. *Taking into account that* $\mathcal{I}$ *is systemic, we conclude that* $\mathcal{I}$ *fails to be system* $c^{\vee}$*-monotone.*

We conclude this section with two examples showing that the classes of $c^{\cup}$-monotone and $c^{\vee}$-monotone π-institutions are incomparable. The first example shows that there exists a $c^{\cup}$-monotone π-institution which is not $c^{\vee}$-monotone.

Example 204 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object* Σ;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4,5\}$;
- $N^\flat$ *is the clone generated by the unary natural transformations* $\rho^\flat, \sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$, *given by*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\rho^\flat_\Sigma(x)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	5	0	0
1	1	1	1
2	2	2	2
3	3	5	3
4	4	4	5
5	5	5	5

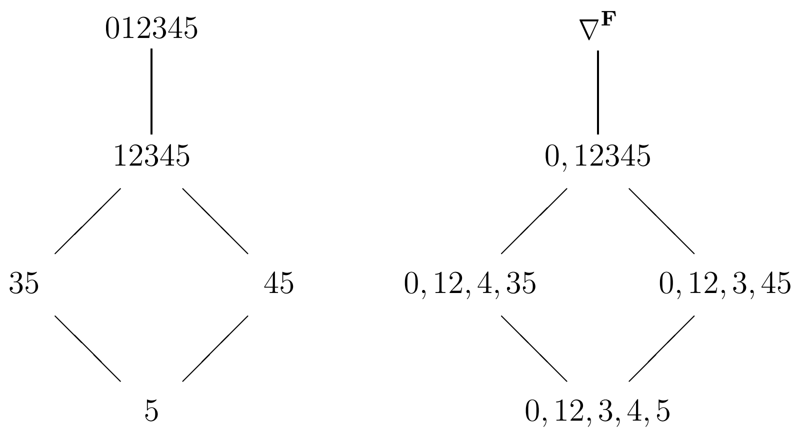


SEN(Σ)

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{5\}, \{3,5\}, \{4,5\}, \{1,2,3,4,5\}, \{0,1,2,3,4,5\}\}.$$

The lattice of theory families and the corresponding Leibniz congruence systems (in block form) are given in the following diagram.



From the diagram one can verify that, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $T' \leq \bigcup_{T \in \mathcal{T}} T$ implies $T' \leq T$, for some $T \in \mathcal{T}$. Therefore, we get $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$ and, hence, $\mathcal{I}$ is $c^\cup$-monotone. On the other hand,

$$\{\{1,2,,3,4,5\}\} \leq \{\{3,5\}\} \vee^{\mathcal{I}} \{\{4,5\}\},$$

whereas

$$\begin{array}{rcl}\Omega(\{\{1,2,3,4,5\}\}) & = & \{\{1,12345\}\} \\ & \nleq & \{\{0,12,345\}\} \\ & = & \{\{0,12,4,35\}\} \vee^{\mathbf{F}} \{\{0,12,3,45\}\} \\ & = & \Omega(\{\{3,5\}\}) \vee^{\mathbf{F}} \Omega(\{\{4,5\}\}).\end{array}$$

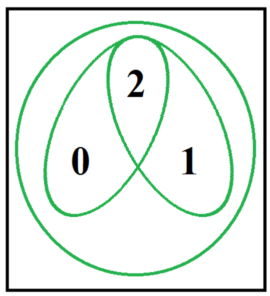
Thus, $\mathcal{I}$ is not $c^\vee$-monotone.

The second example exhibits a $c^\vee$-monotone π-institution which is not $c^\cup$-monotone.

Example 205 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone generated by the unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	2	0
1	1	2
2	2	2

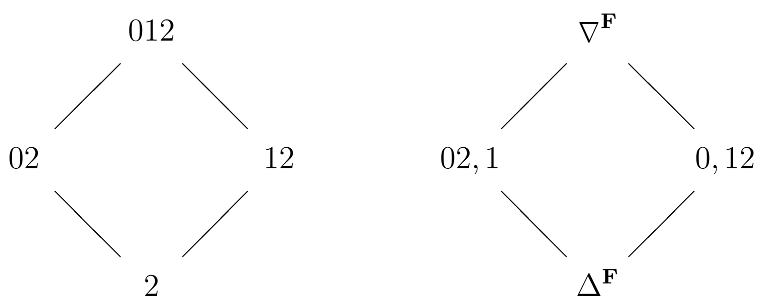


SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

The lattice of theory families and the corresponding Leibniz congruence systems (in block form) are given in the following diagram.



Note that

$$\{\{0, 1, 2\}\} = \{\{0, 2\}\} \cup \{\{1, 2\}\} = \{\{0, 2\}\} \vee^{\mathcal{I}} \{\{1, 2\}\}.$$

But, even though

$$\begin{array}{rcl}\Omega(\{\{0, 1, 2\}\}) & = & \nabla^{\mathbf{F}} \\ & = & \{\{02, 1\}\} \vee^{\mathbf{F}} \{\{0, 12\}\} \\ & = & \Omega(\{\{0, 2\}\}) \vee^{\mathbf{F}} \Omega(\{\{1, 2\}\}),\end{array}$$

we have

$$\begin{array}{rcl}\Omega(\{\{0,1,2\}\}) & = & \nabla^{\mathbf{F}} \\ & \not\leq & \{\{02,1\}\} \cup \{\{0,12\}\} \\ & = & \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\}),\end{array}$$

since $\langle 0,1\rangle \in \nabla^{\mathbf{F}}_{\Sigma}$, *whereas* $\langle 0,1\rangle \notin \{\{02,1\}\} \cup \{\{0,12\}\}$. *Thus,* $\mathcal{I}$ *is* $c^{\vee}$*-monotone but not* $c^{\cup}$*-monotone.*

3.6 Injectivity

In this section we study classes of π-institutions defined using injectivity properties of the Leibniz operator.

Definition 206 (Injectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **family injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T = T'.$$
- $\mathcal{I}$ *is called* **left injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} = \overleftarrow{T'}.$$
- $\mathcal{I}$ *is called* **right injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T = T'.$$
- $\mathcal{I}$ *is called* **system injective** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T = T'.$$

First, we show that right injectivity is so strong that it implies systemicity and, hence, a fortiori, stability.

Lemma 207 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is right injective, then it is systemic.*

Proof: Suppose that $\mathcal{I}$ is right injective and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, by Proposition 42, that $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Therefore, we get $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$. Hence, by right injectivity, we get that $\overleftarrow{T} = T$. Thus, $T \in \mathrm{ThSys}(\mathcal{I})$. This proves that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, whence $\mathcal{I}$ is systemic. ∎

Next we look into establishing the *injectivity hierarchy* of π-institutions. The following relationships can be established between the four injectivity classes.

Proposition 208 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is right injective, then it is family injective;*

(b) If $\mathcal{I}$ *is family injective, then it is left injective;*

(c) If $\mathcal{I}$ *is left injective, then it is system injective.*

Proof:

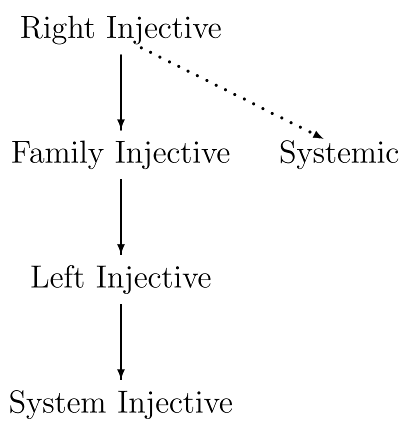
(a) Suppose that $\mathcal{I}$ is right injective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. By Lemma 207, $\mathcal{I}$ is systemic, whence $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Thus, we get $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Now applying right injectivity, we get $T = T'$. This proves that $\mathcal{I}$ is family injective.

(b) Suppose that $\mathcal{I}$ is family injective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by family injectivity, we get $T = T'$, whence $\overleftarrow{T} = \overleftarrow{T'}$. Therefore $\mathcal{I}$ is left injective.

(c) Suppose that $\mathcal{I}$ is left injective and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. By left injectivity, we conclude that $\overleftarrow{T} = \overleftarrow{T'}$. However, since T, T' are theory systems, we have $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Hence we get $T = T'$ and $\mathcal{I}$ is system injective.

■

We have now established the following **injectivity hierarchy** of π-institutions.



There are two additional properties that can be formulated concerning the relationships between these classes. First, it turns out that the separating property between system injectivity and right injectivity is exactly systemicity.

Proposition 209 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is right injective if and only if it is system injective and systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is right injective. Then, by Lemma 207, it is systemic and by Proposition 208 it is system injective.

Suppose conversely, that $\mathcal{I}$ is system injective and systemic and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. By system injectivity we get $\overleftarrow{T} = \overleftarrow{T'}$. Hence, by systemicity, $T = T'$. Thus, $\mathcal{I}$ is right injective. ∎

Second, we show that system injectivity reinforced with stability implies left injectivity.

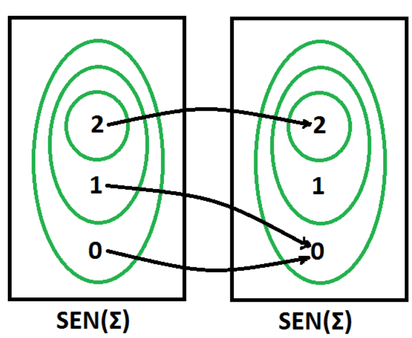
Proposition 210 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is system injective and stable, then it is left injective.*

Proof: Suppose that $\mathcal{I}$ is system injective and stable and consider $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by stability $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Hence, since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, by system injectivity, $\overleftarrow{T} = \overleftarrow{T'}$. This shows that $\mathcal{I}$ is left injective. ∎

We now present three examples to show that all inclusions established between injectivity classes and depicted in the diagram above are proper inclusions. The first example will show that the class of right injective π-institutions is a proper subclass of the class of family injective π-institutions.

Example 211 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



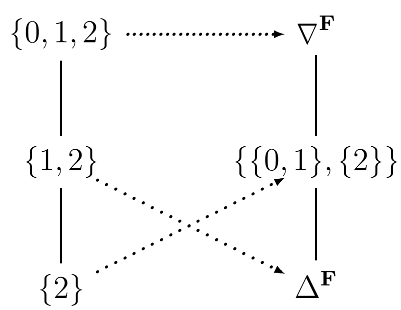
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

Since $\{\{1,2\}\}$ is a theory family that is not a theory system, $\mathcal{I}$ is not systemic.

The lattice of theory families and that of the corresponding Leibniz congruence systems are depicted below:



It is obvious from the diagram that $\mathcal{I}$ is family injective, since each of the three theory families has a different Leibniz congruence system.

On the other hand, $\mathcal{I}$ is not right injective. This can be seen either by applying Proposition 209 or directly. Take $T = \{\{2\}\}$ and $T' = \{\{1,2\}\}$. Then, we have $\overleftarrow{T} = \overleftarrow{T'} = T$, whence $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$, whereas, obviously, $T \neq T'$.

The second example shows that the class of family injective π-institutions is properly included in the class of left injective π-institutions.

Example 212 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

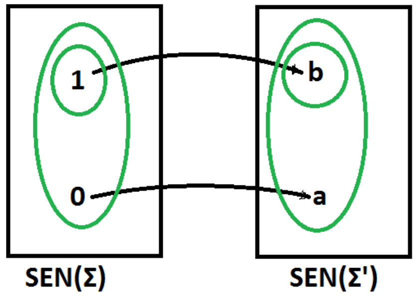
- $\mathbf{Sign}^\flat$ *is the category with objects Σ and Σ' and a unique (non-identity) morphism $f : \Sigma \to \Sigma'$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

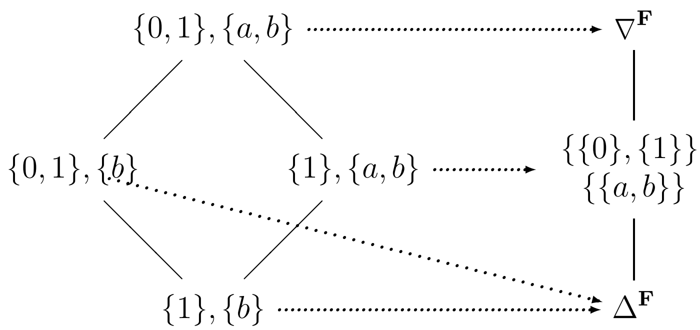
$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

The following table shows the action of $\overleftarrow{\ }$ on theory families, where rows correspond to T_Σ and columns to $T_{\Sigma'}$ and each entry is written as $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$



The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



Since the only two theory families that have the same Leibniz congruence system are $\{\{0,1\},\{b\}\}$ *and* $\{\{1\},\{b\}\}$ *and it holds that*

$$\overleftarrow{\{\{0,1\},\{b\}\}} = \overleftarrow{\{\{1\},\{b\}\}} = \{\{1\},\{b\}\},$$

we conclude that $\mathcal{I}$ *is left injective.*

From the diagram, it is also clear that $\mathcal{I}$ *is not family injective, since the two theory families* $\{\{0,1\},\{b\}\}$ *and* $\{\{1\},\{b\}\}$ *have the same Leibniz congruence system.*

In conclusion we have shown that $\mathcal{I}$ *is left injective but not family injective.*

The next example shows that the class of left injective π-institutions is properly included in the class of all system injective π-institutions.

Example 213 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the two object category with objects* Σ, Σ' *and two (non-identity) morphisms*

$$\Sigma \underset{g}{\overset{f}{\rightleftarrows}} \Sigma'$$

  such that $g \circ f = i_\Sigma$ *and* $f \circ g = i_{\Sigma'}$*;*

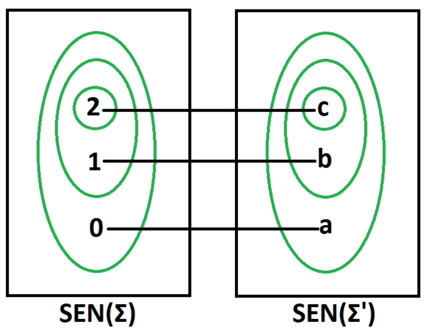
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$ *and*

$$\begin{array}{lll}\mathrm{SEN}^\flat(f)(0) = a, & \mathrm{SEN}^\flat(f)(1) = b, & \mathrm{SEN}^\flat(f)(2) = c;\\ \mathrm{SEN}^\flat(g)(a) = 0, & \mathrm{SEN}^\flat(g)(b) = 1, & \mathrm{SEN}^\flat(g)(c) = 2;\end{array}$$

- $N^\flat$ *is the clone on* $\mathrm{SEN}^\flat$ *generated by the natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	0
1	1
2	0

$y \in \mathrm{SEN}^\flat(\Sigma')$	$\sigma^\flat_{\Sigma'}(y)$
a	a
b	b
c	a



Next, define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{c\},\{b,c\},\{a,b,c\}\}.$$

The table giving the action of $\overleftarrow{}$ *on theory families is shown below:*

$\leftarrow$	$\{c\}$	$\{b,c\}$	$\{a,b,c\}$
$\{2\}$	$\{2\},\{c\}$	$\{2\},\{c\}$	$\{2\},\{c\}$
$\{1,2\}$	$\{2\},\{c\}$	$\{1,2\},\{b,c\}$	$\{1,2\},\{b,c\}$
$\{0,1,2\}$	$\{2\},\{c\}$	$\{1,2\},\{b,c\}$	$\{0,1,2\},\{a,b,c\}$

The following table gives the Leibniz congruence systems associated with each of the nine theory families of $\mathcal{I}$*, where we have denoted by* θ *the Leibniz congruence system with* $\theta_\Sigma = \{\{0,1\},\{2\}\}$ *and* $\theta_{\Sigma'} = \{\{a,b\},\{c\}\}$*:*

$\Omega(\{T_\Sigma, T_{\Sigma'}\})$	$\{c\}$	$\{b,c\}$	$\{a,b,c\}$
$\{2\}$	θ	$\Delta^{\mathbf{F}}$	θ
$\{1,2\}$	$\Delta^{\mathbf{F}}$	$\Delta^{\mathbf{F}}$	$\Delta^{\mathbf{F}}$
$\{0,1,2\}$	θ	$\Delta^{\mathbf{F}}$	$\nabla^{\mathbf{F}}$

Observe, first, that there are only three theory systems $\{\{2\},\{c\}\}$, $\{\{1,2\},\{b,c\}\}$ *and* $\{\{0,1,2\},\{a,b,c\}\}$. *To each of these corresponds a different Leibniz congruence system. It follows that* $\mathcal{I}$ *is system injective.*

On the other hand, for $T = \{\{2\},\{b,c\}\}$ *and* $T' = \{\{1,2\},\{b,c\}\}$, *we have* $\Omega(T) = \Omega(T') = \Delta^{\mathbf{F}}$, *but* $\overleftarrow{T} = \{\{2\},\{c\}\} \neq \{\{1,2\},\{b,c\}\} = \overleftarrow{T'}$. *Therefore* $\mathcal{I}$ *is not left injective.*

The injectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to the collections of all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 214 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

- *(a)* $\mathcal{I}$ *is family injective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T = T'$.
- *(b)* $\mathcal{I}$ *is left injective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $\overleftarrow{T} = \overleftarrow{T'}$.
- *(c)* $\mathcal{I}$ *is right injective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $T = T'$.
- *(d)* $\mathcal{I}$ *is system injective if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T = T'$.

Proof: We will prove Parts (a) and (b) to establish the method.

- (a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$ and taking into account that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$, by Lemma 51.

  For the "only if", suppose that $\mathcal{I}$ is family injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) = \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) = \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, we have that $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying family injectivity, $\alpha^{-1}(T) = \alpha^{-1}(T')$. Finally, the surjectivity of $\langle F,\alpha\rangle$ yields that $T = T'$.

- (b) The "if" follows as in Part (a).

  For the "only if", suppose that $\mathcal{I}$ is left injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) = \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) = \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, we have that $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying left injectivity, $\overleftarrow{\alpha^{-1}(T)} = \overleftarrow{\alpha^{-1}(T')}$. Thus, by Lemma 6, $\alpha^{-1}(\overleftarrow{T}) = \alpha^{-1}(\overleftarrow{T'})$. Finally, the surjectivity of $\langle F,\alpha\rangle$ yields that $\overleftarrow{T} = \overleftarrow{T'}$.

■

Finally, we may recast the injectivity classes in terms of the injectivity of mappings from posets of theory or filter families/systems into posets of congruence systems.

Given two posets $\mathbf{P} = \langle P, \leq \rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq \rangle$, we call a mapping $f : P \to Q$ **injective** if it is injective as a set map, i.e., if, for all $p_1, p_2 \in P$,

$$f(p_1) = f(p_2) \quad \text{implies} \quad p_1 = p_2.$$

Proposition 215 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is family injective;*

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system injectivity, we have

Proposition 216 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is system injective;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

3.7 Reflectivity

In this section we look at classes of π-institutions defined using the order reflectivity of the Leibniz operator.

Definition 217 (Reflectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **family reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) \leq \Omega(T') \quad \text{implies} \quad T \leq T'.$$

- $\mathcal{I}$ *is* **left reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) \leq \Omega(T') \quad \text{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$

- $\mathcal{I}$ *is* **right reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T \le T'.$$

- $\mathcal{I}$ *is* **system reflective** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) \le \Omega(T') \quad \textit{implies} \quad T \le T'.$$

We first establish the fact that both family and right reflectivity imply systemicity.

Lemma 218 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family reflective, then it is systemic;*

(b) If $\mathcal{I}$ *is right reflective, then it is systemic.*

Proof:

(a) Suppose $\mathcal{I}$ is family reflective and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, by Proposition 20, $\Omega(T) \le \Omega(\overleftarrow{T})$. Applying family reflectivity, we get $T \le \overleftarrow{T}$. Since, by Proposition 42, it always holds that $\overleftarrow{T} \le T$, we get $\overleftarrow{T} = T$. This shows that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ and, thus, $\mathcal{I}$ is systemic.

(b) Suppose $\mathcal{I}$ is right reflective and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, by Proposition 42, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Thus, we get $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$ and, hence $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{\overleftarrow{T}})$. Applying right reflectivity, we get $T \le \overleftarrow{T}$. Since, by Proposition 42, it always holds that $\overleftarrow{T} \le T$, we get $\overleftarrow{T} = T$. This shows that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ and, thus, $\mathcal{I}$ is systemic.

■

Lemma 218 enables us to prove that family reflectivity and right reflectivity are actually equivalent properties.

Proposition 219 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family reflective if and only if it is right reflective.*

Proof: Suppose, first, that $\mathcal{I}$ is family reflective. Then, by Lemma 218, it is systemic, and, by Proposition 152, it is stable. To see that it is right reflective, let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. Then, by stability, $\Omega(T) \le \Omega(T')$. Hence, by family reflectivity, $T \le T'$. Thus, $\mathcal{I}$ is right reflective.

Suppose, conversely, that $\mathcal{I}$ is right reflective. Then, by Lemma 218, it is systemic, and, by Proposition 152, it is stable. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then by stability, we get $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Now we use right reflectivity to get $T \leq T'$. Thus, $\mathcal{I}$ is family reflective. ■

Now we establish several relationships among the three reflectivity classes. First, we show that, if a π-institution is family reflective, then it is left reflective.

Proposition 220 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family reflective, then it is left reflective.*

Proof: Suppose $\mathcal{I}$ if family reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. By family reflectivity, $T \leq T'$. But, by Lemma 218, $\mathcal{I}$ is systemic, whence we get $\overleftarrow{T} \leq \overleftarrow{T'}$ and, hence, $\mathcal{I}$ is left reflective. ■

Next, we show that left reflectivity implies system reflectivity and, moreover system reflectivity supplied with stability implies left reflectivity.

Proposition 221 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is left reflective, then it is system reflective;*

(b) If $\mathcal{I}$ *is system reflective and stable, then it is left reflective.*

Proof:

(a) Suppose that $\mathcal{I}$ is left reflective and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by left reflectivity, $\overleftarrow{T} \leq \overleftarrow{T'}$. But, as T, T' are theory systems, we have $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$, whence $T \leq T'$ and $\mathcal{I}$ is system reflective.

(b) Suppose that $\mathcal{I}$ is system reflective and stable. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by stability, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, we apply system reflectivity to get $\overleftarrow{T} \leq \overleftarrow{T'}$. Thus, $\mathcal{I}$ is left reflective.

■

Finally, we show that systemicity is exactly the separating property between family reflectivity and system reflectivity.

Proposition 222 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family reflective if and only if it is system reflective and systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is family reflective. Then, by Lemma 218, it is systemic. Moreover, by hypothesis, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$, we get, $T \leq T'$. So $\mathcal{I}$ is also system reflective.

Suppose, conversely, that $\mathcal{I}$ is system reflective and systemic and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. By systemicity, $T, T' \in \mathrm{ThSys}(\mathcal{I})$, whence, by hypothesis, we get $T \leq T'$. Thus, $\mathcal{I}$ is family reflective. ∎

We have now established the following **reflectivity hierarchy**:

Family/Right Reflective

$\downarrow$

Left Reflective

$\downarrow$

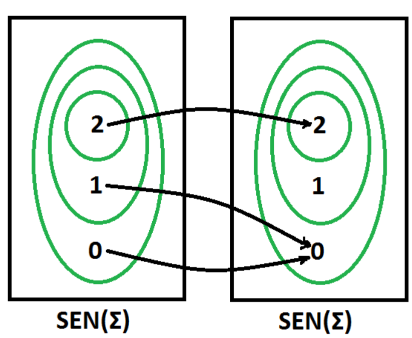
System Reflective

We present now some examples to show that the inclusions shown in the diagram are indeed proper inclusions.

The first example showcases a π-institution which is left reflective, but not systemic, and, hence, according to Proposition 220, not family reflective.

Example 223 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



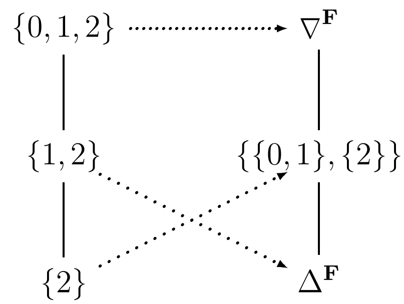
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

Since $\{\{1,2\}\}$ is a theory family that is not a theory system, $\mathcal{I}$ is not systemic.

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



By the diagram, keeping in mind that $\overleftarrow{\{\{1,2\}\}} = \{\{2\}\}$, one can see that $\mathcal{I}$ is left reflective. But, clearly, it is not family reflective, as $\Omega(\{\{1,2\}\}) \leq \Omega(\{\{2\}\})$, whereas, obviously, $\{\{1,2\}\} \nleq \{\{2\}\}$.

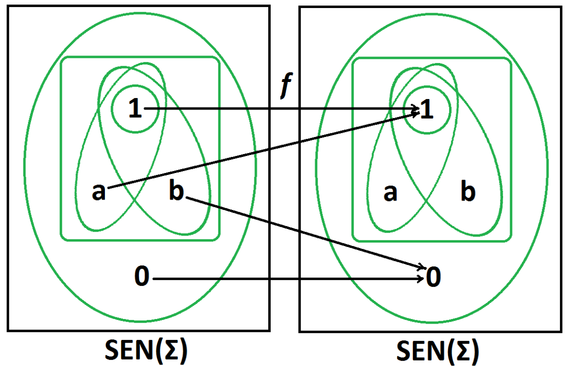
The second example presents a π-institution which is system reflective, but fails to be left reflective and, hence, by Proposition 221, is not stable.

Example 224 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(a) = 1$, $\mathrm{SEN}^\flat(f)(b) = 0$ *and* $\mathrm{SEN}^\flat(f)(1) = 1$*;*
- $N^\flat$ *is the category of natural transformations generated by the two binary natural transformations* $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following tables:*

$\wedge_\Sigma$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee_\Sigma$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1



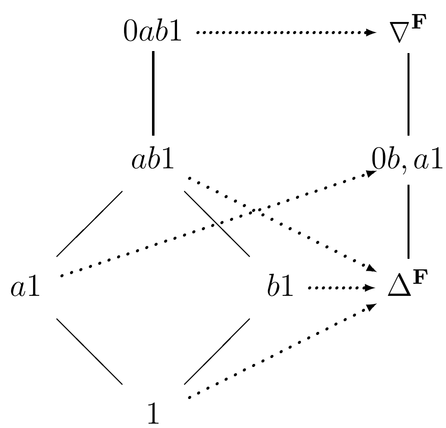
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{1\}, \{a,1\}, \{b,1\}, \{a,b,1\}, \{0,a,b,1\}\}.$$

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{1\}$	$\{1\}$
$\{a,1\}$	$\{a,1\}$
$\{b,1\}$	$\{1\}$
$\{a,b,1\}$	$\{a,1\}$
$\{0,a,b,1\}$	$\{0,a,b,1\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Since $\Omega(\overleftarrow{\{\{a,b,1\}\}}) = \Omega(\{\{a,1\}\}) = \{\{0,b\},\{a,1\}\} \neq \Delta^{\mathbf{F}} = \Omega(\{\{a,b,1\}\})$*, we conclude that* $\mathcal{I}$ *is not stable.*

Since $\{\{1\}\}$*,* $\{\{a,1\}\}$ *and* $\mathrm{SEN}^\flat$ *are the only theory systems of* $\mathcal{I}$*, it is clear from the diagram above that* $\mathcal{I}$ *is system reflective. On the other hand, we have*

$$\Omega(\{\{a,b,1\}\}) = \Delta^{\mathbf{F}} = \Omega(\{\{b,1\}\}),$$

but

$$\overleftarrow{\{\{a,b,1\}\}} = \{\{a,1\}\} \nleq \{\{1\}\} = \overleftarrow{\{\{b,1\}\}},$$

whence, $\mathcal{I}$ is not left reflective.

We turn now to transfer theorems regarding the reflectivity properties studied in this section.

Theorem 225 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is family reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $T \leq T'$.

(b) $\mathcal{I}$ is left reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathrm{FiFam}^{\mathcal{A}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\overleftarrow{T} \leq \overleftarrow{T'}$.

(c) $\mathcal{I}$ is system reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathrm{FiSys}^{\mathcal{A}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $T \leq T'$.

Proof: We prove Part (b).

The "if" is obtained by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$, by Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is left reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Apply the inverse of $\langle F, \alpha \rangle$ to get $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Thus, by Proposition 24, we get $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Take into account the fact that, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$ and apply left reflectivity to get $\overleftarrow{\alpha^{-1}(T)} \leq \overleftarrow{\alpha^{-1}(T')}$. Hence, by Lemma 6, we get $\alpha^{-1}(\overleftarrow{T}) \leq \alpha^{-1}(\overleftarrow{T'})$. Finally, by the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\overleftarrow{T} \leq \overleftarrow{T'}$. ■

Turning to characterizations in terms of mappings between posets, we get the following characterizations of family and system reflectivity in terms of the order reflectivity of mappings from posets of theory or filter families/systems into posets of congruence systems. Given posets $\mathbf{P} = \langle P, \leq \rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq \rangle$, call a mapping $f : P \to Q$ **order reflecting** if, for all $p_1, p_2 \in P$,

$$f(p_1) \preccurlyeq f(p_2) \quad \text{implies} \quad p_1 \leq p_2.$$

Proposition 226 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The following statements are equivalent:*

(a) $\mathcal{I}$ is family reflective;

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is order reflecting;

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system reflectivity, we have

Proposition 227 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is system reflective;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

We continue our studies of reflectivity properties by looking at the relationships governing classes defined using reflectivity with corresponding classes defined using injectivity. We have the following result:

Proposition 228 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family/right reflective, then it is right injective;*

(b) If $\mathcal{I}$ *is left reflective, then it is left injective;*

(c) If $\mathcal{I}$ *is system reflective, then it is system injective.*

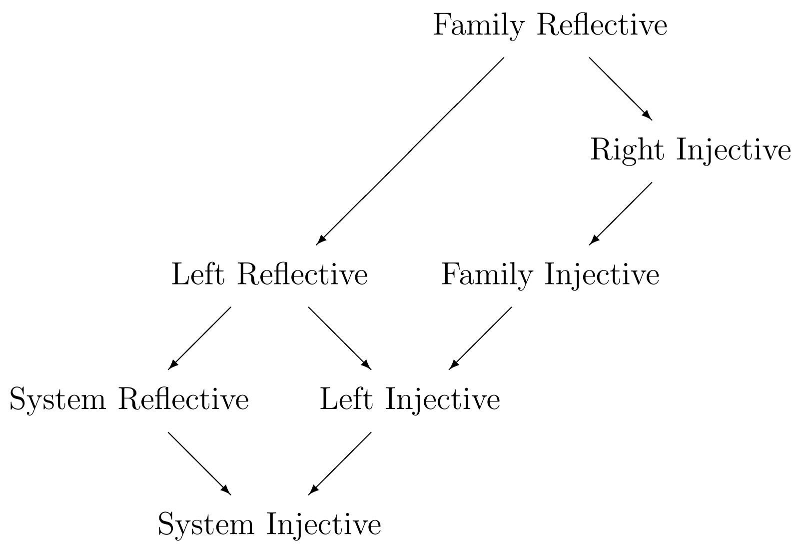
Proof:

(a) Suppose $\mathcal{I}$ is right reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Then, a fortiori, $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$ and $\Omega(\overleftarrow{T'}) \le \Omega(\overleftarrow{T})$. Thus, by right reflectivity, $T \le T'$ and $T' \le T$. It follows that $T = T'$. Therefore, $\mathcal{I}$ is right injective.

(b),(c) Very similar to Part (a).

■

Proposition 228 has established the following combined hierarchy of injectivity and reflectivity properties.

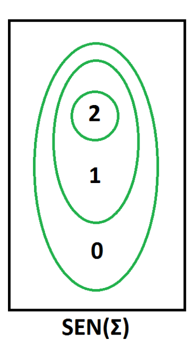


Now we turn to an example that will show that all three fresh inclusions depicted in the diagram, i.e., those established in Proposition 228, are actually proper inclusions.

Example 229 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor determined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone generated by the natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, defined by the following table:*

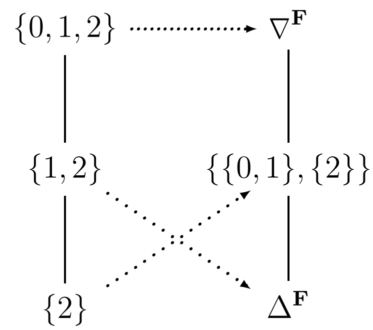
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	0
1	0
2	2



The π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is defined by setting

$$\mathcal{C}_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\}.$$

Note that $\mathcal{I}$ is systemic, since the category $\mathbf{Sign}^\flat$ is trivial. The lattice of theory families and that of the corresponding Leibniz congruence systems are shown in the diagram.



Since all three theory families/systems have distinct Leibniz congruence systems, $\mathcal{I}$ is right injective.

On the other hand, $\Omega(\{\{1,2\}\}) \leq \Omega(\{\{2\}\})$, whereas, obviously, $\{\{1,2\}\} \nleq \{\{2\}\}$, whence $\mathcal{I}$ is not system reflective.

We close this section on reflectivity by looking at the relationships between the various reflectivity classes and the classes in the loyalty hierarchy.

Proposition 230 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is family reflective, then it is family loyal;

(b) If $\mathcal{I}$ is left reflective, then it is left loyal;

(c) If $\mathcal{I}$ is system reflective, then it is system loyal.

Proof:

(a) Suppose that $\mathcal{I}$ is family reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) > \Omega(T')$. Then, a fortiori, $\Omega(T) \geq \Omega(T')$. Therefore, by family reflectivity, $T \geq T'$ and, hence $T \nless T'$. We conclude that $\mathcal{I}$ is family loyal.

(b) Suppose that $\mathcal{I}$ is left reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) > \Omega(T')$. Then, a fortiori, $\Omega(T) \geq \Omega(T')$. Hence, by left reflectivity, $\overleftarrow{T} \geq \overleftarrow{T'}$. But this implies that $\overleftarrow{T} \nless \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is left loyal.

(c) Very similar to Parts (a) and (b).

■

Proposition 230 establishes the following combined hierarchy of reflectivity and loyalty classes of π-institutions.

Family/Right Reflective

Family Loyal Left Reflective

Left Loyal System Reflective

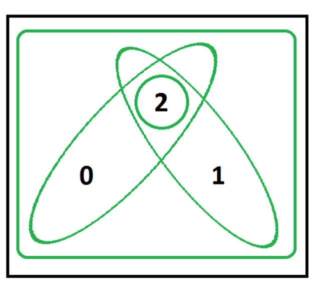
System/Right Loyal

We reinforce the picture by constructing a π-institution that is family loyal but fails to be system reflective. This demonstrates that all three inclusions established in Proposition 230 are proper.

Example 231 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category, with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor determined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone of natural transformations generated by the three unary natural transformations* $\rho^\flat, \sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, defined by the following table:*

$x \in \mathrm{SEN}^\flat(\Sigma)$	$\rho^\flat_\Sigma(x)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	0	0	1
1	2	0	1
2	2	2	2



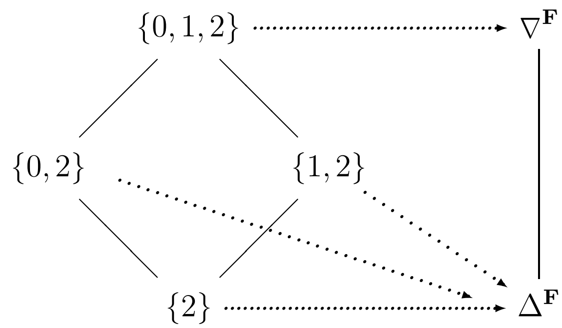
SEN(Σ)

The π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is defined by setting

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

Note that, since $\mathbf{Sign}^\flat$ is trivial, all theory families are theory systems.

The lattice of theory families and the corresponding Leibniz congruence systems are given in the following diagram.



From the diagram it is clear that there are no theory families T, T', such that $T < T'$ and $\Omega(T) > \Omega(T')$. Thus, $\mathcal{I}$ is family loyal.

On the other hand, setting $T = \{\{0,2\}\}$ and $T' = \{\{1,2\}\}$, we have $\Omega(T) \leq \Omega(T')$, whereas, obviously, $T \nleq T'$. Therefore $\mathcal{I}$ is not system reflective.

3.8 Complete Reflectivity

In this section we define the classes arising by imposing the various versions of the property of complete order reflectivity.

Definition 232 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

- *$\mathcal{I}$ is* **family completely reflective** *if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,*

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T\in\mathcal{T}} T \leq T'.$$

- *$\mathcal{I}$ is* **left completely reflective** *if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,*

$$\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}.$$

- *$\mathcal{I}$ is* **right completely reflective** *if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,*

$$\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad \bigcap_{T\in\mathcal{T}} T \leq T'.$$

- $\mathcal{I}$ *is* **system completely reflective** *if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

For the sake of brevity, we sometimes shorten "complete reflectivity" to **c-reflectivity**.

Lemma 218 allows us to obtain easily the fact that both family c-reflectivity and right c-reflectivity imply systemicity.

Lemma 233 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ is family completely reflective, then it is systemic;

(b) If $\mathcal{I}$ is right completely reflective, then it is systemic.

Proof: Note that, if $\mathcal{I}$ is family completely reflective, then it is family reflective and that, if $\mathcal{I}$ is right completely reflective, then it is right reflective. Therefore, the conclusion is obtained by applying Lemma 218. ■

Now we show in an analog of Proposition 219 for complete reflectivity that family complete reflectivity and right complete reflectivity are equivalent properties.

Proposition 234 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *$\mathcal{I}$ is family completely reflective if and only if it is right completely reflective.*

Proof: Suppose, first, that $\mathcal{I}$ is family completely reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. By Lemma 233, $\mathcal{I}$ is systemic, whence we get $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. This allows us to apply family c-reflectivity to obtain $\bigcap \mathcal{T} \leq T'$. Hence $\mathcal{I}$ is right completely reflective.

Suppose, conversely, that $\mathcal{I}$ is right completely reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. By Lemma 233, $\mathcal{I}$ is systemic, whence, we get $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Applying right c-reflectivity, we get that $\bigcap \mathcal{T} \leq T'$. Therefore, $\mathcal{I}$ is family completely reflective. ■

We now look at the relationships that govern the three complete reflectivity classes, which also parallel the ones established in Propositions 220, 221 and 222 for the various classes defined using reflectivity.

We show, first, that family complete reflectivity implies left complete reflectivity.

Proposition 235 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *If $\mathcal{I}$ is family completely reflective then it is left completely reflective.*

Proof: Suppose that $\mathcal{I}$ is family completely reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. By family complete reflectivity, we get $\bigcap_{T\in\mathcal{T}} T \leq T'$, whence, by Lemma 233, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Thus, $\mathcal{I}$ is left completely reflective. ■

Next, we show that left complete reflectivity implies system complete reflectivity and, moreover, system complete reflectivity, combined with stability, implies left complete reflectivity.

Proposition 236 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is left completely reflective, then it is system completely reflective;*

(b) If $\mathcal{I}$ *is system completely reflective and stable, then it is left completely reflective.*

Proof:

(a) Suppose that $\mathcal{I}$ is left c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by left c-reflectivity, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. But, as $\mathcal{T} \cup \{T'\}$ consists of theory systems, we get $\bigcap \mathcal{T} \leq T'$. So $\mathcal{I}$ is system c-reflective.

(b) Suppose that $\mathcal{I}$ is system c-reflective and stable. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by stability, we get $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Since $\{\overleftarrow{T} : T \in \mathcal{T}\} \cup \{\overleftarrow{T'}\} \in \mathrm{ThSys}(\mathcal{I})$, we apply system c-reflectivity to get $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Thus, $\mathcal{I}$ is left c-reflective.

■

Finally, it is not difficult to see that family complete reflectivity is tantamount to system complete reflectivity plus systemicity.

Proposition 237 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family completely reflective if and only if it is system completely reflective and systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is family completely reflective. Then, by Lemma 233, it is systemic. Moreover, by Propositions 235 and 236, it is system completely reflective.

Suppose, conversely, that $\mathcal{I}$ is system completely reflective and systemic and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Since, by systemicity, we get $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, we get, by system complete reflectivity, $\bigcap_{T\in\mathcal{T}} T \leq T'$. Thus, $\mathcal{I}$ is family completely reflective. ■

We have now established the following **complete reflectivity hierarchy**:

Family/Right c-Reflective

↓

Left c-Reflective

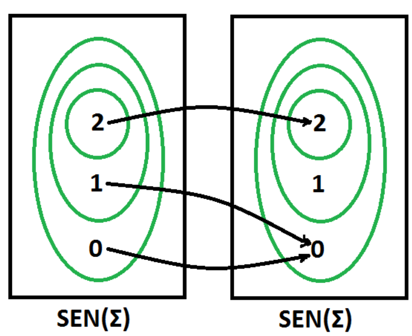
↓

System c-Reflective

We now provide two examples to show that the inclusions depicted in the diagram between the three complete reflectivity classes introduced in this section are proper. The first example presents a π-institution which is left completely reflective, but not systemic, and, hence, according to Proposition 237, not family completely reflective.

Example 238 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



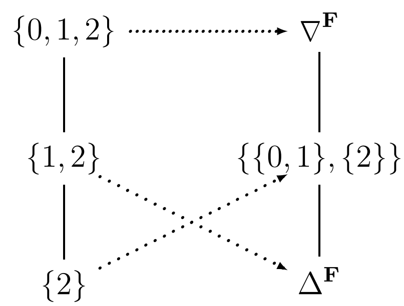
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1, 2\}$	$\{2\}$
$\{0, 1, 2\}$	$\{0, 1, 2\}$

Since $\{\{1,2\}\}$ is a theory family that is not a theory system, $\mathcal{I}$ is not systemic.

The lattice of theory families and that of the corresponding Leibniz congruence systems are depicted below:



By the diagram, keeping in mind that $\overleftarrow{\{\{1,2\}\}} = \{\{2\}\}$, one can see that $\mathcal{I}$ is left c-reflective. But, clearly, it is not family c-reflective, as $\Omega(\{\{1,2\}\}) \le \Omega(\{\{2\}\})$, whereas, obviously, $\{\{1,2\}\} \nleq \{\{2\}\}$, giving, as we have already seen in Example 223, that $\mathcal{I}$ is not even family reflective.

The second example presents a π-institution which is system c-reflective, but fails to be left c-reflective and, hence, by Proposition 236, is not stable.

Example 239 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

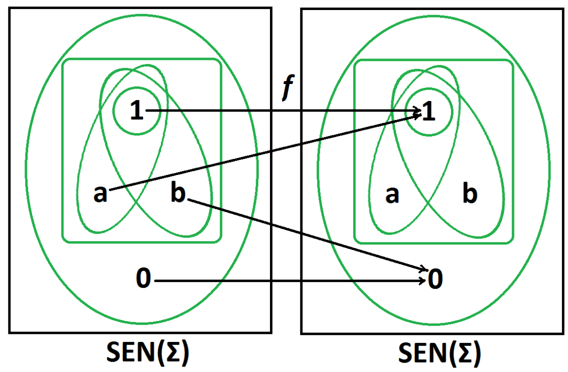
- *$\mathbf{Sign}^\flat$ is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is the functor specified by $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$ and $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(a) = 1$, $\mathrm{SEN}^\flat(f)(b) = 0$ and $\mathrm{SEN}^\flat(f)(1) = 1$;*
- *$N^\flat$ is the category of natural transformations generated by the two binary natural transformations $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by the following tables:*

$\wedge_\Sigma$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee_\Sigma$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution defined by setting

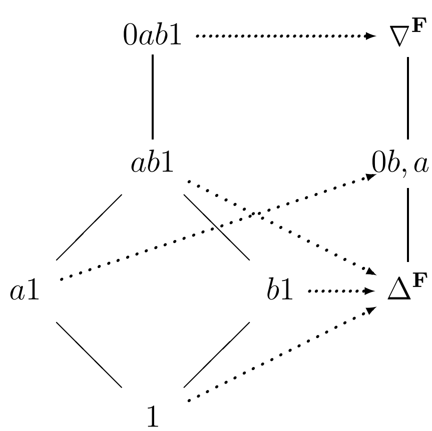
$$\mathcal{C}_\Sigma = \{\{1\}, \{a,1\}, \{b,1\}, \{a,b,1\}, \{0,a,b,1\}\}.$$



The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{1\}$	$\{1\}$
$\{a,1\}$	$\{a,1\}$
$\{b,1\}$	$\{1\}$
$\{a,b,1\}$	$\{a,1\}$
$\{0,a,b,1\}$	$\{0,a,b,1\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Since $\Omega(\overleftarrow{\{\{a,b,1\}\}}) = \Omega(\{\{a,1\}\}) = \{\{0,b\},\{a,1\}\} \neq \Delta^{\mathbf{F}} = \Omega(\{\{a,b,1\}\})$, *we conclude that $\mathcal{I}$ is not stable.*

Note that, since $\{\{1\}\}$, $\{\{a,1\}\}$ *and* $\mathrm{SEN}^\flat$ *are the only theory systems of* $\mathcal{I}$, *the Leibniz operator* $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism. Hence, $\mathcal{I}$ is system completely reflective. On the other hand, we have*

$$\Omega(\{\{a,b,1\}\}) = \Delta^{\mathbf{F}} = \Omega(\{\{b,1\}\}),$$

but

$$\overleftarrow{\{\{a,b,1\}\}} = \{\{a,1\}\} \nleq \{\{1\}\} = \overleftarrow{\{\{b,1\}\}},$$

whence, $\mathcal{I}$ is not left reflective and, a fortiori, it is not left completely reflective either.

We turn now to transfer theorems regarding the reflectivity properties studied in this section.

Theorem 240 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is family completely reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap \mathcal{T} \leq T'$.

(b) $\mathcal{I}$ is left completely reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{A}}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$.

(c) $\mathcal{I}$ is system completely reflective if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiSys}^{\mathcal{A}}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap_{T \in \mathcal{T}} T \leq T'$.

Proof: We prove Part (b).

The "if" is obtained by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$, by Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is left c-reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Apply the inverse of $\langle F, \alpha \rangle$ to get $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. This yields that $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Thus, by Proposition 24, we get $\bigcap_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Take into account the fact that, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$ and apply left c-reflectivity to get $\bigcap_{T \in \mathcal{T}} \overleftarrow{\alpha^{-1}(T)} \leq \overleftarrow{\alpha^{-1}(T')}$. Hence, by Lemma 6, we get $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\overleftarrow{T}) \leq \alpha^{-1}(\overleftarrow{T'})$. Hence, $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \overleftarrow{T}) \leq \alpha^{-1}(\overleftarrow{T'})$. Finally, by the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. ■

Next, we obtain characterizations of family and system c-reflectivity in terms of the complete order reflectivity of mappings from posets of theory or filter families/systems into posets of congruence systems. Given complete lattices $\mathbf{P} = \langle P, \leq \rangle$ and $\mathbf{Q} = \langle Q, \preccurlyeq \rangle$, call a mapping $f : P \to Q$ **completely order reflecting** if, for all $X \cup \{y\} \subseteq P$,

$$\bigwedge_{x \in X}^{\mathbf{Q}} f(x) \preccurlyeq f(y) \quad \text{implies} \quad \bigwedge_{x \in X}^{\mathbf{P}} x \leq y.$$

Proposition 241 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The following statements are equivalent:*

(a) *$\mathcal{I}$ is family completely reflective;*

(b) $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}(\mathcal{I})$ *is completely order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *is completely order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system c-reflectivity, we have

Proposition 242 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) *$\mathcal{I}$ is system completely reflective;*

(b) $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}(\mathcal{I})$ *is completely order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ *is completely order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

We look now at the relationships governing classes defined using complete reflectivity with corresponding classes defined using reflectivity. We have referred to this straightforward relationships already in the proof of Lemma 233.

Proposition 243 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

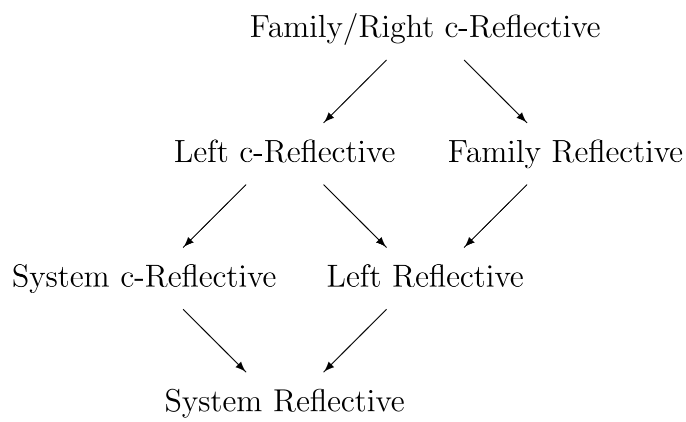
(a) *If $\mathcal{I}$ is family/right completely reflective, then it is family/right reflective;*

(b) *If $\mathcal{I}$ is left completely reflective, then it is left reflective;*

(c) *If $\mathcal{I}$ is system completely reflective, then it is system reflective.*

Proof: All three parts are based on the observation that the reflectivity conditions are specializations of the corresponding complete reflectivity conditions to the special case of singleton collections of theory families/systems on the left hand sides of the relevant inequalities. ∎

Proposition 243 has established the following combined hierarchy of injectivity and reflectivity properties.



Now we turn to an example that will show that all three inclusions established in Proposition 243 and depicted in the diagram are proper. Namely, we construct a family reflective π-institution that is not system completely reflective.

Example 244 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category, with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2, 3, 4\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the two unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by the following table:*

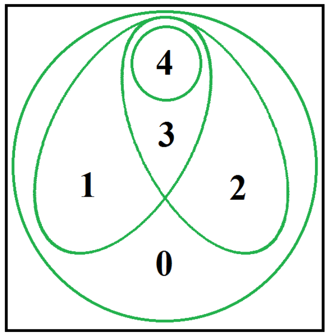
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	2	0
1	2	0
2	2	0
3	1	2
4	2	0

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{4\}, \{3, 4\}, \{1, 3, 4\}, \{2, 3, 4\}, \{0, 1, 2, 3, 4\}\}.$$

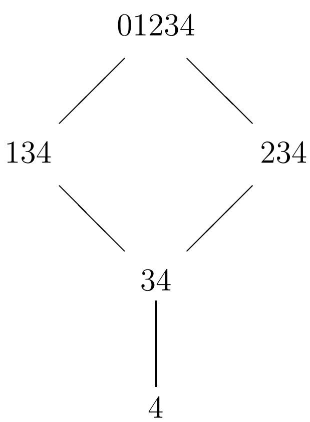
Clearly, since $\mathbf{Sign}^\flat$ *is trivial,* $\mathcal{I}$ *is systemic.*

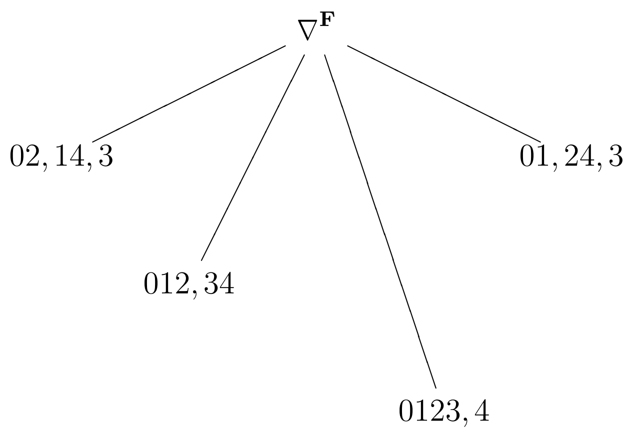
The lattice of theory families and the corresponding Leibniz congruence



SEN(Σ)

systems are shown in the diagram.





From the diagram, it is clear that, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ *implies* $T \leq T'$, *i.e.,* $\mathcal{I}$ *is family reflective. On the other hand, setting* $T^1 = \{\{1,3,4\}\}$, $T^2 = \{\{2,3,4\}\}$ *and* $T' = \{\{4\}\}$, *we get*

$$\begin{array}{rcl}\Omega(T^1) \cap \Omega(T^2) & = & \{\{02,14,3\}\} \cap \{\{01,24,3\}\}\\ & = & \Delta^{\mathbf{F}}\\ & \leq & \{\{0123,4\}\} = \Omega(T'),\end{array}$$

whereas $T^1 \cap T^2 = \{\{3,4\}\} \nleq \{\{4\}\} = T'$. *Hence,* $\mathcal{I}$ *is not system completely reflective.*

Chapter 4

The Semantic Leibniz Hierarchy: Top Half

4.1 Introduction

In this chapter, we study the classes of π-institutions that result when combining monotonicity properties of the Leibniz operator with injectivity, reflectivity or complete reflectivity. As such, all those classes correspond, in the categorical framework, to the class of weakly algebraizable sentential logics [62], which is obtained by combining protoalgebraicity [28] (see, also, [26]) with truth equationality [77] (see, also, Section 6.4 of [86]). It should also be mentioned that algebraizable logics, as introduced in [35] and generalized in [43, 53, 54], form subclasses of weakly algebraizable ones obtained by strengthening protoalgebraicity to equivalentiality [19, 23, 24]. The analogs of equivalentiality for π-institutions and the corresponding subclasses of algebraizable π-institutions will be considered in Chapters 5 and 5.

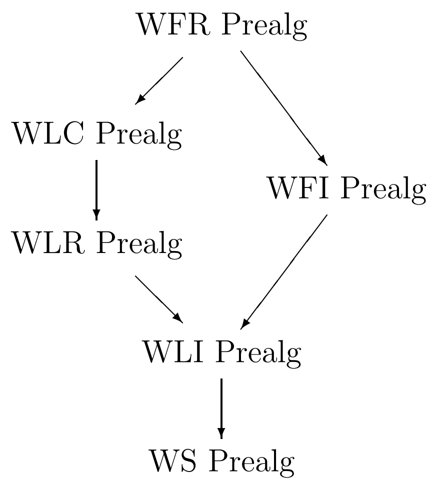
In Section 4.2, we study the hierarchy that results when combining prealgebraicity, i.e., monotonicity of the Leibniz operator on theory systems (Section 3.3) with each of the various flavors of injectivity (Section 3.6), reflectivity (Section 3.7) or complete reflectivity (Section 3.8). Since there are four different flavors of injectivity, three of reflectivity and three of complete reflectivity, we get, a priori, ten classes of *weakly prealgebraizable π-institutions*. The qualifier "weakly" suggests the use of monotonicity rather than equivalentiality, and the prefix "pre" in prealgebraizable that prealgebraicity, i.e., system monotonicity, rather than protoalgebraicity, i.e., family monotonicity, is used in the definition of these ten classes. Since prealgebraicity is common to all ten, the differentiating factor is the type of injectivity, reflectivity or c-reflectivity being imposed. Accordingly, the following ten classes are obtained, all named "weakly X prealgebraizable", or "WX Prealgebraizable" for short, where the string X stands for one of the following:

- SI for system injective, LI for left injective, FI for family injective, RI for right injective; or
- SR for system reflective, LR for left reflective, FR for family reflective; or
- SC for system c-reflective, LC for left c-reflective, FC for family c-reflective.

A fundamental result is that, under prealgebraicity, all three system properties (SI, SR and SC) coincide. Thus, WSI, WSR and WSC prealgebraizability are identical properties. We call π-institutions belonging to this class *WS prealgebraizable*. It is shown that WS prealgebraizability transfers. Moreover, WS prealgebraizable π-institutions $\mathcal{I} = \langle \mathbf{F}, C \rangle$ are characterized by the property that $\Omega^{\mathcal{A}}$ on $\mathcal{I}$-filter systems is an order embedding, for every $\mathbf{F}$-algebraic system $\mathcal{A}$. As prealgebraicity identifies also family reflectivity with family c-reflectivity, the classes of WFR prealgebraizable and WFC prealgebraizable

π-institutions coincide. Finally, both WFR and WRI prealgebraizability turn out to be equivalent, as they are both equivalent to WFI prealgebraizability plus systemicity. Hence, at the top of the weak prealgebraizability hierarchy, only two of the four classes are potentially different. We refer to them as *WFR* and *WFI prealgebraizability*. Both properties transfer. Moreover, both have characterizations in terms of the Leibniz operator viewed as a mapping between ordered sets. Namely, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is WFR prealgebraizable iff $\Omega^{\mathcal{A}}$ is an order isomorphism and it is WFI prealgebraizable iff $\Omega^{\mathcal{A}}$ is a bijection on $\mathcal{I}$-filter families, which restricts to an order embedding on $\mathcal{I}$-filter systems, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

As no further identifications seem possible, one obtains the hierarchy

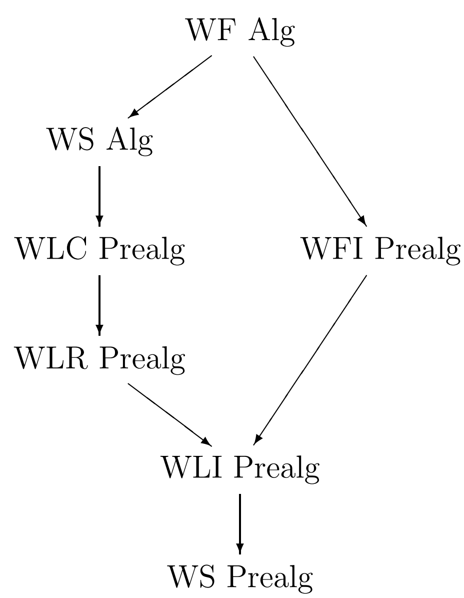


Some specialized results reduce the hierarchy further under additional provisos. First, under systemicity, the entire hierarchy collapses to a single class. Second, it is shown that, under stability, the two family properties coincide, as do all four remaining properties. Thus, under stability, the hierarchy reduces to only two distinct classes.

The section focuses, next, to the three left properties. More precisely, it is shown that all three of WLI, WLR and WLC prealgebraizability versions transfer and that each is characterized via theorems perceiving the Leibniz operator as a mapping from filter families to congruence systems over arbitrary algebraic systems. Briefly, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, it turns out that $\mathcal{I}$ is WLI (WLR, WLC, respectively) prealgebraizable iff, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}(\mathcal{A})$ is a left injective (left order reflecting, left completely order reflecting, respectively) surjection, which restricts to an order embedding on filter systems.

In Section 4.3, we study those classes that are formed by combining protoalgebraicity (family monotonicity) with each of the ten versions of injectivity, reflectivity or complete reflectivity properties. So, once more, a priori, before any detailed study, one obtains ten potentially different classes of weakly algebraizable π-institutions. However, since protoalgebraicity is a stronger condition than prealgebraicity, one obtains immediately at least those identifications that apply to the weak prealgebraizability hierarchy. So, e.g., we get that WFI, WRI, WFR and WFC algebraizable π-institutions coincide. We term the corresponding property *WF algebraizability*. It turns out to be equivalent to the conjunction of WS prealgebraizability and systemicity. WF algebraizability transfers and, moreover, it can be characterized by $\Omega^{\mathcal{A}}$ being an order isomorphism on every algebraic system $\mathcal{A}$. It follows that this class of π-institutions is actually identical to the class of WFR prealgebraizable ones, i.e., those belonging to the top class in the weak prealgebraizability hierarchy. What is a massive collapse, however, results from showing that the lowest class in the weak algebraizability hierarchy, WSI algebraizability, can be characterized as the conjunction of stability with $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ being an order isomorphism. This allows showing that all classes of WS, WLI, WLR, WLC and WFI algebraizable π-institutions are identical. We term the corresponding property *WS algebraizability*. It is shown that WS algebraizability also transfers.

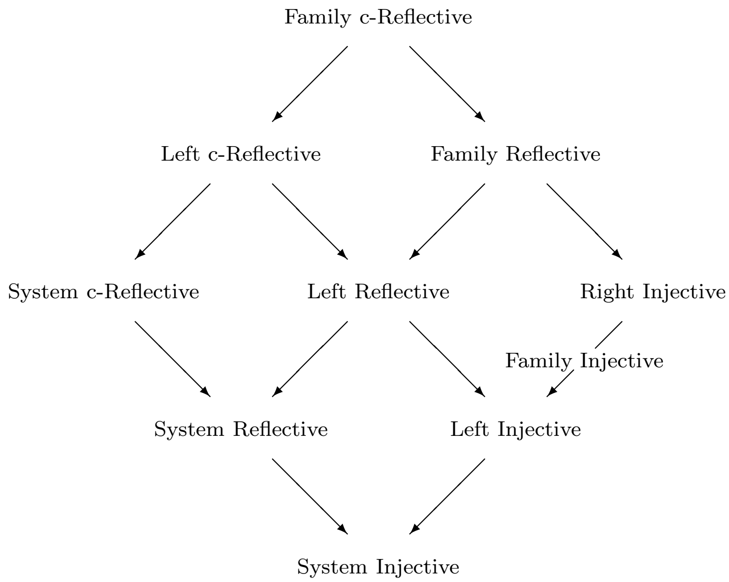
Having reduced the weak algebraizability hierarchy down to two classes, we conclude Section 4.3 (and Chapter 4) by merging it with the weak prealgebraizability hierarchy to obtain the following refinement of the classes that correspond, in the categorical framework, to the class of weakly algebraizable deductive systems.



4.2 Weak PreAlgebraizability

We now shift attention to classes of π-institutions that are defined as a result of interactions between the various kinds of injectivity, reflectivity and complete reflectivity, on the one hand, and prealgebraicity and protoalgebraicity, on the other.

Recall that the hierarchy that was established in the preceding chapter as regards the various versions of injectivity, reflectivity and complete reflectivity has the following form:



Thus, a priori, based on the preceding hierarchy, and combining with prealgebraicity, we obtain a mimicking hierarchy of ten classes which are defined, and whose hierarchy is shown, below.

Definition 245 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **weakly system injective prealgebraizable** *or* **WSI Prealgebraizable***, for short, if it is system injective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly left injective prealgebraizable** *or* **WLI Prealgebraizable***, for short, if it is left injective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly family injective prealgebraizable** *or* **WFI Prealgebraizable***, for short, if it is family injective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly right injective prealgebraizable** *or* **WRI Prealgebraizable***, for short, if it is right injective and prealgebraic.*

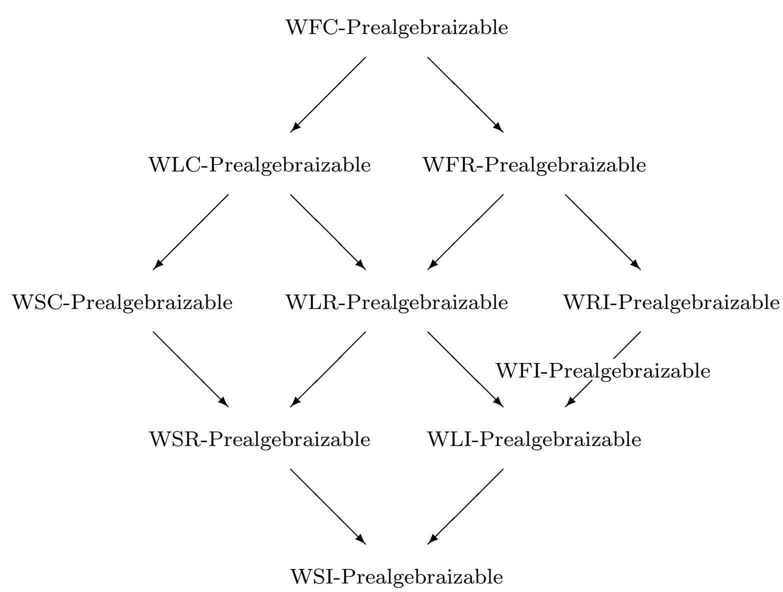
Definition 246 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **weakly system reflective prealgebraizable** *or* **WSR Prealgebraizable***, for short, if it is system reflective and prealgebraic.*

- $\mathcal{I}$ *is* **weakly left reflective prealgebraizable** *or* **WLR Prealgebraizable**, *for short, if it is left reflective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly family reflective prealgebraizable** *or* **WFR Prealgebraizable**, *for short, if it is family reflective and prealgebraic.*

Definition 247 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **weakly system completely reflective prealgebraizable** *or* **WSC Prealgebraizable**, *for short, if it is system completely reflective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly left completely reflective prealgebraizable** *or* **WLC Prealgebraizable**, *for short, if it is left completely reflective and prealgebraic.*
- $\mathcal{I}$ *is* **weakly family completely reflective prealgebraizable** *or* **WFC Prealgebraizable**, *for short, if it is family completely reflective and prealgebraic.*



A few words in the nomenclature used in this diagram are in order.

- W stands for "weakly" which refers to the fact that these classes are defined using forms of monotonicity of the Leibniz operator without any stipulation as to commutativity of the Leibniz operator with inverse special endomorphisms (to be studied later in the chapter). If one adds that condition (using essentially (pre)equivalentiality instead of pre- or protoalgebraicity), then the letter is dropped.

- The letters S for "system", L for "left", R for "right" and F for "family" have obvious meanings referring to which of the four versions (family, left, right or system) of injectivity (I), reflectivity (R) or complete reflectivity (C) conditions are used in the definition.
- Finally, the term "prealgebraizable" is associated with application of monotonicity to theory systems only (as in "prealgebraic"), as opposed to the term "algebraizable", which stipulates monotonicity for all theory families.

We start by proving that under prealgebraicity, system injectivity, system reflectivity and system complete reflectivity turn out to be equivalent properties.

Theorem 248 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is prealgebraic, then the following statements are equivalent:*

(a) $\mathcal{I}$ *is system injective;*

(b) $\mathcal{I}$ *is system reflective;*

(c) $\mathcal{I}$ *is system completely reflective.*

Proof:

(a)⇒(b) Suppose that $\mathcal{I}$ is system injective. Let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) \le \Omega(T')$. Then we get $\Omega(T) = \Omega(T) \cap \Omega(T')$. Moreover, by Lemma 23, $\Omega(T) \cap \Omega(T') \le \Omega(T \cap T')$. On the other hand, by prealgebraicity, we have $\Omega(T \cap T') \le \Omega(T)$ and $\Omega(T \cap T') \le \Omega(T')$, whence $\Omega(T \cap T') \le \Omega(T) \cap \Omega(T')$. We conclude that

$$\Omega(T) = \Omega(T) \cap \Omega(T') = \Omega(T \cap T').$$

Now we use system injectivity to get $T = T \cap T'$. Therefore, $T \le T'$. So $\mathcal{I}$ is also system reflective.

(b)⇒(c) Suppose, next, that $\mathcal{I}$ is system reflective. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T')$. Since $\mathcal{I}$ is prealgebraic, i.e., Ω is monotone on theory systems, we have, for all $T \in \mathcal{T}$, $\Omega(\bigcap \mathcal{T}) \le \Omega(T)$. Therefore, we get

$$\Omega(\bigcap_{T \in \mathcal{T}} T) \le \bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T').$$

Since, by hypothesis, $\mathcal{I}$ is system reflective, we get $\bigcap_{T \in \mathcal{T}} T \le T'$. Thus, $\mathcal{I}$ is system completely reflective.

(c)⇒(a) Suppose, finally, that $\mathcal{I}$ is system completely reflective. By Proposition 243, it is system reflective, and, then, by Proposition 228, it is system injective.

■

Theorem 248 shows that three of the classes in the previous diagram coincide.

Corollary 249 *The classes of WSI prealgebraizable, WSR prealgebraizable, and WSC prealgebraizable π-institutions coincide.*

Taking advantage of Corollary 249 we define:

Definition 250 (WS Prealgebraizable) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is called* **weakly system prealgebraizable** *(or* **WS prealgebraizable** *for short) if it is prealgebraic and system injective, i.e., if the Leibniz operator is monotone and injective on theory systems: For all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$T \le T' \quad \textit{implies} \quad \Omega(T) \le \Omega(T');$$
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T = T'.$$

We present two examples of WS prealgebraizable π-institutions. They are crafted to provide a sneak preview of the state of affairs in the case of systemic and non-systemic π-institutions with regards to weak prealgebraizability. The reader will notice that, in both examples, there is an order isomorphism between the lattice of theory systems of the π-institution and that of the associated Leibniz congruence systems. On the other hand, for this isomorphism to extend to an isomorphism between the lattice of all theory families and the corresponding Leibniz congruence systems, the condition of systemicity on the π-institution under consideration seems to be required (and is, as we shall see later).

Example 251 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

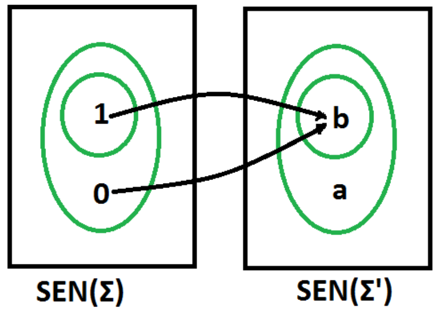
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = b = \mathrm{SEN}^\flat(f)(1)$;
- $N^\flat$ *is the trivial clone.*

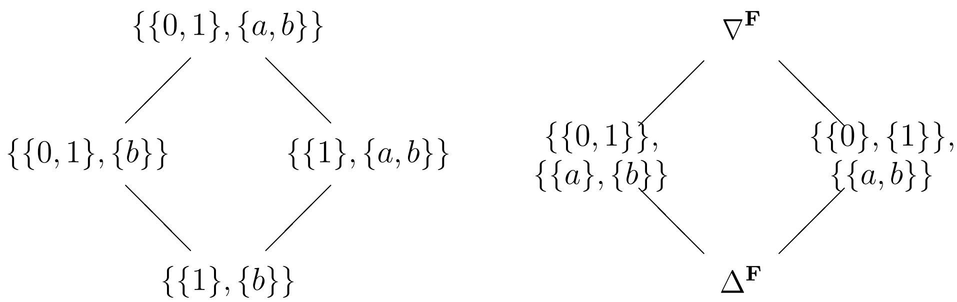
Specify the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

Notice that every theory family is a theory system, whence $\mathcal{I}$ *is systemic.*

The following diagrams show the lattices of theory families and of the corresponding Leibniz congruence systems:

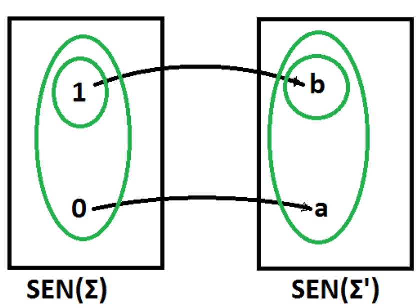




Note that the π-institution $\mathcal{I}$ is WS prealgebraizable and that the two lattices are clearly isomorphic.

Example 252 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two objects* Σ, Σ' *and a single (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by setting* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$*,* $\mathrm{SEN}^\flat(f)(0) = a$ *and* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Specify the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

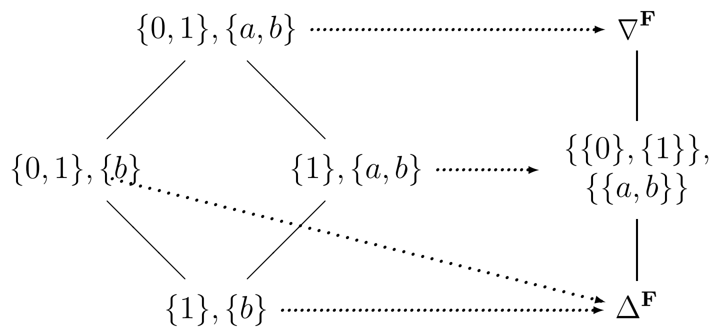
Notice that the theory family $T = \{\{0,1\},\{b\}\}$ *is not a theory system, whence* $\mathcal{I}$ *is not systemic. In fact,* $\overleftarrow{} : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ThSys}(\mathcal{I})$ *is given by the following table:*

	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

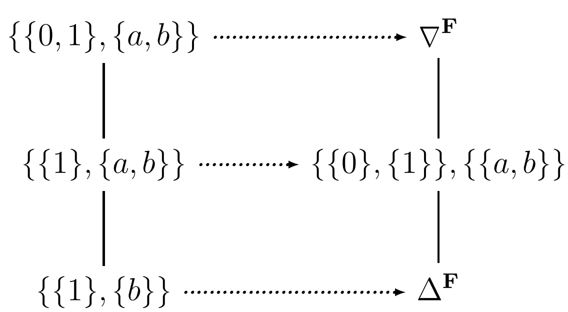
The next table gives the theory families and the associated Leibniz congruence systems:

T	$\Omega(T)$
$\{\{1\},\{b\}\}$	$\{\{0\},\{1\}\},\{\{a\},\{b\}\}$
$\{\{0,1\},\{b\}\}$	$\{\{0\},\{1\}\},\{\{a\},\{b\}\}$
$\{\{1\},\{a,b\}\}$	$\{\{0\},\{1\}\},\{\{a,b\}\}$
$\{\{0,1\},\{a,b\}\}$	$\{\{0,1\}\},\{\{a,b\}\}$

So, even though the lattices of theory families and of the corresponding Leibniz congruence systems are not isomorphic,



the lattices of theory systems and of the corresponding Leibniz congruence systems are indeed isomorphic:



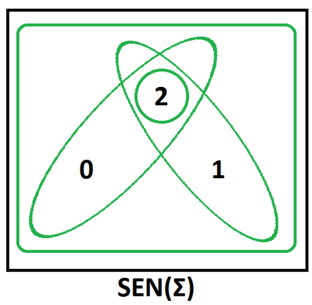
This π*-institution is also WS prealgebraizable.*

We present next examples to show that the class of weakly system prealgebraizable π-institutions is properly included in both the class of prealgebraic and that of system completely reflective π-institutions.

Example 253 *Consider the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the clone of natural transformations on* $\mathrm{SEN}^\flat$ *generated by the the two unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by the following table:*

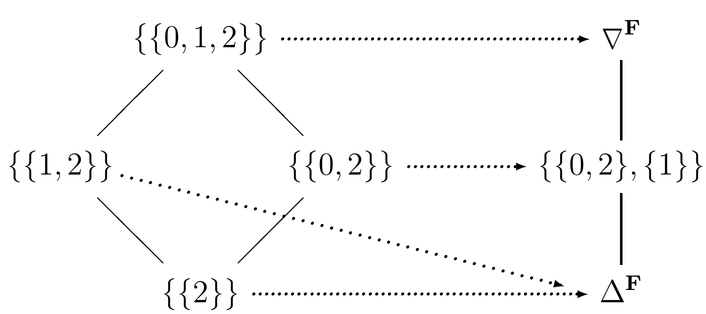
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	0	0
1	1	2
2	0	2



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$*, by setting*

$$C_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

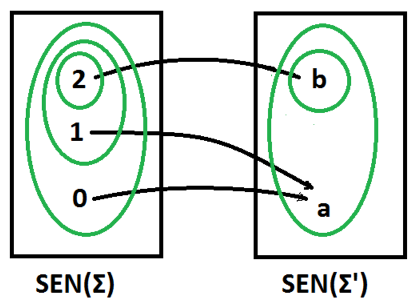
The lattice of the theory systems of $\mathcal{I}$ *and that of the associated Leibniz congruence systems are shown in the following diagrams*



It is clear that the Leibniz operator is monotone. On the other hand, the Leibniz operator is not injective on theory systems. Therefore, we conclude that $\mathcal{I}$ *is prealgebraic but that it fails to be WS prealgebraizable.*

Example 254 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

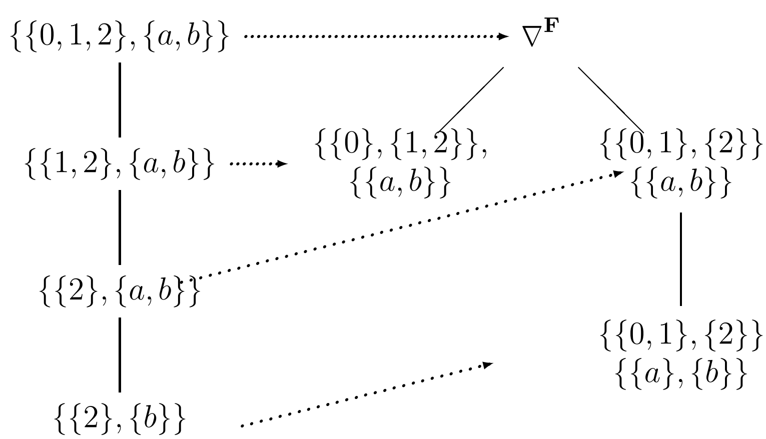
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = a$ *and* $\mathrm{SEN}^\flat(f)(2) = b$*;*
- $N^\flat$ *is the trivial clone.*



We consider the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *defined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

This π*-institution has six theory families, but only four theory systems. The lattice of theory systems and the associated congruence systems are shown below.*



It is clear from these that the Leibniz operator is completely order reflecting on the theory systems of $\mathcal{I}$*, but it is not monotonic. It follows that* $\mathcal{I}$ *is system c-reflective but not prealgebraic. Therefore, it is system c-reflective, but fails to be weakly system prealgebraizable.*

The defining properties of weak system prealgebraizability transfer from theory systems to filter systems over arbitrary algebraic systems. This result follows naturally from corresponding constituent pieces that have already been put in place when studying monotonicity and injectivity.

Theorem 255 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WS prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the Leibniz operator on* $\mathcal{A}$ *is monotone and injective on the* $\mathcal{I}$*-filter systems of* $\mathcal{A}$*, i.e., for all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*,*

$$\begin{array}{rcl} T \le T' & \textit{implies} & \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T'); \\ \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T') & \textit{implies} & T = T'. \end{array}$$

Proof: Suppose, first, that the displayed implications hold for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $\mathcal{I}$-filter systems T, T' on $\mathcal{A}$. By taking $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and keeping in mind Lemma 51, we conclude that the Leibniz operator is monotone and injective on all theory systems of $\mathcal{I}$. Thus, by definition, $\mathcal{I}$ is WS prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is WS prealgebraizable. Then, by definition, it is prealgebraic and system injective. Thus, by Theorems 179 and 214, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator $\Omega^{\mathcal{A}}$ is monotone and injective on the $\mathcal{I}$-filter systems of $\mathcal{A}$. ■

We finally establish the result that we alluded to before presenting Examples 251 and 252. Namely, we show that WS prealgebraizability can be equivalently characterized by the fact that the Leibniz operator $\Omega^{\mathcal{A}}$ over an arbitrary $\mathbf{F}$-algebraic system $\mathcal{A}$ establishes an order embedding from the lattice of filter systems on $\mathcal{A}$ into the poset of all relative congruence systems on $\mathcal{A}$ with respect to the class $\mathrm{AlgSys}^*(\mathcal{I})$.

Consider an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, observe that the $\mathcal{I}$-matrix family $\langle \mathcal{A}^{\Omega^{\mathcal{A}}(T)}, T/\Omega^{\mathcal{A}}(T) \rangle$ is Leibniz reduced. Hence, the $\mathbf{F}$-algebraic system $\mathcal{A}^{\Omega^{\mathcal{A}}(T)}$ is in $\mathrm{AlgSys}^*(\mathcal{I})$. Equivalently, we have that $\Omega^{\mathcal{A}}(T) \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Thus, the Leibniz operator is always a well defined function

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

In particular, it restricts to a well-defined function

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Additionally, by definition of $\mathrm{AlgSys}^\bullet(\mathcal{I})$, this may be perceived also as a function

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}),$$

where, we set

$$\mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}) = \{\theta \in \mathrm{ConSys}(\mathcal{A}) : \mathcal{A}/\theta \in \mathrm{AlgSys}^{\bullet}(\mathcal{I})\}.$$

We keep these remarks in mind in the formulation of several of the following results.

Theorem 256 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat}\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WS prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding.

Proof: Suppose, first, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\Omega^{\mathcal{A}}$ is an order embedding. In particular, because of Lemma 51,

$$\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^{*}(\mathcal{I})$$

is an order embedding. This implies that the Leibniz operator is monotone and injective on theory systems. Thus $\mathcal{I}$ is WS prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is WS prealgebraizable. Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. Consider the mapping

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

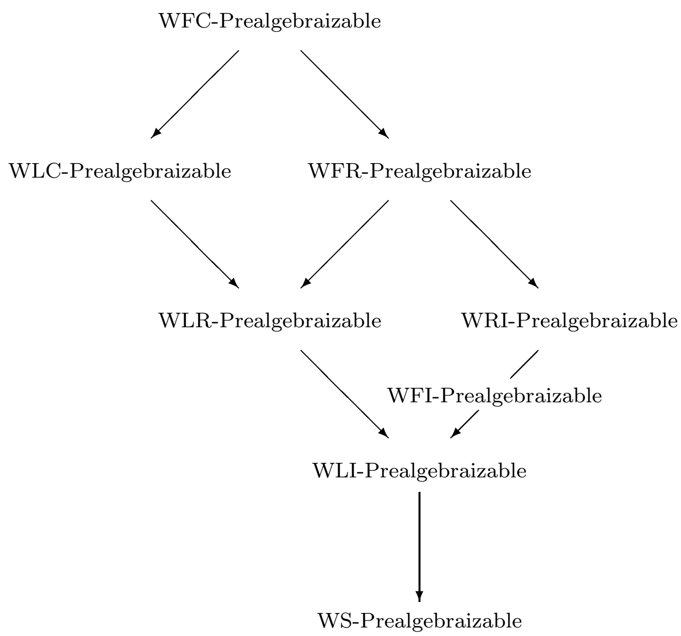
By Theorem 255, this mapping is monotone and injective. To show that it is an order embedding, we must show that it is also order reflecting. By Theorem 225, it suffices to show that $\mathcal{I}$ is system reflective. But this was accomplished in Theorem 248. ∎

Corollary 257 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat}\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WS prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$$

is an order isomorphism.

At this point in our studies we have the following hierarchy, which results from the preceding one by the identification established in Corollary 249.



We continue our study by showing that all three upper diagonal classes, namely those of WFC, WFR and WRI prealgebraizable π-institutions also coincide. To accomplish this for WFC and WFR prealgebraizability, we prove a partial analog of Theorem 248 that under prealgebraicity, family reflectivity and family complete reflectivity turn out to be equivalent properties. The crucial observation is that, as shown in Lemma 218, family reflectivity implies systemicity.

Theorem 258 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is prealgebraic and family reflective, then it is family completely reflective.*

Proof: Since $\mathcal{I}$ is family reflective, by Lemma 218, it is systemic. Since it is prealgebraic and system reflective, by Theorem 248, it is also system completely reflective. Hence, by systemicity, it is also family completely reflective. ■

Theorem 258 shows that two of the top classes in the previous diagram coincide.

Corollary 259 *The classes of WFR prealgebraizable and WFC prealgebraizable* π*-institutions coincide.*

Next we show that the classes of WFR and WRI prealgebraizable π-institutions coincide. We do this indirectly by providing identical characterizations of both classes involving WFI prealgebraizability and systemicity.

First, we need a result which will also prove useful later in our investigations. Namely, we look at an interesting and useful connection between family injectivity and family reflectivity, by means of protoalgebraicity, that forms a partial analog of Theorem 248, which related system injectivity with system reflectivity in the presence of prealgebraicity.

Proposition 260 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is protoalgebraic and family injective, then it is family reflective.*

Proof: Suppose that $\mathcal{I}$ is protoalgebraic and family injective. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then we get $\Omega(T) = \Omega(T) \cap \Omega(T')$. Moreover, by Lemma 23, $\Omega(T) \cap \Omega(T') \leq \Omega(T \cap T')$. On the other hand, by protoalgebraicity, we have $\Omega(T \cap T') \leq \Omega(T)$ and $\Omega(T \cap T') \leq \Omega(T')$, whence $\Omega(T \cap T') \leq \Omega(T) \cap \Omega(T')$. We conclude that

$$\Omega(T) = \Omega(T) \cap \Omega(T') = \Omega(T \cap T').$$

Now we use family injectivity to get $T = T \cap T'$. Therefore, $T \leq T'$. So $\mathcal{I}$ is also family reflective. ∎

Now we characterize WFR prealgebraizability.

Theorem 261 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Then* $\mathcal{I}$ *is WFR prealgebraizable if and only if it is WFI prealgebraizable and systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is WFR prealgebraizable. Then it is, by definition, prealgebraic, it is, by Lemma 218, systemic and, by Proposition 228, it is family injective. Thus, it is WFI prealgebraizable and systemic.

Suppose, conversely, that $\mathcal{I}$ is WFI prealgebraizable and systemic. Then, it is, by definition, prealgebraic and family injective, which, by systemicity, imply that it is protoalgebraic and family injective. Thus, by Proposition 260, it is protoalgebraic and family reflective. Hence, it is, a fortiori, WFR prealgebraizable. ∎

But it is easy to show also that WRI prealgebraizability has exactly the same characterization as WFR prealgebraizability.

Theorem 262 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Then* $\mathcal{I}$ *is WRI prealgebraizable if and only if it is WFI prealgebraizable and systemic.*

Proof: This follows directly from Proposition 209. ∎

Corollary 263 *The classes of WFR prealgebraizable and WRI prealgebraizable* π*-institutions coincide.*

Proof: The conclusion follows from Theorems 261 and 262. ■

Corollaries 259 and 263 show that, among the top four classes of the hierarchy in the preceding diagram, only two may be (and are, as we show in the following example) different. We keep the names WFR prealgebraizable and WFI prealgebraizable for the π-institutions in each of these classes. Thus, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$:

- $\mathcal{I}$ is *WFR prealgebraizable* if it prealgebraic and family reflective (or, equivalently, family c-reflective or right injective), i.e., if

$$\begin{array}{rcl} T \leq T' & \text{implies} & \Omega(T) \leq \Omega(T'), \text{ for all } T, T' \in \mathrm{ThSys}(\mathcal{I}); \\ \Omega(T) \leq \Omega(T') & \text{implies} & T \leq T', \text{ for all } T, T' \in \mathrm{ThFam}(\mathcal{I}); \end{array}$$

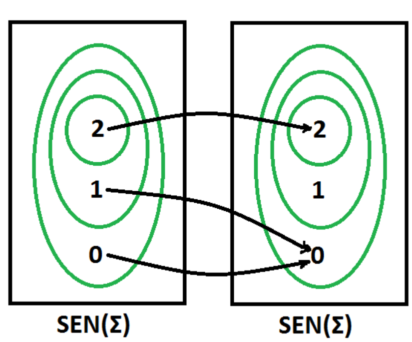
- $\mathcal{I}$ is *WFI prealgebraizable* if it is prealgebraic and family injective, i.e., if

$$\begin{array}{rcl} T \leq T' & \text{implies} & \Omega(T) \leq \Omega(T'), \text{ for all } T, T' \in \mathrm{ThSys}(\mathcal{I}); \\ \Omega(T) = \Omega(T') & \text{implies} & T = T', \text{ for all } T, T' \in \mathrm{ThFam}(\mathcal{I}). \end{array}$$

We provide an example to show that these two classes of π-institutions are indeed different, i.e., we exhibit a WFI prealgebraizable π-institution which is not WFR prealgebraizable.

Example 264 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

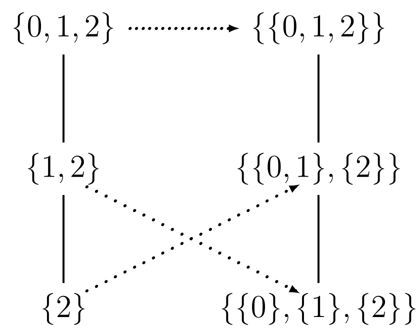


Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The table giving the action of $\overleftarrow{\ }$ on theory families is shown below. It is clear that $\mathcal{I}$ is not systemic.

T_Σ	$\{2\}$	$\{1,2\}$	$\{0,1,2\}$
$\overleftarrow{T}_\Sigma$	$\{2\}$	$\{2\}$	$\{0,1,2\}$

The following diagram gives the lattice of theory families and the corresponding Leibniz congruence systems.



We can see that $\mathcal{I}$ is prealgebraic and family injective. Since it is not systemic, by Theorem 261, it follows that it is not family reflective, a fact that can also be directly verified by the diagram. We conclude that $\mathcal{I}$ is a WFI prealgebraizable π-institution, which is not WFR prealgebraizable.

We now provide a theorem to the effect that both classes are characterized by theorems asserting that their properties transfer from theory systems/families to filter systems/families on arbitrary algebraic systems.

Theorem 265 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is WFI prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter systems and injective on $\mathcal{I}$-filter families, i.e.,*

$$T \leq T' \text{ implies } \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'), \text{ for all } T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A});$$
$$\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T') \text{ implies } T = T', \text{ for all } T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

Proof: The "if" direction follows by specializing to $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is WFI prealgebraizable and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By definition, $\mathcal{I}$ is prealgebraic and family injective. Thus, by Theorem 179, the Leibniz operator on the $\mathcal{I}$-filter systems of $\mathcal{A}$ is monotone and, by Theorem 214, the Leibniz operator on the $\mathcal{I}$-filter families of $\mathcal{A}$ is injective. ∎

Theorem 266 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WFR prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the Leibniz operator on* $\mathcal{A}$ *is monotone on* $\mathcal{I}$*-filter systems and order reflecting on* $\mathcal{I}$*-filter families, i.e.,*

$$T \leq T' \text{ implies } \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'), \text{ for all } T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A});$$
$$\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \text{ implies } T \leq T', \text{ for all } T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

Proof: The "if" direction follows by specializing to $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is WFR prealgebraizable and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By definition, $\mathcal{I}$ is prealgebraic and family reflective. Thus, by Theorem 179, the Leibniz operator on the $\mathcal{I}$-filter systems of $\mathcal{A}$ is monotone and, by Theorem 225, the Leibniz operator on the $\mathcal{I}$-filter families of $\mathcal{A}$ is injective. ■

Next we give two important results, along the lines of the characterization Theorem 256 for WS prealgebraizability, characterizing the classes of WFI prealgebraizable and WFR prealgebraizable π-institutions.

Theorem 267 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WFI prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a bijection which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Suppose, first, that $\mathcal{I}$ is WFI prealgebraizable. Then, it is a fortiori WS prealgebraizable. Thus, by Theorem 256, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding. So it suffices to show that it extends to a bijection from $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ onto $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Since $\mathcal{I}$ is family injective, this mapping is injective. It is also surjective: Given $\theta \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$, we have by definition, $\mathcal{A}^\theta \in \mathrm{AlgSys}^*(\mathcal{I})$. Thus, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)$, such that $\Omega^{\mathcal{A}^\theta}(T) = \Delta^{\mathcal{A}^\theta}$. Now applying the inverse of the canonical quotient morphism $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}^\theta$, we get $\pi^{\theta^{-1}}(\Omega^{\mathcal{A}^\theta}(T)) = \pi^{\theta^{-1}}(\Delta^{\mathcal{A}^\theta})$, whence, by Proposition 24, $\Omega^{\mathcal{A}}(\pi^{\theta^{-1}}(T)) = \theta$. Since, by Corollary 55, $\pi^{\theta^{-1}}(T) \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that the Leibniz operator is also surjective.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a bijection which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Then, by Theorem 256, $\mathcal{I}$ is WS prealgebraizable. Thus, in particular, it is prealgebraic. The fact that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is a bijection ensures that the Leibniz operator on $\mathrm{ThFam}(\mathcal{I})$ is injective. Thus $\mathcal{I}$ is also family injective and, therefore, it is WFI prealgebraizable. ∎

And now an analogous characterization for WFR prealgebraizability.

Theorem 268 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is WFR prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Suppose, first, that $\mathcal{I}$ is WFR prealgebraizable. Then, it is a fortiori WFI prealgebraizable. So by Theorem 267

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding which extends to a bijection

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

But, by Theorem 261, $\mathcal{I}$ is systemic. Therefore, we get an order isomorphism

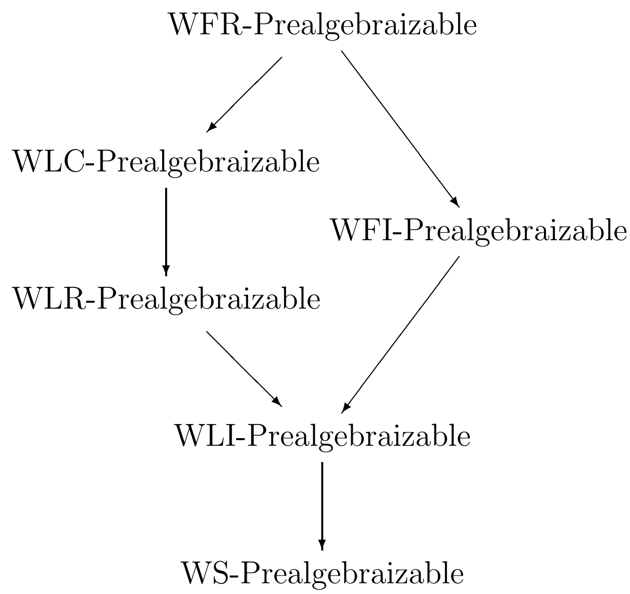
$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. In particular, $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F})$ is an order isomorphism. This ensures that the Leibniz operator is monotone on theory families, hence on theory systems, and, moreover, that it is reflective on theory families. Thus, $\mathcal{I}$ is prealgebraic and family reflective, i.e., it is a WFR prealgebraizable π-institution. ∎

We take a break again to draw the hierarchy incorporating the information that we have currently available.



Recall again the formal definitions of the three classes that have not yet been at the focus of our investigations, namely those of WLC, WLR and WLI prealgebraizable π-institutions:

- $\mathcal{I}$ is *WLI Prealgebraizable* if it is prealgebraic and left injective, i.e., if

$$T \leq T' \text{ implies } \Omega(T) \leq \Omega(T'), \text{ for all } T, T' \in \mathrm{ThSys}(\mathcal{I});$$
$$\Omega(T) = \Omega(T') \text{ implies } \overleftarrow{T} = \overleftarrow{T'}, \text{ for all } T, T' \in \mathrm{ThFam}(\mathcal{I});$$

- $\mathcal{I}$ is *WLR Prealgebraizable* if it is prealgebraic and left reflective, i.e., if

$$T \leq T' \text{ implies } \Omega(T) \leq \Omega(T'), \text{ for all } T, T' \in \mathrm{ThSys}(\mathcal{I});$$
$$\Omega(T) \leq \Omega(T') \text{ implies } \overleftarrow{T} \leq \overleftarrow{T'}, \text{ for all } T, T' \in \mathrm{ThFam}(\mathcal{I});$$

- $\mathcal{I}$ is *WLC Prealgebraizable* if it is prealgebraic and left completely reflective, i.e., if

$$T \leq T' \text{ implies } \Omega(T) \leq \Omega(T'), \text{ for all } T, T' \in \mathrm{ThSys}(\mathcal{I});$$
$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \text{ implies } \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}, \text{ for all } \mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I}).$$

We showed in Example 264 that the top right arrow in the preceding diagram represents a proper inclusion. Moreover, we showed in Theorem 261 that the two classes are separated by systemicity. Now we study the remaining five inclusions to reveal relationships between them and to verify that they are also proper.

We look, first, at the top left arrow, i.e., at the inclusion of the class of WFR prealgebraizable into that of WLC prealgebraizable π-institutions. We have the following extension of Theorem 261, which shows that systemicity is actually the property that separates the top class from every other class in this hierarchy.

Theorem 269 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WFR prealgebraizable if and only if it is WLC, WLR, WFI, WLI or WS prealgebraizable and systemic.*

Proof: Suppose that $\mathcal{I}$ is WFR prealgebraizable. We showed in Theorem 261 that it is systemic. Moreover, it belongs, a fortiori, to all other classes in the hierarchy, since the conditions defining them are weaker than prealgebraicity and family complete reflectivity (which was showed to be equivalent to family reflectivity under prealgebraicity in Theorem 261).

Suppose, conversely, that $\mathcal{I}$ is WS prealgebraizable and systemic. This implies, by definition, that it is prealgebraic and system completely reflective. Thus, by systemicity, it is also family completely reflective. Therefore, since it is prealgebraic and family completely reflective, it is, by definition, WFR prealgebraizable. ∎

A more interesting, perhaps, view is the status of this hierarchy under the milder assumption of stability. Even though systemicity leads to a total collapse of the hierarchy into a single class, it turns out that stability allows for a two-class hierarchy.

Proposition 270 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is WFI prealgebraizable and stable, then it is systemic.*

Proof: Suppose that $\mathcal{I}$ is WFI prealgebraizable and stable and let $T \in \mathrm{ThFam}(\mathcal{I})$. Since $\mathcal{I}$ is stable, we have $\Omega(T) = \Omega(\overleftarrow{T})$. Thus, using family injectivity, we get $T = \overleftarrow{T}$. It follows that $T \in \mathrm{ThSys}(\mathcal{I})$. We now conclude that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ and, therefore, $\mathcal{I}$ is systemic. ∎

Theorem 271 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WFR prealgebraizable if and only if it is WFI prealgebraizable and stable.*

Proof: If $\mathcal{I}$ is WFR prealgebraizable, then it is, a fortiori, WFI prealgebraizable and, by Theorem 261, systemic and, therefore, stable. On the other hand, if $\mathcal{I}$ is WFI prealgebraizable and stable, then, by Proposition 270, it is systemic and, hence, by Theorem 269, it is WFR prealgebraizable. ∎

Proposition 272 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is WS prealgebraizable and stable, then it is WLC prealgebraizable.*

Proof: Suppose that $\mathcal{I}$ is WS prealgebraizable and stable and consider $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. By stability, we get that $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Since $\{\overleftarrow{T} : T \in \mathcal{T}\} \cup \{\overleftarrow{T'}\} \subseteq \mathrm{ThSys}(\mathcal{I})$, we get, by WS prealgebraizability, that $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. This proves that $\mathcal{I}$ is left c-reflective and, hence, that it is WLC prealgebraizable. ■

Theorem 273 *For stable π-institutions the weak prealgebraizability hierarchy collapses to the classes of weakly family prealgebraizable and weakly system/left prealgebraizable classes that are related as follows*

WF Prealgebraizable

↓

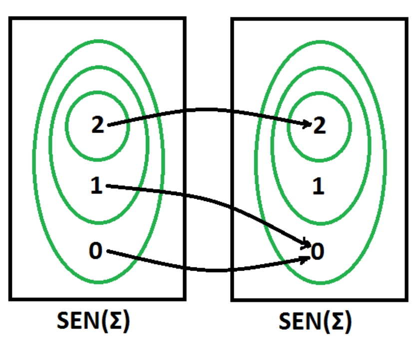
WS Prealgebraizable

Proof: This follows by Theorem 271 and Proposition 272. ■

Now we look at an example to verify that WFR prealgebraizable π-institutions form a proper subclass of WLC prealgberaizable π-institutions.

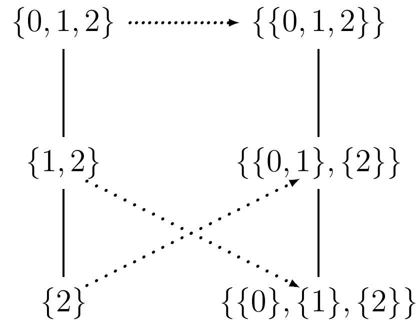
Example 274 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

It has three theory families $T :=$ Thm$(\mathcal{I})$, T' and $T'' :=$ SEN, with $T_\Sigma = \{2\}$, $T'_\Sigma = \{1,2\}$ and $T''_\Sigma = \{0,1,2\}$, but only two theory systems T and T'', *since* $\overleftarrow{T'} = T$. *A look at the lattice of theory families and the corresponding Leibniz congruence systems shows that it is prealgebraic and left completely reflective.*



On the other hand, it is not family reflective, since $\Omega(T') \le \Omega(T)$, *but* $T' \nleq T$. *So* $\mathcal{I}$ *it is WLC prealgebraizable, but not WFR prealgebraizable.*

For WLC prealgebraizable π-institutions we have the following transfer theorem.

Theorem 275 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is WLC prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*, the Leibniz operator on* $\mathcal{A}$ *is monotone on* $\mathcal{I}$*-filter systems and left completely order reflecting on* $\mathcal{I}$*-filter families, i.e.,*

$$T \le T' \text{ implies } \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T'), \text{ for all } T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A});$$
$$\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T') \text{ implies } \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \le \overleftarrow{T'}, \text{ for all } \mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

Proof: The "if" direction follows by specializing to $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is WLC prealgebraizable and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By definition, $\mathcal{I}$ is prealgebraic and left completely reflective. Thus, by Theorem 179, the Leibniz operator on the $\mathcal{I}$-filter systems of $\mathcal{A}$ is monotone and, by Theorem 240, the Leibniz operator on the $\mathcal{I}$-filter families of $\mathcal{A}$ is left completely order reflecting. ∎

Moreover, we obtain the following characterization theorem:

Theorem 276 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is WLC prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Suppose, first, that $\mathcal{I}$ is WLC prealgebraizable. Then, it is a fortiori WS prealgebraizable. Thus, by Theorem 256, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding. So it suffices to show that it extends to a left completely order reflecting surjection from $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ onto $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Since $\mathcal{I}$ is left completely order reflective, by Theorem 275, this mapping is left completely order reflecting. That it is also surjective may be seen by the same argument used in the proof of Theorem 267.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

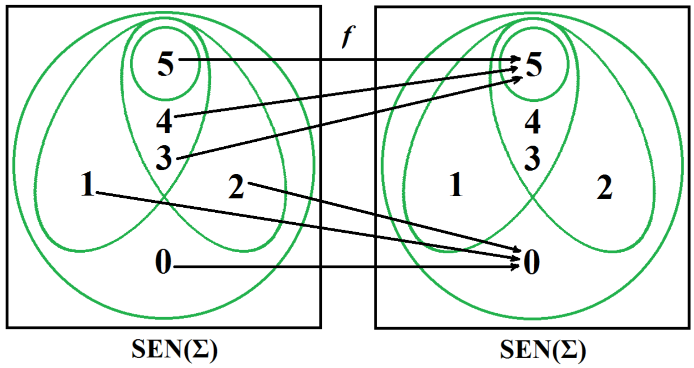
$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Then, by Theorem 256, $\mathcal{I}$ is WS prealgebraizable. Thus, in particular, it is prealgebraic. The fact that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{F})$ is left completely order reflecting ensures that the Leibniz operator on $\mathrm{ThFam}(\mathcal{I})$ is left completely order reflecting. Thus $\mathcal{I}$ is also completely order reflective and, therefore, it is WLC prealgebraizable. ■

We switch to the left vertical arrow in the diagram. We present an example to verify that WLC prealgebraizable π-institutions form a proper subclass of WLR prealgebraizable π-institutions.

Example 277 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4,5\}$ *and*
$$\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = \mathrm{SEN}^\flat(f)(2) = 0,$$
$$\mathrm{SEN}^\flat(f)(3) = \mathrm{SEN}^\flat(f)(4) = \mathrm{SEN}^\flat(f)(5) = 5;$$
- $N^\flat$ *is the category of natural transformations generated by the two unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$, *with*
$$\sigma^\flat_\Sigma, \tau^\flat_\Sigma : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma)$$
defined by
  - $\sigma^\flat_\Sigma(3) = 1$ *and* $\sigma^\flat_\Sigma(x) = 0$, *for all* $x \in \{0,1,2,4,5\}$;
  - $\sigma^\flat_\Sigma(4) = 2$ *and* $\sigma^\flat_\Sigma(x) = 0$, *for all* $x \in \{0,1,2,3,5\}$.



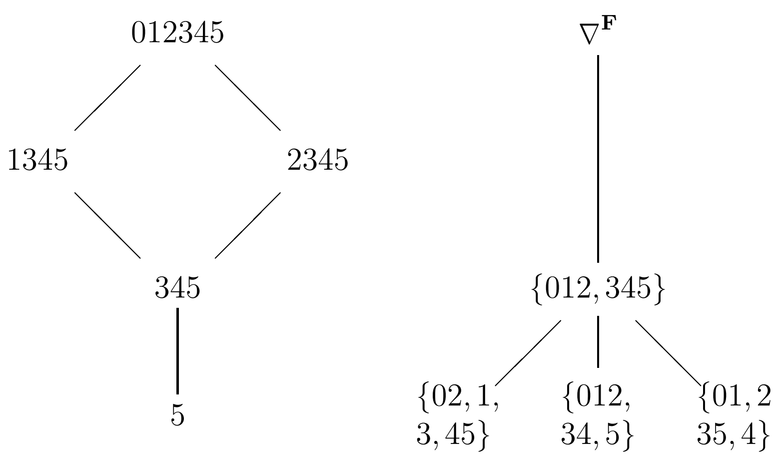
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{5\}, \{3,4,5\}, \{1,3,4,5\}, \{2,3,4,5\}, \{0,1,2,3,4,5\}\}.$$

$\mathcal{I}$ has five theory families but only three theory systems. The action of $\overleftarrow{}$ on theory families is given by the following table.

T	$\overleftarrow{T}$
$\{5\}$	$\{5\}$
$\{3,4,5\}$	$\{3,4,5\}$
$\{1,3,4,5\}$	$\{3,4,5\}$
$\{2,3,4,5\}$	$\{3,4,5\}$
$\{0,1,2,3,4,5\}$	$\{0,1,2,3,4,5\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, it is clear that $\mathcal{I}$ is prealgebraic, i.e., that, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$, $T \le T'$ implies $\Omega(T) \le \Omega(T')$. Moreover, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$, if $\Omega(T) \le \Omega(T')$, then $\overleftarrow{T} \le \overleftarrow{T'}$, i.e., $\mathcal{I}$ is left reflective. Therefore,

$\mathcal{I}$ if WLR prealgebraizable. On the other hand, setting, $T^1 = \{\{1,3,4,5\}\}$, $T^2 = \{\{2,3,4,5\}\}$ and $T' = \{\{5\}\}$, we get

$$\begin{array}{rcl}\Omega(T^1) \cap \Omega(T^2) & = & \{\{02,1,3,45\}\} \cap \{\{01,2,35,4\}\} \\ & = & \Delta^{\mathbf{F}} \\ & \leq & \{\{012,34,5\}\} = \Omega(T'),\end{array}$$

whereas

$$\overleftarrow{T^1} \cap \overleftarrow{T^2} = \{\{3,4,5\}\} \cap \{\{3,4,5\}\} = \{\{3,4,5\}\} \nleq \{\{5\}\} = \overleftarrow{T'}.$$

Hence, $\mathcal{I}$ is not left completely reflective and, thus, a fortiori, it fails to be WLC prealgebraizable.

For WLR prealgebraizable π-institutions we have the following transfer theorem.

Theorem 278 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is WLR prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter systems and left order reflecting on $\mathcal{I}$-filter families, i.e.,*

$$\begin{array}{c} T \leq T' \text{ implies } \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'), \text{ for all } T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}); \\ \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \text{ implies } \overleftarrow{T} \leq \overleftarrow{T'}, \text{ for all } T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}). \end{array}$$

Proof: The "if" direction follows by specializing to $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is WLR prealgebraizable and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By definition, $\mathcal{I}$ is prealgebraic and left reflective. Thus, by Theorem 179, the Leibniz operator on the $\mathcal{I}$-filter systems of $\mathcal{A}$ is monotone and, by Theorem 225, the Leibniz operator on the $\mathcal{I}$-filter families of $\mathcal{A}$ is left order reflecting. ■

Moreover, we obtain the following characterization theorem:

Theorem 279 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is WLR prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Suppose, first, that $\mathcal{I}$ is WLR prealgebraizable. Then, it is, a fortiori, WS prealgebraizable. Thus, by Theorem 256, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding. So it suffices to show that it extends to a left order reflecting surjection from $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ onto $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Since $\mathcal{I}$ is left reflective, by Theorem 278, this mapping is left order reflecting. That it is also surjective may be seen by the same argument used in the proof of Theorem 267.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Then, by Theorem 256, $\mathcal{I}$ is WS prealgebraizable. So, it is prealgebraic. The fact that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is left order reflecting ensures that the Leibniz operator on $\mathrm{ThFam}(\mathcal{I})$ is left order reflecting. Thus $\mathcal{I}$ is also left reflective and, hence, WLR prealgebraizable. ∎

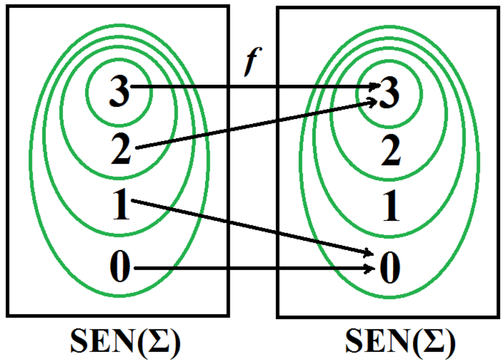
We switch to the bottom left arrow in the diagram. We present an example to verify that WLR prealgebraizable π-institutions form a proper subclass of WLI prealgebraizable π-institutions.

Example 280 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and*
$$\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0,$$
$$\mathrm{SEN}^\flat(f)(2) = \mathrm{SEN}^\flat(f)(3) = 3;$$
- $N^\flat$ *is the category of natural transformations generated by the single unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by* $\sigma^\flat_\Sigma(0) = \sigma^\flat_\Sigma(1) = \sigma^\flat_\Sigma(3) = 0$ *and* $\sigma^\flat_\Sigma(2) = 1$.

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

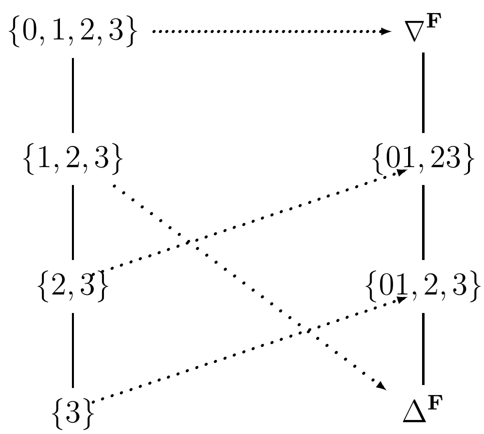
$$\mathcal{C}_\Sigma = \{\{3\}, \{2,3\}, \{1,2,3\}, \{0,1,2,3\}\}.$$



$\mathcal{I}$ has four theory families but only three theory systems. The action of $\leftarrow$ on theory families is given by the following table.

T	$\overleftarrow{T}$
$\{3\}$	$\{3\}$
$\{2,3\}$	$\{2,3\}$
$\{1,2,3\}$	$\{2,3\}$
$\{0,1,2,3\}$	$\{0,1,2,3\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, it is clear that $\mathcal{I}$ is prealgebraic, i.e., that, for all $T,T' \in \mathrm{ThSys}(\mathcal{I})$, $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$. Moreover, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$, the implication $\Omega(T) = \Omega(T')$ implies $\overleftarrow{T} = \overleftarrow{T'}$ holds trivially, since no two different theory families share a common Leibniz congruence system. Hence, $\mathcal{I}$ is left injective. We conclude that $\mathcal{I}$ if WLI prealgebraizable. On the other hand, setting, $T = \{\{1,2,3\}\}$ and $T' = \{\{3\}\}$, we get

$$\Omega(T) = \Delta^{\mathbf{F}} \leq \{\{01,2,3\}\} = \Omega(T'),$$

whereas

$$\overleftarrow{T} = \{\{2,3\}\} \nleq \{\{3\}\} = \overleftarrow{T'}.$$

Hence, $\mathcal{I}$ is not left reflective and, therefore, a fortiori, it is not WLR prealgebraizable.

For WLI prealgebraizable π-institutions we have the following transfer theorem.

Theorem 281 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is WLI prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter systems and left injective on $\mathcal{I}$-filter families, i.e.,*

$$T \leq T' \text{ implies } \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'), \text{ for all } T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A});$$
$$\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T') \text{ implies } \overleftarrow{T} = \overleftarrow{T'}, \text{ for all } T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

Proof: The "if" direction follows by specializing to $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account Lemma 51.

For the "only if" suppose that $\mathcal{I}$ is WLI prealgebraizable and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By definition, $\mathcal{I}$ is prealgebraic and left injective. Thus, by Theorem 179, the Leibniz operator on the $\mathcal{I}$-filter systems of $\mathcal{A}$ is monotone and, by Theorem 214, the Leibniz operator on the $\mathcal{I}$-filter families of $\mathcal{A}$ is left injective. ■

For WLI prealgebraizable π-institutions, we obtain the following characterization theorem:

Theorem 282 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is WLI prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left injective surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Suppose, first, that $\mathcal{I}$ is WLI prealgebraizable. Then, it is, a fortiori, WS prealgebraizable. Thus, by Theorem 256, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a lattice embedding. So it suffices to show that it extends to a left injective surjection from $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ onto $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Since $\mathcal{I}$ is left injective, by Theorem 281, this mapping is left injective. That it is also surjective may be seen by the same argument used in the proof of Theorem 267.

Suppose, conversely, that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left injective surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

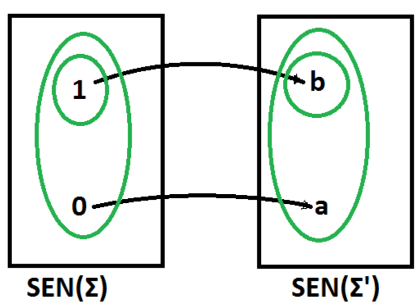
Then, by Theorem 256, $\mathcal{I}$ is WS prealgebraizable. Thus, in particular, it is prealgebraic. The fact that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is left injective ensures that the Leibniz operator on $\mathrm{ThFam}(\mathcal{I})$ is left injective. Thus $\mathcal{I}$ is also left injective and, hence, WLI prealgebraizable. ■

We turn next to the bottom right arrow in the diagram.

We know by Proposition 208 that WFI π-institutions form a subclass of the class of WLI π-institutions. Moreover, we know by Theorem 269 that, if $\mathcal{I}$ is WLI prealgebraizable and systemic, then it is WFI prealgebraizable. We give now an example showing that the inclusion of the class of WFI prealgebraizable π-institutions into the class of WLI prealgebraizable π-institutions is proper.

Example 283 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



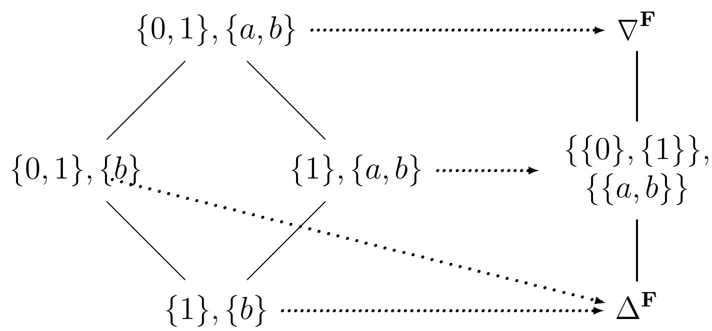
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

The table yielding the action of $\overleftarrow{\ }$ *on theory families is shown below.*

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The accompanying diagram gives the structure of the lattice of theory families and the corresponding Leibniz congruence systems.



From the diagram one can check that the Leibniz operator is monotone on theory systems and left injective on theory families. Thus, the π-institution is prealgebraic and left injective, i.e., WLI prealgebraizable.

On the other hand, letting $T = \{\{1\},\{b\}\}$ and $T' = \{\{0,1\},\{b\}\}$, we have $\Omega(T) = \Omega(T')$, but $T \neq T'$, whence $\mathcal{I}$ is not family injective and, therefore, it is not WFI prealgebraizable.

We look now at the very bottom arrow of the diagram. By Theorem 273, if $\mathcal{I}$ is a WS prealgebraizble and stable π-institution, then it is WLI prealgebraizable. We provide, next, an example to show that these two classes are different, i.e., the class of WLI prealgebraizable π-institutions is properly included in that of WS prealgebraizble π-institutions.

Example 284 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

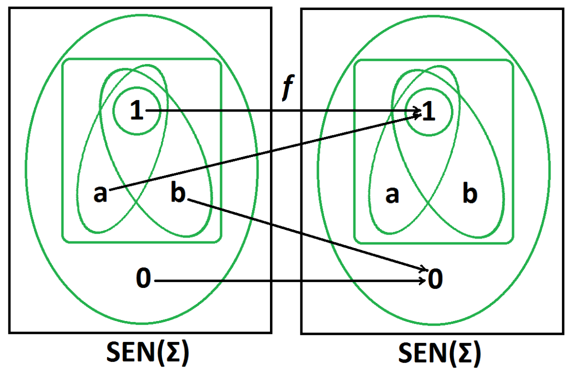
- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(a) = 1$, $\mathrm{SEN}^\flat(f)(b) = 0$ *and* $\mathrm{SEN}^\flat(f)(1) = 1$;
- $N^\flat$ *is the category of natural transformations generated by the two binary natural transformations $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by the following tables:*

$\wedge$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution, defined by setting

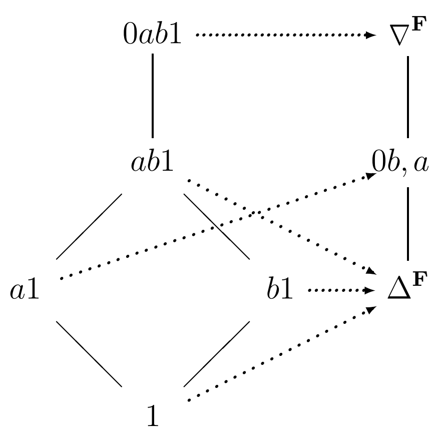
$$C_\Sigma = \{\{1\},\{a,1\},\{b,1\},\{a,b,1\},\{0,a,b,1\}\}.$$



The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{1\}$	$\{1\}$
$\{a,1\}$	$\{a,1\}$
$\{b,1\}$	$\{1\}$
$\{a,b,1\}$	$\{a,1\}$
$\{0,a,b,1\}$	$\{0,a,b,1\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Since $\Omega(\overleftarrow{\{\{a,b,1\}\}}) = \Omega(\{\{a,1\}\}) = \{\{0,b\},\{a,1\}\} \neq \Delta^{\mathbf{F}} = \Omega(\{\{a,b,1\}\})$, *we conclude that* $\mathcal{I}$ *is not stable.*

Note that, since $\{\{1\}\}$, $\{\{a,1\}\}$ *and* $\mathrm{SEN}^\flat$ *are the only theory systems of* $\mathcal{I}$, *the Leibniz operator* $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism. Hence,* $\mathcal{I}$ *is both prealgebraic and system injective, i.e., it is WS prealgebraizable. On the other hand, we have*

$$\Omega(\{\{a,b,1\}\}) = \Delta^{\mathbf{F}} = \Omega(\{\{b,1\}\}),$$

but

$$\overleftarrow{\{\{a,b,1\}\}} = \{\{a,1\}\} \neq \{\{1\}\} = \overleftarrow{\{\{b,1\}\}},$$

whence, $\mathcal{I}$ is not left injective and, hence, it fails to be WLI prealgebraizable.

4.3 Weak Algebraizability

We now shift attention to classes of π-institutions that are defined as a result of interactions between the various kinds of injectivity, reflectivity and complete reflectivity, on the one hand, and protoalgebraicity on the other. A priori, based on the ordering of the various injectivity, reflectivity and complete reflectivity properties, we have ten classes, which are defined below and whose hierarchy is shown in the accompanying diagram.

Definition 285 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

- *$\mathcal{I}$ is* **weakly system injective algebraizable** *or* **WSI Algebraizable***, for short, if it is system injective and protoalgebraic.*
- *$\mathcal{I}$ is* **weakly left injective algebraizable** *or* **WLI Algebraizable***, for short, if it is left injective and protoalgebraic.*
- *$\mathcal{I}$ is* **weakly family injective algebraizable** *or* **WFI Algebraizable***, for short, if it is family injective and protoalgebraic.*
- *$\mathcal{I}$ is* **weakly right injective algebraizable** *or* **WRI Algebraizable***, for short, if it is right injective and protoalgebraic.*

Definition 286 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

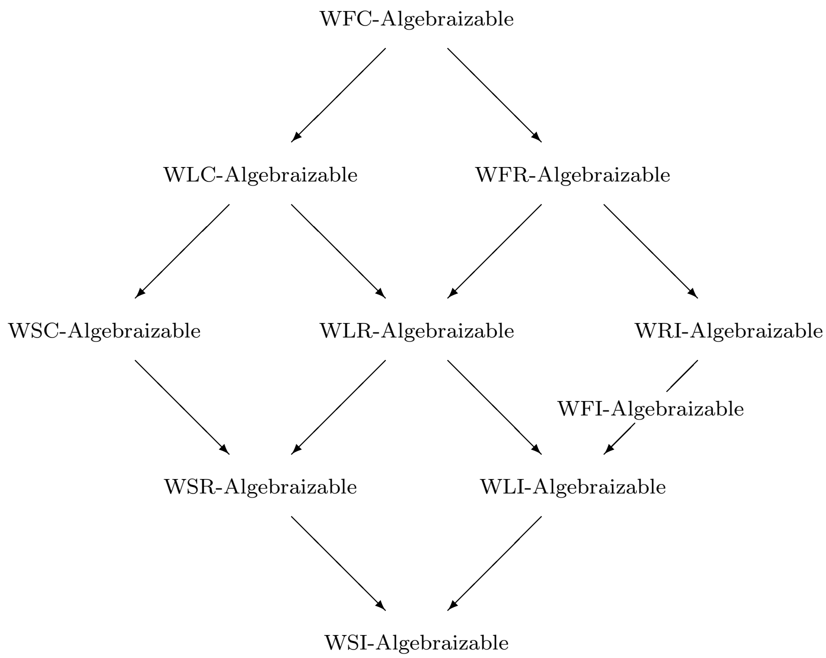
- *$\mathcal{I}$ is* **weakly system reflective algebraizable** *or* **WSR Algebraizable***, for short, if it is system reflective and protoalgebraic.*
- *$\mathcal{I}$ is* **weakly left reflective algebraizable** *or* **WLR Algebraizable***, for short, if it is left reflective and protoalgebraic.*
- *$\mathcal{I}$ is* **weakly family reflective algebraizable** *or* **WFR Algebraizable***, for short, if it is family reflective and protoalgebraic.*

Definition 287 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

- *$\mathcal{I}$ is* **weakly system completely reflective algebraizable** *or* **WSC Algebraizable***, for short, if it is system completely reflective and protoalgebraic.*

- *$\mathcal{I}$ is* **weakly left completely reflective algebraizable** *or* **WLC Algebraizable**, *for short, if it is left completely reflective and protoalgebraic.*

- *$\mathcal{I}$ is* **weakly family completely reflective algebraizable** *or* **WFC Algebraizable**, *for short, if it is family completely reflective and protoalgebraic.*



In view of the remarks made about terminology at the beginning of Section 4.2, the naming conventions here should be fairly obvious. The only difference is that the term "prealgebraizable" has been replaced by the term "algebraizable" to reflect the fact that the condition that the π-institution be prealgebraic is being replaced in the definitions by that of being protoalgebraic.

Recall from Theorem 248 that, under prealgebraicity, the properties of being system injective, system reflective and system completely reflective coincide. A similar result holds for the properties of family injectivity, right injectivity, family reflectivity and family complete reflectivity under the assumption of protoalgebraicity.

Theorem 288 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *If $\mathcal{I}$ is protoalgebraic, then the following statements are equivalent:*

(a) $\mathcal{I}$ is family injective;

(b) $\mathcal{I}$ is family reflective;

(c) $\mathcal{I}$ is family completely reflective;

(d) $\mathcal{I}$ is right injective.

Proof:

(a)⇒(b) Suppose that $\mathcal{I}$ is fanily injective. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then we get $\Omega(T) = \Omega(T) \cap \Omega(T')$. Moreover, by Lemma 23, $\Omega(T) \cap \Omega(T') \leq \Omega(T \cap T')$. On the other hand, by protoalgebraicity, we have $\Omega(T \cap T') \leq \Omega(T)$ and $\Omega(T \cap T') \leq \Omega(T')$, whence $\Omega(T \cap T') \leq \Omega(T) \cap \Omega(T')$. We conclude that

$$\Omega(T) = \Omega(T) \cap \Omega(T') = \Omega(T \cap T').$$

Now we use family injectivity to get $T = T \cap T'$. Therefore, $T \leq T'$. So $\mathcal{I}$ is also family reflective.

(b)⇒(c) Suppose, next, that $\mathcal{I}$ is family reflective. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Since $\mathcal{I}$ is protoalgebraic, i.e., Ω is monotone on theory families, we have, for all $T \in \mathcal{T}$, $\Omega(\bigcap \mathcal{T}) \leq \Omega(T)$. Therefore, we get

$$\Omega(\bigcap_{T \in \mathcal{T}} T) \leq \bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T').$$

Since, by hypothesis, $\mathcal{I}$ is family reflective, we get $\bigcap_{T \in \mathcal{T}} T \leq T'$. Thus, $\mathcal{I}$ is family completely reflective.

(c)⇒(d) Suppose that $\mathcal{I}$ is family completely reflective. By Proposition 243, it is family reflective, and, then, by Proposition 228, it is right injective.

(d)⇒(a) Suppose, finally, that $\mathcal{I}$ is right injective. Then, by Proposition 208, it is family injective.

■

Theorem 288 shows that four of the classes in the previous diagram coincide.

Corollary 289 *The classes of WFI, WRI, WFR and WFC algebraizable π-institutions coincide.*

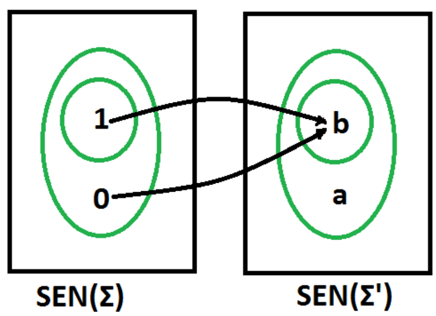
Given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$, we use the term **weakly family algebraizable** (ot **WF algebraizable** for short) for $\mathcal{I}$ if it is protoalgebraic and family injective (or, equivalently, right injective or family reflective or family completely reflective), i.e., if the Leibniz operator is monotone and injective on theory families: For all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\begin{array}{rcl} T \leq T' & \text{implies} & \Omega(T) \leq \Omega(T'); \\ \Omega(T) = \Omega(T') & \text{implies} & T = T'. \end{array}$$

We revisit a previously constructed example to give a WF algebraizable π-institution. Note that the π-institution in question is systemic. As we will see in Theorem 291, this is no coincidence!

Example 290 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = b = \mathrm{SEN}^\flat(f)(1)$*;*
- $N^\flat$ *is the trivial clone.*

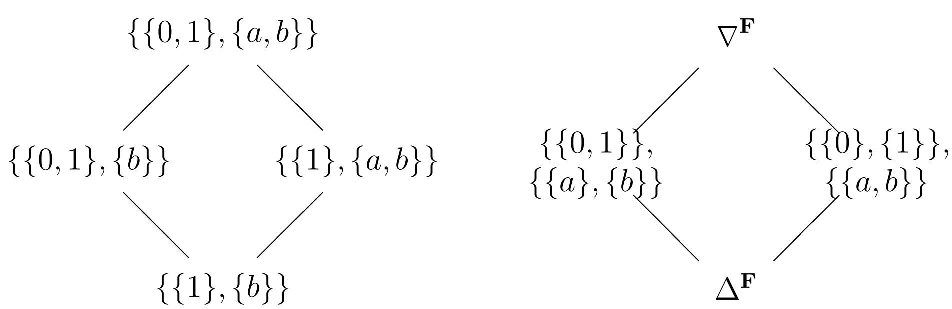


Specify the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

Notice that every theory family is a theory system, whence $\mathcal{I}$ *is systemic.*

The following diagrams show the lattices of theory families and of the corresponding Leibniz congruence systems:



$\mathcal{I}$ *is protoalgebraic and family injective. Therefore, it is a WF algebraizable* π*-institution.*

We show that a π-institution that is WF algebraizable is necessarily systemic.

Theorem 291 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is WF algebraizable, then it is systemic.*

Proof: Suppose that $\mathcal{I}$ is WF algebraizable. Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, by Proposition 42, $T, \overleftarrow{T} \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{T} \leq T$. Thus, by protoalgebraicity, we get $\Omega(\overleftarrow{T}) \leq \Omega(T)$. But, by Proposition 20, it is always the case that $\Omega(T) \leq \Omega(\overleftarrow{T})$. Therefore, we have $\Omega(\overleftarrow{T}) = \Omega(T)$. Thus, by family injectivity, we conclude that $\overleftarrow{T} = T$. Therefore $T \in \mathrm{ThSys}(\mathcal{I})$. We conclude that $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ and, hence, $\mathcal{I}$ is systemic. ■

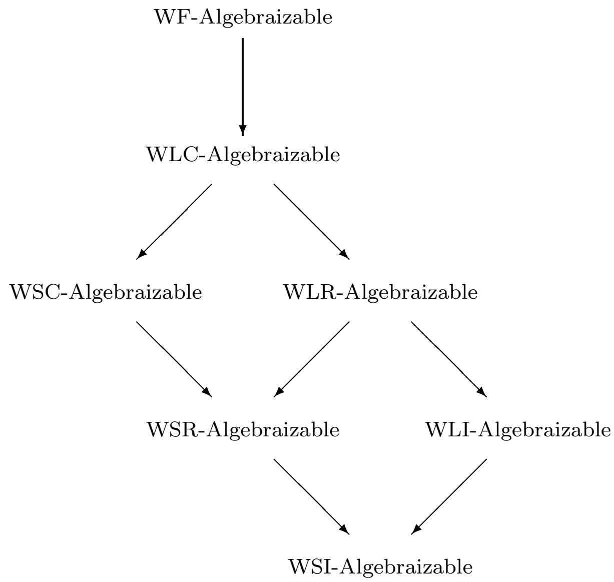
An interesting consequence of Theorem 291 is an exact characterization of those WS prealgebraizable π-institutions that are WF algebraizable.

Corollary 292 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then* $\mathcal{I}$ *is WF algebraizable if and only if it is WS prealgebraizable and systemic.*

Proof: Suppose $\mathcal{I}$ is WF algebraizable. Then, by Theorem 291, it is systemic. Moreover, by definition, its Leibniz operator is monotone and injective on theory families. Thus, it is also monotone and injective on theory systems. So $\mathcal{I}$ is WS prealgebraizable.

Suppose conversely, that $\mathcal{I}$ is WS prealgebraizable and systemic. Then, by definition, its Leibniz operator is monotone and injective on theory systems. But, by systemicity, the collection of theory systems coincides with the collection of theory families. Therefore, the Leibniz operator is monotone and injective on theory families. It follows, by definition, that $\mathcal{I}$ is WF algebraizable. ■

We pause to give an updated version of the hierarchical diagram regarding weak algebraizability classes:



We present examples to show that the class of weakly family algebraizable π-institutions is properly included in both the class of protoalgebraic and that of family completely reflective π-institutions.

Example 293 *Consider the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *defined as follows:*

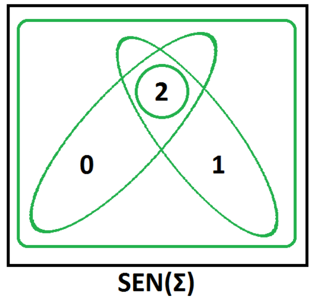
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the clone of natural transformations on* $\mathrm{SEN}^\flat$ *generated by the the two unary natural transformations* $\sigma^\flat, \tau^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *given by the following table:*

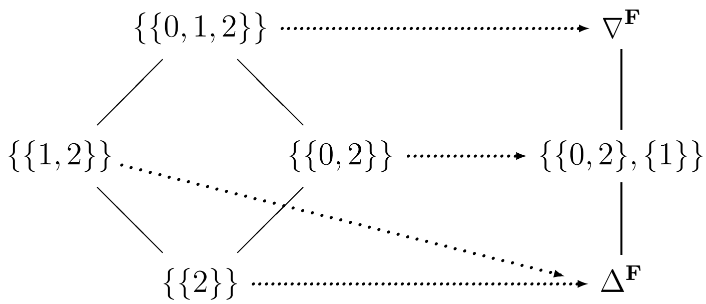
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$
0	0	0
1	1	2
2	0	2

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$*, by setting*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

The lattice of theory families of $\mathcal{I}$ *and the associated Leibniz congruence systems are shown in the diagram.*

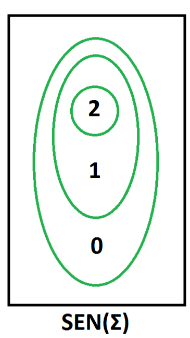




The Leibniz operator is monotone, but not injective on theory families. Therefore, we conclude that $\mathcal{I}$ is protoalgebraic but that it fails to be WF algebraizable.

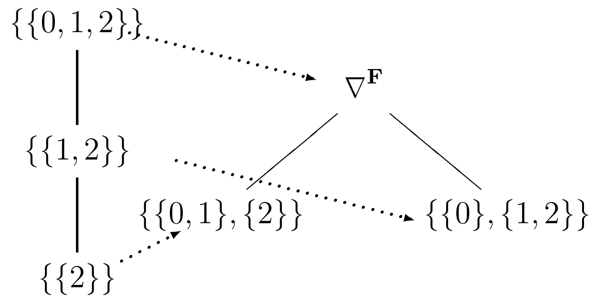
Example 294 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The lattice of theory families and the associated Leibniz congruence systems (in block form) are shown in the diagram.



It is clear from these that the Leibniz operator is completely order reflecting on the theory families of $\mathcal{I}$, but it is not monotone. It follows that $\mathcal{I}$ is family completely reflective but not protoalgebraic. Therefore, $\mathcal{I}$ is family completely reflective, but fails to be WF algebraizable.

The properties defining weak family algebraizability transfer from theory families to filter families over arbitrary algebraic systems.

Theorem 295 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WF algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the Leibniz operator on* $\mathcal{A}$ *is monotone and injective on* $\mathcal{I}$*-filter families, i.e., for all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\begin{array}{rcl} T \leq T' & \textit{implies} & \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'); \\ \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T') & \textit{implies} & T = T'. \end{array}$$

Proof: Suppose, first, that the displayed implications hold for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $\mathcal{I}$-filter families T, T' on $\mathcal{A}$. By taking $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and keeping in mind Lemma 51, we conclude that the Leibniz operator is monotone and injective on all theory families of $\mathcal{I}$. Thus, by definition, $\mathcal{I}$ is WF algebraizable.

Suppose, conversely, that $\mathcal{I}$ is WF algebraizable. Then, by Theorem 288, it is protoalgebraic and family completely reflective. Thus, by Theorems 179 and 240, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator $\Omega^{\mathcal{A}}$ is monotone and completely order reflecting on the $\mathcal{I}$-filter families of $\mathcal{A}$. Thus, by Propositions 243 and 228, the Leibniz operator is monotone and injective on the $\mathcal{I}$-filter families of $\mathcal{A}$. ■

We showed in Theorem 256 that WS prealgebraizability is equivalent to the Leibniz operator $\Omega^{\mathcal{A}}$ over an arbitrary $\mathbf{F}$-algebraic system $\mathcal{A}$ establishing an order embedding from the lattice of $\mathcal{I}$-filter systems on $\mathcal{A}$ into the poset of all $\mathrm{AlgSys}^*(\mathcal{I})$-congruence systems on $\mathcal{A}$. We show, next, that WF algebraizability has a similar characterization. Namely, it can be characterized by the fact that the Leibniz operator $\Omega^{\mathcal{A}}$ over an arbitrary **F**-algebraic system $\mathcal{A}$ establishes an order isomorphism from the lattice of $\mathcal{I}$-filter families of $\mathcal{A}$ into the lattice of all $\mathrm{AlgSys}^*(\mathcal{I})$-congruence systems on $\mathcal{A}$.

Recall the function

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that we have introduced before Theorem 256, that restricts to a well-defined function from $\mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ into $\mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$.

Theorem 296 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WF algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Suppose, first, that, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is an order isomorphism. Then, by Theorem 268, $\mathcal{I}$ is WFR prealgebraizable. To show that it is WF algebraizable, it suffices, by Corollary 292, to show that it is systemic. But, by Theorem 261, every WFR prealgebraizable π-institution is systemic.

Suppose, conversely, that $\mathcal{I}$ is WF algebraizable. Then it is, a fortiori, WFR prealgebraizable. Therefore, by Theorem 268, for every **F**-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. ∎

We now have the following corollary to the effect that the classes of WF algebraizable π-institutions and of WFR prealgebraizable π-institutions coincide.

Corollary 297 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WF algebraizable if and only if it is WFR prealgebraizable.*

Proof: By Theorems 268 and 296, membership in each of these two classes is characterized by $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ being an order isomorphism, for every **F**-algebraic system $\mathcal{A}$. ∎

In light of Corollary 297, we shall call both the class of WF algebraizable π-institutions and the class of WFR prealgebraizable π-institutions by the term **weakly family algebraizable** or **WF algebraizable**, for short.

We now work towards a sweeping contraction of the classes appearing in the weak algebraizability hierarchy. To accomplish this, we provide, first, a characterization of the class of WSI algebraizable π-institutions. Namely, we show that a π-institution is WSI algebraizable if and only if it is stable and $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism, for all **F**-algebraic systems $\mathcal{A}$.

Theorem 298 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is WSI algebraizable if and only if* $\mathcal{I}$ *is stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Suppose, first, that $\mathcal{I}$ is WSI algebraizable. Then it is, by definition, protoalgebraic and, hence, by Lemma 170, it is stable. Also, it is, a fortiori, WS prealgebraizable. Thus, by Theorem 256, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding. So it suffices to show that $\Omega^{\mathcal{A}}$ on $\mathcal{I}$-filter systems on $\mathcal{A}$ is surjective. To this end, consider $\theta \in \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Then $\mathcal{A}^\theta \in \mathrm{AlgSys}^*(\mathcal{I})$. Thus, there exists $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)$, such that $\Omega^{\mathcal{A}^\theta}(T) = \Delta^{\mathcal{A}^\theta}$. Applying the inverse of $\langle I, \pi^\theta \rangle : \mathcal{A} \to \mathcal{A}^\theta$, we get $\pi^{\theta^{-1}}(\Omega^{\mathcal{A}^\theta}(T)) = \pi^{\theta^{-1}}(\Delta^{\mathcal{A}^\theta})$. So, by Proposition 24, $\Omega^{\mathcal{A}}(\pi^{\theta^{-1}}(T)) = \theta$. By stability and Theorem 154, we get that $\Omega^{\mathcal{A}}(\overleftarrow{\pi^{\theta^{-1}}(T)}) = \theta$. Hence, by Lemma 6, $\Omega^{\mathcal{A}}(\pi^{\theta^{-1}}(\overleftarrow{T})) = \theta$. Now, by Proposition 53 and Lemma 51, $\pi^{\theta^{-1}}(\overleftarrow{T}) \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is surjective, as was to be shown.

Suppose, conversely, that $\mathcal{I}$ is stable and for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. In particular, we have that $\Omega : \mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an order isomorphism. This yields immediately that the Leibniz operator is injective on theory systems and, hence $\mathcal{I}$ is system injective. The isomorphism also yields that the Leibniz operator is monotone on theory systems, i.e., that $\mathcal{I}$ is prealgebraic. So it suffices to show that it is monotone on all theory families. To this end, let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$. Thus, taking into account Proposition 42, by prealgebraicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Now using the postulated stability of $\mathcal{I}$, we get $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is protoalgebraic. ■

Using this characterization of WSI algebraizable π-institutions, we now show that the class of WSI algebraizable π-institutions and that of WLC algebraizable π-institutions coincide. This causes a collapse of both squares of the diagram describing the weak algebraizability hierarchy (i.e., of all six bottom classes) into a single class.

Theorem 299 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is WSI algebraizable, then it is WLC algebraizable.*

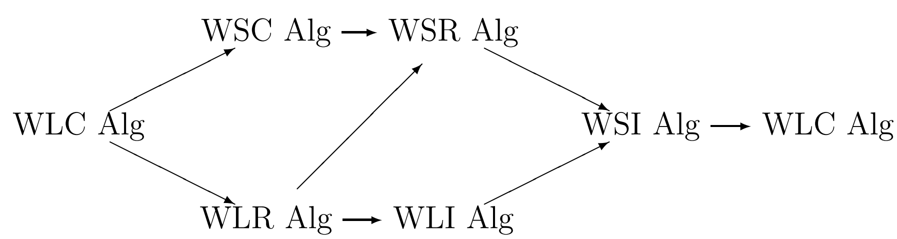
Proof: Suppose $\mathcal{I}$ is WSI algebraizable. Then it is, by definition, protoalgebraic. Moreover, by Theorem 298, it is stable and, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. To see that it is WLC algebraizable, it suffices to show that it is left completely reflective. So consider $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. By protoalgebraicity, we get $\bigcap_{T \in \mathcal{T}} \Omega(T) = \Omega(\bigcap_{T \in \mathcal{T}} T)$. Thus, $\Omega(\bigcap_{T \in \mathcal{T}} T) \leq \Omega(T')$. By stability, $\Omega(\overleftarrow{\bigcap_{T \in \mathcal{T}} T}) \leq \Omega(\overleftarrow{T'})$. By Proposition 42 and the hypothesis, $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \overleftarrow{T'}$. By Lemma 3, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. We conclude that the Leibniz operator is left completely order reflecting on theory families and, therefore, $\mathcal{I}$ is WLC algebraizable. ∎

Corollary 300 *The classes of WLC, WSC, WLR, WSR, WLI and WSI algebraizable π-institutions coincide.*

Proof: According to Theorem 299 and because of the hierarchy of the defining properties, we get the following diagram, where the arrows denote inclusions.



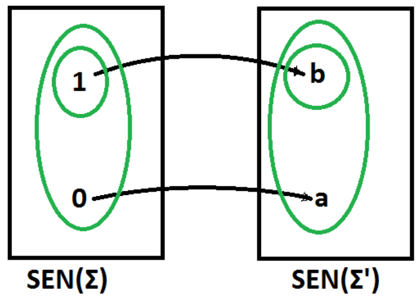
The conclusion readily follows. ∎

Because of Corollary 300, we shall call a π-institution belonging to any of these six classes **weakly** (**system**) **algebraizable**, or **W algebraizable** (sometimes **WS algebraizable**) for short.

We revisit an example showing that the inclusion of the class of WF algebraizable π-institutions into the class of WS algebraizable π-institutions is proper.

Example 301 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



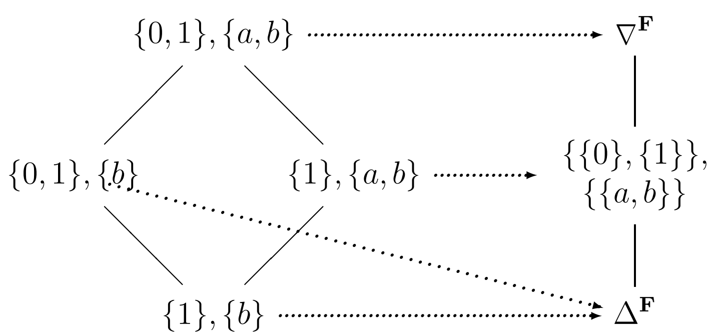
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a,b\}\}.$$

The table yielding the action of $\overleftarrow{\ }$ *on theory families is shown below.*

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The accompanying diagram gives the structure of the lattice of theory families and the corresponding Leibniz congruence systems.



From the diagram one can check that the Leibniz operator is monotone on theory families and left injective on theory families (or injective on theory systems). Thus, the π*-institution is protoalgebraic and system injective, i.e., WS algebraizable. On the other hand,* $\mathcal{I}$ *is, obviously, not family injective and, therefore, it is not WF algebraizable.*

As with other classes in the hierarchy, we have a number of transfer theorems for weakly algebraizable π-institutions. We choose here to formalize the result by providing the two most powerful implications:

Theorem 302 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then the following statements are equivalent:*

(a) *$\mathcal{I}$ is weakly system algebraizable;*

(b) *For every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator on $\mathcal{A}$ is monotone and left completely order reflecting on $\mathcal{I}$-filter families, i.e., for all $\mathcal{T} \cup \{T, T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\begin{array}{rcl} T \leq T' & \textit{implies} & \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T'); \\ \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') & \textit{implies} & \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}. \end{array}$$

(c) *For every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter families and injective on $\mathcal{I}$-filter systems.*

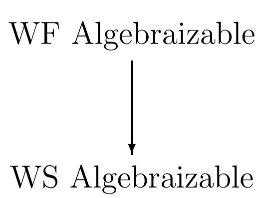
Proof:

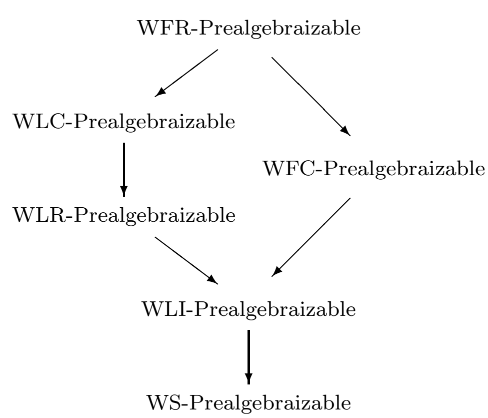
(a)⇒(b) Suppose that $\mathcal{I}$ is weakly system algebraizable. Then, by Theorem 300, it is protoalgebraic and family completely reflective. Thus, by Theorems 179 and 240, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator $\Omega^{\mathcal{A}}$ is monotone and left completely order reflecting on $\mathcal{I}$-filter families.

(b)⇒(c) Let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system. By hypothesis, the Leibniz operator is monotone and left completely order reflecting on the $\mathcal{I}$-filter families of $\mathcal{A}$. By Propositions 243 and 228, the Leibniz operator is monotone on the $\mathcal{I}$-filter families and injective on the $\mathcal{I}$-filter systems of $\mathcal{A}$.

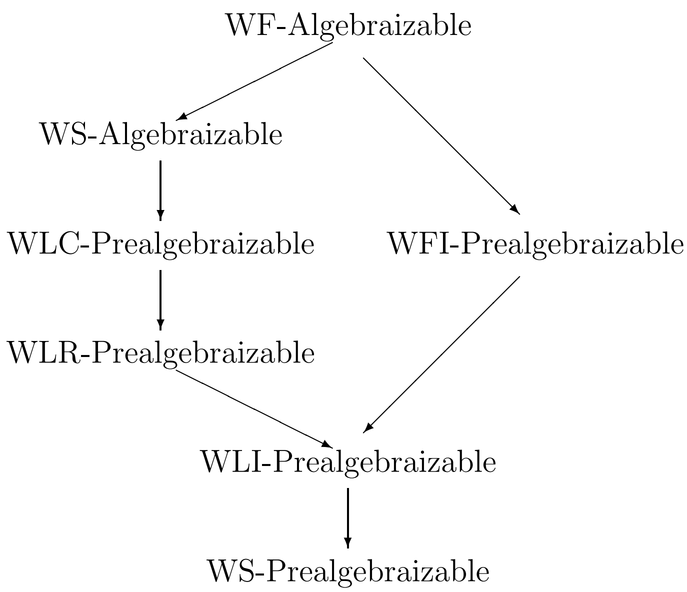
(c)⇒(a) Suppose that, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the Leibniz operator is monotone on the $\mathcal{I}$-filter families and injective on the $\mathcal{I}$-filter systems of $\mathcal{A}$. By taking $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and keeping in mind Lemma 51, we conclude that the Leibniz operator is monotone on all theory families and injective on all theory systems of $\mathcal{I}$. Thus, by definition, $\mathcal{I}$ is weakly system algebraizable. ∎

We are left now with a weak algebraizability hierarchy consisting of only two classes as shown on the left below. On the right is reprinted the weak prealgebraizability hierarchy, as revealed in the previous section.





Recalling that, by Corollary 297, the classes of WF algebraizable π-institutions and WFR prealgebraizable π-institutions coincide and noting that the class of weakly algebraizable π-institutions (coinciding with WLC algebraizable π-institutions) is included in the class of WLC prealgebraizable π-institutions, we get the following complete picture of weak (pre)algebraizability.



We close with an example that shows that the class of weakly system algebraizable π-institutions is properly contained in the class of WLC prealgebraizable π-institutions.

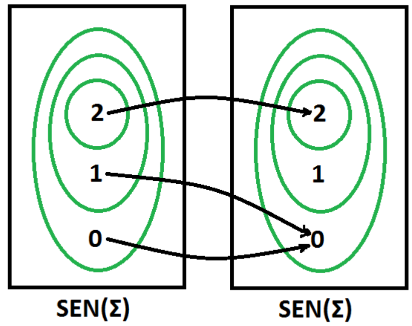
Example 303 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

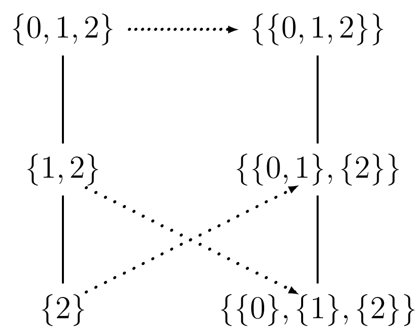
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$



The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ is prealgebraic, but not protoalgebraic. Moreover, it is left completely reflective. Thus, it is WLC prealgebraizable but not WS algebraizable.

Chapter 5

The Semantic Leibniz Hierarchy: Extensionality

5.1 Introduction

Protoalgebraic sentential logics were introduced by Czelakowski in [26, 29] and studied by Blok and Pigozzi [28]. Perhaps the best known among several existing characterizations of protoalgebraicity is the property of monotonicity of the Leibniz operator on the filters of a logic over arbitrary algebras (of the same algebraic type). Equivalential logics were introduced by Prucnal and Wroński [19] and studied by Czelakowski [22, 24]. A Leibniz characterization asserts that a sentential logic is equivalential iff, for every algebra, the Leibniz operator on its filters is monotone and commutes with inverse endomorphisms. More details may be found in Section 3.4 of [69], Sections 6.1-6.3 of [86] and Chapters 1-3 of [64]. In addition, whereas protoalgebraicity, in conjunction with injectivity of the Leibniz operator, is used to define weakly algebraizable logics [62], the stronger condition of equivalentiality, coupled with injectivity of the Leibniz operator, is used to define algebraizable logics [35, 54]. Section 3.4 of [69], Sections 6.4 and 6.5 of [86] and Chapter 4 of [64] provide detailed information about these classes of sentential logics.

In Section 3.3, we studied classes of π-institutions defined using monotonicity properties of the Leibniz operator. In Chapter 4, we used monotonicity to define the weak algebraizability hierarchy of π-institutions. The present chapter introduces analogs of the property of equivalentiality for π-institutions, strengthening monotonicity. Further, by replacing monotonicity by equivalentiality, one obtains from the weak algebraizability hierarchy the hierarchy of algebraizable π-institutions.

Strengthening protoalgebraicity to equivalentiality involves adding, on top of monotonicity properties, some property that emulates (or forms an analog of) the property of commutativity of the Leibniz operator with inverse endomorphisms. This desideratum informs the structure of the current chapter. In Sections 5.2 and 5.3, properties that can be used as analogs of commutativity with inverse endomorphisms in the framework of π-institutions are discussed and some of their interrelationships are explored. These are combined with monotonicity in Section 5.4 to define equivalentiality. Finally, in Sections 5.5 and 5.6, we obtain the (pre)algebraizability hierarchy of π-institutions, based on the weak (pre)algebraizability hierarchy, studied in Chapter 4. More details, by section, follow.

In Section 5.2, we study *extensionality*. Recall that, given an algebraic system $\mathbf{F}$ and a sentence family X of $\mathbf{F}$, one may determine the subsystem $\langle X\rangle$ of $\mathbf{F}$ generated by X. Moreover, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ and a subsystem $\mathbf{F}'$ of $\mathbf{F}$, $\mathbf{F}'$ determines a π-subinstitution $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ of $\mathcal{I}$ which is obtained by restricting the action of C on $\mathbf{F}'$. For details on these constructions, see Section 2.12. A π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is said to be *family extensional* if, roughly speaking, the action of the Leibniz operator on theory families of subinstitutions can be obtained as the restriction of the Leibniz operator of $\mathcal{I}$ on the universe corresponding to the subinstitution. More precisely, $\mathcal{I}$ is *family extensional* if, for every sentence family X of $\mathbf{F}$ and every theory family T of $\mathcal{I}$, $\Omega^{\langle X\rangle}(T \cap \langle X\rangle) = \Omega(T) \cap \langle X\rangle^2$. *System extensionality* is defined similarly, except that T is allowed to range over theory systems only, instead of over arbitrary theory families. By definition, family extensionality implies system extensionality. Further, system extensionality, combined with stability, implies family extensionality. The significance of extensionality stems, in part, from allowing important properties of a π-institution to be inherited by its subinstitutions. Indicative of this phenomenon are the facts that, under system extensionality, stability in inherited and, under family (system, respectively) extensionality, prealgebraicity (protoalgebraicity, respectively) is also inherited. Both versions of extensionality transfer. A seemingly weaker version of extensionality is *2-extensionality*. Roughly speaking, 2-extensionality is extensionality restricted to universes generated by two sentences over the same signature. More precisely, a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is *family 2-extensional* if, for every signature Σ, all Σ-sentences ϕ, ψ and every theory family T, $\langle \phi, \psi\rangle \in \Omega_\Sigma(T)$ if and only if $\langle \phi, \psi\rangle \in \Omega_\Sigma^{\langle \phi,\psi\rangle}(T \cap \langle \phi, \psi\rangle)$. If T is quantified over theory systems, *system 2-extensionality* is obtained instead. Despite its apparent weakness in comparison to extensionality, it turns out that a π-institution is family/system extensional if and only if it is family/system 2-extensional, respectively. Extensionality is one manifestation of the property that is used as an analog of commutativity with inverse endomorphisms, employed in the sentential framework to define equivalentiality. An alternative formalization, closer in spirit to commutativity, is introduced in Section 5.3.

In Section 5.3, we study *Leibniz commutativity* or, simply, *commutativity*, a property closer in spirit to the original property used in the sentential context to characterize equivalentiality. Let $\mathbf{F}$ be an algebraic system and X a sentence family of $\mathbf{F}$. Recall the subsystem $\langle X\rangle$ of $\mathbf{F}$ generated by X. A morphism of the form $\langle I, \alpha\rangle : \langle X\rangle \to \mathbf{F}$, where I is the identity functor on signatures, is called an *extension*. Recall also that, if $\mathbf{F}$ happens to be the base algebraic system of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, then X induces a π-subinstitution $\mathcal{I}^{\langle X\rangle} = \langle \langle X\rangle, C^{\langle X\rangle}\rangle$ of $\mathcal{I}$ based on $\langle X\rangle$, whose closure system is essentially C restricted on $\langle X\rangle$ and whose theory families are obtained by the theory families of $\mathcal{I}$ via restriction on $\langle X\rangle$. In this enriched context, an extension $\langle I, \alpha\rangle : \langle X\rangle \to \mathbf{F}$ is called *logical*, denoted by $\langle I, \alpha\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$, if it preserves the closure structure in the sense that, for all signatures Σ and all $\Phi \subseteq \langle X\rangle_\Sigma$, $\alpha_\Sigma(C_\Sigma^{\langle X\rangle}(\Phi)) \subseteq C_\Sigma(\alpha_\Sigma(\Phi))$. This condition is tantamount to preservation of theory families under α^{-1}, i.e., to $\alpha^{-1}(T)$ being a theory family of $\mathcal{I}^{\langle X\rangle}$, for every theory family T of $\mathcal{I}$. Logical extensions lay the groundwork for building the notion of (*Leibniz*) *commutativity*. We say that a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is *family commuting* if, for all sentence families X of $\mathbf{F}$, all logical extensions $\langle I, \alpha\rangle : \mathcal{I}^{\langle X\rangle} \to \mathcal{I}$ and all theory families T' of $\mathcal{I}^{\langle X\rangle}$, $\alpha(\Omega^{\langle X\rangle}(T')) \leq \Omega(C(\alpha(T')))$. *System commutativity* applies the same condition on theory systems only. A similar, but not identical in general, property is *inverse* (*Leibniz*) *commutativity*. $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is *family inverse commuting* if, for every sentence family X, all logical extensions $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ and all theory families T of $\mathcal{I}$, $\alpha^{-1}(\Omega(T)) = \Omega^{\langle X \rangle}(\alpha^{-1}(T))$. *System inverse commutativity* results by quantifying T over theory systems instead. It is elementary to check, based on the definition of $\mathcal{I}^{\langle X \rangle}$, that injection morphisms $\langle I, j \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ qualify as logical extensions. This permits establishing that family (system, repectively) inverse commutativity implies family (system, respectively) extensionality. Also, since theory systems form a subclass of theory families, it is obvious that family inverse commutativity is stronger than the system version. In addition, it is shown that the system version, coupled with stability, implies the family version. The last results of Section 5.3 are critical for our further investigations.

Since commutativity and inverse commutativity are used mainly in conjunction with monotonicity properties to obtain equivalentiality, it is important that, under system (family) monotonicity (i.e., pre- and protoalgebraicity, respectively), system (family, respectively) commutativity and system (family, respectively) inverse commutativity coincide. Further, in a result that allows us to switch between commutativity properties and the extensionality properties of Section 5.2, and which strengthens a previously mentioned implication, it is shown that system (family) inverse commutativity is equivalent to system (family, respectively) extensionality. Based on these equivalences and a transfer theorem from Section 5.2, it is also shown that both versions of inverse commutativity transfer. Summarizing, the corresponding (system or family) versions of extensionality and 2-extensionality and of inverse commutativity are equivalent without proviso. On the other hand, for these three to be equivalent to the corresponding commutativity version, a sufficient condition is that the corresponding version of monotonicity holds.

In Section 5.4, we define versions of *equivalentiality*, resulting by combining monotonicity and extensionality properties. Since both come in two flavors, we get, a priori, four potentially different equivalentiality classes. A π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is (*family*) *equivalential* if it is protoalgebraic and family extensional. Weakening protoalgebraicity to prealgebraicity we get *family preequivalentiality*. On the other hand, weakening family to system extensionality, we get *system equivalentiality*. Finally, if both properties are weakened in tandem, we get (*system*) *preequivalentiality*. Equivalentiality, as opposed to preequivalentiality, incorporates protoalgebraicity, which implies stability. But, under stability, the two versions of extensionality coincide. This reasoning shows that family and system equivalentiality are identical properties. So when referring to this property, we use the term *equivalentiality*, without qualification. It turns out to be equivalent to preequivalentiality plus stability. All three distinct versions transfer. We also obtain characterizations of both equivalentiality and preequivalentiality in terms of the Leibniz operator seeing as a mapping between lattices of filter families (systems) and congruence systems over arbitrary algebraic systems.

In Section 5.5, we explore the hierarchy of *prealgebraizable π-institutions*. Prealgebraizability results from weak prealgebraizability when prealgebraicity is strengthened to either family or system preequivalentiality, i.e., when either family or system extensionality is added into the mix. Accordingly, two parallel hierarchies mimicking that of weakly prealgebraizable π-institutions, detailed in Chapter 4, are formed depending on the version of preequivalentiality used. If family preequivalentiality is postulated, we get the five classes of *XF prealgebraizable π-institutions*, whereas, if (system) preequivalentiality is dictated, we get five corresponding *X prealgebraizability* classes, where X is a string reflecting which injectivity, reflectivity or complete reflectivity condition is coupled with preequivalentiality, i.e., X can be one of:

- LC for left complete reflectivity;
- LR for left reflectivity;
- FI for family injectivity;
- LI for left injectivity; and
- S for system (injectivity, reflectivity and complete reflectivity all being equivalent under preequivalentiality).

Systemicity leads to a total collapse of the ten classes into a single class. Stability results to FIF and FI prealgebraizable π-institutions being identified and to a collapse of all remaining eight classes into a single class. Thus, it yields a 2-class hierarchy. After showing that all ten prealgebraizability properties transfer, the section is dedicated to obtaining characterization theorems for each of the classes in terms of the Leibniz operator on arbitrary algebraic systems perceived as a mapping between ordered sets. The ten characterizations can be divided into five pairs, each pair addressing XF and X prealgebraizability for the same X in {LC, LR, FI, LI, S}. Making a somewhat arbitrary choice here, we look at the cases of LR and S to provide a flavor of these results. The interested reader is, of course, referred to the main text for further details on all ten properties. A π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is LRF prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left order reflecting surjection commuting with inverse logical extensions, which restricts to an order embedding on filter systems. A subtle, but important, change occurs in most pairs in passing from the XF to the X sibling. $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is LR prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left order reflecting surjection, which restricts to an order embedding commuting with inverse logical extensions on filter systems. Along similar lines, we get that $\mathcal{I}$ is SF prealgebraizable iff, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ commutes with inverse logical extensions and restricts to an order embedding on filter systems, whereas $\mathcal{I}$ is S prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding commuting with inverse logical extensions.

In Section 5.6, we examine *algebraizability*. This hierarchy results from weak algebraizability when protoalgebraicity is replaced by equivalentiality. Equivalently, it ensues from prealgebraizability when, instead of imposing family or system preequivalentiality, we insist on the stronger condition of equivalentiality. Exactly due to this strengthening, only two classes may be distinguished here, *family algebraizability*, combining equivalentiality with family injectivity, and (*system*) *algebraizability*, coupling equivalentiality with system injectivity. The family version is equivalent to the system version augmented by systemicity. Both flavors transfer. Finally, a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ is family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions, whereas it is system algebraizable if and only if it is stable and, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions.

5.2 Extensionality

The first two important ingredients in classifying π-institutions according to their algebraic character were:

- the monotonicity properties of the Leibniz operator, which gave rise to the classes of prealgebraic and protoalgebraic π-institutions, as well as the various classes defined using versions of complete monotonicity;
- the various properties involving injectivity and reflectivity, varying from the weakest, system injectivity, to the strongest, family complete reflectivity.

Two additional important properties are the extensionality of the Leibniz operator and the commutativity of the Leibniz operator, which we now introduce and study. The variants studied here will give rise to classes in the equivalential hierarchy of π-institutions and, based on these, in the semantic hierarchy of algebraizable π-institutions (as opposed to *weak* (pre)algebraizability, studied in Chapter 4).

We first define two versions of the extensionality property and two corresponding versions of 2-extensionality, which is an apparently relaxed version of extensionality, but will be shown to be equivalent to extensionality.

Recall from Section 2.12 that, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ and a sentence family $X \in \mathrm{SenFam}(\mathbf{F})$, we denote by $\langle X\rangle = \{\langle X\rangle_\Sigma\}_{\Sigma\in|\mathbf{Sign}^\flat|}$ the universe of $\mathbf{F}$ generated by X, i.e., $\langle X\rangle = \nu(\overrightarrow{X})$.

Definition 304 (Extensionality) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **family extensional** *if, for all* $X \in \mathrm{SenFam}(\mathcal{I})$ *and all* $T \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(T) \cap \langle X \rangle^2 = \Omega^{\langle X \rangle}(T \cap \langle X \rangle);$$
- $\mathcal{I}$ *is called* **system extensional** *if, for all* $X \in \mathrm{SenFam}(\mathcal{I})$ *and all* $T \in \mathrm{ThSys}(\mathcal{I})$,
$$\Omega(T) \cap \langle X \rangle^2 = \Omega^{\langle X \rangle}(T \cap \langle X \rangle).$$

Taking into account Proposition 89, one obtains the following equivalent formulations.

Lemma 305 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family (system) extensional if and only if, for all* $X \in \mathrm{SenFam}(\mathcal{I})$ *and all* $T \in \mathrm{ThFam}(\mathcal{I})$ *(*$T \in \mathrm{ThSys}(\mathcal{I})$*, respectively),*
$$\Omega^{\langle X \rangle}(T \cap \langle X \rangle) \leq \Omega(T) \cap \langle X \rangle^2.$$

Proof: Since, by Proposition 89, for all $X \in \mathrm{SenFam}(\mathcal{I})$ and $T \in \mathrm{ThFam}(\mathcal{I})$, the inclusion
$$\Omega(T) \cap \langle X \rangle^2 \leq \Omega^{\langle X \rangle}(T \cap \langle X \rangle)$$
always holds, we get the statement using the definition. ∎

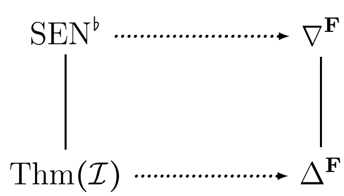
Here is a simple example of a family extensional π-institution.

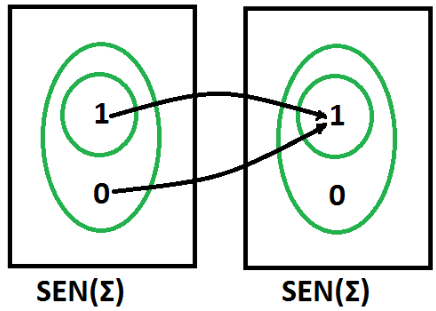
Example 306 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 1$, $\mathrm{SEN}^\flat(f)(1) = 1$*;*
- $N^\flat$ *is the trivial category of natural transformations, consisting of the projections only.*

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution, defined by setting* $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.





Note that the only universes are $\mathrm{Thm}(\mathcal{I}) = \{\{1\}\}$ *and* $\mathrm{SEN}^\flat$. *For the second one,* $\Omega(T) \cap \langle X\rangle^2 = \Omega^{\langle X\rangle}(T \cap \langle X\rangle)$ *holds trivially for all* $T \in \mathrm{ThFam}(\mathcal{I})$, *since both sides boil down to* $\Omega(T)$. *For the first, we have*

$$\Omega^{\mathrm{Thm}(\mathcal{I})}(\mathrm{Thm}(\mathcal{I}) \cap \mathrm{Thm}(\mathcal{I})) = \mathrm{Thm}(\mathcal{I})^2 = \Omega(\mathrm{Thm}(\mathcal{I})) \cap \mathrm{Thm}(\mathcal{I})^2;$$
$$\Omega^{\mathrm{Thm}(\mathcal{I})}(\mathrm{SEN}^\flat \cap \mathrm{Thm}(\mathcal{I})) = \mathrm{Thm}(\mathcal{I})^2 = \Omega(\mathrm{SEN}^\flat) \cap \mathrm{Thm}(\mathcal{I})^2.$$

So $\mathcal{I}$ *is family extensional, that is, for all* $X \in \mathrm{SenFam}(\mathcal{I})$ *and all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \cap \langle X\rangle^2 = \Omega^{\langle X\rangle}(T \cap \langle X\rangle)$.

We present, now, two examples of π-institutions that are not system extensional.

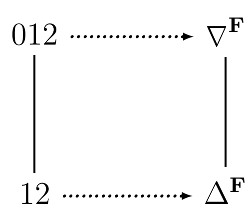
Example 307 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

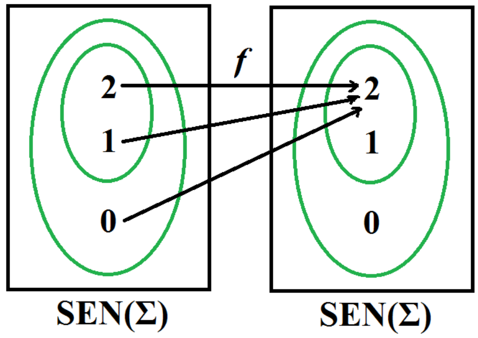
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(x) = 2$, *for all* $x \in \{0, 1, 2\}$;
- $N^\flat$ *is the category of natural transformations generated by the binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following table:*

$\sigma^\flat_\Sigma$	0	1	2
0	0	0	2
1	0	1	1
2	2	1	2

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution defined by setting* $C_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}$.

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.





For the universe $\mathbf{X} = \{\{1,2\}\}$ *and the theory system* $T = \{\{1,2\}\}$*, we get*

$$\Omega(T) \cap \mathbf{X}^2 = \{\{1\},\{2\}\} \subsetneq \{\{1,2\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Therefore, $\mathcal{I}$ *is not system extensional.*

And here is a second example of a non-system extensional π-institution.

Example 308 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the two binary natural transformations* $\wedge : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *and* $\vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following tables:*

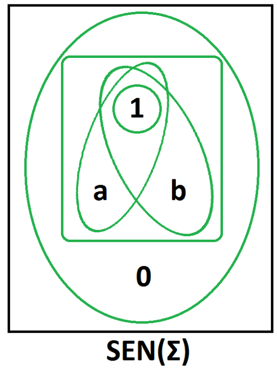
$\wedge$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

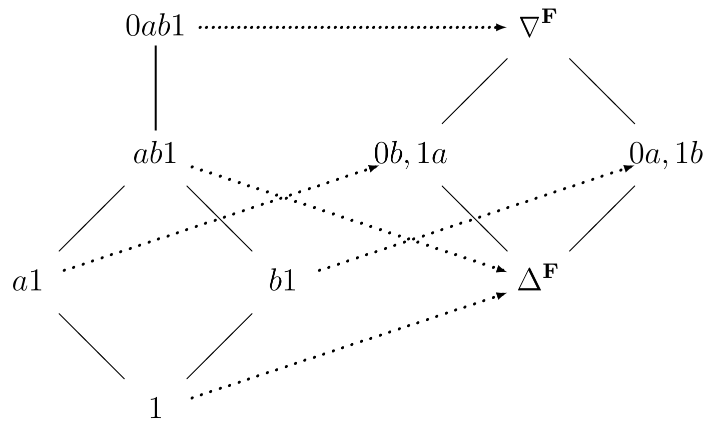
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{1\},\{a,1\},\{b,1\},\{a,b,1\},\{0,a,b,1\}\}.$$

The lattice of theory families and the corresponding Leibniz congruence



systems are shown in the diagram.



For the universe $\mathbf{X} = \{\{0, a, 1\}\}$ *and the theory system* $T = \{\{a, b, 1\}\}$, *we get*

$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\}, \{a\}, \{1\}\} \subsetneqq \{\{0\}, \{a, 1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Therefore, $\mathcal{I}$ *is not system extensional and, a fortiori, not family extensional either.*

The following clarifies the relation between family and system extensionality.

Proposition 309 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) *If* $\mathcal{I}$ *is family extensional, then it is system extensional.*

(b) *If* $\mathcal{I}$ *is system extensional and stable, then it is family extensional.*

Proof:

(a) Since all theory systems are also theory families, it follows that every family extensional π-institution is also system extensional.

(b) Suppose that $\mathcal{I}$ is system extensional and stable. Let $X \in \mathrm{SenFam}(\mathcal{I})$ and $T \in \mathrm{ThFam}(\mathcal{I})$. Then we have

$$\begin{array}{rcll}\Omega^{\langle X\rangle}(T \cap \langle X\rangle) & \leq & \Omega^{\langle X\rangle}(\overleftarrow{T \cap \langle X\rangle}) & \text{(by Proposition 20)}\\ & = & \Omega^{\langle X\rangle}(\overleftarrow{T} \cap \langle X\rangle) & \text{(by Lemma 3)}\\ & = & \Omega(\overleftarrow{T}) \cap \langle X\rangle^2 & \text{(by system extensionality)}\\ & = & \Omega(T) \cap \langle X\rangle^2. & \text{(by stability)}\end{array}$$

By Lemma 305, $\mathcal{I}$ is family extensional.

■

According to Proposition 309 we have the following **extensionality hierarchy**:

Family Extensional

↓

System Extensional

The reverse, however, does not hold in general, as the following example, exhibiting a π-institution which is system but not family extensional, shows.

Example 310 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

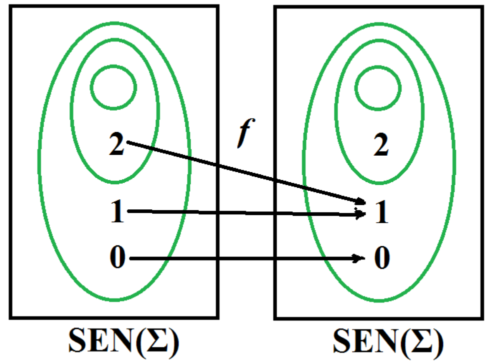
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 1$ *and* $\mathrm{SEN}^\flat(f)(2) = 1$;
- $N^\flat$ *is the category of natural transformations generated by the binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following table:*

$\sigma^\flat_\Sigma$	0	1	2
0	1	1	2
1	1	1	1
2	2	1	2

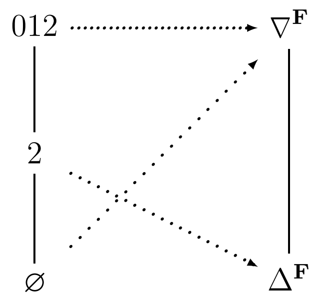
Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has three theory families,* $\overline{\varnothing}$, $T = \{\{2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only* $\overline{\varnothing}$ *and* $\mathrm{SEN}^\flat$ *are theory systems. The lattice of theory families and the corresponding*



Leibniz congruence systems are shown in the diagram.



Moreover, $\mathbf{F}$ *has five universes* $\{\{0\}\}$, $\{\{1\}\}$, $\{\{0,1\}\}$, $\{\{1,2\}\}$ *and* $\{\{0,1,2\}\}$. *Since the only theory systems of* $\mathcal{I}$ *are* $\overline{\varnothing}$ *and* $\mathrm{SEN}^\flat$, *it is trivial to check that* $\mathcal{I}$ *is system extensional.*

For the universe $\mathbf{X} = \{\{0,1\}\}$ *and the theory family* $T = \{\{2\}\}$, *we get*

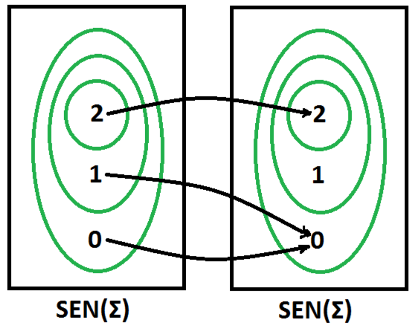
$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\},\{1\}\} \subsetneq \{\{0,1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Therefore, $\mathcal{I}$ *is not family extensional.*

Moreover, as the following example shows, the converse of Part (b) of Proposition 309 does not hold in general, i.e., stability is not necessary for family extensionality.

Example 311 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

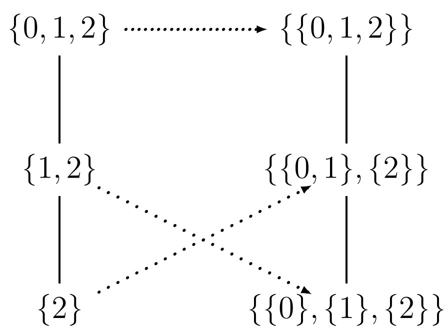
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

$\mathcal{I}$ has three theory families, $\mathrm{Thm}(\mathcal{I})$*,* $T = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$*, but only* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



It is not difficult to check that $\mathcal{I}$ is family extensional, that is, for all $X \in$ $\mathrm{SenFam}(\mathcal{I})$ *and all $T \in$* $\mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) \cap \langle X \rangle^2 = \Omega^{\langle X \rangle}(T \cap \langle X \rangle).$$

In fact, $\mathbf{F}$ has five universes $\{\{0\}\}$, $\{\{2\}\}$, $\{\{0,1\}\}$, $\{\{0,2\}\}$ and $\{\{0,1,2\}\}$, only two of which are proper and non-singletons. $\mathcal{I}$ has three theory families, two of which are different from $\mathrm{SEN}^\flat$*. Thus, there are only four cases to check, shown below, adopting, for brevity, an obvious shorthand notation.*

$$\begin{aligned}
&\Omega(2) \cap (01)^2 = \{\{0,1\}\} = \Omega^{01}(2 \cap 01),\\
&\Omega(12) \cap (01)^2 = \{\{0\},\{1\}\} = \Omega^{01}(12 \cap 01),\\
&\Omega(2) \cap (02)^2 = \{\{0\},\{2\}\} = \Omega^{02}(2 \cap 02),\\
&\Omega(12) \cap (02)^2 = \{\{0\},\{2\}\} = \Omega^{02}(12 \cap 02).
\end{aligned}$$

Clearly, since for $T \in$ $\mathrm{ThFam}(\mathcal{I}) \backslash \mathrm{ThSys}(\mathcal{I})$*,*

$$\Omega(T) = \Delta^{\mathbf{F}} \neq \{\{0,1\},\{2\}\} = \Omega(\mathrm{Thm}(\mathcal{I})) = \Omega(\overleftarrow{T}),$$

$\mathcal{I}$ is not stable.

A related result is that, under system extensionality, stability is inherited by π-subinstitutions of a given π-institution.

Proposition 312 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a system extensional* π*-institution based on* $\mathbf{F}$ *and* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat\rangle \leq \mathbf{F}$ *an algebraic subsystem of* $\mathbf{F}$*. If* $\mathcal{I}$ *is stable, then* $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ *is also stable.*

Proof: Suppose that $\mathcal{I}$ is system extensional and stable. Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then we have

$$\begin{array}{rcll}\Omega^{\mathbf{F}'}(\overleftarrow{T \cap \mathrm{SEN}'^\flat}) & = & \Omega^{\mathbf{F}'}(\overleftarrow{T} \cap \mathrm{SEN}'^\flat) & \text{(by Lemma 3)}\\ & = & \Omega^{\mathbf{F}}(\overleftarrow{T}) \cap (\mathrm{SEN}'^\flat)^2 & \text{(by system extensionality)}\\ & = & \Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^\flat)^2 & \text{(by stability)}\\ & \leq & \Omega^{\mathbf{F}'}(T \cap \mathrm{SEN}'^\flat). & \text{(by Proposition 89)}\end{array}$$

Since, by Proposition 20, the reverse inclusion always holds, we conclude that $\mathcal{I}'$ is also stable. ∎

A similar preservation result, under extensionality, may also be proven with regards to pre- and protoalgebraicity. More precisely, we show that if a π-institution is family extensional and protoalgebraic, then all its π-subinstitutions are also protoalgebraic. Analogously, if a π-institution is system extensional and prealgebraic, then prealgebraicity is inherited by all its π-subinstitutions.

Proposition 313 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family extensional and protoalgebraic, then, for all* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat\rangle \leq \mathbf{F}$*,* $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ *is also protoalgebraic;*

(b) If $\mathcal{I}$ *is system extensional and prealgebraic, then, for all* $\mathbf{F}' = \langle \mathbf{Sign}^\flat, \mathrm{SEN}'^\flat, N'^\flat\rangle \leq \mathbf{F}$*,* $\mathcal{I}' = \langle \mathbf{F}', C'\rangle$ *is also prealgebraic.*

Proof: We only prove Part (a). Part (b) may be proven similarly. Suppose that $\mathcal{I}$ is family extensional and protoalgebraic and let $\mathbf{F}' \leq \mathbf{F}$. If $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$, then, by protoalgebraicity, $\Omega^{\mathbf{F}}(T) \leq \Omega^{\mathbf{F}}(T')$. Thus, $\Omega^{\mathbf{F}}(T) \cap (\mathrm{SEN}'^\flat)^2 \leq \Omega^{\mathbf{F}}(T') \cap (\mathrm{SEN}'^\flat)^2$. Therefore, by family extensionality, $\Omega^{\mathbf{F}'}(T \cap \mathrm{SEN}'^\flat) \leq \Omega^{\mathbf{F}'}(T' \cap \mathrm{SEN}'^\flat)$. By Proposition 87, we conclude that $\mathcal{I}'$ is also protoalgebraic. ∎

There are transfer theorems that hold for both system and family extensionality.

Theorem 314 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family (system) extensional if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $Y \in \mathrm{SenFam}(\mathcal{A})$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *(*$T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, respectively)*

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

Proof: We present the proof for theory families. The case of theory systems is similar.

The "if" direction follows by taking $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and observing that, in that case, the displayed condition reduces to the definition of family extensionality.

For the "only if", assume that $\mathcal{I}$ is family extensional and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $Y \in \mathrm{SenFam}(\mathcal{A})$, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega^{\langle Y \rangle}_{F(\Sigma)}(T \cap \langle Y \rangle).$$

Then we have

$$\begin{array}{lll}
\langle \phi, \psi \rangle & \in & \alpha_\Sigma^{-1}(\Omega^{\langle Y \rangle}_{F(\Sigma)}(T \cap \langle Y \rangle)) \quad \text{(set theory)} \\
& = & \Omega_\Sigma^{\alpha^{-1}(\langle Y \rangle)}(\alpha^{-1}(T) \cap \alpha^{-1}(\langle Y \rangle)) \quad \text{(Corollary 92)} \\
& = & \Omega_\Sigma(\alpha^{-1}(T)) \cap \alpha_\Sigma^{-1}(\langle Y \rangle_{F(\Sigma)})^2 \quad \text{(hypothesis)} \\
& = & \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T)) \cap \alpha_\Sigma^{-1}(\langle Y \rangle_{F(\Sigma)})^2 \quad \text{(Proposition 24)} \\
& = & \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T) \cap \langle Y \rangle^2_{F(\Sigma)}). \quad \text{(set theory)}
\end{array}$$

Therefore $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T) \cap \langle Y \rangle^2_{F(\Sigma)}$. Since, by Proposition 89, the opposite inclusion always holds, we get, taking into account the surjectivity of $\langle F, \alpha \rangle$, that

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

The conclusion now follows. ∎

We define, next, the second property, a seemingly relaxed version of extensionality that we call 2-extensionality.

Definition 315 (2-Extensionality) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **family 2-extensional** *if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \textit{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle);$$

- $\mathcal{I}$ *is called* **system 2-extensional** *if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \textit{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle).$$

Taking into account Proposition 89, one obtains the following equivalent formulations.

Lemma 316 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family (system) 2-extensional if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *(*$T \in \mathrm{ThSys}(\mathcal{I})$*, respectively), all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle) \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

Proof: By Proposition 89, for all $T \in \mathrm{ThFam}(\mathcal{I})$, the inclusion

$$\Omega(T) \cap \langle \phi, \psi \rangle^2 \leq \Omega^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle)$$

always holds. Since $\phi, \psi \in \langle \phi, \psi \rangle_\Sigma$, if $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, then $\langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle)$.

Thus, 2-extensionality is, by definition, equivalent to

$$\langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle) \quad \text{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

■

It turns out that the corresponding versions of extensionality and 2-extensionality are equivalent. That extensionality implies 2-extensionality is fairly straightforward.

Proposition 317 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family (system) extensional, then it is family (system, respectively) 2-extensional.*

Proof: We present the proof for theory families. The case of theory systems is similar. Suppose $\mathcal{I}$ is family extensional and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle)$. Then, by family extensionality, we get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \cap \langle \phi, \psi \rangle_\Sigma^2$, which implies that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Thus, by Lemma 316, $\mathcal{I}$ is family 2-extensional. ■

The full equivalence is given in the following

Theorem 318 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family (system) extensional if and only if it is family (system, respectively) 2-extensional.*

Proof: Again we prove only the equivalence of the family versions of the two properties, since the system versions can be proven similarly.

The "only if" was the content of Proposition 317. For the "if", suppose that $\mathcal{I}$ is family 2-extensional and let $X \in \mathrm{SenFam}(\mathcal{I})$, $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \notin \Omega_\Sigma(T) \cap \langle X \rangle_\Sigma^2$.

If $\langle \phi, \psi \rangle \notin \langle X \rangle_\Sigma^2$, then, a fortiori, $\langle \phi, \psi \rangle \notin \Omega_\Sigma^{\langle X \rangle}(T \cap \langle X \rangle)$, and we are done.

If, on the other hand, $\langle\phi,\psi\rangle\in\langle X\rangle_\Sigma^2$, then, we have $\langle\phi,\psi\rangle\notin\Omega_\Sigma(T)$. Thus, by hypothesis, $\langle\phi,\psi\rangle\notin\Omega_\Sigma^{\langle\phi,\psi\rangle}(T\cap\langle\phi,\psi\rangle)$. So, by Theorem 19, there exist $\sigma^\flat\in N^\flat$, $\Sigma'\in|\mathbf{Sign}^\flat|$, $f\in\mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi}\in\langle\phi,\psi\rangle_{\Sigma'}$, such that (without loss of generality)

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})\in T_{\Sigma'}\cap\langle\phi,\psi\rangle_{\Sigma'}\\ \qquad\text{but}\quad\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})\notin T_{\Sigma'}\cap\langle\phi,\psi\rangle_{\Sigma'}.\end{array}$$

Since $\phi,\psi\in\langle X\rangle_\Sigma$ and $\vec{\chi}\in\langle\phi,\psi\rangle_{\Sigma'}$, we get that

$$\begin{array}{l}\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})\in T_{\Sigma'}\cap\langle X\rangle_{\Sigma'}\\ \qquad\text{but}\quad\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})\notin T_{\Sigma'}\cap\langle X\rangle_{\Sigma'}.\end{array}$$

Thus, again by Theorem 19, we get $\langle\phi,\psi\rangle\notin\Omega_\Sigma^{\langle X\rangle}(T\cap\langle X\rangle)$. Hence, $\Omega^{\langle X\rangle}(T\cap\langle X\rangle)\le\Omega(T)\cap\langle X\rangle^2$. We now conclude, using Lemma 305, that $\mathcal{I}$ is family extensional. ■

5.3 Leibniz Commutativity

Another important property is that of commutativity with a special type of logical morphism, which we now introduce and study.

Let $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $X\in\mathrm{SenFam}(\mathbf{F})$. An algebraic system morphism of the form $\langle I,\alpha\rangle:\langle X\rangle\to\mathbf{F}$, where $I:\mathbf{Sign}^\flat\to\mathbf{Sign}^\flat$ is the identity functor, will be called an **extension**.

Further, given a π-institution $\mathcal{I}=\langle\mathbf{F},C\rangle$ based on $\mathbf{F}$, an extension $\langle I,\alpha\rangle:\langle X\rangle\to\mathbf{F}$ is said to be **logical** if it is a logical morphism $\langle I,\alpha\rangle:\mathcal{I}^{\langle X\rangle}\to\mathcal{I}$, where $\mathcal{I}^{\langle X\rangle}=\langle\langle X\rangle,C^{\langle X\rangle}\rangle$ is the π-subinstitution of $\mathcal{I}$ induced by $\langle X\rangle$. In other words $\langle I,\alpha\rangle:\langle X\rangle\to\mathbf{F}$ is a logical extension if, for all $\Sigma\in|\mathbf{Sign}^\flat|$ and all $\Phi\subseteq\langle X\rangle_\Sigma$,

$$\alpha_\Sigma(C_\Sigma^{\langle X\rangle}(\Phi))\subseteq C_\Sigma(\alpha_\Sigma(\Phi)).$$

This is abbreviated to $\alpha(C^{\langle X\rangle}(\Phi))\le C(\alpha(\Phi))$.

Using Lemma 47, we get the following characterization:

Corollary 319 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system,* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a π-institution based on* $\mathbf{F}$*,* $X\in\mathrm{SenFam}(\mathbf{F})$ *and* $\langle I,\alpha\rangle:\langle X\rangle\to\mathbf{F}$ *an extension.* $\langle I,\alpha\rangle:\mathcal{I}^{\langle X\rangle}\to\mathcal{I}$ *is a logical extension if and only if*

$$\alpha^{-1}(T)\in\mathrm{ThFam}(\mathcal{I}^{\langle X\rangle}),\ \textit{for all } T\in\mathrm{ThFam}(\mathcal{I}).$$

Proof: Immediate by Lemma 47. ■

We now define the two notions of Leibniz commutativity that we wish to study.

Definition 320 (Leibniz Commutativity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **family (Leibniz) commuting** *if the Leibniz operator on theory families commutes with logical extensions, i.e., if, for every* $X \in \mathrm{SenFam}(\mathcal{I})$, *all logical extensions* $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ *and all* $T' \in \mathrm{ThFam}(\mathcal{I}^{\langle X \rangle})$,
$$\alpha(\Omega^{\langle X \rangle}(T')) \leq \Omega(C(\alpha(T')));$$
- $\mathcal{I}$ *is called* **system (Leibniz) commuting** *if the Leibniz operator on theory systems commutes with logical extensions, i.e., if, for every* $X \in \mathrm{SenFam}(\mathcal{I})$, *all logical extensions* $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ *and all* $T' \in \mathrm{ThSys}(\mathcal{I}^{\langle X \rangle})$,
$$\alpha(\Omega^{\langle X \rangle}(T')) \leq \Omega(C(\alpha(T'))).$$

We now give a useful characterization of those two properties, in the case of protoalgebraic and of prealgebraic π-institutions, respectively. To do this, however, we need some preliminary work. First, we note that injection morphisms are logical extensions.

Lemma 321 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *For all* $X \in \mathrm{SenFam}(\mathcal{I})$, $\langle I, j \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ *is a logical extension, where* $\langle I, j \rangle : \langle X \rangle \to \mathbf{F}$ *is the injection morphism.*

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have
$$j^{-1}(T) = T \cap \langle X \rangle \in \mathrm{ThFam}(\mathcal{I}^{\langle X \rangle}),$$
where the membership follows by Proposition 87. Therefore, by Corollary 319, $\langle I, j \rangle$ is a logical extension. ■

Next we define two alternative versions of Leibniz commutativity, which we term inverse Leibniz commutativity.

Definition 322 (Inverse (Leibniz) Commutativity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **family inverse (Leibniz) commuting** *if, for all* $X \in \mathrm{SenFam}(\mathcal{I})$, *all logical extensions* $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ *and all* $T \in \mathrm{ThFam}(\mathcal{I})$,
$$\alpha^{-1}(\Omega(T)) = \Omega^{\langle X \rangle}(\alpha^{-1}(T));.$$
- $\mathcal{I}$ *is* **system inverse (Leibniz) commuting** *if, for all* $X \in \mathrm{SenFam}(\mathcal{I})$, *all logical extensions* $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ *and all* $T \in \mathrm{ThSys}(\mathcal{I})$,
$$\alpha^{-1}(\Omega(T)) = \Omega^{\langle X \rangle}(\alpha^{-1}(T)).$$

We now show that inverse commutativity implies extensionality. Naturally enough, we have two versions of this implication.

Proposition 323 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is family (system) inverse commuting, then it is family (system, respectively) extensional.*

Proof: We show the family version. The system version is similar.

Assume that $\mathcal{I}$ is family inverse commuting and let $X \in \mathrm{SenFam}(\mathcal{I})$, $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\langle \phi, \psi \rangle \in \Omega^{\langle X \rangle}_\Sigma (T \cap \langle X \rangle).$$

Considering the injection morphism $\langle I, j \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$, which is a logical extension by Lemma 321, the hypothesis can be rewritten as $\langle \phi, \psi \rangle \in \Omega^{\langle X \rangle}_\Sigma (j^{-1}(T))$. Thus, by inverse family commutativity, $\langle \phi, \psi \rangle \in j^{-1}_\Sigma (\Omega_\Sigma(T))$. But this is equivalent to $\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \cap \langle X \rangle^2_\Sigma$. We conclude, using Lemma 305, that $\mathcal{I}$ is family extensional. ■

It is clear that family inverse commutativity implies system inverse commutativity. We show, next, that under stability, the system and the family versions of inverse commutativity coincide.

Proposition 324 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is family inverse commuting, then it is system inverse commuting;*

(b) If $\mathcal{I}$ *is system inverse commuting and stable, then it is also family inverse commuting.*

Proof: Family inverse commutativity always implies system inverse commutativity. Conversely, assume that $\mathcal{I}$ is stable and system inverse commuting and let $X \in \mathrm{SenFam}(\mathcal{I})$, $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ a logical extension and $T \in \mathrm{ThFam}(\mathcal{I})$. Then we have

$$\begin{array}{rcll} \alpha^{-1}(\Omega(T)) & = & \alpha^{-1}(\Omega(\overleftarrow{T})) & \text{(stability)} \\ & = & \Omega^{\langle X \rangle}(\alpha^{-1}(\overleftarrow{T})) & \text{(system inverse commutativity)} \\ & = & \Omega^{\langle X \rangle}(\overleftarrow{\alpha^{-1}(T)}) & \text{(Lemma 6)} \\ & = & \Omega^{\langle X \rangle}(\alpha^{-1}(T)). & \text{(Propositions 323 and 312)} \end{array}$$

Thus, $\mathcal{I}$ is family inverse commuting. ■

Finally, the promised characterization that relates family (system) commutativity with family (system) inverse commutativity under the hypothesis of proto(pre)algebraicity. We present the two results separately for the sake of clarity.

Theorem 325 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a protoalgebraic* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family commuting if and only if it is family inverse commuting.*

Proof: Note, first, that, for all $X \in \mathrm{SenFam}(\mathcal{I})$, all logical extensions $\langle F, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ and all $T \in \mathrm{ThFam}(\mathcal{I})$, $\alpha^{-1}(\Omega(T))$ is a congruence system on $\langle X \rangle$ that is compatible with $\alpha^{-1}(T)$. Thus, by the maximality property of the Leibniz congruence system, we have, regardless of commutativity, that, for all $X \in \mathrm{SenFam}(\mathcal{I})$, all $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ and all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\alpha^{-1}(\Omega(T)) \le \Omega^{\langle X \rangle}(\alpha^{-1}(T)).$$

Therefore, it suffices to show that $\mathcal{I}$ is family commuting if and only if, for all $X \in \mathrm{SenFam}(\mathcal{I})$, all $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ and all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega^{\langle X \rangle}(\alpha^{-1}(T)) \le \alpha^{-1}(\Omega(T)).$$

For the "only if" direction, assume that $\mathcal{I}$ is family commuting and let $X \in \mathrm{SenFam}(\mathcal{I})$, $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$, $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega^{\langle X \rangle}_\Sigma(\alpha^{-1}(T))$. Then we have

$$\begin{array}{rcll}
\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle & \in & \alpha_\Sigma(\Omega^{\langle X \rangle}_\Sigma(\alpha^{-1}(T))) & \\
& \subseteq & \Omega_\Sigma(C(\alpha(\alpha^{-1}(T)))) & \text{(commutativity)} \\
& \subseteq & \Omega_\Sigma(C(T)) & \text{(protoalgebraicity)} \\
& = & \Omega_\Sigma(T). &
\end{array}$$

We conclude that $\langle \phi, \psi \rangle \in \alpha^{-1}_\Sigma(\Omega_\Sigma(T))$. Therefore, $\mathcal{I}$ is family inverse commuting.

For the "if" direction, assume $\mathcal{I}$ is family inverse commuting and let $X \in \mathrm{SenFam}(\mathcal{I})$, $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ and $T' \in \mathrm{ThFam}(\mathcal{I}^{\langle X \rangle})$. Then we have

$$\begin{array}{rcl}
\alpha(\Omega^{\langle X \rangle}(T')) & \le & \alpha(\Omega^{\langle X \rangle}(\alpha^{-1}(C(\alpha(T'))))) \\
& & \qquad \text{(Propositions 323 and 313)} \\
& = & \alpha(\alpha^{-1}(\Omega(C(\alpha(T'))))) \\
& & \qquad \text{(inverse commutativity)} \\
& \le & \Omega(C(\alpha(T'))). \quad \text{(set theory)}
\end{array}$$

Thus, $\mathcal{I}$ is family commuting. ■

Similarly, we may obtain the following analog for the system versions of the corresponding properties.

Theorem 326 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a prealgebraic* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is system commuting if and only if it is system inverse commuting.*

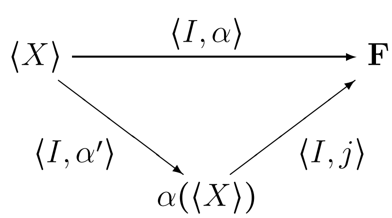
Proof: Along the lines of the proof of Theorem 325. ∎

In Proposition 323 we saw that inverse commutativity implies extensionality. We now show that extensionality is in fact equivalent to inverse commutativity.

Theorem 327 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family (system) inverse commuting if and only if it is family (system, respectively) extensional.*

Proof: By Proposition 323, family inverse commutativity implies family extensionality.

Suppose, conversely, that $\mathcal{I}$ is family extensional and let $X \in \mathrm{SenFam}(\mathcal{I})$, $\langle I, \alpha \rangle : \mathcal{I}^{\langle X \rangle} \to \mathcal{I}$ be a logical extension and $T \in \mathrm{ThFam}(\mathcal{I})$. We exploit the epi-mono factorization of $\langle I, \alpha \rangle$ provided in Proposition 81:



We have

$$\begin{array}{rcl}
\Omega^{\langle X \rangle}(\alpha^{-1}(T)) & = & \Omega^{\langle X \rangle}(\alpha'^{-1}(j^{-1}(T))) \quad (\langle I, \alpha \rangle = \langle I, j \rangle \circ \langle I, \alpha' \rangle) \\
& = & \Omega^{\langle X \rangle}(\alpha'^{-1}(T \cap \mathrm{SEN}^{\flat\alpha})) \quad (\text{definition of } \langle I, j \rangle) \\
& = & \alpha'^{-1}(\Omega^{\alpha(\langle X \rangle)}(T \cap \mathrm{SEN}^{\flat\alpha})) \quad (\text{Proposition 24}) \\
& = & \alpha'^{-1}(\Omega(T) \cap (\mathrm{SEN}^{\flat\alpha})^2) \quad (\text{extensionality}) \\
& = & \alpha'^{-1}(j^{-1}(\Omega(T))) \quad (\text{definition of } \langle I, j \rangle) \\
& = & \alpha^{-1}(\Omega(T)). \quad (\langle I, \alpha \rangle = \langle I, j \rangle \circ \langle I, \alpha' \rangle)
\end{array}$$

Therefore, $\mathcal{I}$ is family inverse commuting.

The system version can be proven analogously. ∎

Finally, we have the following transfer theorem for inverse commutativity.

Theorem 328 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family (system) inverse commuting if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the* π*-institution* $\langle \mathbf{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ *is family (system, respectively) inverse commuting.*

Proof: This follows by combining Theorem 327 with Theorem 314. ∎

5.4 Equivalential π-Institutions

By combining prealgebraicity or protoalgebraicity, on the one hand, with system or family extensionality, on the other, we obtain another hierarchy, the hierarchy of *equivalential π-institutions*. The terminology is built by abiding to the following guidelines:

- The qualification "system" or "family" refers to the version of extensionality employed;

- "preequivalential" or "equivalential" is used depending on whether prealgebraicity or protoalgebraicity is assumed.

According to this nomenclature, we may define four classes of π-institutions as follows:

Definition 329 ((Pre)Equivalentiality) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$.

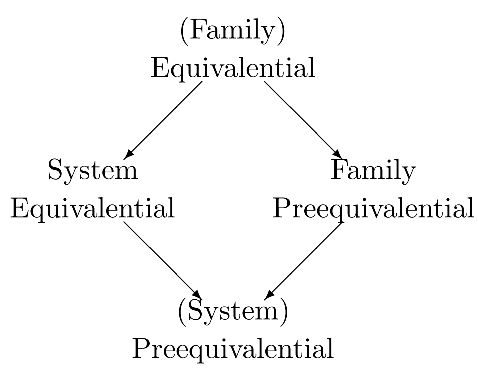
- $\mathcal{I}$ *is* **(family) equivalential** *if it is protoalgebraic and family extensional;*

- $\mathcal{I}$ *is* **system equivalential** *if it is protoalgebraic and system extensional;*

- $\mathcal{I}$ *is* **family preequivalential** *if it is prealgebraic and family extensional;*

- $\mathcal{I}$ *is* **(system) preequivalential** *if it is prealgebraic and system extensional.*

A priori, these four classes form the hierarchy depicted in the diagram.



However, it is easy to show that family and system equivalentiality are equivalent properties.

Proposition 330 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family equivalential if and only if it is system equivalential.*

Proof: First, if $\mathcal{I}$ is family equivalential, then it is also system equivalential, since family extensionality implies system extensionality.

Suppose, conversely, that $\mathcal{I}$ is system equivalential. Then, by Theorem 175, it is stable and, by definition, it is system extensional, whence, by Proposition 309, it is also family extensional. Since it is protoalgebraic and family extensional, it is family equivalential. ■

Taking into account Proposition 330, we call $\mathcal{I}$ **equivalential** if it is protoalgebraic and (family or system) extensional.

Using this terminology, the hierarchy depicted in the preceding diagram reduces to the following linear **equivalentiality hierarchy**:

Equivalential

↓

Family Preequivalential

↓

(System) Preequivalential

It is easy to see that the separating property of the top level from the bottom level in the hierarchy is exactly stability.

Proposition 331 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is equivalential if and only if it is system preequivalential and stable.*

Proof: If $\mathcal{I}$ is equivalential, then it is trivially system preequivalential. Moreover, it is protoalgebraic and, therefore, by Theorem 175, it is stable.

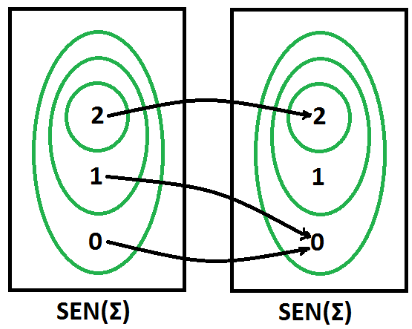
Suppose, conversely, that $\mathcal{I}$ is system prequivalential and stable. Then, by definition, it is system extensional, prealgebraic and stable. Thus, again by Theorem 175, it is system extensional and protoalgebraic and, hence, by Proposition 330, equivalential. ■

Examples are in order to show that the inclusions between the three classes of the equivalentiality hierarchy are proper.

We revisit, first, a familiar example of a π-institution that turns out to be family preequivalential but not equivalential.

Example 332 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

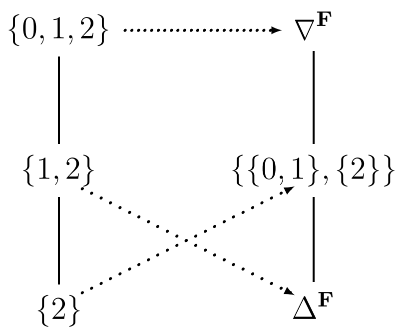
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$*.*

The theory family $\{\{1, 2\}\}$ *is not a theory system.*

The structure of the lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



It is clear from the diagram that $\mathcal{I}$ *is prealgebraic but not protoalgebraic. So to see that it is family preequivalential but not equivalential, it suffices to show that* $\mathcal{I}$ *is family extensional. We can easily see that* $\mathbf{F}$ *has two nontrivial proper universes and three theory families:*

Universes	$\mathbf{F}_{01} = \{\{0, 1\}\}$	$\mathbf{F}_{02} = \{\{0, 2\}\}$	
Theory Families	$\mathrm{Thm}(\mathcal{I})$	$T = \{\{1, 2\}\}$	$\mathrm{SEN}^\flat$

For verification we perform the following calculations, since the case of $\mathrm{SEN}^\flat$ *is trivial:*

$$\begin{array}{rcccl}
\Omega^{\mathbf{F}_{01}}(\mathrm{Thm}(\mathcal{I}) \cap \mathbf{F}_{01}) & = & \mathbf{F}_{01}^2 & = & \Omega(\mathrm{Thm}(\mathcal{I})) \cap \mathbf{F}_{01}^2;\\
\Omega^{\mathbf{F}_{02}}(\mathrm{Thm}(\mathcal{I}) \cap \mathbf{F}_{02}) & = & \Delta^{\mathbf{F}_{02}} & = & \Omega(\mathrm{Thm}(\mathcal{I})) \cap \mathbf{F}_{02}^2;\\
\Omega^{\mathbf{F}_{01}}(T \cap \mathbf{F}_{01}) & = & \Delta^{\mathbf{F}_{01}} & = & \Omega(T) \cap \mathbf{F}_{01}^2;\\
\Omega^{\mathbf{F}_{02}}(T \cap \mathbf{F}_{02}) & = & \Delta^{\mathbf{F}_{02}} & = & \Omega(T) \cap \mathbf{F}_{02}^2.
\end{array}$$

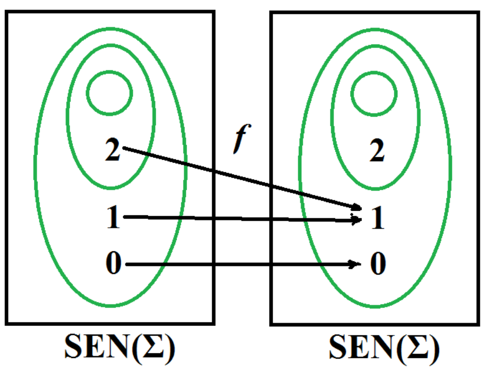
We conclude that $\mathcal{I}$ is indeed family extensional. Thus, $\mathcal{I}$ is an example of a family preequivalential π-institution, which is not equivalential.

Next we give an example of a π-institution that is system preequivalential but not family preequivalential.

Example 333 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 1$ *and* $\mathrm{SEN}^\flat(f)(2) = 1$*;*
- $N^\flat$ *is the category of natural transformations generated by the binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following table:*

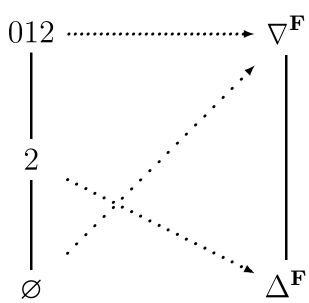
$\sigma^\flat_\Sigma$	0	1	2
0	1	1	2
1	1	1	1
2	2	1	2



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *has three theory families,* $\overline{\varnothing}$*,* $T = \{\{2\}\}$ *and* $\mathrm{SEN}^\flat$*, but only* $\overline{\varnothing}$ *and* $\mathrm{SEN}^\flat$ *are theory systems. The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.*



From the diagram and the fact that $T \notin \mathrm{ThSys}(\mathcal{I})$ it follows that $\mathcal{I}$ is prealgebraic.

$\mathbf{F}$ has five universes $\{\{0\}\}$, $\{\{1\}\}$, $\{\{0,1\}\}$, $\{\{1,2\}\}$ and $\{\{0,1,2\}\}$. Since the only theory systems of $\mathcal{I}$ are $\overline{\varnothing}$ and $\mathrm{SEN}^\flat$, it is trivial to check that $\mathcal{I}$ is system extensional. Hence, being prealgebraic and system extensional, $\mathcal{I}$ is preequivalential.

For the universe $\mathbf{X} = \{\{0,1\}\}$ and the theory family $T = \{\{2\}\}$, we get

$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\},\{1\}\} \subsetneq \{\{0,1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

This shows that $\mathcal{I}$ is not family extensional and, hence, $\mathcal{I}$ is not family preequivalential.

Theorems 179 and 314 allow us to formulate transfer results for (pre)equivalential π-institutions.

Theorem 334 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is equivalential if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter families and, for all $Y \in \mathrm{SenFam}(\mathcal{A})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

Proof: This follows from Theorems 179 and 314. ∎

Similarly, we have the following versions for the preequivalentiality properties:

Theorem 335 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is family (system) preequivalential if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$-filter systems and, for all $Y \in \mathrm{SenFam}(\mathcal{A})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ ($T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, respectively),*

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

Proof: This follows from Theorems 179 and 314. ∎

The definitions of equivalentiality and of system preequivalentiality may be recast in terms of properties of mappings between the lattice of theory families/systems and congruence systems. We have the following

Theorem 336 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is equivalential if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$:*

- *The mapping $\Omega : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ is monotone;*

- *The following diagram commutes, for every* $Y \in \mathrm{SenFam}(\mathcal{A})$*.*

$$\begin{array}{ccc}
\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) & \xrightarrow{\Omega} & \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) \\
{\scriptstyle - \cap \langle Y\rangle}\downarrow & & \downarrow{\scriptstyle - \cap \langle Y\rangle^2} \\
\mathrm{FiFam}^{\mathcal{I}^{\alpha^{-1}(\langle Y\rangle)}}(\langle Y\rangle) & \xrightarrow[\Omega^{\langle Y\rangle}]{} & \mathrm{ConSys}^{\mathcal{I}^{\alpha^{-1}(\langle Y\rangle)}}(\langle Y\rangle)
\end{array}$$

Proof: The "only if" follows from Theorem 334. The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$. ■

The version for system preequivalentiality has the following form.

Theorem 337 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is preequivalential if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*:*

- *The mapping* $\Omega : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A})$ *is monotone;*
- *The following diagram commutes, for every* $Y \in \mathrm{SenFam}(\mathcal{A})$*.*

$$\begin{array}{ccc}
\mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) & \xrightarrow{\Omega} & \mathrm{ConSys}^{\mathcal{I}}(\mathcal{A}) \\
{\scriptstyle - \cap \langle Y\rangle}\downarrow & & \downarrow{\scriptstyle - \cap \langle Y\rangle^2} \\
\mathrm{FiSys}^{\mathcal{I}^{\alpha^{-1}(\langle Y\rangle)}}(\langle Y\rangle) & \xrightarrow[\Omega^{\langle Y\rangle}]{} & \mathrm{ConSys}^{\mathcal{I}^{\alpha^{-1}(\langle Y\rangle)}}(\langle Y\rangle)
\end{array}$$

Proof: Along the lines of Theorem 336, using Theorem 335. ■

We now state formally some straightforward relationships between the classes in the equivalential hierarchy and those in the monotonicity hierarchy.

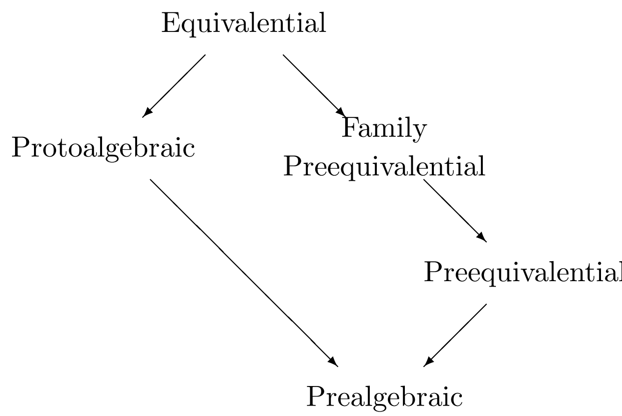
Proposition 338 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is equivalential, then it is protoalgebraic;*

(b) If $\mathcal{I}$ *is system preequivalential, then it is prealgebraic.*

Proof: Both statements follow directly from the definitions of equivalentiality and system preequivalentiality. ■

Proposition 338 establishes the following hierarchy:



The next example shows that the two inclusions from the classes in the equivalential hierarchy to the monotonicity hierarchy are proper inclusions. More precisely, a π-institution is constructed that is protoalgebraic but fails to be (system) preequivalential.

Example 339 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the two binary natural transformations* $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following tables:*

$\wedge$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

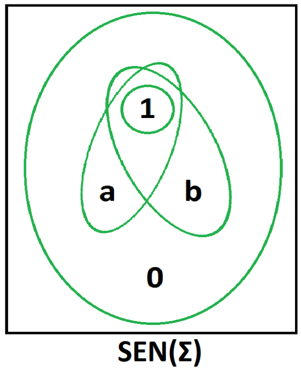
$\vee$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

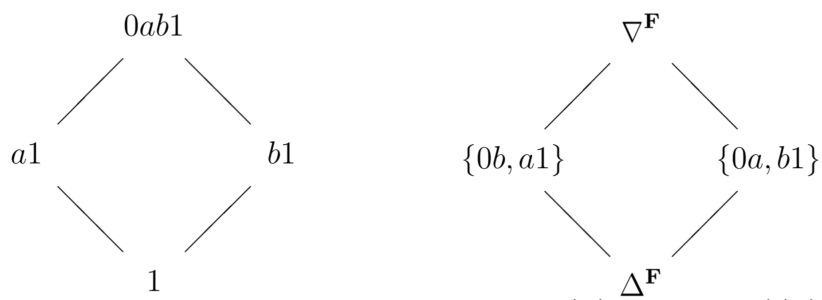
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{1\}, \{a, 1\}, \{b, 1\}, \{0, a, b, 1\}\}.$$

$\mathcal{I}$ *has four theory families, all of which are also theory systems.*

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.





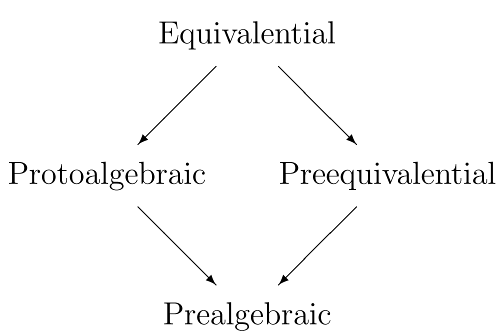
From the diagram, we can see that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism, whence,* $\mathcal{I}$ *is, in particular, protoalgebraic.*

On the other hand, for the universe $\mathbf{X} = \{\{0,a,1\}\}$ *and the theory system* $T = \{\{1\}\}$*, we get*

$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\},\{a\},\{1\}\} \subsetneq \{\{0,a\},\{1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Thus, $\mathcal{I}$ *is not system extensional and, therefore, it fails to be (system) preequivalential.*

In our future work we will deal mostly with equivalential and system preequivalential π-institutions, referring to them as *equivalential* and *preequivalential*, respectively (as has already been suggested). So we focus mostly on the following part of the hierarchy:



Whenever the need to refer to family preequivalential π-institutions arises, the "family" qualification shall not be omitted to avoid confusion.

5.5 PreAlgebraizability

We study now the hierarchy that results by taking the various classes of weakly prealgebraizable π-institutions and adding to them family or system extensionality. Equivalently, we may replace prealgebraicity by either family or system preequivalentiality. Since, for every weak prealgebraizability class, we have two strengthening (or replacement) options, we get a sort of a double (or parallel) hierarchy whose classes are defined formally as follows and which is depicted in the accompanying diagram.

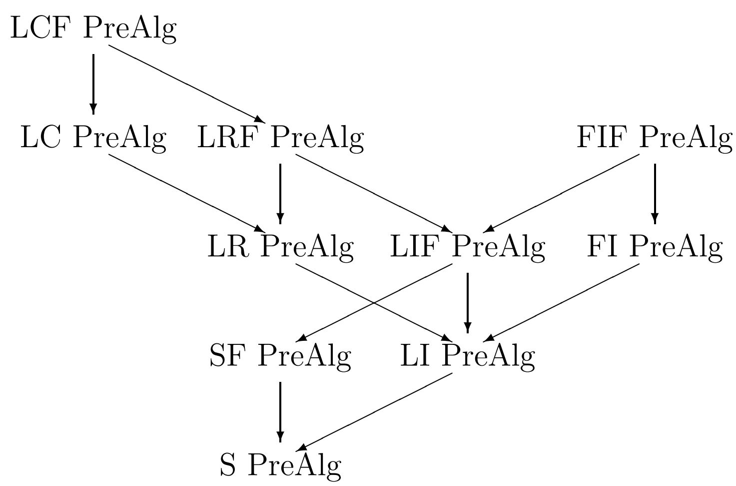
Definition 340 (Family PreAlgebraizability) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **left completely reflective family prealgebraizable***, or* **LCF prealgebraizable** *for short, if it is family preequivalential and left completely reflective, i.e., if it is system monotone, family extensional and left completely reflective;*
- $\mathcal{I}$ *is* **left reflective family prealgebraizable***, or* **LRF prealgebraizable** *for short, if it is family preequivalential and left reflective, i.e., if it is system monotone, family extensional and left reflective;*
- $\mathcal{I}$ *is* **family injective family prealgebraizable***, or* **FIF prealgebraizable** *for short, if it is family preequivalential and family injective, i.e., if it is system monotone, family extensional and family injective;*
- $\mathcal{I}$ *is* **left injective family prealgebraizable***, or* **LIF prealgebraizable** *for short, if it is family preequivalential and left injective, i.e., if it is system monotone, family extensional and left injective;*
- $\mathcal{I}$ *is* **system family prealgebraizable***, or* **SF prealgebraizable** *for short, if it is family preequivalential and system injective, i.e., if it is system monotone, family extensional and system injective.*

Definition 341 (PreAlgebraizability) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **left completely reflective prealgebraizable***, or* **LC prealgebraizable** *for short, if it is preequivalential and left completely reflective, i.e., if it is system monotone, system extensional and left completely reflective;*
- $\mathcal{I}$ *is* **left reflective prealgebraizable***, or* **LR prealgebraizable** *for short, if it is preequivalential and left reflective, i.e., if it is system monotone, system extensional and left reflective;*

- $\mathcal{I}$ *is* **family injective prealgebraizable**, *or* **FI prealgebraizable** *for short, if it is preequivalential and family injective, i.e., if it is system monotone, system extensional and family injective;*
- $\mathcal{I}$ *is* **left injective prealgebraizable**, *or* **LI prealgebraizable** *for short, if it is preequivalential and left injective, i.e., if it is system monotone, system extensional and left injective;*
- $\mathcal{I}$ *is* **system prealgebraizable**, *or* **S prealgebraizable** *for short, if it is preequivalential and system injective, i.e., if it is system monotone, system extensional and system injective.*



The nomenclature here uses the term "prealgebraizable" to suggest that we are applying prealgebraicity. The first two qualifying capitals reflect the kind of injectivity, reflectivity or c-reflectivity that is applied and, finally, the addition or omission of "F" conveys whether family or system extensionality is applied, i.e., (together with prealgebraicity) whether family or system preequivalentiality is postulated. For instance, a π-institution is *LRF prealgebraizable* if it is

- prealgebraic;
- left reflective;
- family extensional,

i.e., if it is family preequivalential and left reflective or, equivalently, if it is weakly LR prealgebraizable and family extensional.

Directly from corresponding theorems pertaining to weakly prealgebraizable π-institutions, we obtain the following results that clarify the status of this hierarchy under systemicity, on the one hand, and under the weaker condition of stability, on the other.

Theorem 342 *For systemic π-institutions, all ten classes shown in the hierarchical diagram coincide.*

Proof: First, if $\mathcal{I}$ is systemic, then it is, a fortiori, stable. Therefore, by Proposition 309, the properties of family and system extensionality coincide. Thus, the two parallel hierarchies of the diagram collapse into one. Finally, by Theorem 269, all these five classes coincide. Therefore, restricted to systemic π-institutions, the entire hierarchy of the diagram collapses into a single class. ■

Theorem 343 *For stable π-institutions, the ten-class prealgebraizability hierarchy shown in the diagram collapses to only two different classes, as shown in the diagram below*

F Prealgebraizable

↓

S Prealgebraizable

where F Prealgebraizable encompasses the classes of FIF and FI Prealgebraizable π-institutions and S Prealgebraizable encompasses the remaining eight classes in the original hierarchy.

Proof: Indeed, by Proposition 309, the properties of family and system extensionality coincide under stability. Therefore, the five pairs of parallel classes of the original hierarchy coincide, giving a 5-class hierarchy. But, according to Theorem 273, under stability, these five classes reduce to only two, as shown in the diagram of the statement. ■

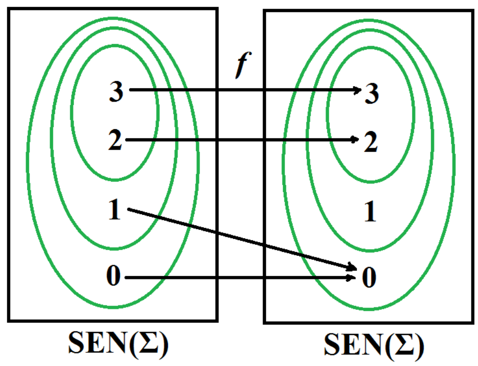
A few examples are now in order to separate the various classes of this prealgebraizability hierarchy. The first example serves in separating each pair of the two parallel hierarchies shown in the diagram. Namely, a π-institution is constructed which is LC prealgebraizable and FI prealgebraizable and, hence, belongs to all five levels of the lower hierarchy, but fails to be SF prealgebraizable and, as a consequence, belongs to none of the five upper levels of the hierarchy.

Example 344 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2, 3\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$*,* $\mathrm{SEN}^\flat(f)(2) = 2$ *and* $\mathrm{SEN}^\flat(f)(3) = 3$*;*

- $N^\flat$ *is the category of natural transformations generated by the binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by the following table:*

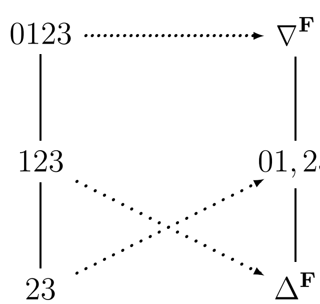
$\sigma^\flat_\Sigma$	0	1	2	3
0	0	0	0	0
1	0	0	0	1
2	0	0	2	2
3	0	1	2	3



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

$\mathcal{I}$ *has three theory families, but only two theory systems. The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.*



From the diagram, we can see that $\mathcal{I}$ *is prealgebraic, i.e., that* Ω *is monotone on* $\mathrm{ThSys}(\mathcal{I})$*, and, also, left c-reflective and family injective.*

To see that $\mathcal{I}$ *is system extensional, note that* $\mathbf{F}$ *has eleven universes,* $\{\{0\}\}$, $\{\{2\}\}$, $\{\{3\}\}$, $\{\{0,1\}\}$, $\{\{0,2\}\}$, $\{\{0,3\}\}$, $\{\{2,3\}\}$, $\{\{0,1,2\}\}$, $\{\{0,1,3\}\}$, $\{\{0,2,3\}\}$ *and* $\{\{0,1,2,3\}\}$*, seven of which are proper and non-singletons. Moreover,* $\mathcal{I}$ *has two theory systems, only one of which is proper. Thus, we* *have seven cases to check, shown below adopting obvious shorthand notation:*

$$\begin{aligned}
&\Omega(23)\cap\{01\}^2=\{01\}=\Omega^{01}(\varnothing)=\Omega^{01}(23\cap 01);\\
&\Omega(23)\cap\{02\}^2=\{0,2\}=\Omega^{02}(2)=\Omega^{01}(23\cap 02);\\
&\Omega(23)\cap\{03\}^2=\{0,3\}=\Omega^{03}(3)=\Omega^{01}(23\cap 03);\\
&\Omega(23)\cap\{23\}^2=\{23\}=\Omega^{23}(23)=\Omega^{01}(23\cap 23);\\
&\Omega(23)\cap\{012\}^2=\{01,2\}=\Omega^{012}(2)=\Omega^{01}(23\cap 012);\\
&\Omega(23)\cap\{013\}^2=\{01,3\}=\Omega^{013}(3)=\Omega^{01}(23\cap 013);\\
&\Omega(23)\cap\{023\}^2=\{0,23\}=\Omega^{023}(23)=\Omega^{01}(23\cap 023).
\end{aligned}$$

On the other hand, for the universe $\mathbf{X}=\{\{0,2,3\}\}$ *and the theory system* $T=\{\{1,2,3\}\}$*, we get*

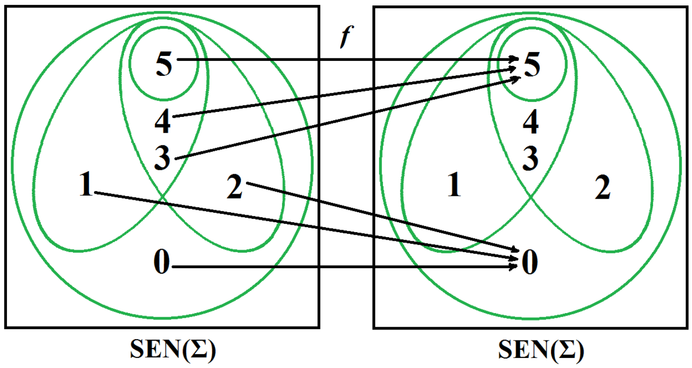
$$\Omega(T)\cap\mathbf{X}^2=\{\{0\},\{2\},\{3\}\}\subsetneqq\{\{0\},\{2,3\}\}=\Omega^{\mathbf{X}}(T\cap\mathbf{X}).$$

Thus, $\mathcal{I}$ *is not family extensional and, therefore, it fails to be SF prealgebraizable.*

We now present examples that separate each parallel step from the one immediately below it. The first is an example of an LRF prealgebraizable π-institution that fails to be LC prealgebraizable. This shows that LCF prealgebraizable π-institutions form a proper subclass of the class of LRF prealgebraizable ones and that the class of LC prealgebraizable π-institutions is a proper subclass of the class of LR prealgebraizable π-institutions.

Example 345 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single non-identity morphism* $f:\Sigma\to\Sigma$*, such that* $f\circ f=f$*;*
- $\mathrm{SEN}^\flat:\mathbf{Sign}^\flat\to\mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma)=\{0,1,2,3,4,5\}$ *and*
  $$\begin{aligned}&\mathrm{SEN}^\flat(f)(0)=\mathrm{SEN}^\flat(f)(1)=\mathrm{SEN}^\flat(f)(2)=0,\\ &\mathrm{SEN}^\flat(f)(3)=\mathrm{SEN}^\flat(f)(4)=\mathrm{SEN}^\flat(f)(5)=5;\end{aligned}$$
- $N^\flat$ *is the category of natural transformations generated by the two unary natural transformations* $\sigma^\flat,\tau^\flat:\mathrm{SEN}^\flat\to\mathrm{SEN}^\flat$*, with*
  $$\sigma^\flat_\Sigma,\tau^\flat_\Sigma:\mathrm{SEN}^\flat(\Sigma)\to\mathrm{SEN}^\flat(\Sigma)$$
  defined by
  - $\sigma^\flat_\Sigma(3)=1$ *and* $\sigma^\flat_\Sigma(x)=0$*, for all* $x\in\{0,1,2,4,5\}$*;*
  - $\sigma^\flat_\Sigma(4)=2$ *and* $\sigma^\flat_\Sigma(x)=0$*, for all* $x\in\{0,1,2,3,5\}$*.*



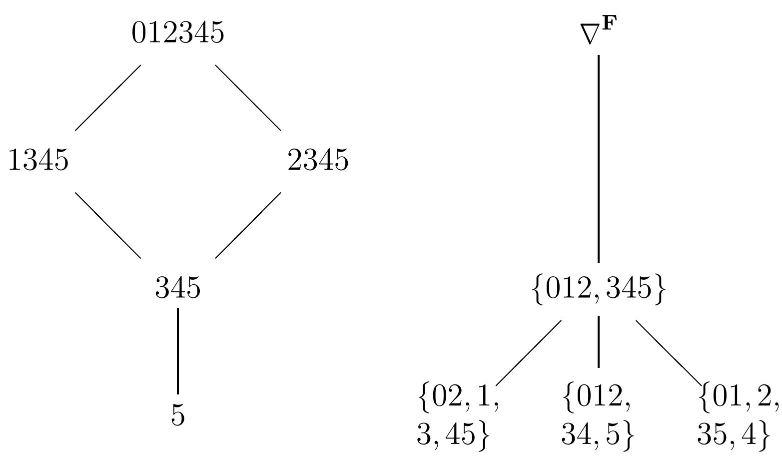
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{5\}, \{3,4,5\}, \{1,3,4,5\}, \{2,3,4,5\}, \{0,1,2,3,4,5\}\}.$$

$\mathcal{I}$ *has five theory families but only three theory systems. The action of* $\overleftarrow{\ }$ *on theory families is given by the following table.*

T	$\overleftarrow{T}$
$\{5\}$	$\{5\}$
$\{3,4,5\}$	$\{3,4,5\}$
$\{1,3,4,5\}$	$\{3,4,5\}$
$\{2,3,4,5\}$	$\{3,4,5\}$
$\{0,1,2,3,4,5\}$	$\{0,1,2,3,4,5\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, it is clear that $\mathcal{I}$ *is prealgebraic, i.e., that, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$, $T \leq T'$ *implies* $\Omega(T) \leq \Omega(T')$. *Moreover, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, *if* $\Omega(T) \leq \Omega(T')$, *then* $\overleftarrow{T} \leq \overleftarrow{T'}$, *i.e.,* $\mathcal{I}$ *is left reflective. On the* *other hand, setting,* $T^1 = \{\{1,3,4,5\}\}$, $T^2 = \{\{2,3,4,5\}\}$ *and* $T' = \{\{5\}\}$, *we get*

$$\begin{array}{rcl}\Omega(T^1)\cap\Omega(T^2) & = & \{\{02,1,3,45\}\}\cap\{\{01,2,35,4\}\}\\ & = & \Delta^{\mathbf{F}}\\ & \leq & \{\{012,34,5\}\} = \Omega(T'),\end{array}$$

whereas

$$\overleftarrow{T^1}\cap\overleftarrow{T^2} = \{\{3,4,5\}\}\cap\{\{3,4,5\}\} = \{\{3,4,5\}\} \not\leq \{\{5\}\} = \overleftarrow{T'}.$$

Hence, $\mathcal{I}$ *is not left completely reflective. Hence to see that* $\mathcal{I}$ *is LRF prealgebraizable but not LC prealgebraizable, it suffices to show that it is family extensional. The verification is routine, but rather tedious. Note that* $\mathbf{F}$ *has eleven proper and non-trivial universes, namely* $\{\{0,1\}\}$, $\{\{0,2\}\}$, $\{\{0,5\}\}$, $\{\{0,1,2\}\}$, $\{\{0,1,5\}\}$, $\{\{0,2,5\}\}$, $\{\{0,1,2,5\}\}$, $\{\{0,1,3,5\}\}$, $\{\{0,2,4,5\}\}$, $\{\{0,1,2,3,5\}\}$ *and* $\{\{0,1,2,4,5\}\}$. *Moreover, it has four proper theory families,* $T^1 = \{\{5\}\}$, $T^2 = \{\{3,4,5\}\}$, $T^3 = \{\{1,3,4,5\}\}$ *and* $T^4 = \{\{2,3,4,5\}\}$. *So, one has to check forty-four cases in total which are summarized in the following table, where each entry in the column labeled by universe* $\mathbf{F}'$ *and the row labeled by theory family* T *shows the congruence system* $\Omega(T)\cap\mathbf{F}'^2 = \Omega^{\mathbf{F}'}(T\cap\mathbf{F}')$ *in shorthand block notation.*

	01	02	05	012	015	025	0125
5	01	02	0,5	012	01,5	02,5	012,5
345	01	02	0,5	012	01,5	02,5	012,5
1345	0,1	02	0,5	02,1	0,1,5	02,5	02,1,5
2345	01	0,2	0,5	01,2	01,5	0,2,5	01,2,5

	0135	0245	01235	01245
5	01,3,5	02,4,5	012,3,5	012,4,5
345	01,35	02,45	012,35	012,45
1345	0,1,3,5	02,45	02,1,3,5	02,1,45
2345	01,35	0,2,4,5	01,2,35	01,2,4,5

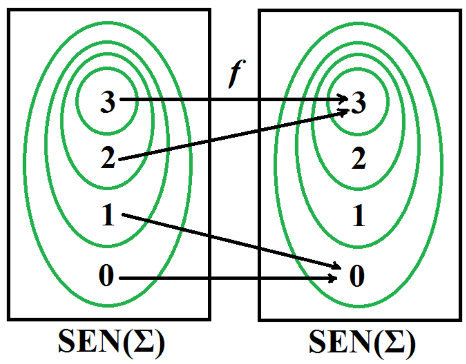
The second example is an example of an LIF prealgebraizable π-institution that fails to be LR prealgebraizable. This shows, on the one hand, that the class of LRF prealgebraizable π-institutions is a proper subclass of the class of LIF prealgebraizable π-institutions and, on the other, that the class of LR prealgebraizable π-institutions is a proper subclass of the class of LI prealgebraizable π-institutions.

Example 346 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f:\Sigma\to\Sigma$, *such that* $f\circ f = f$;

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(f)(2) = 3$ *and* $\mathrm{SEN}^\flat(f)(3) = 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by the following table:*

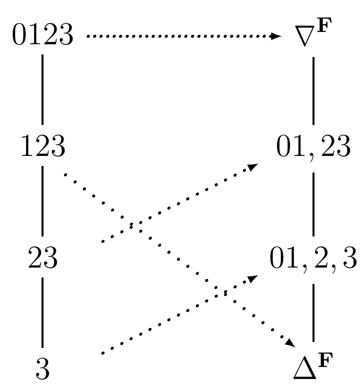
x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	0	1	1	0



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{3\},\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

$\mathcal{I}$ *has four theory families, but only three theory systems. The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.*



From the diagram, we can see that $\mathcal{I}$ *is prealgebraic, i.e., that* Ω *is monotone on* $\mathrm{ThSys}(\mathcal{I})$ *and, also left injective. But* $\mathcal{I}$ *is not left reflective, since* $\Omega(\{1,2,3\}) \le \Omega(\{3\})$*, whereas* $\overleftarrow{\{1,2,3\}} = \{2,3\} \nleq \{3\} = \overleftarrow{\{3\}}$*. Therefore, to see that* $\mathcal{I}$ *is LIF prealgebraizable but not LR prealgebraizable, it suffices to show that it is family extensional.*

Note that $\mathbf{F}$ *has three proper and non-singleton universes,* $\{\{0,1\}\}$, $\{\{0,3\}\}$ *and* $\{\{0,1,3\}\}$. *Moreover,* $\mathcal{I}$ *has three proper theory families. Thus, we only have nine cases to check, shown in the following array, which in the row labeled by theory family* T *and the column labeled by universe* $\mathbf{F}'$ *shows the congruence system* $\Omega(T)\cap\mathbf{F}'^2 = \Omega^{\mathbf{F}'}(T\cap\mathbf{F}')$ *in an obvious shorthand notation in terms of blocks.*

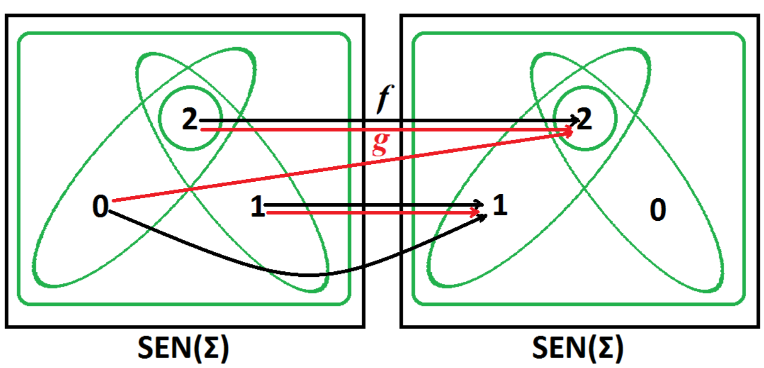
	01	03	013
3	01	0,3	01,3
23	01	0,3	01,3
123	0,1	0,3	0,1,3

We conclude that $\mathcal{I}$ *is LIF prealgebraizable but not LR prealgebraizable.*

The third example is an example of an LIF prealgebraizable π-institution that fails to be FI prealgebraizable. This shows that the class of FIF prealgebraizable π-institutions is a proper subclass of the class of LIF prealgebraizable π-institutions and that the class of FI prealgebraizable π-institutions is a proper subclass of the class of LI prealgebraizable π-institutions.

Example 347 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

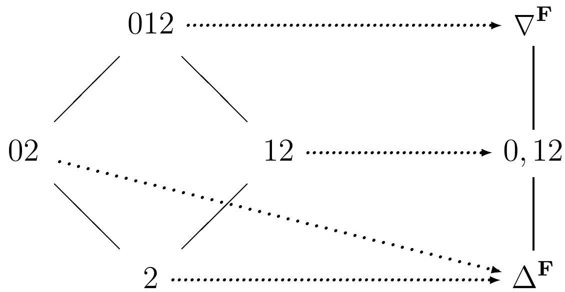
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and two (non-identity) morphisms* $f,g:\Sigma\to\Sigma$, *such that* $f\circ f = f$, $f\circ g = g$, $g\circ f = f$ *and* $g\circ g = g$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and, on morphisms* $\mathrm{SEN}^\flat(f)(0) = 1$, $\mathrm{SEN}^\flat(f)(1) = 1$, $\mathrm{SEN}^\flat(f)(2) = 2$ *and* $\mathrm{SEN}^\flat(g)(0) = 2$, $\mathrm{SEN}^\flat(g)(1) = 1$ *and* $\mathrm{SEN}^\flat(g)(2) = 2$;
- $N^\flat$ *is the trivial category of natural transformations.*



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution defined by setting*

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

$\mathcal{I}$ has four theory families, but only three theory systems. The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, we can see that $\mathcal{I}$ is prealgebraic and left injective. But $\mathcal{I}$ is clearly not family injective, since the theory families $\{\{2\}\}$ and $\{\{0,2\}\}$ map to the same congruence system. Therefore, to see that $\mathcal{I}$ is LIF prealgebraizable but not FI prealgebraizable, it suffices to show that it is family extensional.

Note that $\mathbf{F}$ has only one proper and non-singleton universe, $\{\{1,2\}\}$, and three proper theory families $\{\{2\}\}$, $\{\{0,2\}\}$ and $\{\{1,2\}\}$. Thus, we only have three cases to check, shown below in a shorthand notation.

$$\begin{aligned}\Omega(2)\cap(12)^2 &= \{1,2\} = \Omega^{12}(2) = \Omega^{12}(2\cap 12);\\ \Omega(02)\cap(12)^2 &= \{1,2\} = \Omega^{12}(2) = \Omega^{12}(02\cap 12);\\ \Omega(12)\cap(12)^2 &= \{12\} = \Omega^{12}(12) = \Omega^{12}(12\cap 12).\end{aligned}$$

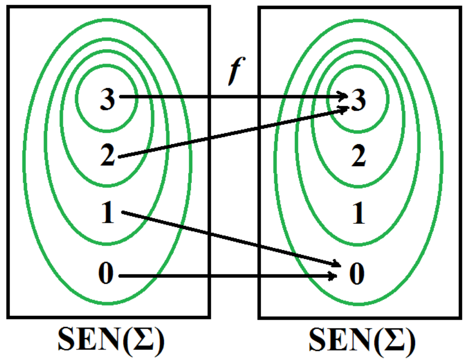
We conclude that $\mathcal{I}$ is LIF prealgebraizable but not FI prealgebraizable.

The last example in this series is an example of an SF prealgebraizable π-institution that fails to be LI prealgebraizable. This shows that LIF prealgebraizable π-institutions form a proper subclass of the class of SF prealgebraizable ones and that the class of LI prealgebraizable π-institutions is a proper subclass of the class of S prealgebraizable ones.

Example 348 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(f)(2) = 3$ *and* $\mathrm{SEN}^\flat(f)(3) = 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ defined by the following table:*

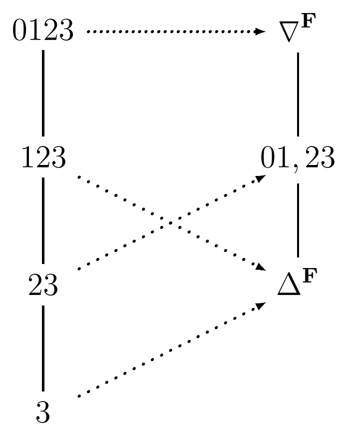
x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	3	2	1	0



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution defined by setting

$$\mathcal{C}_\Sigma = \{\{3\}, \{2,3\}, \{1,2,3\}, \{0,1,2,3\}\}.$$

$\mathcal{I}$ has four theory families, but only three theory systems. The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, we can see that $\mathcal{I}$ is prealgebraic, i.e., that Ω is monotone on ThSys($\mathcal{I}$) *and, also system injective, i.e., Ω is injective on theory systems. But $\mathcal{I}$ is not left injective, since $\Omega(\{1,2,3\}) = \Omega(\{3\})$, whereas $\overleftarrow{\{1,2,3\}} = \{2,3\} \neq \{3\} = \overleftarrow{\{3\}}$. Therefore, to see that $\mathcal{I}$ is SF prealgebraizable but not LI prealgebraizable, it suffices to show that it is family extensional.*

Note that $\mathbf{F}$ has only one proper and non-singleton universe, $\{\{0,3\}\}$. Moreover, $\mathcal{I}$ has three proper theory families. Thus, we have only three cases to check, shown below in shorthand notation:

$$\begin{array}{l}\Omega(3) \cap \{03\}^2 = \{0,3\} = \Omega^{03}(3) = \Omega^{03}(3 \cap 03);\\ \Omega(23) \cap \{03\}^2 = \{0,3\} = \Omega^{03}(3) = \Omega^{03}(23 \cap 03);\\ \Omega(123) \cap \{03\}^2 = \{0,3\} = \Omega^{03}(3) = \Omega^{03}(123 \cap 03).\end{array}$$

We conclude that $\mathcal{I}$ is SF prealgebraizable but not LI prealgebraizable.

We now turn to establishing transfer properties for the π-institutions belonging to the various classes of the preceding hierarchy. We do this by formulating a comprehensive result encompassing the transference of all ten properties of the above hierarchy. It is hoped that, despite its all-encompassing character, the formulation will be sufficiently clear.

Theorem 349 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *belongs to one of the ten prealgebraizability classes in the prealgebraizability hierarchy if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the Leibniz operator on* $\mathcal{A}$*, relative to* $\mathcal{I}$*, satisfies the properties defining the corresponding class.*

For example, $\mathcal{I}$ is FIF prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter systems, injective on $\mathcal{I}$-filter families and family extensional, i.e.,

- for all $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $T \leq T'$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;
- for all $T, T' \in \mathrm{ThFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ implies $T = T'$;
- for all $Y \in \mathrm{SenFam}(\mathcal{A})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

Proof: First, observe that the "if" is trivially satisfied, since, if the postulated conditions hold for every $\mathbf{F}$-algebraic system, then they hold, in particular, for $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and this ensures that, by definition, $\mathcal{I}$ belongs to the corresponding prealgebraizability class.

So we turn to the "only if". First, in all cases $\mathcal{I}$ is prealgebraic, i.e., system monotone, and this property transfers to all $\mathbf{F}$-algebraic systems and $\mathcal{I}$-filter systems by Theorem 179. Then, depending on whether $\mathcal{I}$ belongs to one of the classes in the upper or the lower hierarchy of the two parallel hierarchies, it is family or system extensional, respectively. But, by Theorem 314, both of these properties transfer. Finally, depending on the class $\mathcal{I}$ is postulated to belong to, it satisfies one of the properties of system injectivity, family injectivity, left injectivity, left reflectivity or left c-reflectivity. The first three properties transfer by Theorem 214, the fourth transfers by Theorem 225 and the last transfers by Theorem 240. Therefore, the conclusion holds for each of the ten prealgebraizability classes in the prealgebraizability hierarchy. ■

Finally, we turn to characterizations of the classes in the hierarchy in the form of isomorphism theorems between lattices of theory families/systems and lattices of congruence systems. We start, first with FIF prealgebraizability.

Theorem 350 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is FIF prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a bijection which commutes with inverse logical extensions and which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: The proof is based on Theorem 267, characterizing weak FI prealgebraizbility. We have that $\mathcal{I}$ is FIF prealgebraizable if and only if, by definition, it is weakly FI prealgebraizable and family extensional if and only if, by Theorem 267 and Theorem 327, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a bijection which commutes with inverse logical extensions and which restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ■

FI prealgebraizability is characterized in a similar way, the difference being that commutativity with inverse logical extensions is restricted to the application of the Leibniz operator on $\mathcal{I}$-filter systems only, rather than being valid for its operation on the entire collection of $\mathcal{I}$-filter families.

Theorem 351 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is FI prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a bijection which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: Similar to the proof of Theorem 350. ■

We turn now to a similar characterization of SF prealgebraizability.

Theorem 352 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is SF prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,* $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *commutes with inverse logical extensions and restricts to an order embedding*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: The proof is based on Theorem 256, characterizing weak system prealgebraizability. We have that $\mathcal{I}$ is SF prealgebraizable if and only if, by definition, it is weakly system prealgebraizable and family extensional if and only if, by Theorem 256 and Theorem 327, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ commutes with inverse logical extensions and restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. ■

S prealgebraizability is characterized in a similar way, the difference being that commutativity with inverse logical extensions is restricted to the application of the Leibniz operator on $\mathcal{I}$-filter systems only, rather than to its operation on the entire collection of $\mathcal{I}$-filter families.

Theorem 353 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is S prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$$

is an order embedding which commutes with inverse logical extensions.

Proof: Similar to the proof of Theorem 352. ■

We continue with LCF prealgebraizability.

Theorem 354 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is LCF prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$$

is a left completely order reflecting surjection, which commutes with inverse logical extensions and which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A}).$$

Proof: The proof is based on Theorem 276, characterizing weak LC prealgebraizbility. We have that $\mathcal{I}$ is LCF prealgebraizable if and only if, by definition, it is weakly LC prealgebraizable and family extensional, if and only if, by Theorem 276 and Theorem 327, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is a left completely order reflecting surjection, which commutes with inverse logical extensions and which restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. ■

LC prealgebraizability is characterized in a similar way, the difference being that commutativity with inverse logical extensions is restricted to the application of the Leibniz operator on $\mathcal{I}$-filter systems only, rather than to its operation on the entire collection of $\mathcal{I}$-filter families.

Theorem 355 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is LC prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: Similar to the proof of Theorem 354. ∎

A characterization of LRF prealgebraizability in the same spirit follows.

Theorem 356 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is LRF prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left order reflecting surjection which commutes with inverse logical extensions and which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: The proof is based on Theorem 279, characterizing weak LR prealgebraizability. We have that $\mathcal{I}$ is LRF prealgebraizable if and only if, by definition, it is weakly LR prealgebraizable and family extensional, if and only if, by Theorem 279 and Theorem 327, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left order reflecting surjection which commutes with inverse logical extensions and which restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ∎

LR prealgebraizability is characterized in a similar way, the difference being that commutativity with inverse logical extensions is restricted to the application of the Leibniz operator on $\mathcal{I}$-filter systems only, rather than to its operation on the entire collection of $\mathcal{I}$-filter families.

Theorem 357 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is LR prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: Similar to the proof of Theorem 356. ∎

Finally, along the same lines we obtain a characterization of LIF prealgebraizability.

Theorem 358 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is LIF prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left injective surjection which commutes with inverse logical extensions and which restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: The proof is based on Theorem 282, characterizing weak LI prealgebraizability. We have that $\mathcal{I}$ is LIF prealgebraizable if and only if, by definition, it is weakly LI prealgebraizable and family extensional, if and only if, by Theorem 282 and Theorem 327, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left injective surjection which commutes with inverse logical extensions and which restricts to an order embedding $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ∎

And, of course, LI prealgebraizability is characterized in a similar way, the difference being that commutativity with inverse logical extensions is restricted to the application of the Leibniz operator on $\mathcal{I}$-filter systems only, rather than to its operation on the entire collection of $\mathcal{I}$-filter families.

Theorem 359 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is LI prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left injective surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: Similar to the proof of Theorem 358. ∎

5.6 Algebraizability

Since equivalentiality implies protoalgebraicity, the hierarchy of algebraizable π-institutions, which results from the hierarchy of weakly algebraizable π-institutions by replacing protoalgebraicity by equivalentiality, is simpler, reflecting the simplicity of the weak algebraizability hierarchy.

Definition 360 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **family algebraizable***, or* **F Algebraizable** *for short, if it is equivalential and family injective, i.e., if it is protoalgebraic, family extensional and family injective;*
- $\mathcal{I}$ *is (***system***)* **algebraizable** *if it is equivalential and system injective, i.e., if it is protoalgebraic, family extensional and system injective.*

These two classes form the following **algebraizability hierarchy**:

Family Algebraizable

↓

(System) Algebraizable

It is clear that these two classes are separated exactly by systemicity, as is shown in the following proposition:

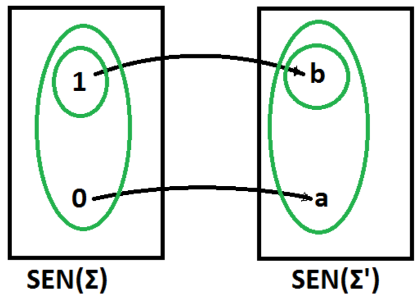
Proposition 361 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I}$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family algebraizable if and only if it is algebraizable and systemic.*

Proof: We have that $\mathcal{I}$ is family algebraizable if and only if, by definition, it is equivalential and family injective if and only if, by Theorem 291 it is equivalential, systemic and system injective if and only if it is, by definition, algebraizable and systemic. ■

We next present an example to show that these two classes are different. It consists of an algebraizable π-institution, which fails to be family algebraizable.

Example 362 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*



- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*

- $N^\flat$ *is the trivial clone.*

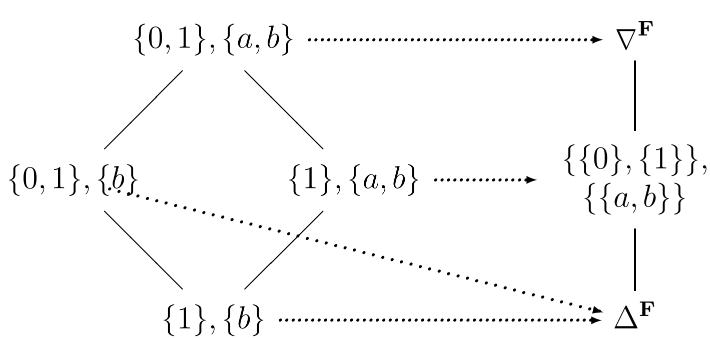
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad and \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

The table yielding the action of $\overleftarrow{\ }$ *on theory families is shown below.*

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The accompanying diagram gives the structure of the lattice of theory families and the corresponding Leibniz congruence systems.



From the diagram one can check that the Leibniz operator is monotone on theory families and injective on theory systems. Thus, the π*-institution is protoalgebraic and system injective. Moreover, as is shown in the following table, which summarizes the congruence systems of the form* $\Omega(T) \cap \langle X\rangle^2 = \Omega^{\langle X\rangle}(T \cap \langle X\rangle)$ *for the various combinations of nonempty universes and theory* *families, $\mathcal{I}$ is family extensional.*

$\langle X\rangle\backslash T$	$1\ b$	$01\ b$	$1\ ab$	$01\ ab$
$0\ a$	$0\ a$	$0\ a$	$0\ a$	$0\ a$
$0\ ab$	$0\ a,b$	$0\ a,b$	$0\ ab$	$0\ ab$
$1\ b$	$1\ b$	$1\ b$	$1\ b$	$1\ b$
$1\ ab$	$1\ a,b$	$1\ a,b$	$1\ ab$	$1\ ab$
$01\ ab$	$0,1\ a,b$	$0,1\ a,b$	$0,1\ ab$	$01\ ab$

Therefore, $\mathcal{I}$ is clearly equivalential and system injective, i.e., it is algebraizable.

On the other hand, letting $T = \{\{1\},\{b\}\}$ and $T' = \{\{0,1\},\{b\}\}$, we have $\Omega(T) = \Omega(T')$, but $T \neq T'$, whence $\mathcal{I}$ is not family injective and, therefore, it is not family algebraizable.

It is not difficult to show, based on preceding work, that both properties transfer.

Theorem 363 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, the Leibniz operator on $\mathcal{A}$ is monotone on $\mathcal{I}$-filter families, injective on $\mathcal{I}$-filter systems and family extensional, i.e.,*

- *for all $T,T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T \leq T'$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;*
- *for all $T,T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ implies $T = T'$;*
- *for all $Y \in \mathrm{SenFam}(\mathcal{A})$ and all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\Omega^{\mathcal{A}}(T) \cap \langle Y\rangle^2 = \Omega^{\langle Y\rangle}(T \cap \langle Y\rangle).$$

Proof: Suppose, first, that the three conditions hold. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I,\iota\rangle\rangle$, where $\langle I,\iota\rangle : \mathbf{F} \to \mathbf{F}$ is the identity morphism. By hypothesis, Ω is monotone on theory families and family extensional. Thus, $\mathcal{I}$ is equivalential. Also by hypothesis, Ω is injective on theory systems. Therefore, by definition, $\mathcal{I}$ is algebraizable.

Assume, conversely, that $\mathcal{I}$ is algebraizable. Thus, it is equivalential and system injective, i.e., its Leibniz operator is monotone on theory families, injective on theory systems and family extensional. Now we use Theorems 179, 214 and 314, which guarantee that monotonicity, injectivity and extensionality, respectively, transfer, to conclude that, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, the Leibniz operator of $\mathcal{A}$ is monotone on $\mathcal{I}$-filter families, injective on $\mathcal{I}$-filter systems and family extensional. ∎

And, similarly, for family algebraizability, we obtain

Theorem 364 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, the Leibniz operator on* $\mathcal{A}$ *is monotone and injective on* $\mathcal{I}$*-filter families and family extensional, i.e.,*

- *for all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $T \le T'$ *implies* $\Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$*;*
- *for all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T = T'$*;*
- *for all* $Y \in \mathrm{SenFam}(\mathcal{A})$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,*

$$\Omega^{\mathcal{A}}(T) \cap \langle Y \rangle^2 = \Omega^{\langle Y \rangle}(T \cap \langle Y \rangle).$$

Proof: The proof is similar to that given for Theorem 363. It suffices to observe that family injectivity, like system injectivity, also transfers from the theory families of a π-institution $\mathcal{I}$ to all $\mathcal{I}$-filter families on an arbitrary $\mathbf{F}$-algebraic system. ■

We turn now to characterizations of the classes in the algebraizability hierarchy in terms of order isomorphisms between lattices of filter families/systems and lattices of congruence systems that satisfy additional properties. For algebraizability we have the following characterization.

Theorem 365 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is algebraizable if and only if* $\mathcal{I}$ *is stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: Suppose, first, that $\mathcal{I}$ is algebraizable. Then it is weakly algebraizable and family extensional. Thus, by Theorem 298, $\mathcal{I}$ is stable and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a lattice isomorphism. Commutativity with inverse logical extensions follows by family extensionality and Theorems 327 and 328.

Assume, conversely, that $\mathcal{I}$ is stable and, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. Then, again by Theorem 298, we get that $\mathcal{I}$ is weakly algebraizable and, by Theorems 328 and 327, that $\mathcal{I}$ is family extensional. It follows, by definition, that $\mathcal{I}$ is algebraizable. ■

For family algebraizability, we get an analogous characterization.

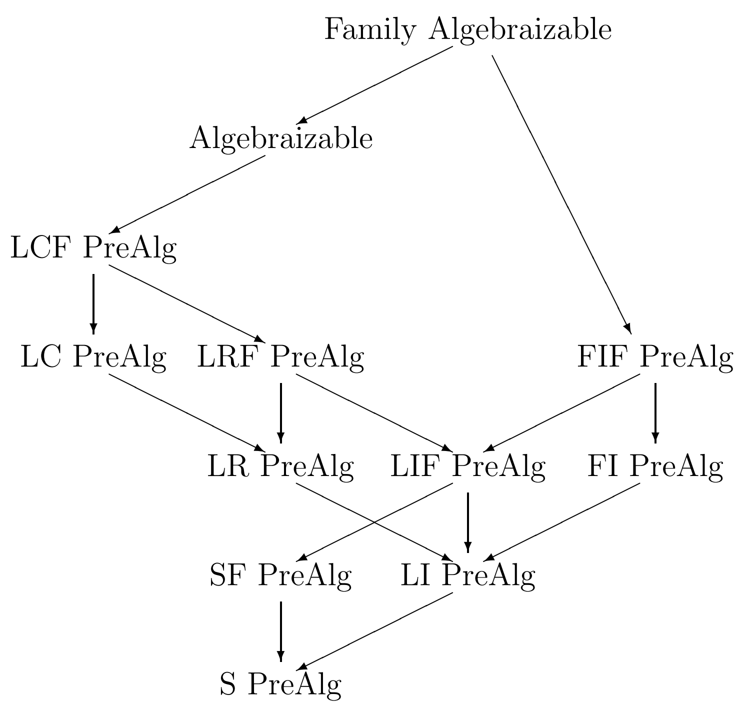
Theorem 366 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: The proof follows along lines similar to the proof of Theorem 365, except references to Theorem 298, characterizing weak algebraizability, must be replaced by referring instead to Theorem 296, which provides a corresponding characterization for weak family algebraizability. ∎

Finally, we note that the two classes sit on top of the prealgebraizability hierarchy that was studied in the preceding section. Namely, we have the hierarchy pictured below:

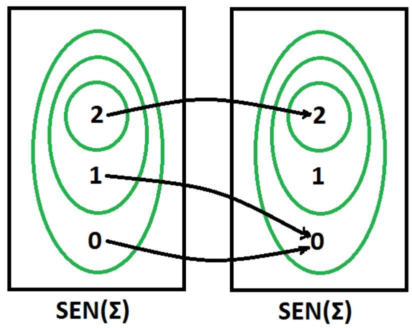


To separate the classes of the algebraizability from those of the prealgebraizability hierarchy, we provide an additional example. It is an example of an LCF and FIF prealgebraizable π-institution which is not algebraizable and, hence, a fortiori, not family algebraizable either.

Example 367 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

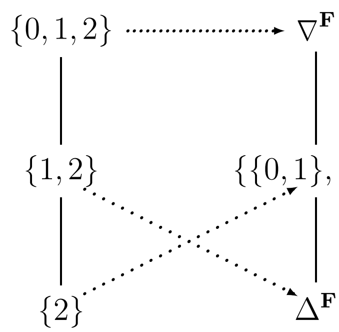
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The theory family $\{\{1,2\}\}$ *is not a theory system.*

The structure of the lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



Since $\mathcal{I}$ *is not protoalgebraic, it is clear that* $\mathcal{I}$ *is not algebraizable and, a fortiori, it is not family algebraizable either. On the other hand,* $\mathcal{I}$ *is prealgebraic and both left c-reflective and family injective. So, to see that it is both LCF and FIF prealgebraizable, it suffices to show that it is also family extensional. This is done by computing, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $X \in \mathrm{SenFam}(\mathcal{I})$ *the congruence systems* $\Omega(T) \cap \langle X\rangle^2$ *and* $\Omega^{\langle X\rangle}(T \cap \langle X\rangle)$ *and verifying that they are identical. This is detailed in the table below:*

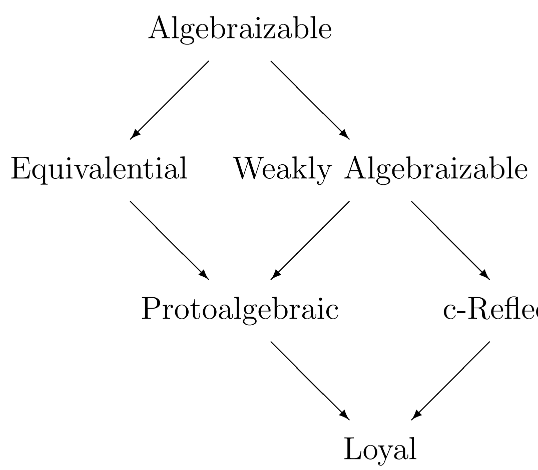
$\langle X\rangle\backslash T$	2	12	012
0	0	0	0
2	2	2	2
01	01	0,1	01
02	0,2	0,2	02
012	01,2	0,1,2	012

We conclude that $\mathcal{I}$ *is family extensional and, therefore, it is, indeed, both LCF and FIF prealgebraizable.*

The last example shows that the hierarchy depicted in the preceding diagram consists of pairwise distinct classes of π-institutions.

5.7 The Semantic Systemic Hierarchy

It is worth stopping momentarily to take a look at the semantic hierarchy that we have studied so far. It has been the case invariably that at each level studied, all classes were identical if restricted to systemic π-institutions. Therefore, considering only systemic π-institutions, one can construct a "skeleton" of the entire hierarchy that is depicted in the accompanying diagram:



It is, therefore, clear that, when restricted to systemic π-institutions, one recovers the fundamental classes and the shape of the well-known Leibniz hierarchy of propositional logics. We view this as a favorable omen that adds credibility to our institutional hierarchical investigations and the hierarchies established through them.

Chapter 6

The Semantic Leibniz Hierarchy: Under the Bottom I

6.1 Introduction

The study of some of the lowest classes in the Leibniz hierarchy of abstract algebraic logic presupposes in a certain sense that the logics studied have theorems. This occurs because the defining conditions of those classes do not hold for nontrivial logics without theorems. Realizing this shortcoming, Moraschini, in Chapter 3 of his Doctoral Dissertation [87] (see, also, [89]) introduced and studied weaker versions accommodating logics without theorems. Our investigations in this chapter have their origins in Moraschini's work, but are suitably adapted to cover logics formalized as π-institutions. At the π-institution level, an injective, and, hence, a fortiori, a reflective or completely reflective, π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ must have theorems. Otherwise, both $\mathrm{SEN}^\flat$ and $\overline{\varnothing}$ are theory families, with $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing})$ and this contradicts injectivity. So, if one wishes to allow, in a context where injectivity is enforced, π-institutions without theorems, the condition of injectivity must be weakened to either exclude, or bypass in some other way, theory families with empty components. In this chapter we present two such attempts. The first is based on the notion of rough equivalence, under which two theory families are identified if, at those signatures Σ where they differ, one has an empty and the other a $\mathrm{SEN}^\flat(\Sigma)$ component. The second, more straightforward, approach disregards all theory families with at least one empty component. The collection of theory families all of whose components are nonempty is denoted by $\mathrm{ThFam}^{\not\flat}(\mathcal{I})$ and, similarly, $\mathrm{ThSys}^{\not\flat}(\mathcal{I})$ stands for the collection of all theory systems all of whose components are nonempty.

In Section 6.2, we introduce the notion of rough equivalence between theory families of a π-institution. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Given a theory family T of $\mathcal{I}$, we define its *rough companion* or *associate* $\widetilde{T}$ to be the theory family resulting from T by replacing each empty Σ-component by $\mathrm{SEN}^\flat(\Sigma)$. Then we say that two theory families T, T' are *roughly equivalent*, written $T \sim T'$, if they have the same rough companion, i.e., if $\widetilde{T} = \widetilde{T'}$. Rough equivalence is an equivalence relation on theory families. The equivalence class of T is denoted by $\widetilde{[T]}$ and the collection of all rough equivalence classes by $\widetilde{\mathrm{ThFam}}(\mathcal{I})$. When restricted to theory systems, it is still an equivalence relation and the equivalence class of a theory system T is denoted $\widetilde{\lfloor T \rfloor}$, whereas the corresponding collection of rough equivalence classes by $\widetilde{\mathrm{ThSys}}(\mathcal{I})$. The key observation making rough equivalence appropriate as a vehicle for defining classes at the bottom of the Leibniz hierarchy is that, if two theory families are roughly equivalent, then they have identical associated Leibniz congruence systems. That is, the Leibniz operator is constant on rough equivalence classes and, hence, may be viewed as an operator on $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ or on $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, depending on the context. The remainder of Section 6.2 deals with several technical issues concerning rough equivalence. First, by definition, $\widetilde{T}$ is the largest theory family in the class $\widetilde{[T]}$. On the other hand, even if T is a theory system, $\widetilde{T}$ may not be one. Nevertheless, $\widetilde{[T]}$ still has a largest element, which, in that case, is clearly different from $\widetilde{T}$. Another drawback is that, even when T and T' are roughly equivalent, it may not be the case that $\overleftarrow{T}$ and $\overleftarrow{T'}$ are roughly equivalent. This introduces some unexpected complications when studying the Leibniz hierarchies based on roughness and narrowness. On the positive side, given an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and an $\mathcal{I}$-filter family $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\widetilde{\alpha^{-1}(T)} = \alpha^{-1}(\widetilde{T})$. Form this it follows that, for all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, if T and T' are roughly equivalent, then so are $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$.

In Section 6.3, we introduce some weakened versions of systemicity adapted to the study of roughness and narrowness. A π-institution is *roughly systemic* if, for every theory family T, $\overleftarrow{T} \sim T$. It is called *narrowly systemic* if, for every theory family T, with all components nonempty, i.e., such that $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\overleftarrow{T} = T$. Finally, it is called *exclusively systemic* if, for all $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we have $\overleftarrow{T} = T$. Systemicity implies both rough and narrow systemicity, and each of these two implies exclusive systemicity. On the other hand, for π-institutions having theorems all four properties become identical.

In Section 6.4, we turn to the study of rough injectivity properties. These are obtained by combining injectivity with rough equivalence. A π-institution $\mathcal{I}$ is *roughly family injective* if, for all theory families T and T', $\Omega(T) = \Omega(T')$ implies $T \sim T'$. $\mathcal{I}$ is *roughly left injective* if the same condition holds, but in the conclusion T, T' are replaced by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively. It is *roughly right injective* if, similarly, the same condition holds, with T, T' in the hypothesis replaced by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively. Finally, $\mathcal{I}$ is *roughly system injective* if the implication defining rough family injectivity holds, but with T, T' allowed to range over theory systems only, instead of over arbitrary theory families. Rough right injectivity is strong enough to imply rough systemicity. It also implies rough family injectivity, which implies rough system injectivity. Rough left injectivity also implies rough system injectivity. Moreover, rough right injectivity is equivalent to rough system injectivity and rough systemicity, whereas rough system injectivity, coupled with stability, implies rough left injectivity. All four rough injectivity properties are equivalent to the corresponding injectivity properties under availability of theorems. In addition, all four rough injectivity properties transfer. Section 6.4 concludes with characterizations of the family and system versions in terms of the Leibniz operator Ω, viewed as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 6.5, we study narrow injectivity properties. These are defined like the injectivity properties of Section 3.6, but only theory families with all components nonempty are taken into account. Accordingly, a π-institution

$\mathcal{I}$ is *narrowly family injective* if, for all theory families $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $\Omega(T) = \Omega(T')$ implies $T = T'$. In the *left version* T and T' are replaced in the conclusion by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively. In the *right version* the same replacement occurs in the hypothesis, whereas the *system version* results by imposing the same condition as in the family version, but T, T' are allowed to range only over $\mathrm{ThSys}^{\nleq}(\mathcal{I})$. Narrow right injectivity implies exclusive systemicity, but does not imply either rough or narrow systemicity. The narrow injectivity hierarchy recovers the linearity of the injectivity hierarchy, which was established in Section 3.6. Narrow right injectivity implies the family version, which implies the left version, which, in turn, implies the system version. The latter, coupled with narrow systemicity, implies narrow right injectivity. A comparison is made between corresponding narrow and rough injectivity properties. The family versions are identical. The left versions are incomparable. For both right and system versions, the rough properties imply the corresponding narrow properties. Each of the narrow injectivity properties is identical to the corresponding injectivity property in the presence of theorems. In addition, all four of them transfer. The section concludes by formulating characterization theorems for the family and system versions in terms of the Leibniz operator seen as a mapping from $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Sections 6.6 and 6.7, we undertake the study of rough and narrow reflectivity properties, respectively, following the format of the study of rough and narrow injectivity from Sections 6.4 and 6.5. Subsequently, Sections 6.8 and 6.9, still following the same paradigm, present an analogous study of rough and narrow complete reflectivity properties. A π-institution $\mathcal{I}$ is *roughly family reflective* if, for all theory families T, T', $\Omega(T) \le \Omega(T')$ implies $\widetilde{T} \le \widetilde{T'}$. *Rough left* and *rough right reflectivity* result by replacing T and T' in the conclusion and in the hypothesis, respectively, by $\overleftarrow{T}$ and $\overleftarrow{T'}$. *Rough system reflectivity* imposes the same condition as the family version, but applies it only to theory systems. Rough right reflectivity implies rough systemicity. Moreover, it implies rough family reflectivity, which implies rough system reflectivity. The left version also implies the system version. Rough right reflectivity is equivalent to the system version plus rough systemicity and, furthermore, the system version, augmented by stability, implies rough left reflectivity. Comparing with previously studied properties, it is fairly obvious that each version of rough reflectivity implies the corresponding rough injectivity version. In addition, each rough reflectivity version is equivalent to the corresponding reflectivity version under the existence of theorems. All four rough reflectivity properties transfer. Finally, characterizations are provided of rough family and rough system reflectivity in terms of the Leibniz operator, perceived as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 6.7, we turn to narrow reflectivity. A π-institution $\mathcal{I}$ is *nar-*

rowly family reflective if, for all theory families T, T', with all components nonempty, $\Omega(T) \leq \Omega(T')$ implies $T \leq T'$. As before, in the *left version* T and T' are replaced in the conclusion by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively, and, in the *right version* the same change is applied in the hypothesis instead. *Narrow system reflectivity* stipulates that the same condition as in the family version hold, but applied only to theory systems with all components nonempty. Narrow family reflectivity implies exclusive systemicity. In terms of the narrow reflectivity hierarchy, the right version is the strongest, followed by the family, then the left and, finally, the system version. Narrow system reflectivity and narrow systemicity imply narrow right reflectivity. Comparisons between the rough reflectivity and the narrow reflectivity classes lead to conclusions similar to those obtained in the injectivity case. The two family versions are equivalent, the left versions are incomparable, whereas rough right and rough system reflectivity imply, respectively, narrow right and narrow system reflectivity. Each narrow reflectivity property implies in a straightforward way the corresponding narrow injectivity property and, moreover, gets identified with the corresponding reflectivity property in the presence of theorems. All four narrow reflectivity properties transfer. Finally, the family and system versions may be characterized in terms of the Leibniz operator, viewed as a mapping from $\mathrm{ThFam}^{\nmid}(\mathcal{I})$ and $\mathrm{ThSys}^{\nmid}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

Section 6.8 starts the study of complete reflectivity with the rough versions, continued in Section 6.9 with the narrow versions. A π-institution $\mathcal{I}$ is *roughly family c-reflective* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}$. In the *left version* all theory families in the conclusion appear in their arrow versions and, in the *right version* the same happens in the hypothesis instead. Finally, the *system version* stipulates that the same condition as in the family version hold, by $\mathcal{T} \cup \{T'\}$ ranges over collections of theory systems only. The hierarchy established here mimics the one of rough reflectivity properties. Rough right c-reflectivity implies the family version, which implies the system version, which is also implied by rough left c-reflectivity. Rough system c-reflectivity and rough systemicity together are equivalent to rough right c-reflectivity. Moreover, rough system c-reflectivity, coupled with stability, implies the left version. It is clear that each rough c-reflectivity property implies the corresponding rough reflectivity property and, further, each rough c-reflectivity property is equivalent to the corresponding c-reflectivity property in the presence of theorems. All four rough c-reflectivity properties transfer and, as previously, one may formulate characterizations of rough family and rough system c-reflectivity in terms of Ω, seen as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

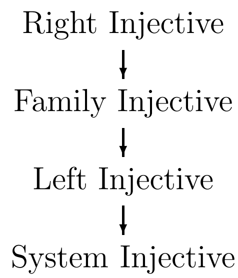
Section 6.9 continues the study of complete reflectivity by looking at narrow c-reflectivity properties. A π-institution $\mathcal{I}$ is *narrowly family c-reflective* if, for every collection $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ implies

$\bigcap \mathcal{T} \leq T'$. The *left* and *right versions* are obtained as before by replacing all theory families in the conclusion and in the hypothesis, respectively, by their arrow versions, whereas the *system version* imposes the condition above for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$. Narrow family c-reflectivity implies exclusive systemicity. The narrow c-reflectivity hierarchy reflects the structure of the narrow reflectivity hierarchy. The right version is the strongest, followed by the family version, then by the left version, while the system version is the weakest of the four. Narrow system c-reflectivity and narrow systemicity imply narrow right c-reflectivity. Comparisons between the rough and narrow versions also follow along lines similar to those between rough and narrow reflectivity properties. The family versions are equivalent, the left versions are incomparable, whereas for both the right and the system versions, rough c-reflectivity implies the corresponding narrow c-reflectivity version. Clearly, each of the four narrow c-reflectivity properties implies the corresponding narrow reflectivity property. As was the case in the rough setting, each narrow c-reflectivity property is identified with the corresponding c-reflectivity property in the presence of theorems. The section concludes with transfer theorems and with characterizations of narrow family and narrow system c-reflectivity via Ω, perceived as a mapping from $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

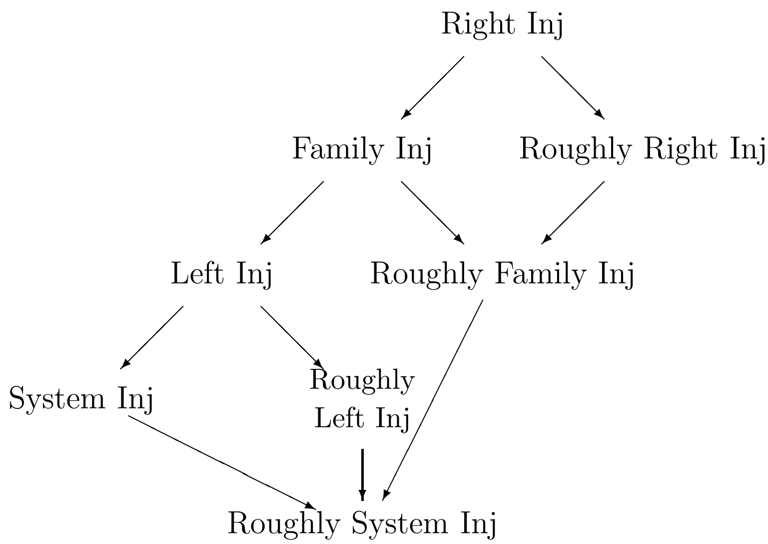
As is clear from all features described, if one considers π-institutions with theorems, the rough and narrow properties become identical to the corresponding properties studied in Chapter 3. Consequently, presence or absence of theorems is a critical characteristic underlying the considerations and hierarchies established in Sections 6.2-6.9. In Section 6.10, the concluding section of the chapter, we turn to some conditions characterizing the existence of theorems via the Frege equivalence family and the Lindenbaum equivalence family operators, introduced in Section 2.11. More precisely, we show that a π-institution $\mathcal{I}$ has theorems if and only if the Frege operator $\lambda : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{EqvFam}(\mathbf{F})$ is injective. Other equivalent conditions to the availability of theorems are the injectivity of the Lindenbaum operator $\widetilde{\lambda}^{\mathcal{I}} : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{EqvFam}(\mathbf{F})$ or, alternatively, its complete reflectivity. Finally, a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ has theorems if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, the induced π-institution $\langle \mathcal{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ has theorems. This constitutes a sort of transfer theorem for the property of possessing theorems.

6.2 Rough Equivalence

Recall from Chapter 3 the injectivity hierarchy, depicted in the following diagram, lying close to the bottom of the semantic Leibniz hierarchy.



Our goal in this section is to add new classes to the semantic Leibniz hierarchy that lie below those injectivity classes. We will eventually build the following hierarchy:



Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Given a theory family $T \in \mathrm{ThFam}(\mathcal{I})$, the **rough companion** or **rough associate** or **rough representative of** T, denoted $\widetilde{T}$, is the theory family of $\mathcal{I}$ that results from T after replacing every empty Σ-component by the corresponding universe $\mathrm{SEN}^\flat(\Sigma)$. More formally, we set

$$\widetilde{T} = \{\widetilde{T}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|},$$

where, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\widetilde{T}_\Sigma = \begin{cases} T_\Sigma, & \text{if } T_\Sigma \neq \varnothing \\ \mathrm{SEN}^\flat(\Sigma), & \text{if } T_\Sigma = \varnothing \end{cases}.$$

The operator $\widetilde{\ }: \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ is clearly idempotent:

Lemma 368 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\widetilde{T}} = \widetilde{T}$.

Proof: We have, by construction, for all $\Sigma \in |\mathbf{Sign}^\flat|$, $\widetilde{T}_\Sigma \neq \varnothing$, whence, we get, by definition, $\widetilde{\widetilde{T}}_\Sigma = \widetilde{T}_\Sigma$. ∎

Define on $\mathrm{ThFam}(\mathcal{I})$ the relation $\sim \subseteq \mathrm{ThFam}(\mathcal{I})^2$ of **rough equivalence** by setting, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \sim T' \quad \text{iff} \quad \widetilde{T} = \widetilde{T'}.$$

It is not difficult to see that rough equivalence is indeed an equivalence relation on the collection of theory families of $\mathcal{I}$, since it is the relational kernel of the mapping $\widetilde{\ } : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$. We call two theories $T, T' \in \mathrm{ThFam}(\mathcal{I})$ **roughly equivalent** if $T \sim T'$. We denote by $\widetilde{[T]}$ the rough equivalence class of a theory family T and let $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ be the collection of all rough equivalence classes of theory families of $\mathcal{I}$.

Since the collection of theory systems of $\mathcal{I}$ is a subcollection of the collection of theory families of $\mathcal{I}$, the rough equivalence relation restricts to an equivalence relation, which we also term **rough equivalence**, on the collection $\mathrm{ThSys}(\mathcal{I})$. We denote by $\widetilde{[T]}$ the rough equivalence class of a theory system T and let $\widetilde{\mathrm{ThSys}}(\mathcal{I})$ be the collection of all rough equivalence classes of theory systems of $\mathcal{I}$.

We now introduce a notation that will prove very handy in subsequent considerations, especially in contexts where the π-institutions under scrutiny may not have theorems. Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We define:

- $\mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$ to be the collection of all theory families of $\mathcal{I}$ with all components nonempty.

  Note that

  $$\begin{array}{rcl}\mathrm{ThFam}^{\not\emptyset}(\mathcal{I}) & = & \{T \in \mathrm{ThFam}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma \neq \varnothing)\} \\ & = & \{T \in \mathrm{ThFam}(\mathcal{I}) : \widetilde{T} = T\}.\end{array}$$

  Note, also, that, in case $\mathcal{I}$ has theorems, $\mathrm{ThFam}^{\not\emptyset}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$.

- $\mathrm{ThSys}^{\not\emptyset}(\mathcal{I})$ to be the collection of all theory systems of $\mathcal{I}$ with all components nonempty.

  Note that

  $$\begin{array}{rcl}\mathrm{ThSys}^{\not\emptyset}(\mathcal{I}) & = & \{T \in \mathrm{ThSys}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^\flat|)(T_\Sigma \neq \varnothing)\} \\ & = & \{T \in \mathrm{ThSys}(\mathcal{I}) : \widetilde{T} = T\}.\end{array}$$

  Note, again, that, in case $\mathcal{I}$ has theorems, $\mathrm{ThSys}^{\not\emptyset}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$.

A key result in our use of the rough equivalence relation to define the semantic hierarchy classes "down under" is the realization that two roughly equivalent theory families have the same Leibniz congruence family and, as a result, the Leibniz operator may be unambiguously applied on rough equivalence classes of theory families. This follows from the fact that, for every theory family T, T and $\widetilde{T}$ share the same Leibniz congruence system.

Proposition 369 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\Omega(T) = \Omega(\widetilde{T}).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$ and $\phi \in \widetilde{T}_\Sigma$.

- If $T_\Sigma = \varnothing$, then $\widetilde{T}_\Sigma = \mathrm{SEN}^\flat(\Sigma)$ and, hence, $\psi \in \widetilde{T}_\Sigma$;
- If $T_\Sigma \neq \varnothing$, then $\widetilde{T}_\Sigma = T_\Sigma$ and, hence, by the compatibility of $\Omega(T)$ with T, we get $\psi \in T_\Sigma = \widetilde{T}_\Sigma$.

We conclude that $\Omega(T)$ is compatible with $\widetilde{T}$ and, hence, $\Omega(T) \leq \Omega(\widetilde{T})$.

Suppose, conversely, that $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma(\widetilde{T})$ and $\phi \in T_\Sigma$. Then $T_\Sigma \neq \varnothing$, whence $\widetilde{T}_\Sigma = T_\Sigma$. Thus, $\phi \in \widetilde{T}_\Sigma$ and, by the compatibility of $\Omega(\widetilde{T})$ with $\widetilde{T}$, we get that $\psi \in \widetilde{T}_\Sigma = T_\Sigma$. Thus, $\Omega(\widetilde{T})$ is compatible with T and we get $\Omega(\widetilde{T}) \leq \Omega(T)$.

We conclude that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\widetilde{T}) = \Omega(T)$. ■

Theorem 370 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. Then, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*

$$T \sim T' \quad \textit{implies} \quad \Omega(T) = \Omega(T').$$

Proof: Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \sim T'$. Then, by definition, $\widetilde{T} = \widetilde{T'}$. Thus, we get, by Proposition 369,

$$\Omega(T) = \Omega(\widetilde{T}) = \Omega(\widetilde{T'}) = \Omega(T')$$

and T and T' have, indeed, the same Leibniz congruence system. ■

We define, next, an ordering relation on the rough equivalence classes of theory families of a π-institution $\mathcal{I}$. But we start by looking at maximal elements.

Proposition 371 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For every* $T \in \mathrm{ThFam}(\mathcal{I})$*,*

$$\widetilde{T} = \max \widetilde{[T]}.$$

Proof: Let $T \in \mathrm{ThFam}(\mathcal{I})$ and consider $T' \in \lceil\widetilde{T}\rceil$. Then, clearly, $T' \leq \widetilde{T'} = \widetilde{T}$. Therefore, $\widetilde{T}$ is a maximum element in $\lceil\widetilde{T}\rceil$. ∎

What is, perhaps, more surprising is that each rough equivalence class in $\mathrm{ThSys}(\mathcal{I})$ also has a maximum element. First, we show that it has maximal elements and then prove that there cannot exist two different maximal elements and, hence, that it has a maximum element.

Proposition 372 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$, $\lceil\widetilde{T}\rceil$ *has a maximal element.*

Proof: Let $T \in \mathrm{ThSys}(\mathcal{I})$. We show that every chain in $\lceil\widetilde{T}\rceil$ has an upper bound in $\lceil\widetilde{T}\rceil$. Then the conclusion follows by applying Zorn's Lemma. Assume that $\{T^i : i \in I\}$ is a chain in $\lceil\widetilde{T}\rceil$. We consider $\bigcup_{i\in I} T^i$.

- $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I})$: Let $\Sigma \in |\mathbf{Sign}^\flat|$. If, for some $j \in I$, $T^j_\Sigma \neq \varnothing$ and $T^j_\Sigma \neq \mathrm{SEN}^\flat(\Sigma)$, then, since all members of $\{T^i : i \in I\}$ are roughly equivalent, we have $\bigcup_{i\in I} T^i_\Sigma = T^j_\Sigma$ is a Σ-theory. If, on the other hand, $T^i_\Sigma = \varnothing$, for all $i \in I$, then $\bigcup_{i\in I} T^i_\Sigma = \varnothing = T^i_\Sigma$, which is again a Σ-theory. Finally, if, for some $i \in I$, $T^i = \mathrm{SEN}^\flat(\Sigma)$, then $\bigcup_{i\in I} T^i_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, which is again a Σ-theory. Therefore, we conclude that $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I})$.

- $\bigcup_{i\in I} T^i \in \mathrm{ThSys}(\mathcal{I})$: Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \bigcup_{i\in I} T^i_\Sigma$. Then, for some $i \in I$, $\phi \in T^i_\Sigma$. Since $T^i \in \mathrm{ThSys}(\mathcal{I})$, we have $\mathrm{SEN}^\flat(f)(\phi) \in T^i_{\Sigma'}$ and, therefore, $\mathrm{SEN}^\flat(f)(\phi) \in \bigcup_{i\in I} T^i_{\Sigma'}$. We conclude that $\bigcup_{i\in I} T^i \in \mathrm{ThSys}(\mathcal{I})$.

- $\bigcup_{i\in I} T^i \sim T$: Let $\Sigma \in |\mathbf{Sign}^\flat|$. If $\bigcup_{i\in I} T^i_\Sigma = \varnothing$, then $T^i_\Sigma = \varnothing$, for all $i \in I$, and hence, $\widetilde{T^i}_\Sigma = \mathrm{SEN}^\flat(\Sigma)$. Therefore, $\widetilde{\bigcup_{i\in I} T^i}_\Sigma = \mathrm{SEN}^\flat(\Sigma) = \widetilde{T^i}_\Sigma$.

  Suppose, next, that $\bigcup_{i\in I} T^i_\Sigma \neq \varnothing$. Thus, there exists $j \in I$, such that $T^j_\Sigma \neq \varnothing$. If there exists $i \in I$, such that $T^i_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, then $\bigcup_{i\in I} T^i_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, whence

  $$(\widetilde{\bigcup_{i\in I} T^i})_\Sigma = \mathrm{SEN}^\flat(\Sigma) = \widetilde{T^i}_\Sigma.$$

  So assume that $T^i_\Sigma \neq \mathrm{SEN}^\flat(\Sigma)$, for all $i \in I$. Then, we conclude that $T^j_\Sigma \neq \varnothing, \mathrm{SEN}^\flat(\Sigma)$ and, therefore, since all T^i's are roughly equivalent, $T^i_\Sigma = T^j_\Sigma$, for all $i \in I$. Then $\bigcup_{i\in I} T^i_\Sigma = T^j_\Sigma$ and, therefore,

  $$(\widetilde{\bigcup_{i\in I} T^i})_\Sigma = T^j_\Sigma = \widetilde{T^j}_\Sigma.$$

  Thus, $\widetilde{\bigcup_{i\in I} T^i} = \widetilde{T}$ and we conclude that $\bigcup_{i\in I} T^i \in \lceil\widetilde{T}\rceil$.

Therefore, $\bigcup_{i\in I} T^i$ is clearly an upper bound of $\{T^i : i \in I\}$ in $\widetilde{[T]}$. By Zorn's Lemma, we conclude that $\widetilde{[T]}$ has a maximal element. ∎

Now we show that in a rough equivalence class in $\mathrm{ThSys}(\mathcal{I})$, there cannot exist two different maximal elements and, therefore, that every rough equivalence class in $\mathrm{ThSys}(\mathcal{I})$ has a maximum element.

Theorem 373 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *Then, for all* $T \in \mathrm{ThSys}(\mathcal{I})$, $\widetilde{[T]}$ *has a maximum element.*

Proof: The proof is quite similar to the proof of Proposition 372. The key is to show that, if $T', T'' \in \mathrm{ThSys}(\mathcal{I})$, such that $T' \sim T''$, then $T' \cup T'' \in \mathrm{ThSys}(\mathcal{I})$, such that $T' \cup T'' \sim T$. So, unless $T' = T''$, not both can be maximal in $\widetilde{[T]}$.

- $T' \cup T'' \in \mathrm{ThFam}(\mathcal{I})$: Let $\Sigma \in |\mathbf{Sign}^\flat|$. If $T'_\Sigma \neq \varnothing, \mathrm{SEN}^\flat(\Sigma)$ and $T''_\Sigma \neq \varnothing, \mathrm{SEN}^\flat(\Sigma)$, then, since $T' \sim T''$, $T'_\Sigma = T''_\Sigma$. Thus, $T'_\Sigma \cup T''_\Sigma = T'_\Sigma$ and, hence, it is a Σ-theory. If $T'_\Sigma = T''_\Sigma = \varnothing$, then $T'_\Sigma \cup T''_\Sigma = \varnothing$, which is again a Σ-theory. Otherwise, $T'_\Sigma \cup T''_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, which is also a Σ-theory.

- $T' \cup T'' \in \mathrm{ThSys}(\mathcal{I})$: Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T'_\Sigma \cup T''_\Sigma$. Then $\phi \in T'_\Sigma$ or $\phi \in T''_\Sigma$. In the first case, $\mathrm{SEN}^\flat(f)(\phi) \in T'_{\Sigma'}$ and, in the second, $\mathrm{SEN}^\flat(f)(\phi) \in T''_{\Sigma'}$. In either case, $\mathrm{SEN}^\flat(f)(\phi) \in T'_{\Sigma'} \cup T''_{\Sigma'}$. Thus, $T' \cup T'' \in \mathrm{ThSys}(\mathcal{I})$.

- $T' \cup T'' \sim T$: Let $\Sigma \in |\mathbf{Sign}^\flat|$. If $T'_\Sigma \cup T''_\Sigma = \varnothing$, then $T'_\Sigma = T''_\Sigma = \varnothing$. So $\widetilde{T' \cup T''}_\Sigma = \mathrm{SEN}^\flat(\Sigma) = \widetilde{T'}_\Sigma = \widetilde{T}_\Sigma$.

  If $T'_\Sigma \cup T''_\Sigma \neq \varnothing$, then $T'_\Sigma \neq \varnothing$ or $T''_\Sigma \neq \varnothing$, say, without loss of generality, $T'_\Sigma \neq \varnothing$. If $T'_\Sigma \neq \mathrm{SEN}^\flat(\Sigma)$, then, since $T' \sim T''$, $T'_\Sigma = T''_\Sigma$ and, hence $T'_\Sigma \cup T''_\Sigma = T'_\Sigma$ and we have $\widetilde{T' \cup T''}_\Sigma = T'_\Sigma = \widetilde{T'}_\Sigma = \widetilde{T}_\Sigma$. If, on the other hand, $T'_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, then $T'_\Sigma \cup T''_\Sigma = \mathrm{SEN}^\flat(\Sigma)$, whence $\widetilde{T' \cup T''}_\Sigma = \mathrm{SEN}^\flat(\Sigma) = \widetilde{T'}_\Sigma = \widetilde{T}_\Sigma$.

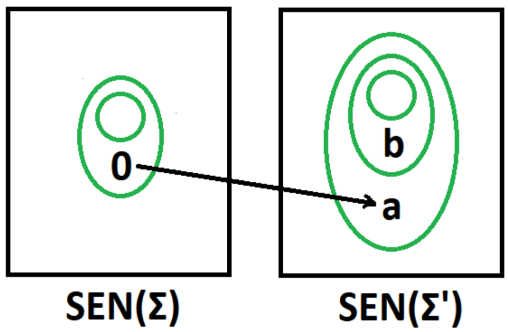
Therefore $T' \cup T'' \in \mathrm{ThSys}(\mathcal{I})$ and $T' \cup T'' \sim T$. We conclude that all maximal elements in $\widetilde{[T]}$ must be equal, i.e., $\widetilde{[T]}$ has a maximum element. ∎

It is worth noting, however, that the maximum element of a class $\widetilde{[T]}$ may not be $\widetilde{T} = \max\widetilde{[T]}$, since this theory family may not be a theory system.

Example 374 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$;
- $N^\flat$ *is the trivial clone.*



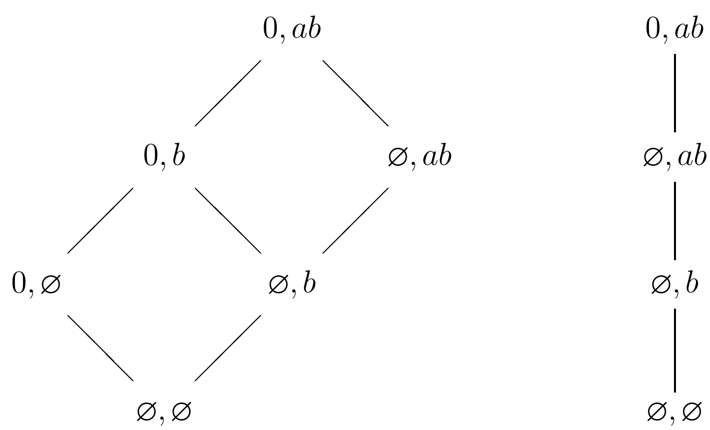
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\emptyset, \{0\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\emptyset, \{b\}, \{a, b\}\}.$$

There are six theory families, but only four theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$
$\emptyset, \emptyset$	$\emptyset, \emptyset$
$0, \emptyset$	$\emptyset, \emptyset$
$\emptyset, b$	$\emptyset, b$
$0, b$	$\emptyset, b$
$\emptyset, ab$	$\emptyset, ab$
$0, ab$	$0, ab$

The complete lattice of theory families is shown on the left:



That of the theory systems is shown on the right. Now note that

$$\max\lfloor \widetilde{\{\emptyset, \{b\}\}} \rfloor = \{\emptyset, \{b\}\},$$

whereas $\widetilde{\{\emptyset, \{b\}\}} = \{\{0\}, \{b\}\} \notin \mathrm{ThSys}(\mathcal{I})$.

For what follows, we also need to point out the fact that, roughly speaking, the $\sim$ operator does not interact smoothly with the $\leftarrow$ operator. More precisely, for arbitrary π-institutions, and theory families T, T',

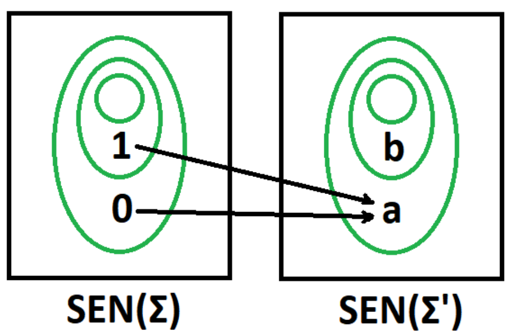
$$\text{the relation } T \sim T' \text{ does not imply, in general, that } \overleftarrow{T} \sim \overleftarrow{T'}.$$

We showcase the potential failure by giving a *counterexample to the statement*, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$T \sim T' \quad \text{implies} \quad \overleftarrow{T} \sim \overleftarrow{T'}.$$

Example 375 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



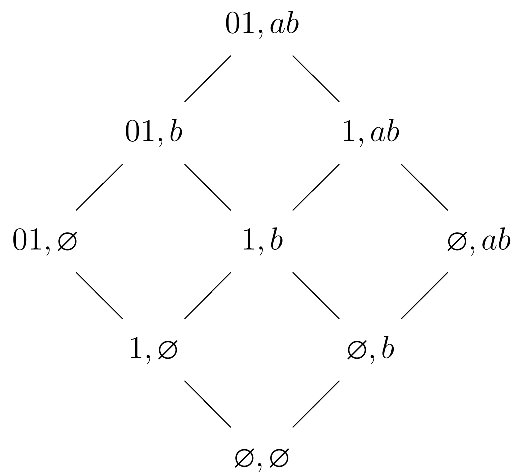
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$

There are nine theory families, but only five theory systems. The action of $\leftarrow$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$\varnothing, \varnothing$	$\varnothing, \varnothing$	$\varnothing, ab$	$\varnothing, ab$
$1, \varnothing$	$\varnothing, \varnothing$	$01, b$	$\varnothing, b$
$\varnothing, b$	$\varnothing, b$	$1, ab$	$1, ab$
$01, \varnothing$	$\varnothing, \varnothing$	$01, ab$	$01, ab$
$1, b$	$\varnothing, b$		

The lattice of theory families of $\mathcal{I}$ is shown in the diagram.



Consider $T = \{\{1\},\{a,b\}\}$ *and* $T' = \{\{1\},\varnothing\}$. *We clearly have* $\widetilde{T} = \widetilde{T'} = T$, *whence* $T \sim T'$. *On the other hand,*

$$\overleftarrow{T} = T \nsim \{\varnothing,\varnothing\} = \overleftarrow{T'}.$$

Therefore, even though $T \sim T'$, *it is not the case that* $\overleftarrow{T} \sim \overleftarrow{T'}$.

To establish some transfer theorems for the classes to be introduced shortly, we need a few results pertaining to the interaction of rough equivalence with inverse images. Key to these considerations is the following technical lemma to the effect that a filter family has an empty component if and only if its inverse theory family has a corresponding empty component. This is a relatively easy consequence of the surjectivity of interpretation morphisms.

Lemma 376 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. *Then, for all* $\Sigma \in |\mathbf{Sign}^\flat|$,

$$T_{F(\Sigma)} = \varnothing \quad \textit{iff} \quad \alpha_\Sigma^{-1}(T_{F(\Sigma)}) = \varnothing.$$

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. If $T_{F(\Sigma)} = \varnothing$, then, obviously, $\alpha^{-1}(T_{F(\Sigma)}) = \varnothing$. If, conversely, $\alpha_\Sigma^{-1}(T_{F(\Sigma)}) = \varnothing$, then, by surjectivity of $\langle F, \alpha \rangle$, $T_{F(\Sigma)} = \alpha_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)})) = \alpha_\Sigma(\varnothing) = \varnothing$. ■

We can now show that the maximum $\widetilde{\alpha^{-1}(T)}$ of the rough equivalence class of the theory family $\alpha^{-1}(T)$ in the π-institution $\mathcal{I}$ coincides with the inverse image $\alpha^{-1}(\widetilde{T})$ of the maximum $\widetilde{T}$ of the rough equivalence class of the $\mathcal{I}$-filter family T of $\mathcal{A}$ in $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Theorem 377 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then*

$$\widetilde{\alpha^{-1}(T)} = \alpha^{-1}(\widetilde{T}).$$

Proof: Let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. We separate two cases depending on whether or not $\alpha_\Sigma^{-1}(T_{F(\Sigma)}) = \varnothing$.

- Suppose $\alpha_\Sigma^{-1}(T_{F(\Sigma)}) = \varnothing$. Then, by Lemma 376, we get $T_{F(\Sigma)} = \varnothing$. Thus, we get

$$\widetilde{\alpha^{-1}(T)}_\Sigma = \mathrm{SEN}^\flat(\Sigma) = \alpha_\Sigma^{-1}(\mathrm{SEN}(F(\Sigma))) = \alpha_\Sigma^{-1}(\widetilde{T}_{F(\Sigma)}).$$

- Suppose $\alpha_\Sigma^{-1}(T_{F(\Sigma)}) \neq \varnothing$. Then, by Lemma 376, we get $T_{F(\Sigma)} \neq \varnothing$. Thus, we get

$$\widetilde{\alpha^{-1}(T)}_\Sigma = \alpha_\Sigma^{-1}(T_{F(\Sigma)}) = \alpha_\Sigma^{-1}(\widetilde{T}_{F(\Sigma)}).$$

In either case, we have $\widetilde{\alpha^{-1}(T)}_\Sigma = \alpha_\Sigma^{-1}(\widetilde{T}_{F(\Sigma)})$. Therefore, we get $\widetilde{\alpha^{-1}(T)} = \alpha^{-1}(\widetilde{T})$. ■

This implies that rough equivalence interacts smoothly with inverse images. More precisely, given two $\mathcal{I}$-filter families $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T \sim T'$ in $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ if and only if $\alpha^{-1}(T) \sim \alpha^{-1}(T')$ in $\mathrm{ThFam}(\mathcal{I})$. Contrast this with the rather rocky interaction between rough equivalence and the $\overleftarrow{\ }$ operator, as detailed before (and in) Example 375.

Corollary 378 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*,* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *an* $\mathbf{F}$*-algebraic system and* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*. Then*

$$T \sim T' \quad \textit{iff} \quad \alpha^{-1}(T) \sim \alpha^{-1}(T').$$

Proof: Let $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. We get

$$\begin{array}{lll} \alpha^{-1}(T) \sim \alpha^{-1}(T') & \text{iff} & \widetilde{\alpha^{-1}(T)} = \widetilde{\alpha^{-1}(T')} \quad (\text{Definition of } \sim) \\ & \text{iff} & \alpha^{-1}(\widetilde{T}) = \alpha^{-1}(\widetilde{T}') \quad (\text{Theorem 377}) \\ & \text{iff} & \widetilde{T} = \widetilde{T}' \quad (\text{Surjectivity of } \langle F, \alpha \rangle) \\ & \text{iff} & T \sim T'. \quad (\text{Definition of } \sim) \end{array}$$

This establishes the conclusion. ■

6.3 Roughness and Systemicity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ was called **systemic** if all its theory families are theory systems. This can be expressed in symbols by writing $\mathrm{ThFam}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$ or, alternatively, by the assertion that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = T$.

We now introduce three other *systemicity* properties that are inspired by the original, but avoid in some way the consideration of theory families with empty components or take into account the rough equivalence relation between theory families.

- We say that $\mathcal{I}$ is **roughly systemic** if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} \sim T$;
- We say that $\mathcal{I}$ is **narrowly systemic** if, for all $T \in \mathrm{ThFam}^{\not\flat}(\mathcal{I})$, $\overleftarrow{T} = T$;
- We say that $\mathcal{I}$ is **exclusively systemic** if, for all $T \in \mathrm{ThFam}^{\not\flat}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\not\flat}(\mathcal{I})$, $\overleftarrow{T} = T$.

The inclusions between these four classes are straightforward and recounted in the following

Proposition 379 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is systemic, then it is both roughly and narrowly systemic;*

(b) If $\mathcal{I}$ *is roughly systemic, then it is exclusively systemic;*

(c) If $\mathcal{I}$ *is narrowly systemic, then it is exclusively systemic.*

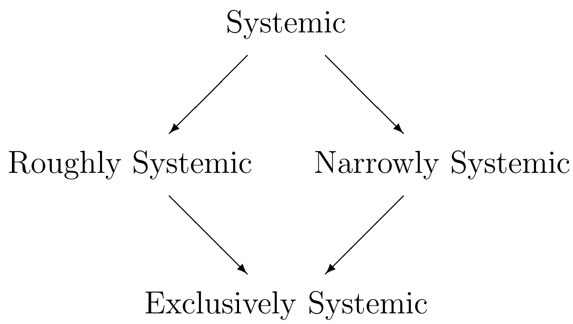
Proof:

(a) Suppose that $\mathcal{I}$ is systemic. If $T \in \mathrm{ThFam}(\mathcal{I})$, then $T = \overleftarrow{T}$. Thus, $\widetilde{T} = \widetilde{\overleftarrow{T}}$, i.e., $T \sim \overleftarrow{T}$ and, hence, $\mathcal{I}$ is roughly systemic. On the other hand, if $T \in \mathrm{ThFam}^{\not\flat}(\mathcal{I})$, then, since $\mathrm{ThFam}^{\not\flat}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by hypothesis, $\overleftarrow{T} = T$. Thus, $\mathcal{I}$ is also narrowly systemic.

(b) Suppose that $\mathcal{I}$ is roughly systemic. Let $T \in \mathrm{ThFam}^{\not\flat}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\not\flat}(\mathcal{I})$. Since $\mathrm{ThFam}^{\not\flat}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by hypothesis, $\overleftarrow{T} \sim T$, i.e., $\widetilde{\overleftarrow{T}} = \widetilde{T}$. However, since $T \in \mathrm{ThFam}^{\not\flat}(\mathcal{I})$ and $\overleftarrow{T} \in \mathrm{ThSys}^{\not\flat}(\mathcal{I})$, we conclude that $\overleftarrow{T} = \widetilde{\overleftarrow{T}} = \widetilde{T} = T$. Thus, $\mathcal{I}$ is exclusively systemic.

(c) Suppose $\mathcal{I}$ is narrowly systemic. Then, by hypothesis, for all $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$ and, therefore, a fortiori, for all such T, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, we get that $\overleftarrow{T} = T$. Hence, $\mathcal{I}$ is exclusively systemic. ■

Proposition 379 establishes the following *hierarchy of roughness and systemicity properties*:



A related result, which partially explains the introduction of the roughness and systemicity classes and which, in fact, forms the undercurrent of much of the ideas underlying developments in the entire chapter, assures that all three bottom properties actually coincide with systemicity itself, in case the π-institution under consideration has theorems.

Proposition 380 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is exclusively systemic and has theorems, then it is systemic.*

Proof: Suppose $\mathcal{I}$ has theorems. Then $\mathrm{ThFam}^{\lightning}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$, and $\mathrm{ThSys}^{\lightning}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$. Moreover, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I}) = \mathrm{ThSys}^{\lightning}(\mathcal{I})$. Therefore, the defining condition of exclusive systemicity is equivalent to asserting that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} = T$, i.e., it is equivalent to systemicity. ■

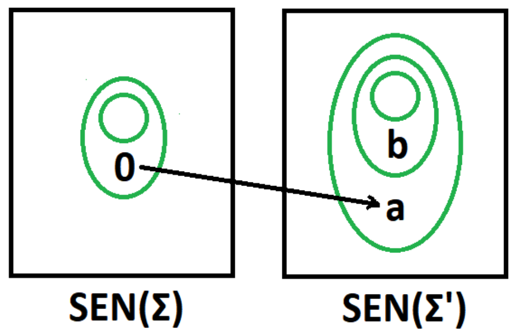
We present two examples that will show that all four classes in the roughness and systemicity hierarchy depicted above are indeed different. The first example shows that the southwest arrows represent proper inclusions, i.e.,

- Systemic π-institutions form a proper subclass of roughly systemic π-institutions;
- Exclusively systemic π-institutions form a proper subclass of narrowly systemic π-institutions.

This is accomplished by presenting a π-institution which is roughly systemic but fails to be narrowly systemic.

Example 381 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*;*
- $N^\flat$ *is the trivial clone.*



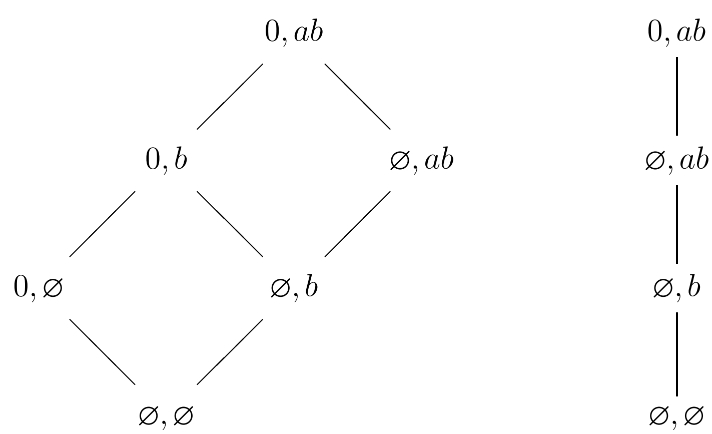
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$

There are six theory families, but only four theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$
$\varnothing, \varnothing$	$\varnothing, \varnothing$
$0, \varnothing$	$\varnothing, \varnothing$
$\varnothing, b$	$\varnothing, b$
$0, b$	$\varnothing, b$
$\varnothing, ab$	$\varnothing, ab$
$0, ab$	$0, ab$

The complete lattice of theory families is shown on the left, whereas that of the theory systems is shown on the right.



To check that this π-institution is roughly systemic, it is only necessary to focus on theory families T for which $\overleftarrow{T} \neq T$. There are two such, namely $T = \{\{0\}, \varnothing\}$ and $T = \{\{0\}, \{b\}\}$. We have (using obvious shorthand):

$$\overleftarrow{\widetilde{0,\varnothing}} = \widetilde{\varnothing,\varnothing} = 0, ab = \widetilde{0,\varnothing};$$
$$\overleftarrow{\widetilde{0,b}} = \widetilde{\varnothing,b} = 0, b = \widetilde{0,b}.$$

Thus, $\mathcal{I}$ is indeed roughly systemic. On the other hand, for the theory $T = \{\{0\}, \{b\}\}$ above, we have $T \in \mathrm{ThFam}^{\not\sharp}(\mathcal{I})$ and, moreover, $\overleftarrow{T} = \{\varnothing, \{b\}\} \neq T$. Hence, $\mathcal{I}$ fails to be narrowly systemic.

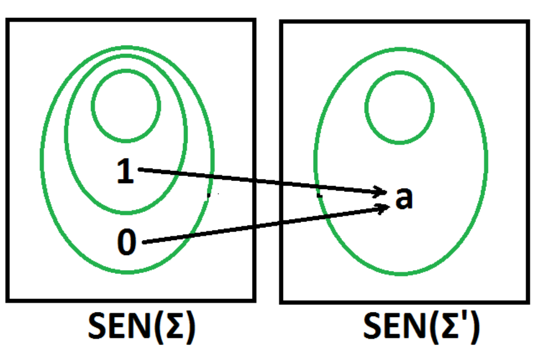
The second example shows that the southeast arrows represent proper inclusions, i.e.,

- The class of systemic π-institutions is a proper subclass of that of narrowly systemic π-institutions;
- The class of roughly systemic π-institutions forms a proper subclass of that of exclusively systemic π-institutions.

It exhibits a π-institution which is narrowly systemic but not roughly systemic.

Example 382 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

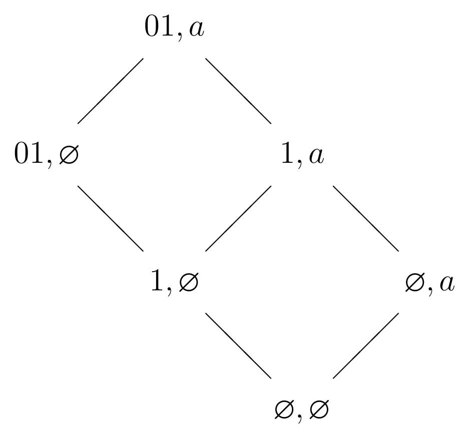
- $\mathbf{Sign}^\flat$ *is the category with objects Σ and Σ' and a unique (non-identity) morphism $f : \Sigma \to \Sigma'$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$

Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$*, only four of which are theory systems, and only two of which are in* $\mathrm{ThFam}^{\nsim}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



Since $\mathrm{ThFam}^{\nsim}(\mathcal{I}) = \{\{1,a\},\{01,a\}\}$ *and* $\overleftarrow{1,a} = 1,a$ *and* $\overleftarrow{01,a} = 01,a$*, we get that $\mathcal{I}$ is narrowly systemic. On the other hand, consider $T = \{\{1\},\varnothing\}$. We have*

$$\widetilde{\overleftarrow{1,\varnothing}} = \widetilde{\varnothing,\varnothing} = 01,a \neq 1,a = \widetilde{1,\varnothing},$$

whence, $\overleftarrow{1,\varnothing} \nsim 1,\varnothing$ *and, hence, $\mathcal{I}$ is not roughly systemic.*

Finally, it is not difficult to show that rough systemicity implies stability.

Lemma 383 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on* $\mathbf{F}$*. If $\mathcal{I}$ is roughly systemic, then it is stable.*

Proof: Suppose $\mathcal{I}$ is roughly systemic and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, by rough systemicity, $\overleftarrow{T} \sim T$, i.e., $\widetilde{\overleftarrow{T}} = \widetilde{T}$. Therefore, using Proposition 369, we get $\Omega(\overleftarrow{T}) = \Omega(\widetilde{\overleftarrow{T}}) = \Omega(\widetilde{T}) = \Omega(T)$. This shows that $\mathcal{I}$ is stable. ∎

6.4 Rough Injectivity

In this section we study classes of π-institutions defined using injectivity properties of the Leibniz operator applied on rough equivalence classes.

Definition 384 (Rough Injectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a π-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **roughly family injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T \sim T';$$

- $\mathcal{I}$ *is called* **roughly left injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} \sim \overleftarrow{T'}.$$

- $\mathcal{I}$ *is called* **roughly right injective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T \sim T'.$$

- $\mathcal{I}$ *is called* **roughly system injective** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T \sim T'.$$

Recall that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$, we say that $\mathcal{I}$ is *roughly systemic* if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T} \sim T$. In an analog of Lemma 207, we show that rough right injectivity implies rough systemicity and, hence, by Theorem 370, stability.

Lemma 385 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is roughly right injective, then it is roughly systemic.*

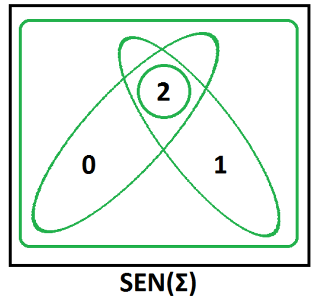
Proof: Suppose that $\mathcal{I}$ is roughly right injective and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, by Proposition 42, that $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Therefore, we get $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$. Hence, by rough right injectivity, we get that $\overleftarrow{T} \sim T$. Hence $\mathcal{I}$ is roughly systemic. ∎

We give another example to show that the converse of Lemma 385 does not hold in general. That is, that there exists a roughly systemic π-institution that is not roughly right injective.

Example 386 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$;
- $N^\flat$ *is the clone generated by the three unary natural transformations* $\sigma^\flat, \tau^\flat, \rho^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *given by the following table:*

x	$\sigma^\flat_\Sigma(x)$	$\tau^\flat_\Sigma(x)$	$\rho^\flat_\Sigma(x)$
0	0	0	0
1	2	1	0
2	2	1	2

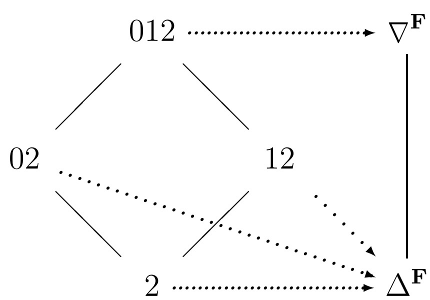


Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has theorems and, therefore, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$. *Moreover, since* $\mathbf{Sign}^\flat$ *is trivial, $\mathcal{I}$ is systemic. These observations imply that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T \sim \overleftarrow{T}$ and, hence, $\mathcal{I}$ is roughly systemic.*

On the other hand, the lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



Since

$$\Omega(\overleftarrow{\{\{0,2\}\}}) = \Omega(\{\{0,2\}\}) = \Delta^{\mathbf{F}} = \Omega(\{\{1,2\}\}) = \Omega(\overleftarrow{\{\{1,2\}\}}),$$

whereas $\{\{0,2\}\} \nsim \{\{1,2\}\}$, we get that $\mathcal{I}$ is not roughly right injective.

Next we look into establishing the *rough injectivity hierarchy* of π-institutions. The following relationships can be established between the four rough injectivity classes.

Proposition 387 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is roughly right injective, then it is roughly family injective;

(b) If $\mathcal{I}$ is roughly family injective, then it is roughly system injective;

(c) *If $\mathcal{I}$ is roughly left injective, then it is roughly system injective.*

Proof:

(a) Suppose that $\mathcal{I}$ is roughly right injective and let $T, T' \in \text{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. By Lemma 385, $\mathcal{I}$ is roughly systemic, whence $\overleftarrow{T} \sim T$ and $\overleftarrow{T'} \sim T'$. Thus, by Theorem 370, we get

$$\Omega(\overleftarrow{T}) = \Omega(T) = \Omega(T') = \Omega(\overleftarrow{T'}).$$

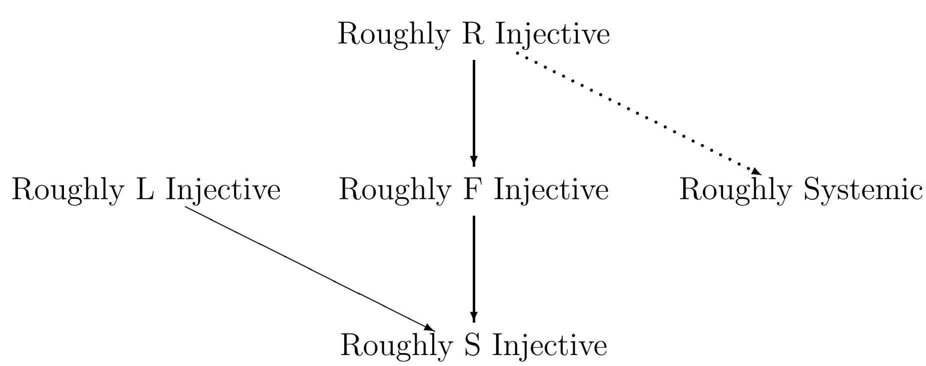
Now applying rough right injectivity gives $T \sim T'$. Hence, $\mathcal{I}$ is roughly family injective.

(b) Suppose that $\mathcal{I}$ is roughly family injective and let $T, T' \in \text{ThSys}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by rough family injectivity, we get $T \sim T'$. Therefore, $\mathcal{I}$ is roughly system injective.

(c) Suppose that $\mathcal{I}$ is roughly left injective and let $T, T' \in \text{ThSys}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. By rough left injectivity, we conclude that $\overleftarrow{T} \sim \overleftarrow{T'}$. However, since T, T' are theory systems, we have $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Hence we get $T \sim T'$ and $\mathcal{I}$ is roughly system injective.

■

We have now established the following **rough injectivity hierarchy** of π-institutions.



We formulate, next, two additional properties concerning the relationships between rough injectivity classes. First, it turns out that the separating property between rough right injectivity and rough system injectivity is exactly rough systemicity.

Proposition 388 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *$\mathcal{I}$ is roughly right injective if and only if it is roughly system injective and roughly systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly right injective. Then, by Lemma 385, it is roughly systemic and by Proposition 387 it is roughly system injective.

Suppose conversely, that $\mathcal{I}$ is roughly system injective and roughly systemic and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. By rough system injectivity and Proposition 42, we get $\overleftarrow{T} \sim \overleftarrow{T'}$. Hence, by rough systemicity, $T \sim \overleftarrow{T} \sim \overleftarrow{T'} \sim T'$. Thus, $\mathcal{I}$ is roughly right injective. ■

Second, we show that rough system injectivity together with stability imply rough left injectivity.

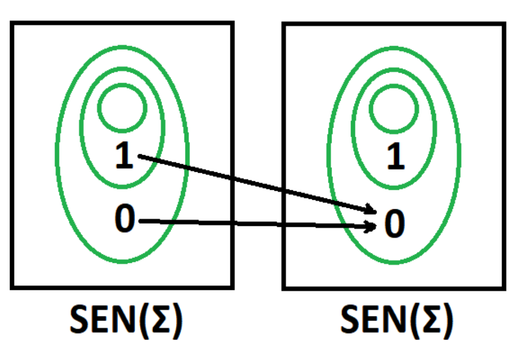
Proposition 389 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system injective and stable, then it is roughly left injective.*

Proof: Suppose that $\mathcal{I}$ is roughly system injective and stable and consider $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by stability, $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Hence, since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, by rough system injectivity, $\overleftarrow{T} \sim \overleftarrow{T'}$. This shows that $\mathcal{I}$ is roughly left injective. ■

Even though rough left injectivity does imply rough system injectivity, as was shown in Proposition 387, rough left injectivity does not imply stability in general, as is shown in the following example, and, hence, the converse of Proposition 389 fails in general.

Example 390 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

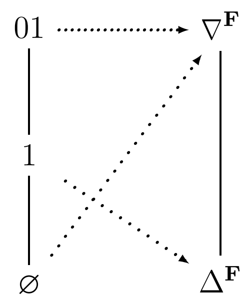
- *$\mathbf{Sign}^\flat$ is the category with the single object Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ and $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;*
- *$N^\flat$ is the trivial clone, consisting of the projections only.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ has three theory families $\{\varnothing\}$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\{\varnothing\}$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



The only theory families for which $\Omega(T) = \Omega(T')$ are $T = \{\{0,1\}\}$ and $T' = \{\varnothing\}$. For those, we get $\overleftarrow{T} = T \sim T' = \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is roughly left injective. On the other hand, we get $\Omega(\overleftarrow{\{\{1\}\}}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} \neq \Delta^{\mathbf{F}} = \Omega(\{\{1\}\})$. Therefore, $\mathcal{I}$ is not a stable π-institution.

We now present three examples to show that all inclusions established between rough injectivity classes and depicted in the diagram above are proper inclusions. The first example will show that the class of roughly right injective π-institutions is a proper subclass of the class of roughly family injective π-institutions.

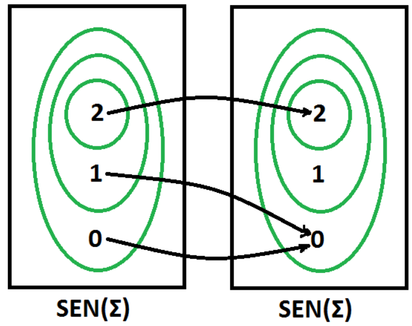
Example 391 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is given by $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ and $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ and $\mathrm{SEN}^\flat(f)(2) = 2$;*
- *$N^\flat$ is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\}, \{1,2\}, \{0,1,2\}\}$. Since $\mathcal{I}$ has theorems, rough equivalence on $\mathrm{ThFam}(\mathcal{I})$ coincides with the identity relation.

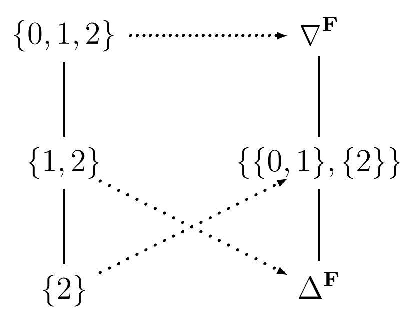
The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$



Since $\{\{1,2\}\}$ is a theory family that is not a theory system, $\mathcal{I}$ is not systemic. Thus, rough equivalence being the identity, $\mathcal{I}$ is not roughly systemic and, hence, by Lemma 385, $\mathcal{I}$ is not roughly right injective.

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



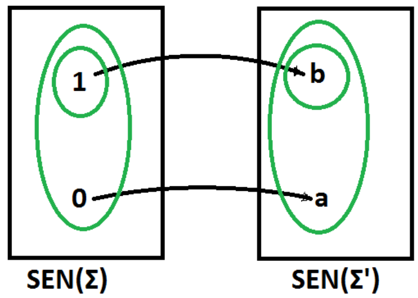
It is obvious from the diagram that $\mathcal{I}$ is family injective, and therefore, rough equivalence being the identity, it is also roughly family injective.

Returning more explicitly to right rough injectivity, note that for $T = \{\{2\}\}$ and $T' = \{\{1,2\}\}$, we have $\overleftarrow{T} = T = \overleftarrow{T'}$, whence $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$, whereas, obviously, $T \neq T'$ and, hence, $T \not\approx T'$.

The second example shows that there exists a roughly left injective π-institution that is not roughly family injective.

Example 392 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with objects Σ and Σ' and a unique (non-identity) morphism $f : \Sigma \to \Sigma'$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ and $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;*
- *$N^\flat$ is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

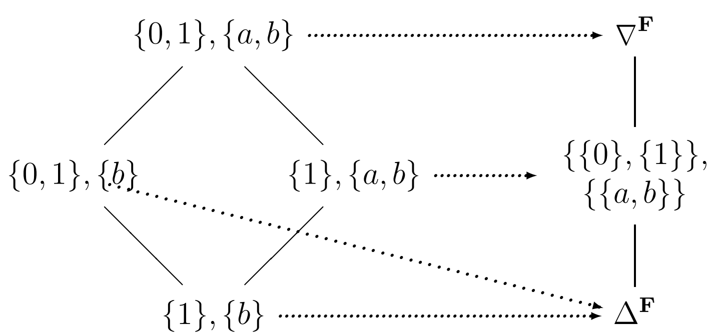
$$\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a,b\}\}.$$

Again, since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$.

The following table shows the action of $\overleftarrow{\ }$ *on theory families, where rows correspond to T_Σ and columns to $T_{\Sigma'}$ and each entry is written as $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.*

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\}, \{b\}$	$\{1\}, \{a,b\}$
$\{0,1\}$	$\{1\}, \{b\}$	$\{0,1\}, \{a,b\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



Since the only two theory families that have the same Leibniz congruence system are $\{\{0,1\},\{b\}\}$ and $\{\{1\},\{b\}\}$ and it holds that

$$\overleftarrow{\{\{0,1\},\{b\}\}} = \overleftarrow{\{\{1\},\{b\}\}} = \{\{1\},\{b\}\},$$

we conclude that $\mathcal{I}$ is left injective. Moreover, since rough equivalence coincides with the identity, $\mathcal{I}$ is also roughly left injective.

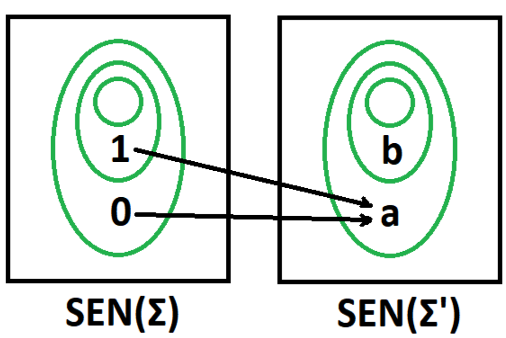
From the diagram, it is also clear that $\mathcal{I}$ is not family injective, since the two theory families $\{\{0,1\},\{b\}\}$ and $\{\{1\},\{b\}\}$ have the same Leibniz *congruence system. The same counterexample, keeping in mind the fact that rough equivalence coincides with the identity, showcases that $\mathcal{I}$ is not roughly family injective either.*

The third example shows that there exists a roughly family injective π-institution that is not roughly left injective. Combined with the preceding example, it has the effect of establishing the following facts:

- The classes of roughly family injective and roughly left injective π-institutions are incomparable. Contrast this with the case of injectivity, where family injectivity implies left injectivity.
- The class of roughly family injective π-institutions is properly contained in the class of roughly system injective π-institutions.
- Similarly, the class of roughly left injective π-institutions is a proper subclass of the class of roughly system injective π-institutions.

Example 393 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = a$;
- $N^\flat$ *is the trivial clone.*



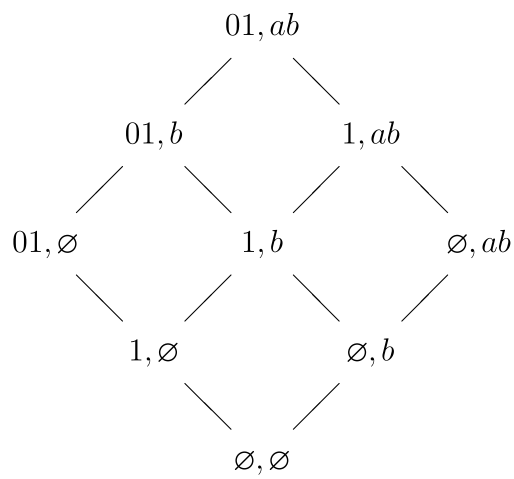
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are nine theory families, but only five theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$\varnothing,\varnothing$	$\varnothing,\varnothing$	$\varnothing,ab$	$\varnothing,ab$
$1,\varnothing$	$\varnothing,\varnothing$	$01,b$	$\varnothing,b$
$\varnothing,b$	$\varnothing,b$	$1,ab$	$1,ab$
$01,\varnothing$	$\varnothing,\varnothing$	$01,ab$	$01,ab$
$1,b$	$\varnothing,b$		

The lattice of theory families of $\mathcal{I}$ *is shown in the diagram.*



We show that $\mathcal{I}$ *is roughly family injective. The following table summarizes the theory families together with their associated Leibniz congruence systems.*

T	$\Omega(T)$
$\{\varnothing,\varnothing\},\{01,\varnothing\},\{\varnothing,ab\},\{01,ab\}$	$\nabla^{\mathbf{F}}$
$\{\varnothing,b\},\{01,b\}$	$\{\nabla^{\mathbf{F}}_{\Sigma},\Delta^{\mathbf{F}}_{\Sigma'}\}$
$\{1,\varnothing\},\{1,ab\}$	$\{\Delta^{\mathbf{F}}_{\Sigma},\nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{1,b\}$	$\Delta^{\mathbf{F}}$

Since, every row on the left column of this table contains roughly equivalent theory families, we conclude that $\mathcal{I}$ *is roughly family injective.*

On the other hand, consider $T=\{1,ab\}$ *and* $T'=\{1,\varnothing\}$. *We have*

$$\overleftarrow{T}=\{1,ab\}\not\sim\{\varnothing,\varnothing\}=\overleftarrow{T'},$$

but

$$\Omega(T)=\Omega(\{1,ab\})=\{\Delta^{\mathbf{F}}_{\Sigma},\nabla^{\mathbf{F}}_{\Sigma'}\}=\Omega(\{1,\varnothing\})=\Omega(T').$$

We conclude that $\mathcal{I}$ *is not roughly left injective.*

We now clarify the connections between rough injectivity and injectivity classes. It turns out that membership in an injectivity class implies membership in the corresponding rough injectivity class and, also, possession of theorems. Conversely, membership in a rough injectivity class plus possession of theorems entails membership in the corresponding injectivity class.

Theorem 394 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is right injective if and only if it is roughly right injective and has theorems;*

(b) $\mathcal{I}$ *is family injective if and only if it is roughly family injective and has theorems;*

(c) $\mathcal{I}$ *is left injective if and only if it is roughly left injective and has theorems;*

(d) $\mathcal{I}$ *is system injective if and only if it is roughly system injective and has theorems.*

Proof:

(a) Suppose that $\mathcal{I}$ is right injective. First, note that $\Omega(\overleftarrow{\mathrm{SEN}^\flat}) = \Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}} = \Omega(\varnothing) = \Omega(\overleftarrow{\varnothing})$. Thus, if $\mathcal{I}$ does not have theorems, $\mathrm{SEN}^\flat = \varnothing$, a contradiction. Therefore, $\mathcal{I}$ has theorems. Second, if $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$, then, by right injectivity, $T = T'$ and, hence, $T \sim T'$. Thus, $\mathcal{I}$ is roughly right injective.

Assume, conversely, that $\mathcal{I}$ is roughly right injective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Then, by rough right injectivity, we get $T \sim T'$. On the other hand, since $\mathcal{I}$ has theorems, rough equivalence collapses to the identity relation, whence $T = T'$. Therefore, $\mathcal{I}$ is right injective.

(b) Suppose that $\mathcal{I}$ is family injective. First, note that $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}} = \Omega(\varnothing)$. Thus, if $\mathcal{I}$ does not have theorems, $\mathrm{SEN}^\flat = \varnothing$, a contradiction. Therefore, $\mathcal{I}$ has theorems. Second, if $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$, then, by family injectivity, $T = T'$ and, hence, $T \sim T'$. Thus, $\mathcal{I}$ is roughly family injective.

Assume, conversely, that $\mathcal{I}$ is roughly family injective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by rough family injectivity, we get $T \sim T'$. On the other hand, since $\mathcal{I}$ has theorems, rough equivalence collapses to the identity relation, whence $T = T'$. Therefore, $\mathcal{I}$ is family injective.

(c) Suppose that $\mathcal{I}$ is left injective. First, note that $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}} = \Omega(\varnothing)$. Thus, if $\mathcal{I}$ does not have theorems, $\mathrm{SEN}^\flat = \overleftarrow{\mathrm{SEN}^\flat} = \overleftarrow{\varnothing} = \varnothing$, a contradiction. Therefore, $\mathcal{I}$ has theorems. Second, if $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$, then, by left injectivity, $\overleftarrow{T} = \overleftarrow{T'}$ and, hence, $\overleftarrow{T} \sim \overleftarrow{T'}$. Thus, $\mathcal{I}$ is roughly left injective.

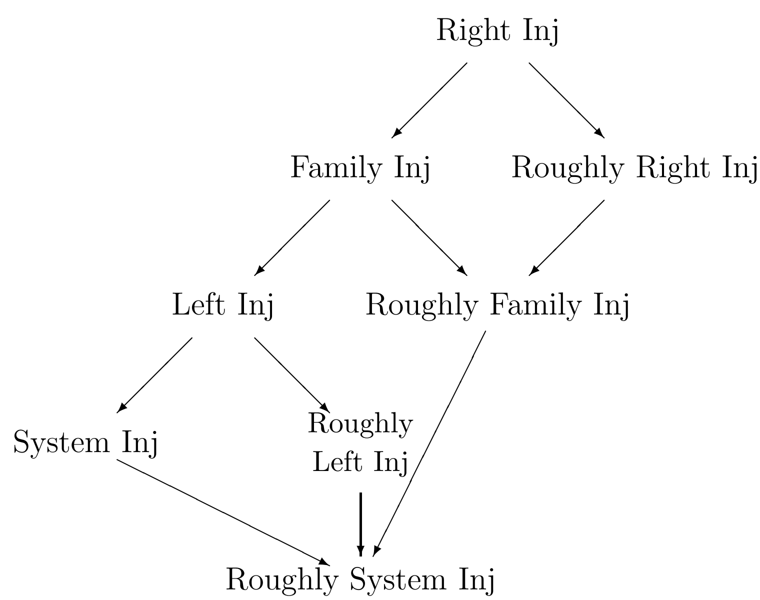
Assume, conversely, that $\mathcal{I}$ is roughly left injective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by rough left injectivity, we get $\overleftarrow{T} \sim \overleftarrow{T'}$. On the other hand, since $\mathcal{I}$ has theorems, rough equivalence collapses to the identity relation, whence $\overleftarrow{T} = \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is left injective.

(d) Suppose that $\mathcal{I}$ is system injective. First, note that $\Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}} = \Omega(\varnothing)$. Thus, if $\mathcal{I}$ does not have theorems, $\mathrm{SEN}^\flat = \varnothing$, a contradiction. Therefore, $\mathcal{I}$ has theorems. Second, if $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$, then, by system injectivity, $T = T'$ and, hence, $T \sim T'$. Thus, $\mathcal{I}$ is roughly system injective.

Assume, conversely, that $\mathcal{I}$ is roughly system injective and has theorems. Let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by rough system injectivity, we get $T \sim T'$. On the other hand, since $\mathcal{I}$ has theorems, rough equivalence collapses to the identity relation, whence $T = T'$. Therefore, $\mathcal{I}$ is system injective.

■

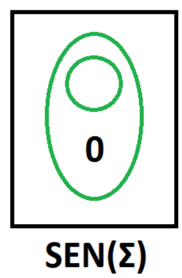
The work in Section 3.6, together with the work done in the present section and Theorem 394, reveal the following hierarchy of injectivity and rough injectivity classes, which was previewed at the beginning of Section 6.2.



To complete the demonstration that all classes in the depicted hierarchy are distinct we provide an example of a π-institution which belongs to all steps in the rough injectivity hierarchy but possesses none of the four (gentle) injectivity properties.

Example 395 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

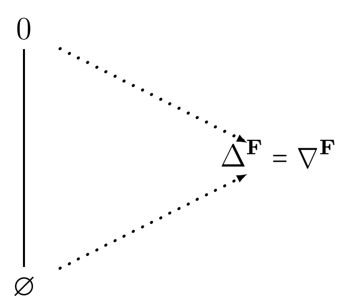
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



$\mathcal{I}$ *is roughly system injective, since* $\Omega(T) = \Omega(T')$ *implies* $T \sim T'$*. Since* $\mathcal{I}$ *is also systemic, it is, a fortiori, roughly systemic and stable. Now, by either direct calculation or based on Propositions 388 and 389, we get that* $\mathcal{I}$ *is also roughly right injective (and, hence, roughly family injective) and roughly left injective, respectively.*

On the other hand, since $\varnothing \neq \{0\}$ *but* $\Omega(\varnothing) = \nabla^{\mathbf{F}} = \Omega(\{0\})$*,* $\mathcal{I}$ *is not system injective and, hence, a fortiori,* $\mathcal{I}$ *has none of the four injectivity properties.*

The rough injectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 396 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is roughly right injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $T \sim T'$*;*

(b) $\mathcal{I}$ *is roughly family injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T \sim T'$*;*

(c) $\mathcal{I}$ *is roughly left injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $\overleftarrow{T} \sim \overleftarrow{T'}$*;*

(d) $\mathcal{I}$ *is roughly system injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T \sim T'$*.*

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$ and taking into account that, by Lemma 51, $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$.

For the "only if", suppose that $\mathcal{I}$ is roughly right injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) = \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\Omega(\alpha^{-1}(\overleftarrow{T})) = \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Hence, by Lemma 6, $\Omega(\overleftarrow{\alpha^{-1}(T)}) = \Omega(\overleftarrow{\alpha^{-1}(T')})$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough right injectivity, $\alpha^{-1}(T) \sim \alpha^{-1}(T')$. Thus, by Corollary 378, $T \sim T'$.

(b) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly family injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) = \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) = \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough family injectivity, $\alpha^{-1}(T) \sim \alpha^{-1}(T')$. Thus, by Corollary 378, $T \sim T'$.

(c) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly left injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) = \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) = \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough left injectivity, $\overleftarrow{\alpha^{-1}(T)} \sim \overleftarrow{\alpha^{-1}(T')}$. Thus, by Lemma 6, $\alpha^{-1}(\overleftarrow{T}) \sim \alpha^{-1}(\overleftarrow{T'})$. Hence, by Corollary 378, $\overleftarrow{T} \sim \overleftarrow{T'}$.

(d) Similar to Part (b).

■

Finally, we may recast the rough injectivity classes in terms of the injectivity of mappings from posets of classes of theory or filter families/systems into posets of congruence systems.

Proposition 397 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly family injective;*

(b) $\Omega : \widetilde{\mathrm{ThFam}}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathrm{FiFam}}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system injectivity, we have

Proposition 398 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly system injective;*

(b) $\Omega : \widetilde{\mathrm{ThSys}}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathrm{FiSys}}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

6.5 Narrow Injectivity

In this section we study classes of π-institutions defined using injectivity properties of the Leibniz operator restricted to $\mathrm{ThFam}^{\natural}(\mathcal{I})$. We call those *narrow injectivity* properties in analogy with the terminology adopted in Section 6.3, differentiating rough systemicity and narrow systemicity, the two strongest properties combining systemicity with rough equivalence.

Definition 399 (Narrow Injectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **narrowly family injective** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T = T';$$
- $\mathcal{I}$ *is called* **narrowly left injective** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} = \overleftarrow{T'}.$$
- $\mathcal{I}$ *is called* **narrowly right injective** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$,
$$\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T = T'.$$
- $\mathcal{I}$ *is called* **narrowly system injective** *if, for all* $T, T' \in \mathrm{ThSys}^{\not\wr}(\mathcal{I})$,
$$\Omega(T) = \Omega(T') \quad \textit{implies} \quad T = T'.$$

These narrow injectivity properties have the following useful characterizations.

Proposition 400 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is narrowly family injective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \Omega(T')$ *implies* $T \sim T'$;

(b) $\mathcal{I}$ *is narrowly left injective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) = \Omega(T')$ *implies* $\overleftarrow{\widetilde{T}} = \overleftarrow{\widetilde{T'}}$;

(c) $\mathcal{I}$ *is narrowly right injective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\overleftarrow{\widetilde{T}}) = \Omega(\overleftarrow{\widetilde{T'}})$ *implies* $T \sim T'$;

(d) $\mathcal{I}$ *is narrowly system injective if and only if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$, *such that* $\widetilde{T}, \widetilde{T'} \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) = \Omega(T')$ *implies* $T \sim T'$.

Proof:

(a) Suppose that $\mathcal{I}$ is narrowly family injective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Consider $\widetilde{T}, \widetilde{T'} \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$. By Proposition 369, $\Omega(\widetilde{T}) = \Omega(T) = \Omega(T') = \Omega(\widetilde{T'})$. Thus, by hypothesis, $\widetilde{T} = \widetilde{T'}$, i.e., $T \sim T'$. Therefore, the asserted condition holds.

Assume, conversely, that the asserted condition holds and let $T, T' \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, since $\mathrm{ThFam}^{\not\wr}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by hypothesis, $T \sim T'$, i.e., $\widetilde{T} = \widetilde{T'}$. Since, however, $T, T' \in \mathrm{ThFam}^{\not\wr}(\mathcal{I})$, we get $T = \widetilde{T} = \widetilde{T'} = T'$. Thus, $\mathcal{I}$ is narrowly family injective.

(b) Suppose that $\mathcal{I}$ is narrowly left injective and let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then $\widetilde{T},\widetilde{T'} \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$ and, by Proposition 369, $\Omega(\widetilde{T}) = \Omega(\widetilde{T'})$. Thus, by hypothesis, $\overleftarrow{\widetilde{T}} = \overleftarrow{\widetilde{T'}}$.

Assume, conversely, that the asserted condition holds and let $T,T' \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by hypothesis, $\overleftarrow{\widetilde{T}} = \overleftarrow{\widetilde{T'}}$. Since, however, $T,T' \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, we get $\overleftarrow{T} = \overleftarrow{\widetilde{T}} = \overleftarrow{\widetilde{T'}} = \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is narrowly left injective.

(c) Suppose that $\mathcal{I}$ is narrowly right injective and let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{\widetilde{T}}) = \Omega(\overleftarrow{\widetilde{T'}})$. Since $\widetilde{T},\widetilde{T'} \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, we get, by hypothesis, $\widetilde{T} = \widetilde{T'}$, i.e., $T \sim T'$.

Assume, conversely, that the asserted condition holds and let $T,T' \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Then, since $T,T' \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, we get $\Omega(\overleftarrow{\widetilde{T}}) = \Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'}) = \Omega(\overleftarrow{\widetilde{T'}})$. Now, by hypothesis, $T \sim T'$, i.e., $\widetilde{T} = \widetilde{T'}$ and, therefore, $T = T'$. We conclude that $\mathcal{I}$ is narrowly right injective.

(d) Suppose $\mathcal{I}$ is narrowly system injective and let $T,T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T},\widetilde{T'} \in \mathrm{ThSys}(\mathcal{I})$ and $\Omega(T) = \Omega(T')$. Then $\widetilde{T},\widetilde{T'} \in \mathrm{ThSys}^{\not\leq}(\mathcal{I})$ and, by Proposition 369, $\Omega(\widetilde{T}) = \Omega(T) = \Omega(T') = \Omega(\widetilde{T'})$. Thus, by hypothesis, $\widetilde{T} = \widetilde{T'}$, i.e., $T \sim T'$.

Assume, conversely, that the asserted condition holds and let $T,T' \in \mathrm{ThSys}^{\not\leq}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, since $T,T' \in \mathrm{ThSys}^{\not\leq}(\mathcal{I})$, we get $\widetilde{T} = T, \widetilde{T'} = T' \in \mathrm{ThSys}(\mathcal{I})$ and, therefore, by hypothesis, $T \sim T'$, i.e., $\widetilde{T} = \widetilde{T'}$. But this gives $T = \widetilde{T} = \widetilde{T'} = T'$. Thus, $\mathcal{I}$ is narrowly system injective.

■

It will be shown, next, in an analog of Lemma 385, that narrow right injectivity implies exclusive systemicity. Recall that, given a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$, we say that $\mathcal{I}$ is *exclusively systemic* if, for all $T \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\not\leq}(\mathcal{I})$, $\overleftarrow{T} = T$.

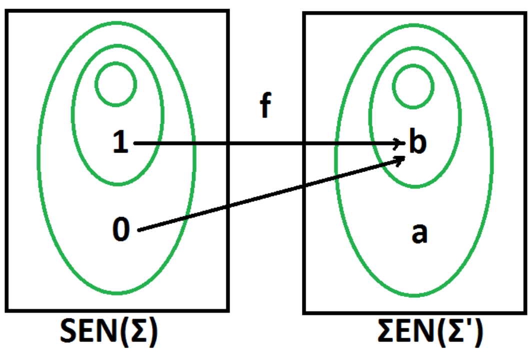
Lemma 401 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly right injective, then it is exclusively systemic.*

Proof: Assume $\mathcal{I}$ is narrowly right injective and let $T \in \mathrm{ThFam}^{\not\leq}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\not\leq}(\mathcal{I})$. Then, since, by Proposition 2, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$, we have $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$ and, hence, by narrow right injectivity, $\overleftarrow{T} = T$. Therefore, $\mathcal{I}$ is exclusively systemic. ■

However, as opposed to rough right injectivity, as the next examples demonstrate, narrow right injectivity implies neither rough nor narrow systemicity, in general. The first example showcases a π-institution which is narrowly right injective, but fails to be roughly systemic.

Example 402 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

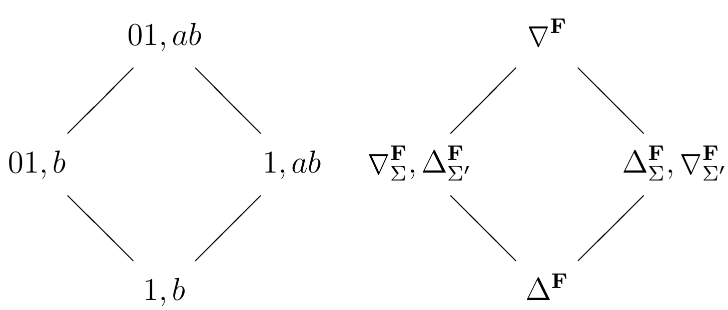
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = b$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

Clearly, there are only four theory families in $\mathrm{ThFam}^\sharp(\mathcal{I})$*, all of which are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*



From this diagram and the fact that all theory families depicted are theory systems, we can see that, for all $T, T' \in \mathrm{ThFam}^\sharp(\mathcal{I})$,

$$\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T = T'.$$

Therefore, $\mathcal{I}$ is indeed narrowly right injective.

On the other hand, consider $T = \{\{1\}, \varnothing\}$. Then we have

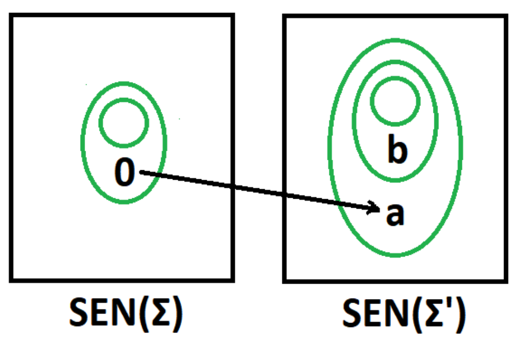
$$\widetilde{\overleftarrow{T}} = \widetilde{\widetilde{\varnothing}} = \mathrm{SEN}^\flat \neq \{\{1\}, \{a,b\}\} = \widetilde{T}.$$

This shows that $\overleftarrow{T} \nsim T$ and, therefore, $\mathcal{I}$ is not roughly systemic.

The next example exhibits a π-institution which is also narrowly right injective, but fails to be narrowly systemic.

Example 403 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects Σ and Σ' and a unique morphism $f : \Sigma \to \Sigma'$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ and $\mathrm{SEN}^\flat(f)(0) = a$;*
- $N^\flat$ *is the trivial clone.*



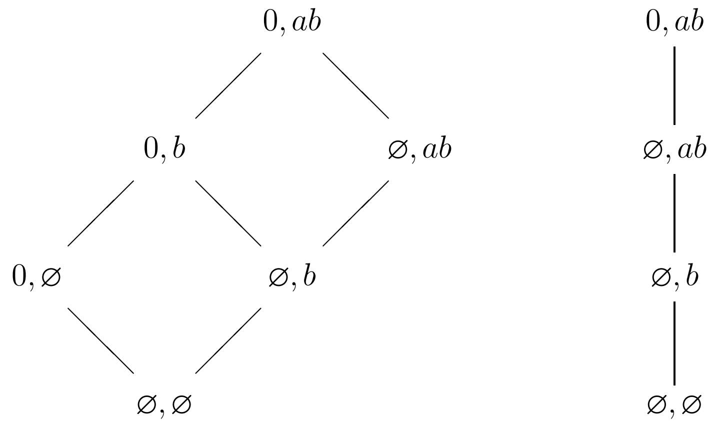
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are six theory families, but only four theory systems. The action of $\overleftarrow{\ }$ on theory families is given in the table below.

T	$\overleftarrow{T}$
$\varnothing, \varnothing$	$\varnothing, \varnothing$
$0, \varnothing$	$\varnothing, \varnothing$
$\varnothing, b$	$\varnothing, b$
$0, b$	$\varnothing, b$
$\varnothing, ab$	$\varnothing, ab$
$0, ab$	$0, ab$

The complete lattice of theory families is shown on the left.



That of the theory systems is shown on the right.

The only theory families in $\mathrm{ThFam}^{\not\sim}(\mathcal{I})$ *are* $T = \{\{0\},\{b\}\}$ *and* $\mathrm{SEN}^\flat$. *Since*

$$\Omega(\overleftarrow{T}) = \Omega(\varnothing,b) = \nabla^{\mathbf{F}}_{\Sigma},\Delta^{\mathbf{F}}_{\Sigma} \neq \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat) = \Omega(\overleftarrow{\mathrm{SEN}^\flat}),$$

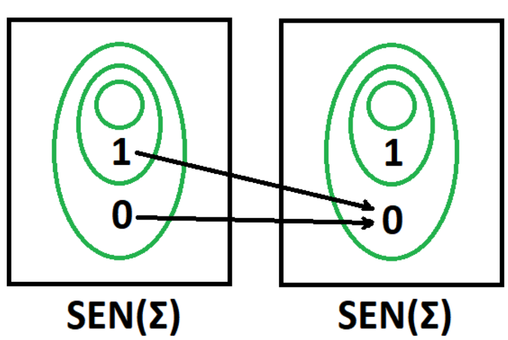
we conclude that $\mathcal{I}$ *is narrowly right injective.*

On the other hand, since $\overleftarrow{T} = \{\varnothing,\{b\}\} \neq T$, $\mathcal{I}$ *is not narrowly systemic.*

The converse of Lemma 401 fails in general. That is, there exists a π-institution which is exclusively systemic but is not narrowly right injective.

Example 404 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

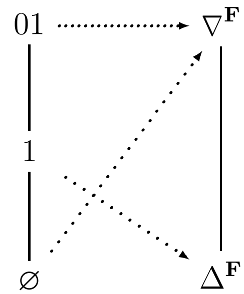
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f:\Sigma\to\Sigma$, *such that* $f\circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ has three theory families, $\varnothing$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\varnothing$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



Since there exists only one theory family T in $\mathrm{ThFam}^\natural(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^\natural(\mathcal{I})$, namely $T = \mathrm{SEN}^\flat$, and $\overleftarrow{\mathrm{SEN}^\flat} = \mathrm{SEN}^\flat$, $\mathcal{I}$ is exclusively systemic. On the other hand, $\{\{1\}\}, \mathrm{SEN}^\flat \in \mathrm{ThFam}^\natural(\mathcal{I})$ and

$$\Omega(\overleftarrow{1}) = \Omega(\varnothing) = \nabla^{\mathbf{F}} = \Omega(\mathrm{SEN}^\flat) = \Omega(\overleftarrow{\mathrm{SEN}^\flat}),$$

but $\{\{1\}\} \neq \mathrm{SEN}^\flat$. Therefore, $\mathcal{I}$ fails to be narrowly right injective.

Following a similar vein, we establish a weakened analog of Lemma 207 for narrow right injectivity. This will play a key role in some of the classifications obtained in this and in subsequent sections.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **narrowly stable** if, for all $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, $\Omega(\overleftarrow{T}) = \Omega(T)$. We return to this notion and study it in more detail in Section 7.2.

Lemma 405 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly right injective, then it is narrowly stable.*

Proof: Suppose that $\mathcal{I}$ is narrowly right injective. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$. If $T \neq \overleftarrow{T} \in \mathrm{ThFam}^\natural(\mathcal{I})$, then, since $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$, we would get $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$ and, hence, by narrow right injectivity, $\overleftarrow{T} = T$, a contradiction. Thus, we get that, for all $T \in \mathrm{ThFam}^\natural(\mathcal{I})$,

$$\overleftarrow{T} = T \quad \text{or} \quad \overleftarrow{T} \notin \mathrm{ThFam}^\natural(\mathcal{I}).$$

If $T \in \mathrm{ThFam}^{\not\vdash}(\mathcal{I})$ is such that $\overleftarrow{T} = \overline{\varnothing}$, then we would have $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{\mathrm{SEN}^\flat}) = \nabla^{\mathbf{F}}$, whence, by narrow right injectivity, $T = \mathrm{SEN}^\flat$, giving $\overline{\varnothing} = \overleftarrow{T} = \overleftarrow{\mathrm{SEN}^\flat} = \mathrm{SEN}^\flat$, a contradiction. Thus, $\overleftarrow{T} \neq \overline{\varnothing}$. So, there exists $P \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{T}_P \neq \varnothing$. If for such P, $\overleftarrow{T}_P \neq T_P$, then, setting $T' = \{T'_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with $T'_\Sigma = \begin{cases} T_\Sigma, & \text{if } \Sigma \neq P \\ \overleftarrow{T}_P, & \text{if } \Sigma = P \end{cases}$, we would get $T, T' \in \mathrm{ThFam}^{\not\vdash}(\mathcal{I})$, with $\overleftarrow{T'} = \overleftarrow{T}$ and $T' \neq T$, contradicting narrow right injectivity. Therefore, for all $T \in \mathrm{ThFam}^{\not\vdash}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$\overleftarrow{T}_\Sigma = T_\Sigma \quad \text{or} \quad \overleftarrow{T}_\Sigma = \varnothing.$$

Based on this fact, given $T \in \mathrm{ThFam}^{\not\vdash}(\mathcal{I})$, we partition the signatures into Part I, consisting of $\Sigma \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{T}_\Sigma = T_\Sigma$, and Part II, consisting of $\Sigma \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{T}_\Sigma = \varnothing$. Note that no morphism can have a domain of Type I and a codomain of Type II. Thus, letting $T' = \{T'_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$T'_\Sigma = \begin{cases} T_\Sigma, & \text{if } \Sigma \text{ is of Type I} \\ \mathrm{SEN}^\flat(\Sigma), & \text{if } \Sigma \text{ is of Type II} \end{cases},$$

we get $\overleftarrow{T'}_\Sigma = \overleftarrow{T}_\Sigma = T_\Sigma$, if Σ is of Type I, and, by the displayed condition above, $\overleftarrow{T'}_\Sigma = \varnothing$ or $\mathrm{SEN}^\flat(\Sigma)$, if Σ is of Type II. In either case, it follows by Theorem 370 that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$, whence, by narrow right injectivity, $T = T'$. We finally conclude that

$$\begin{array}{rcll} \Omega(\overleftarrow{T}) & = & \Omega(\overleftarrow{T'}) & (T = T') \\ & = & \Omega(T') & (\text{Theorem } 370) \\ & = & \Omega(T). & (T = T') \end{array}$$

Therefore, $\mathcal{I}$ is narrowly stable. ■

We establish, next, the narrow injectivity hierarchy. The following proposition forms an analog of Proposition 387, which established the rough injectivity hierarchy.

Proposition 406 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is narrowly right injective, then it is narrowly family injective;

(b) If $\mathcal{I}$ is narrowly family injective, then it is narrowly left injective;

(c) If $\mathcal{I}$ is narrowly left injective, then it is narrowly system injective.

Proof:

(a) Suppose that $\mathcal{I}$ is narrowly right injective and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. By hypothesis and Lemma 405, $\Omega(\overleftarrow{T}) = \Omega(T) = \Omega(T') = \Omega(\overleftarrow{T'})$. By narrow right injectivity, we conclude that $T = T'$. Hence, $\mathcal{I}$ is narrowly family injective.

(b) Suppose that $\mathcal{I}$ is narrowly family injective and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by hypothesis, $T = T'$, whence, $\overleftarrow{T} = \overleftarrow{T'}$. Thus, $\mathcal{I}$ is narrowly left injective.

(c) Suppose that $\mathcal{I}$ is narrowly left injective and let $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by hypothesis, we get $\overleftarrow{T} = \overleftarrow{T'}$. Therefore, since T, T' are theory systems, $T = T'$ and, hence, $\mathcal{I}$ is narrowly system injective.

■

We have now established the following **narrow injectivity hierarchy** of π-institutions.

Narrowly R Injective
↓
Narrowly F Injective
↓
Narrowly L Injective
↓
Narrowly S Injective

We give some additional relations governing the hierarchy of narrow injectivity. The following proposition may be viewed as an analog of Propositions 388 and 389.

Proposition 407 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly system injective and narrowly systemic, then it is narrowly right injective.*

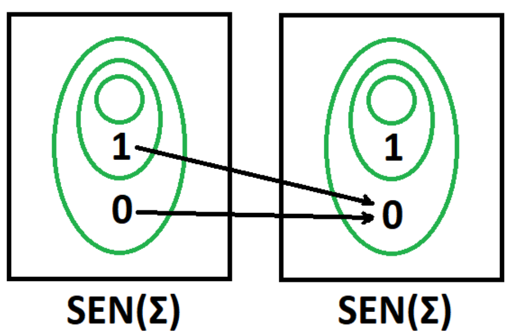
Proof: Suppose $\mathcal{I}$ is narrowly system injective and narrowly systemic. Let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. By narrow systemicity, $T = \overleftarrow{T}$ and $T' = \overleftarrow{T'}$. Hence, on the one hand, $\Omega(T) = \Omega(T')$ and, on the other, $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$. Thus, by narrow system injectivity, $T = T'$. Thus, $\mathcal{I}$ is narrowly right injective. ■

It was shown in Example 403 that narrow right injectivity does not imply, in general, narrow systemicity. Thus, the converse of Proposition 407 does not hold in general.

We present three examples to show that all inclusions established between the narrow injectivity classes and shown in the preceding diagram are indeed proper inclusions. The first example depicts a π-institution which is narrowly family injective but not narrowly right injective. This shows that the class of narrowly right injective π-institutions constitutes a proper subclass of the class of narrowly family injective π-institutions.

Example 408 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

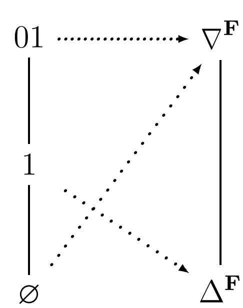
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ *has three theory families,* $\varnothing$, $\{\{1\}\}$ *and* $\{\{0,1\}\}$, *but only two theory systems,* $\varnothing$ *and* $\{\{0,1\}\}$. *The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since there exists only two theory families in $\mathrm{ThFam}^{\nparallel}(\mathcal{I})$, $\{\{0,1\}\}$ *and* $\{\{1\}\}$, *and* $\Omega(\{\{0,1\}\}) \neq \Omega(\{\{1\}\})$, $\mathcal{I}$ *is trivially narrowly family injective. On the other hand,* $\{\{1\}\},\{\{0,1\}\} \in \mathrm{ThFam}^{\nparallel}(\mathcal{I})$ *and*

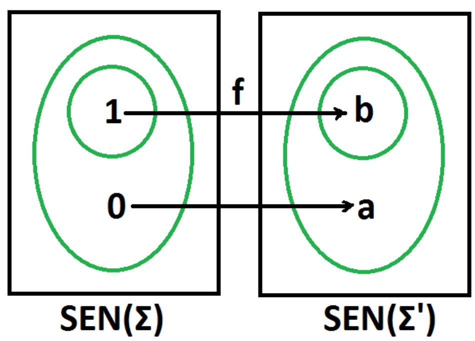
$$\Omega(\overleftarrow{\{\{1\}\}}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} = \Omega(\{\{0,1\}\}) = \Omega(\overleftarrow{\{\{0,1\}\}}),$$

but $\{\{1\}\} \neq \{\{0,1\}\}$. *Therefore,* $\mathcal{I}$ *fails to be narrowly right injective.*

The next example depicts a π-institution which is narrowly left injective but not narrowly family injective. This shows that the class of narrowly family injective π-institutions constitutes a proper subclass of the class of narrowly left injective π-institutions.

Example 409 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

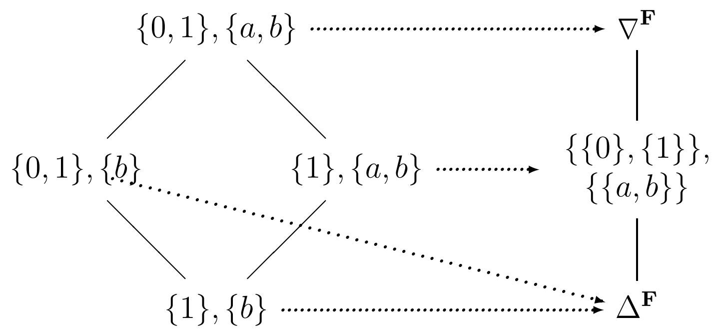
$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

Since $\mathcal{I}$ *has theorems, we get* $\mathrm{ThFam}^{\nparallel}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$. *Hence, both narrow family injectivity and narrow left injectivity coincide with family injectivity and left injectivity, respectively.*

The following table shows the action of $^{\leftarrow}$ *on theory families, where rows correspond to* T_Σ *and columns to* $T_{\Sigma'}$ *and each entry is written as* $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right.



Since the only two theory families that have the same Leibniz congruence system are $\{\{0,1\},\{b\}\}$ *and* $\{\{1\},\{b\}\}$ *and it holds that*

$$\overleftarrow{\{\{0,1\},\{b\}\}} = \overleftarrow{\{\{1\},\{b\}\}} = \{\{1\},\{b\}\},$$

we conclude that $\mathcal{I}$ *is left injective. Therefore, taking into account the remark above, we get that* $\mathcal{I}$ *is also narrowly left injective.*

From the diagram, it is also clear that $\mathcal{I}$ *is not family injective, since the two theory families* $\{\{0,1\},\{b\}\}$ *and* $\{\{1\},\{b\}\}$ *have the same Leibniz congruence system. The same counterexample shows that* $\mathcal{I}$ *is not narrowly family injective either.*

We finish the sequence of examples by presenting a narrowly system injective π-institution which, however, fails to be narrowly left injective. This example shows that narrowly left injective π-institutions form a proper subclass of the class of narrowly system injective π-institutions.

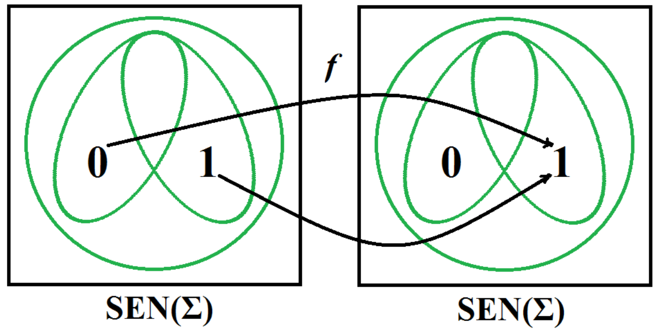
Example 410 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 1$ *and* $\mathrm{SEN}^\flat(f)(1) = 1$*;*
- $N^\flat$ *is the trivial clone.*

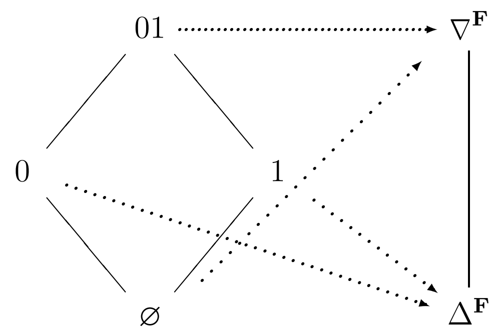
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{1\}, \{0,1\}\}$*.*

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*.*

T	$\overleftarrow{T}$
$\varnothing$	$\varnothing$
$\{0\}$	$\varnothing$
$\{1\}$	$\{1\}$
$\{0,1\}$	$\{0,1\}$



The lattice of theory families and the corresponding Leibniz congruence systems are depicted below.



It is obvious from the diagram that for no $T, T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$*, such that* $T \neq T'$ *is it the case that* $\Omega(T) = \Omega(T')$*. Therefore,* $\mathcal{I}$ *is trivially narrowly system injective. On the other hand, for* $T = \{\{0\}\}$*,* $T' = \{\{1\}\}$*, both members of* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*, we have* $\Omega(T) = \Omega(T') = \Delta^{\mathbf{F}}$*, whereas* $\overleftarrow{T} = \{\varnothing\} \neq \{\{1\}\} = \overleftarrow{T'}$*. Therefore,* $\mathcal{I}$ *fails to be narrowly left injective.*

We turn now to the relationships between corresponding classes of the rough injectivity and the narrow injectivity hierarchies.

First, it is easy to see, using the characterization in Part (a) of Proposition 400 that the two types of family injectivity involved coincide.

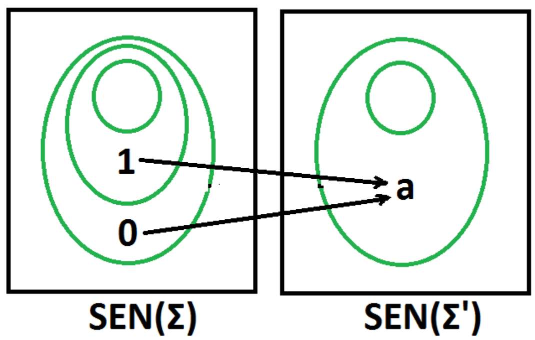
Corollary 411 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly family injective if and only if it is narrowly family injective.*

Proof: Part (a) of Proposition 400. ∎

Unfortunately, the relationship between the remaining classes are not so straightforward, due to the necessity of investigating the mode of interaction between rough equivalence and the $\leftarrow$ operator. We look, next, at the two classes of left injective π-institutions. We start by showing that the class of narrow left injective π-institutions is not included in the class of roughly left injective π-institutions. The next example exhibits a π-institution which is narrowly left injective but not roughly left injective.

Example 412 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

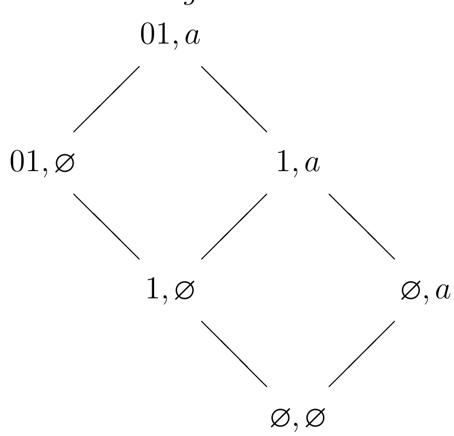
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$;
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$

Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$, *only four of which are theory systems, and only two of which are in* $\mathrm{ThFam}^{\natural}(\mathcal{I})$. *The lattice of theory families is shown in the diagram:*



Since $\mathrm{ThFam}^{\natural}(\mathcal{I}) = \{\{1,a\},\{01,a\}\}$ *and* $\Omega(1,a) = \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\} \neq \nabla^{\mathbf{F}} = \Omega(01,a)$, *it follows that* $\mathcal{I}$ *is trivially narrowly left injective.*

On the other hand, consider $T = \{1,\varnothing\}$ *and* $T' = \{1,a\}$. *We have* $\Omega(1,\varnothing) = \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(1,a)$, *but*

$$\overleftarrow{\widetilde{1,\varnothing}} = \widetilde{\varnothing,\varnothing} = 01,a \neq 1,a = \widetilde{1,a} = \overleftarrow{\widetilde{1,a}}.$$

This proves that $\mathcal{I}$ *is not roughly left injective.*

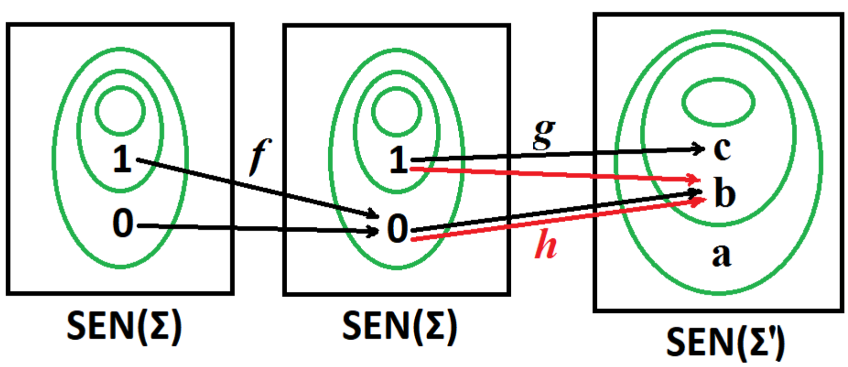
We now look at a π-institution that is roughly left injective, while it fails to be narrowly left injective. Combined with Example 412, this will show that the two left injectivity classes, rough and narrow, are incomparable from the point of view of inclusion.

Example 413 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and three nonidentity morphisms* $f : \Sigma \to \Sigma$ *and* $g, h : \Sigma \to \Sigma'$*, such that* $f \circ f = f$*,* $g \circ f = h$ *and* $h \circ f = h$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b, c\}$*,* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$*,* $\mathrm{SEN}^\flat(g)(0) = b$*,* $\mathrm{SEN}^\flat(g)(1) = c$ *and* $\mathrm{SEN}^\flat(h)(0) = \mathrm{SEN}^\flat(h)(1) = b$*;*
- $N^\flat$ *is the clone generated by a single binarry natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, whose components are defined by the following tables:*

$\sigma^\flat_\Sigma$	0	1
0	0	1
1	1	1

$\sigma^\flat_{\Sigma'}$	a	b	c
a	a	a	c
b	a	b	c
c	c	c	c



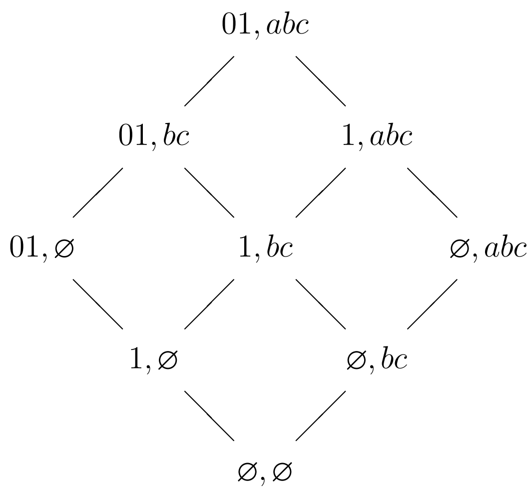
It is not difficult, albeit slightly tedious, to check that this is a well-defined natural transformation. We summarize the checking in the accompanying table.

(x, y)	$f(\sigma^\flat_\Sigma(x, y)) = \sigma^\flat_\Sigma(f(x), f(y))$	$g(\sigma^\flat_\Sigma(x, y)) = \sigma^\flat_{\Sigma'}(g(x), g(y))$	$h(\sigma^\flat_\Sigma(x, y)) = \sigma^\flat_{\Sigma'}(h(x), h(y))$
$(0, 0)$	$0 = 0$	$b = b$	$b = b$
$(0, 1)$	$0 = 0$	$c = c$	$b = b$
$(1, 0)$	$0 = 0$	$c = c$	$b = b$
$(1, 1)$	$0 = 0$	$c = c$	$b = b$

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b,c\}, \{a,b,c\}\}.$$

Clearly, there are nine theory families in $\mathrm{ThFam}(\mathcal{I})$*, five of which are theory systems, and four of which are in* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



The action of $\overleftarrow{\ }$ *on theory families is given in the following table.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$01, abc$	$01, abc$	$\varnothing, abc$	$\varnothing, abc$
$01, bc$	$01, bc$	$1, \varnothing$	$\varnothing, \varnothing$
$1, abc$	$\varnothing, abc$	$\varnothing, bc$	$\varnothing, bc$
$01, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$
$1, bc$	$\varnothing, bc$		

The table below provides the Leibniz congruence systems associated with the theory families of $\mathcal{I}$*.*

T	$\Omega(T)$
$\{01, abc\}, \{01, \varnothing\}, \{\varnothing, abc\}, \{\varnothing, \varnothing\}$	$\nabla^{\mathbf{F}}$
$\{1, abc\}, \{1, \varnothing\}$	$\{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{01, bc\}, \{1, bc\}, \{\varnothing, bc\}$	$\Delta^{\mathbf{F}}$

To see that $\mathcal{I}$ *is roughly left injective, note that all elements in a single row of the table have associated theory systems that are roughly equivalent.*

$$\widetilde{\overleftarrow{\{01, abc\}}} = \widetilde{\overleftarrow{\{01, \varnothing\}}} = \widetilde{\overleftarrow{\{\varnothing, abc\}}} = \widetilde{\overleftarrow{\{\varnothing, \varnothing\}}} = \{01, abc\};$$
$$\widetilde{\overleftarrow{\{1, abc\}}} = \widetilde{\overleftarrow{\{1, \varnothing\}}} = \{01, abc\};$$
$$\widetilde{\overleftarrow{\{01, bc\}}} = \widetilde{\overleftarrow{\{1, bc\}}} = \widetilde{\overleftarrow{\{\varnothing, bc\}}} = \{01, bc\}.$$

But $\mathcal{I}$ *is not narrowly left injective. In fact, setting* $T = \{1, bc\}$ *and* $T' = \{01, bc\}$*, we get* $\Omega(T) = \Omega(T') = \Delta^{\mathbf{F}}$*, whereas* $\overleftarrow{T} = \{\varnothing, bc\} \neq \{01, bc\} = \overleftarrow{T'}$*.*

We turn, next to the relationship between the two kinds of right injectivity. We show, first, that rough right injectivity implies narrow right injectivity.

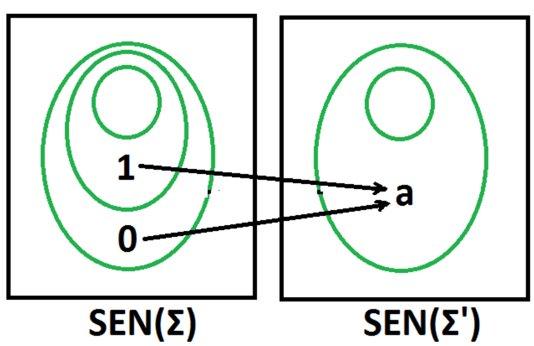
Proposition 414 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly right injective, then it is narrowly right injective.*

Proof: Suppose $\mathcal{I}$ is roughly right injective and let $T, T' \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. By rough right injectivity, we get that $T \sim T'$, i.e., that $\widetilde{T} = \widetilde{T'}$. Since, however, $T, T' \in \mathrm{ThFam}^{\not\,}(\mathcal{I})$, we get $T = \widetilde{T} = \widetilde{T'} = T'$. Therefore, $\mathcal{I}$ is narrowly right injective. ■

The converse, on the other hand, does not hold in general, as the following example demonstrates.

Example 415 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

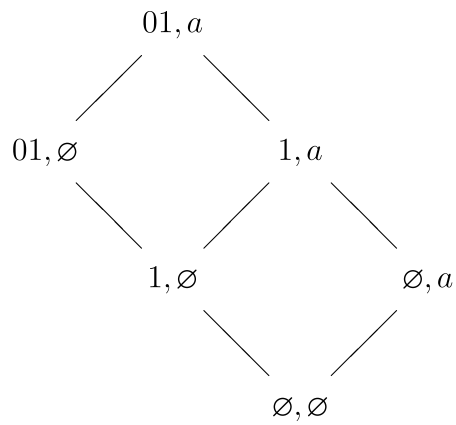
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$

Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$*, only four of which are theory systems and only two of which are in* $\mathrm{ThFam}^{\not\,}(\mathcal{I})$*. The lattice of* *theory families is shown in the diagram.*



The only theory families in $\mathrm{ThFam}^{\natural}(\mathcal{I})$ *are* $\{1, a\}$ *and* $\{01, a\}$*. Moreover,*

$$\Omega(\overleftarrow{\{1, a\}}) = \Omega(\{1, a\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma}\} \neq \nabla^{\mathbf{F}} = \Omega(\{01, a\}) = \Omega(\overleftarrow{\{01, a\}}).$$

Thus, $\mathcal{I}$ *is trivially narrowly right injective.*

On the other hand, letting $T = \{1, \varnothing\}$ *and* $T' = \{01, \varnothing\}$*, we get*

$$\Omega(\overleftarrow{T}) = \Omega(\{\varnothing, \varnothing\}) = \nabla^{\mathbf{F}} = \Omega(\{\varnothing, \varnothing\}) = \Omega(\overleftarrow{T'}),$$

but, clearly, $\widetilde{T} = \{1, a\} \neq \{01, a\} = \widetilde{T'}$*, i.e.,* $T \nsim T'$*. Therefore,* $\mathcal{I}$ *is not roughly right injective.*

Finally, we look at system injectivity. Again, it turns out that rough system injectivity implies narrow system injectivity. However, the converse fails in general.

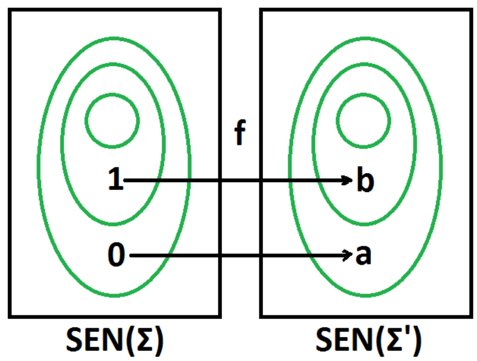
Proposition 416 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly system injective, then it is narrowly system injective.*

Proof: Suppose $\mathcal{I}$ is roughly system injective and let $T, T' \in \mathrm{ThSys}^{\natural}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by rough system injectivity, $T \sim T'$, i.e., $\widetilde{T} = \widetilde{T'}$. However, since $T, T' \in \mathrm{ThSys}^{\natural}(\mathcal{I})$, we get $T = \widetilde{T} = \widetilde{T'} = T'$. Therefore, $\mathcal{I}$ is narrowly system injective. ∎

And now we present an example of a π-institution that is narrowly system injective but not roughly system injective. This, combined with Proposition 416, shows that the class of narrowly system injective π-institutions properly contains the class of roughly system injective π-institutions.

Example 417 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ *be the algebraic system defined as follows:*

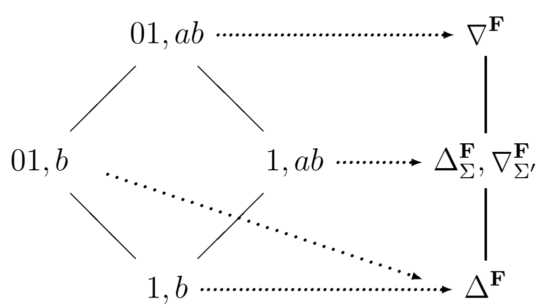
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are only four theory families in $\mathrm{ThFam}^{\natural}(\mathcal{I})$, *all of which except for* $\{01, b\}$ *are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*

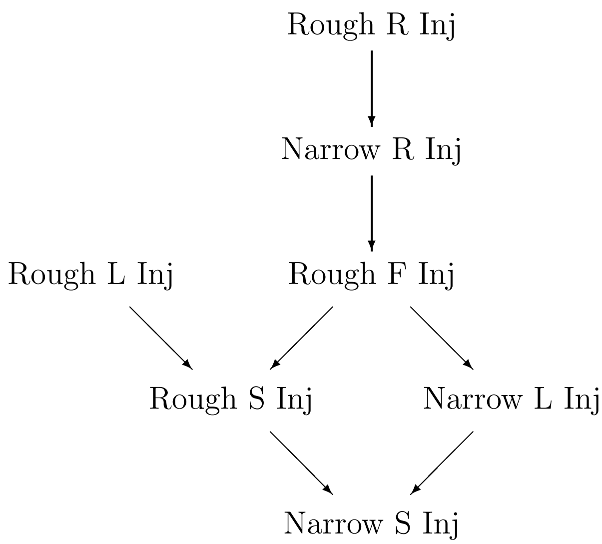


From this diagram we see that for no $T, T' \in \mathrm{ThSys}^{\natural}(\mathcal{I})$, *with* $T \neq T'$ *is it the case that* $\Omega(T) = \Omega(T')$. *Therefore,* $\mathcal{I}$ *is trivially narrowly system injective.*

On the other hand, consider $T = \{1, b\}$, $T' = \{\varnothing, b\} \in \mathrm{ThSys}(\mathcal{I})$. *Even though* $T \not\leftrightarrow T'$, *we have* $\Omega(T) = \Delta^{\mathbf{F}} = \Omega(T')$. *Hence,* $\mathcal{I}$ *is not roughly system injective.*

The results obtained and the counterexamples presented, thus far, reveal the following mixed hierarchy of rough and narrow injectivity classes of π-

institutions.



A theorem, analogous to Theorem 394 asserts that ordinary injectivity is equivalent to narrow injectivity in the presence of theorems. This holds for all four injectivity classes.

Theorem 418 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is right injective if and only if it is narrowly right injective and has theorems;*

(b) $\mathcal{I}$ *is family injective if and only if it is narrowly family injective and has theorems;*

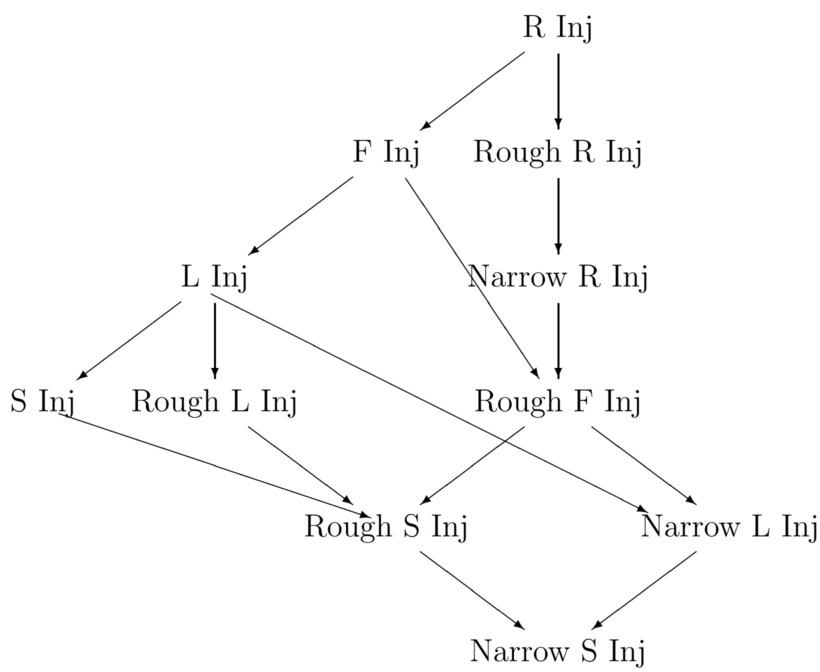
(c) $\mathcal{I}$ *is left injective if and only if it is narrowly left injective and has theorems;*

(d) $\mathcal{I}$ *is system injective if and only if it is narrowly system injective and has theorems.*

Proof: By Theorem 394, if $\mathcal{I}$ has one of the four injectivity properties, then it has theorems. Moreover, by the same theorem, an injectivity property implies the corresponding rough injectivity property and, by Corollary 411, Proposition 414 and Proposition 416, each implies the corresponding narrow injectivity property except in the case of left injectivity, where (as actually in all other cases, as well) one can easily see directly, that left injectivity implies narrow left injectivity, since the defining condition of the latter is a specialization of that of the former.

All converses are also easily verified, since, in the presence of theorems, $\mathrm{ThFam}^{\lightning}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$ and $\mathrm{ThSys}^{\lightning}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, which makes the four defining conditions for the narrow classes identical with the corresponding conditions for the ordinary injectivity classes. ■

We now have the following hierarchy.



The narrow injectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems. This result forms an analog of Theorem 396, which applied to rough injectivity classes.

Theorem 419 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is narrowly right injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\natural}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $T = T'$*;*

(b) $\mathcal{I}$ *is narrowly family injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\natural}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T = T'$*;*

(c) $\mathcal{I}$ *is narrowly left injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\natural}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $\overleftarrow{T} = \overleftarrow{T'}$*;*

(d) $\mathcal{I}$ *is narrowly system injective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}\natural}(\mathcal{A})$*,* $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ *implies* $T = T'$*.*

Proof: The proof follows the steps of the proofs of the various parts of Theorem 214, but, in addition, it takes into account Lemma 376. We do Part (a) in detail to give a flavor of what is involved.

The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{ThFam}^{\lightning}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{F})$, by Lemmas 51 and 376.

For the "only if", suppose that $\mathcal{I}$ is narrowly right injective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(\overleftarrow{T}) = \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) = \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\Omega(\alpha^{-1}(\overleftarrow{T})) = \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Hence, by Lemma 6, $\Omega(\overleftarrow{\alpha^{-1}(T)}) = \Omega(\overleftarrow{\alpha^{-1}(T')})$. Since, by Lemmas 51 and 376, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by applying narrow right injectivity, $\alpha^{-1}(T) = \alpha^{-1}(T')$. This yields, taking into account the surjectivity of $\langle F, \alpha \rangle$, $T = T'$. ■

We finally recast narrow injectivity in terms of the injectivity of mappings from posets of theory or filter families/systems into posets of congruence systems. The following results form, roughly, analogs of Propositions 397 and 398, respectively, except that special attention must be paid to the fact that neither $\mathrm{ThFam}^{\lightning}(\mathcal{I})$ nor $\mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{A})$ is necessarily a lattice.

Proposition 420 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly family injective;*

(b) $\Omega : \mathrm{ThFam}^{\lightning}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system injectivity, we have

Proposition 421 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly system injective;*

(b) $\Omega : \mathrm{ThSys}^{\lightning}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is injective;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

6.6 Rough Reflectivity

In this section we study classes of π-institutions defined using reflectivity properties of the Leibniz operator applied on rough equivalence classes.

Definition 422 (Rough Reflectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **roughly family reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \widetilde{T} \leq \widetilde{T'}.$$
- $\mathcal{I}$ *is called* **roughly left reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}.$$
- $\mathcal{I}$ *is called* **roughly right reflective** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad \widetilde{T} \leq \widetilde{T'}.$$
- $\mathcal{I}$ *is called* **roughly system reflective** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$,
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \widetilde{T} \leq \widetilde{T'}.$$

In a partial analog of Lemma 218, we show that rough right reflectivity implies rough systemicity and, hence, by Theorem 370, stability.

Lemma 423 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly right reflective, then it is roughly systemic.*

Proof: Suppose that $\mathcal{I}$ is roughly right reflective and let $T \in \mathrm{ThFam}(\mathcal{I})$. Then, we have, by Proposition 42, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$. Therefore, we get $\Omega(\overleftarrow{\overleftarrow{T}}) = \Omega(\overleftarrow{T})$. Hence, by rough right reflectivity, we get that $\widetilde{\overleftarrow{T}} = \widetilde{T}$, i.e., $\overleftarrow{T} \sim T$. Hence $\mathcal{I}$ is roughly systemic. ■

Next we look into establishing the *rough reflectivity hierarchy* of π-institutions. The following relationships can be established between the four rough reflectivity classes.

Proposition 424 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is roughly right reflective, then it is roughly family reflective;*

(b) If $\mathcal{I}$ *is roughly family reflective, then it is roughly system reflective;*

(c) If $\mathcal{I}$ *is roughly left reflective, then it is roughly system reflective.*

Proof:

(a) Suppose that $\mathcal{I}$ is roughly right reflective and let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \le \Omega(T')$. By Lemma 423, $\mathcal{I}$ is roughly systemic, whence $\overleftarrow{T} \sim T$ and $\overleftarrow{T'} \sim T'$. Thus, by Theorem 370, we get

$$\Omega(\overleftarrow{T}) = \Omega(T) \le \Omega(T') = \Omega(\overleftarrow{T'}).$$

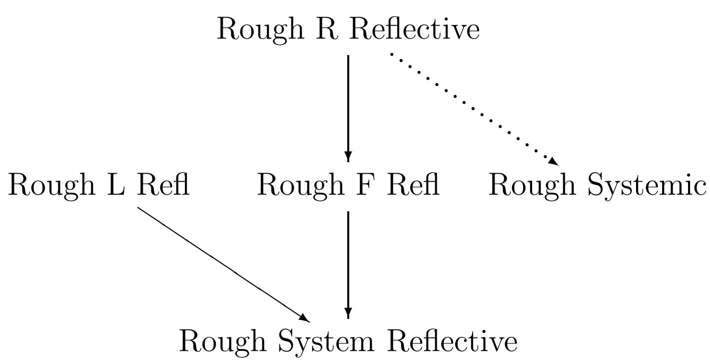
Now applying rough right reflectivity, we get $\widetilde{T} \le \widetilde{T'}$. This proves that $\mathcal{I}$ is roughly family reflective.

(b) Suppose that $\mathcal{I}$ is roughly family reflective and let $T,T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) \le \Omega(T')$. Then, by rough family reflectivity, we get $\widetilde{T} \le \widetilde{T'}$, whence, $\mathcal{I}$ is roughly system reflective.

(c) Suppose that $\mathcal{I}$ is roughly left reflective and let $T,T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\Omega(T) \le \Omega(T')$. By rough left reflectivity, we conclude that $\widetilde{\overleftarrow{T}} \le \widetilde{\overleftarrow{T'}}$. However, since T,T' are theory systems, we have $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$. Hence we get $\widetilde{T} \le \widetilde{T'}$ and $\mathcal{I}$ is roughly system reflective.

■

We have now established the following **rough reflectivity hierarchy** of π-institutions.



We formulate two additional properties concerning the relationships between rough reflectivity classes. First, rough right reflectivity turns out to be equivalent to rough system reflectivity combined with rough systemicity.

Proposition 425 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly right reflective if and only if it is roughly system reflective and roughly systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly right reflective. Then, by Lemma 423, it is roughly systemic and by Proposition 424 it is roughly system reflective.

Suppose, conversely, that $\mathcal{I}$ is roughly system reflective and roughly systemic and let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. By rough system reflectivity and Proposition 42, we get $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. Hence, by rough systemicity, $\widetilde{T} = \widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}} = \widetilde{T'}$. Thus, $\mathcal{I}$ is roughly right reflective. ■

Second, we show that rough system reflectivity together with stability imply rough left reflectivity.

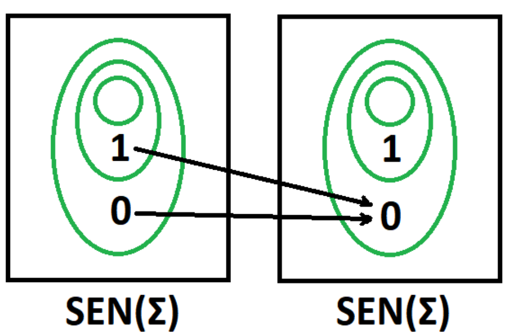
Proposition 426 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly system reflective and stable, then it is roughly left reflective.*

Proof: Suppose that $\mathcal{I}$ is roughly system reflective and stable and consider $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by stability $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Hence, since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, by rough system reflectivity, $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. This shows that $\mathcal{I}$ is roughly left reflective. ■

We present three examples to show that all inclusions established between rough reflectivity classes and depicted in the diagram above are proper inclusions. The first example will show that the class of roughly right reflective π-institutions is a proper subclass of the class of roughly family reflective π-institutions.

Example 427 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

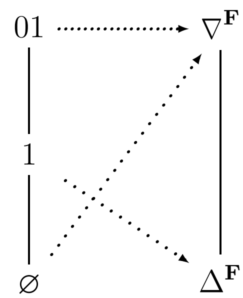
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (no-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ has three theory families $\{\varnothing\}$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\{\varnothing\}$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



It is easy to see that $\mathcal{I}$ is roughly family reflective. Suppose that for $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$.

- *If $\Omega(T') = \Delta^{\mathbf{F}}$, then $\Omega(T) = \Delta^{\mathbf{F}}$, whence $T' = T = \{\{1\}\}$. Thus, $\widetilde{T} \leq \widetilde{T'}$.*
- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \{\varnothing\}$ or $T' = \{\{0,1\}\}$. In either case, $\widetilde{T} \leq \{\{0,1\}\} = \widetilde{T'}$.*

On the other hand, for $T = \{\{1\}\}$, we get $\widetilde{T} = \{\{1\}\} \neq \{\{0,1\}\} = \widetilde{\{\varnothing\}} = \overleftarrow{\widetilde{T}}$, whence $T \not\approx \overleftarrow{T}$ and, hence, $\mathcal{I}$ is not roughly systemic. Therefore, by Lemma 423, $\mathcal{I}$ is not roughly right reflective.

The second example shows that there exists a roughly left reflective π-institution that is not roughly family reflective.

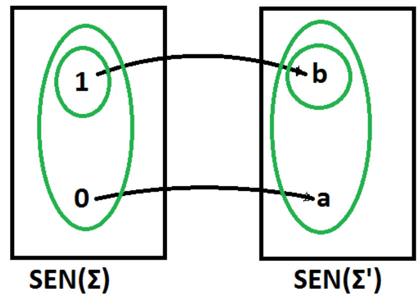
Example 428 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with objects Σ and Σ' and a unique (non-identity) morphism $f : \Sigma \to \Sigma'$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ and $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;*
- *$N^\flat$ is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\},\{a,b\}\}.$$

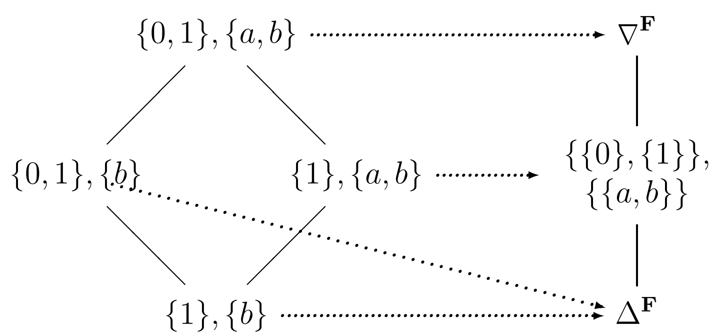
Again, since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$.



The following table shows the action of $\leftarrow$ *on theory families, where rows correspond to* T_Σ *and columns to* $T_{\Sigma'}$ *and each entry is written as* $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



To see that $\mathcal{I}$ *is roughly left reflective, suppose* $T,T' \in \mathrm{ThFam}(\mathcal{I})$, *such that* $\Omega(T) \leq \Omega(T')$.

- *If* $\Omega(T') = \nabla^{\mathbf{F}}$, *then* $T' = \{\{0,1\},\{a,b\}\}$, *whence* $\overleftarrow{T} \leq \{\{0,1\},\{a,b\}\} = \overleftarrow{T'}$ *and, hence,* $\overleftarrow{\overleftarrow{T}} \leq \overleftarrow{\overleftarrow{T'}}$.
- *If* $\Omega(T') = \{\{\{0\},\{1\}\},\{\{a,b\}\}\}$, *then* $T' = \{\{1\},\{a,b\}\}$ *and* $T = \{\{0,1\},\{b\}\}$ *or* $T = \{\{1\},\{b\}\}$. *In either case* $\overleftarrow{T} = \{\{1\},\{b\}\} \leq T' = \overleftarrow{T'}$ *and, hence,* $\overleftarrow{\overleftarrow{T}} \leq \overleftarrow{\overleftarrow{T'}}$.
- *If* $\Omega(T') = \Delta^{\mathbf{F}}$, *then both* T *and* T' *have to be either* $\{\{0,1\},\{b\}\}$ *or* $\{\{1\},\{b\}\}$. *Thus, we get* $\overleftarrow{T} = \{\{1\},\{b\}\} = \overleftarrow{T'}$ *and, hence,* $\overleftarrow{\overleftarrow{T}} \leq \overleftarrow{\overleftarrow{T'}}$.

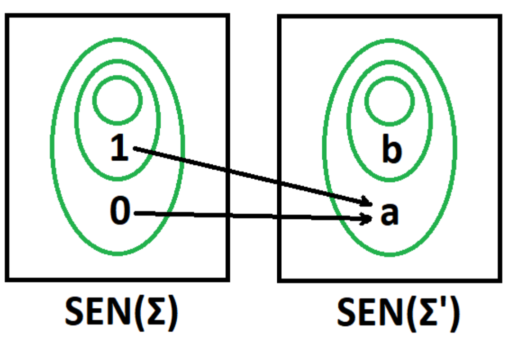
On the other hand, we have $\Omega(\{\{0,1\},\{b\}\}) \leq \Omega(\{\{1\},\{b\}\})$*, but, clearly,* $\{\{0,1\},\{b\}\} \nleq \{\{1\},\{b\}\}$*. Thus, since rough equivalence is the identity on* $\mathrm{ThFam}(\mathcal{I})$*, we conclude that* $\mathcal{I}$ *is not roughly family reflective.*

The third example shows that there exists a roughly family reflective π-institution that is not roughly left reflective. Combined with the preceding example, it has the effect of establishing the following facts:

- The classes of roughly family reflective and roughly left reflective π-institutions are incomparable.
- The class of roughly family reflective π-institutions is properly contained in the class of roughly system reflective π-institutions.
- Similarly, the class of roughly left reflective π-institutions is a proper subclass of the class of roughly system reflective π-institutions.

Example 429 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



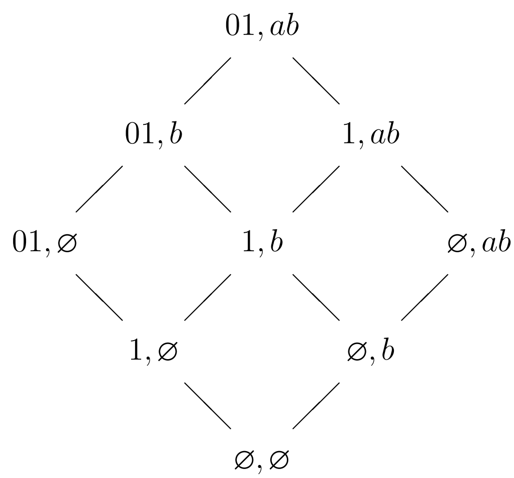
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are nine theory families, but only five theory systems. The action of $\overleftarrow{}$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$\varnothing,\varnothing$	$\varnothing,\varnothing$	$\varnothing,ab$	$\varnothing,ab$
$1,\varnothing$	$\varnothing,\varnothing$	$01,b$	$\varnothing,b$
$\varnothing,b$	$\varnothing,b$	$1,ab$	$1,ab$
$01,\varnothing$	$\varnothing,\varnothing$	$01,ab$	$01,ab$
$1,b$	$\varnothing,b$		

The lattice of theory families of $\mathcal{I}$ *is shown in the diagram.*



We show that $\mathcal{I}$ *is roughly family reflective. The following table summarizes the theory families together with their associated Leibniz congruence systems.*

T	$\Omega(T)$
$\{\varnothing,\varnothing\},\{01,\varnothing\},\{\varnothing,ab\},\{01,ab\}$	$\nabla^{\mathbf{F}}$
$\{\varnothing,b\},\{01,b\}$	$\{\nabla^{\mathbf{F}}_{\Sigma},\Delta^{\mathbf{F}}_{\Sigma'}\}$
$\{1,\varnothing\},\{1,ab\}$	$\{\Delta^{\mathbf{F}}_{\Sigma},\nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{1,b\}$	$\Delta^{\mathbf{F}}$

Let $T,T' \in \mathrm{ThFam}(\mathcal{I})$*, such that* $\Omega(T) \le \Omega(T')$*.*

- *If* $\Omega(T') = \nabla^{\mathbf{F}}$*, then* $\widetilde{T} \le \{01,ab\} = \widetilde{T'}$*.*
- *If* $\Omega(T') = \{\Delta^{\mathbf{F}}_{\Sigma},\nabla^{\mathbf{F}}_{\Sigma'}\}$*, then* $\widetilde{T} = \{1,ab\}$ *or* $\widetilde{T} = \{1,b\}$ *and, hence,* $\widetilde{T} \le \{1,ab\} = \widetilde{T'}$*.*
- *If* $\Omega(T') = \{\nabla^{\mathbf{F}}_{\Sigma},\Delta^{\mathbf{F}}_{\Sigma'}\}$*, then* $\widetilde{T} = \{01,b\}$ *or* $\widetilde{T} = \{1,b\}$ *and, hence,* $\widetilde{T} \le \{01,b\} = \widetilde{T'}$*.*
- *If* $\Omega(T') = \Delta^{\mathbf{F}}$*, then* $\widetilde{T} = \{1,b\} = \widetilde{T'}$*.*

On the other hand, consider $T = \{1, \varnothing\}$ *and* $T' = \{1, ab\}$. *We have*

$$\Omega(T) = \Omega(\{1, \varnothing\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(\{1, ab\}) = \Omega(T'),$$

whereas

$$\overleftarrow{\widetilde{T}} = \widetilde{\{\varnothing, \varnothing\}} = \{01, ab\} \nleq T' = \widetilde{T'} = \overleftarrow{\widetilde{T'}}.$$

Hence, $\mathcal{I}$ *is not roughly left reflective.*

We look, next, at the connections between rough reflectivity and rough injectivity classes. It turns out that membership in a rough reflectivity class implies membership in the corresponding rough injectivity class. We have the following straightforward inclusions.

Theorem 430 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is roughly right reflective, then it is roughly right injective;*

(b) If $\mathcal{I}$ *is roughly family reflective, then it is roughly family injective;*

(c) If $\mathcal{I}$ *is roughly left reflective, then it is roughly left injective;*

(d) If $\mathcal{I}$ *is roughly system reflective, then it is roughly system injective.*

Proof:

(a) Suppose that $\mathcal{I}$ is roughly right reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Then, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$ and $\widetilde{T'} \leq \widetilde{T}$, whence $\widetilde{T} = \widetilde{T'}$, i.e., $T \sim T'$. Therefore, $\mathcal{I}$ is roughly right injective.

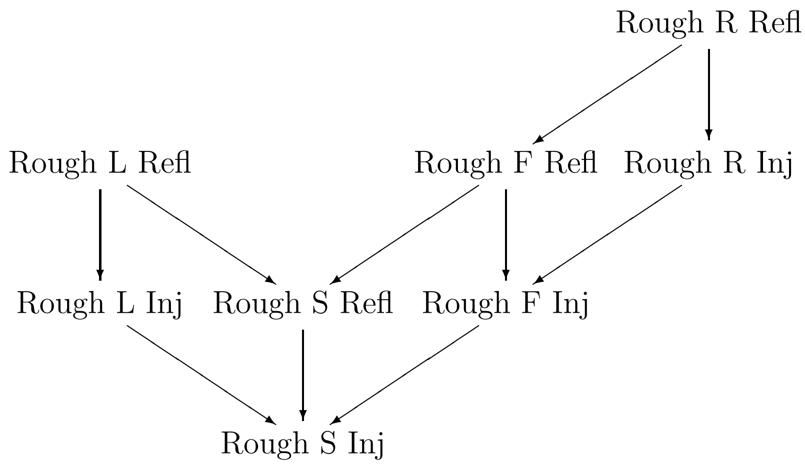
(b) Suppose that $\mathcal{I}$ is roughly family reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$ and $\widetilde{T'} \leq \widetilde{T}$, whence $\widetilde{T} = \widetilde{T'}$, i.e., $T \sim T'$. Therefore, $\mathcal{I}$ is roughly family injective.

(c) Suppose that $\mathcal{I}$ is roughly left reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, by hypothesis, $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$ and $\overleftarrow{\widetilde{T'}} \leq \overleftarrow{\widetilde{T}}$, whence $\overleftarrow{\widetilde{T}} = \overleftarrow{\widetilde{T'}}$, i.e., $\overleftarrow{T} \sim \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is roughly left injective.

(d) Similar to Part (b).

■

Theorem 430 establishes the mixed rough hierarchy depicted in the diagram.

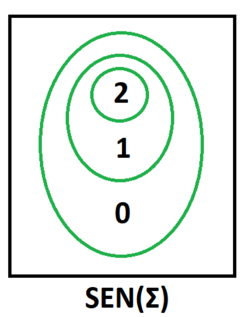


To see that all classes in the hierarchy are different, we give an example of a π-institution satisfying all four rough injectivity properties, which is not, however, roughly system reflective and, therefore, a fortiori, belongs to none of the four rough reflectivity classes.

Example 431 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the clone generated by the single unary operation* $\sigma : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *determined by the following table:*

x	0	1	2
$\sigma^\flat_\Sigma(x)$	0	0	2

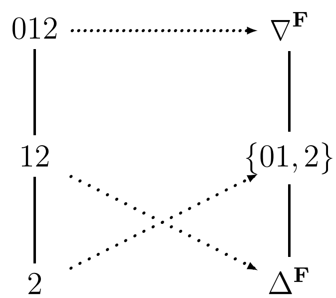


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has three theory families $\{\{2\}\}$ and $\{\{1,2\}\}$ and $\{\{0,1,2\}\}$, all of which are theory systems. Moreover, $\mathcal{I}$ has theorems. It follows that the action of $\overleftarrow{\ }$ is trivial and that rough equivalence in $\mathcal{I}$ coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$.

The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



We show that $\mathcal{I}$ is both roughly right and roughly left injective and, hence, belongs to all four classes in the rough injectivity hierarchy.

- *Suppose $\Omega(\overleftarrow{T}) = \Omega(\overleftarrow{T'})$. Then $\Omega(T) = \Omega(T')$ and, hence, $T = T'$, i.e., $T \sim T'$. Thus, $\mathcal{I}$ is rough right injective.*

- *Suppose $\Omega(T) = \Omega(T')$. Then $T = T'$. This gives $\overleftarrow{T} = \overleftarrow{T'}$, which, in turn, implies $\overleftarrow{T} \sim \overleftarrow{T'}$. Thus, $\mathcal{I}$ is roughly left injective.*

On the other hand, we have $\Omega(\{\{1,2\}\}) = \Delta^{\mathbf{F}} \leq \{\{0,1\},\{2\}\} = \Omega(\{2\})$, but $\{\{1,2\}\} \nleq \{\{2\}\}$, whence $\mathcal{I}$ is not roughly system reflective.

We now clarify the connections between rough reflectivity and reflectivity classes. It turns out that membership in a reflectivity class implies membership in the corresponding rough reflectivity class and, also, possession of theorems and, conversely, that membership in a rough reflectivity class plus possession of theorems entails membership in the corresponding reflectivity class.

Theorem 432 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is right/family reflective if and only if it is roughly right reflective and has theorems;

(b) $\mathcal{I}$ is right/family reflective if and only if it is roughly family reflective and has theorems;

(c) $\mathcal{I}$ is left reflective if and only if it is roughly left reflective and has theorems;

(d) *$\mathcal{I}$ is system reflective if and only if it is roughly system reflective and has theorems.*

Proof:

(a) Suppose that $\mathcal{I}$ is right reflective. Then, by Proposition 228, it is right injective. Hence, by Theorem 394, it has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Then, by right reflectivity, $T \leq T'$. Since $\mathcal{I}$ has theorems, $\widetilde{T} = T$ and $\widetilde{T'} = T'$. Therefore, $\widetilde{T} \leq \widetilde{T'}$ and $\mathcal{I}$ is roughly right reflective.

Assume, conversely, that $\mathcal{I}$ is roughly right reflective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Then, by rough right reflectivity, we get $\widetilde{T} \leq \widetilde{T'}$. On the other hand, since $\mathcal{I}$ has theorems, $\widetilde{T} = T$ and $\widetilde{T'} = T'$. Therefore, $T \leq T'$ and $\mathcal{I}$ is right reflective.

(b) Suppose that $\mathcal{I}$ is family reflective. Then, by Proposition 228, it is family injective. Hence, by Theorem 394, it has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by family reflectivity, $T \leq T'$. Since $\mathcal{I}$ has theorems, $\widetilde{T} = T$ and $\widetilde{T'} = T'$. Therefore, $\widetilde{T} \leq \widetilde{T'}$ and $\mathcal{I}$ is roughly family reflective.

Assume, conversely, that $\mathcal{I}$ is roughly family reflective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by rough family reflectivity, we get $\widetilde{T} \leq \widetilde{T'}$. On the other hand, since $\mathcal{I}$ has theorems, $\widetilde{T} = T$ and $\widetilde{T'} = T'$. Therefore, $T \leq T'$ and $\mathcal{I}$ is family reflective.

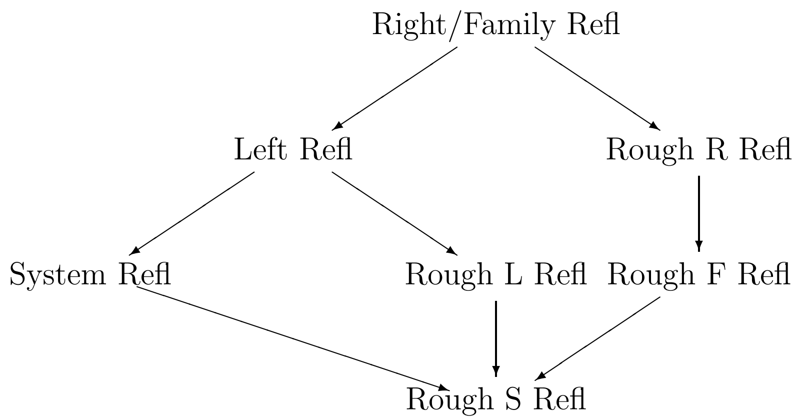
(c) Suppose that $\mathcal{I}$ is left reflective. Then, by Proposition 228, it is left injective. Hence, by Theorem 394, it has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by left reflectivity, $\overleftarrow{T} \leq \overleftarrow{T'}$. Since $\mathcal{I}$ has theorems, $\widetilde{\overleftarrow{T}} = \overleftarrow{T}$ and $\widetilde{\overleftarrow{T'}} = \overleftarrow{T'}$. Therefore, $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$ and $\mathcal{I}$ is roughly left reflective.

Assume, conversely, that $\mathcal{I}$ is roughly left reflective and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by rough left reflectivity, we get $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. On the other hand, since $\mathcal{I}$ has theorems, $\widetilde{\overleftarrow{T}} = \overleftarrow{T}$ and $\widetilde{\overleftarrow{T'}} = \overleftarrow{T'}$. Therefore, $\overleftarrow{T} \leq \overleftarrow{T'}$ and $\mathcal{I}$ is left reflective.

(d) Similar to Part (b).

■

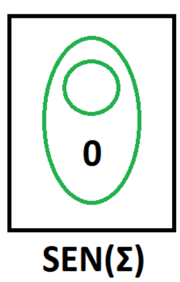
The work in Chapter 3, together with the work done in the present section and Theorem 432, reveal a hierarchy of reflectivity and rough reflectivity classes shown in the accompanying diagram.



To complete the demonstration that all classes in the depicted hierarchy are distinct we provide an example of a π-institution which belongs to all steps in the rough reflectivity hierarchy but possesses none of the four (gentle) reflectivity properties.

Example 433 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

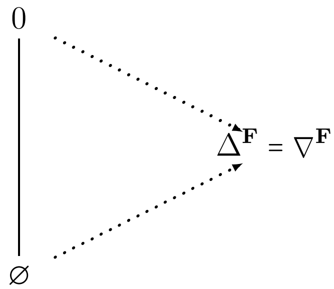
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz* *congruence systems are shown in the diagram.*



Note that $\widetilde{\{\{0\}\}} = \widetilde{\{\varnothing\}} = \{\{0\}\}$, *whence, trivially,* $\mathcal{I}$ *is both roughly right and roughly left reflective.*

On the other hand, since $\Omega(\{\{0\}\}) = \nabla^{\mathbf{F}} = \Omega(\{\varnothing\})$, *whereas* $\{\{0\}\} \nleq \{\varnothing\}$, $\mathcal{I}$ *is not system reflective and, hence, a fortiori,* $\mathcal{I}$ *has none of the four reflectivity properties.*

The rough reflectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 434 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is roughly right reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $\widetilde{T} \leq \widetilde{T'}$;

(b) $\mathcal{I}$ *is roughly family reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\widetilde{T} \leq \widetilde{T'}$;

(c) $\mathcal{I}$ *is roughly left reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$;

(d) $\mathcal{I}$ *is roughly system reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\widetilde{T} \leq \widetilde{T'}$.

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$ and taking into account that, by Lemma 51, $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$.

For the "only if", suppose that $\mathcal{I}$ is roughly right reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that

$\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\Omega(\alpha^{-1}(\overleftarrow{T})) \leq \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Hence, by Lemma 6, $\Omega(\overleftarrow{\alpha^{-1}(T)}) \leq \Omega(\overleftarrow{\alpha^{-1}(T')})$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough right reflectivity, $\widetilde{\alpha^{-1}(T)} \leq \widetilde{\alpha^{-1}(T')}$. Thus, by Theorem 377, $\alpha^{-1}(\widetilde{T}) \leq \alpha^{-1}(\widetilde{T'})$. Therefore, taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that $\widetilde{T} \leq \widetilde{T'}$.

(b) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly family reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough family reflectivity, $\widetilde{\alpha^{-1}(T)} \leq \widetilde{\alpha^{-1}(T')}$. Thus, by Theorem 377, $\alpha^{-1}(\widetilde{T}) \leq \alpha^{-1}(\widetilde{T'})$. Therefore, taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that $\widetilde{T} \leq \widetilde{T'}$.

(c) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly left reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough left reflectivity, $\widetilde{\overleftarrow{\alpha^{-1}(T)}} \leq \widetilde{\overleftarrow{\alpha^{-1}(T')}}$. Thus, by Lemma 6, $\widetilde{\alpha^{-1}(\overleftarrow{T})} \leq \widetilde{\alpha^{-1}(\overleftarrow{T'})}$. Hence, by Theorem 377, $\alpha^{-1}(\widetilde{\overleftarrow{T}}) \leq \alpha^{-1}(\widetilde{\overleftarrow{T'}})$. Therefore, taking into account the surjectivity of $\langle F, \alpha\rangle$, we conclude that $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$.

(d) Similar to Part (b).

■

Finally, we may recast the rough reflectivity classes in terms of the order reflectivity of mappings from posets of classes of theory or filter families/systems into posets of congruence systems.

Note for the following, that the collections $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$ may be ordered by setting, respectively, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{[T]} \leq \widetilde{[T']} \quad \text{iff} \quad \widetilde{T} \leq \widetilde{T'}$$

and, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$

$$\widetilde{\lfloor T\rfloor} \leq \widetilde{\lfloor T'\rfloor} \quad \text{iff} \quad \widetilde{T} \leq \widetilde{T'}.$$

We denote by $\widetilde{\mathbf{ThFam}}(\mathcal{I}) = \langle \widetilde{\mathrm{ThFam}}(\mathcal{I}), \leq\rangle$ and $\widetilde{\mathbf{ThSys}}(\mathcal{I}) = \langle \widetilde{\mathrm{ThSys}}(\mathcal{I}), \leq\rangle$, respectively, the corresponding ordered sets.

Proposition 435 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly family reflective;*

(b) $\Omega : \widetilde{\mathbf{ThFam}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is order reflecting;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiFam}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for system reflectivity, we have

Proposition 436 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly system reflective;*

(b) $\Omega : \widetilde{\mathbf{ThSys}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is order reflecting;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiSys}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

6.7 Narrow Reflectivity

In this section we study classes of π-institutions defined using reflectivity properties of the Leibniz operator restricted to $\mathrm{ThFam}^{\nleq}(\mathcal{I})$. We call those *narrow reflectivity* properties in analogy with the terminology adopted when differentiating rough injectivity and narrow injectivity classes.

Definition 437 (Narrow Reflectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **narrowly family reflective** *if, for all* $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$*,*
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad T \leq T';$$
- $\mathcal{I}$ *is called* **narrowly left reflective** *if, for all* $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$*,*
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$
- $\mathcal{I}$ *is called* **narrowly right reflective** *if, for all* $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$*,*
$$\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad T \leq T'.$$
- $\mathcal{I}$ *is called* **narrowly system reflective** *if, for all* $T, T' \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$*,*
$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad T \leq T'.$$

The narrow reflectivity properties have the following characterizations, paralleling those given for the narrow injectivity classes in Proposition 400.

Proposition 438 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is narrowly family reflective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ *implies* $\widetilde{T} \leq \widetilde{T'}$*;*

(b) $\mathcal{I}$ *is narrowly left reflective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ *implies* $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$*;*

(c) $\mathcal{I}$ *is narrowly right reflective if and only if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\Omega(\overleftarrow{\widetilde{T}}) \leq \Omega(\overleftarrow{\widetilde{T'}})$ *implies* $\widetilde{T} \leq \widetilde{T'}$*;*

(d) $\mathcal{I}$ *is narrowly system reflective if and only if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$, *such that* $\widetilde{T}, \widetilde{T'} \in \mathrm{ThSys}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ *implies* $\widetilde{T} \leq \widetilde{T'}$.

Proof:

(a) Suppose that $\mathcal{I}$ is narrowly family reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Consider $\widetilde{T}, \widetilde{T'} \in \mathrm{ThFam}^\natural(\mathcal{I})$. By Proposition 369, $\Omega(\widetilde{T}) = \Omega(T) \leq \Omega(T') = \Omega(\widetilde{T'})$. Thus, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. Therefore, the asserted condition holds.

Assume, conversely, that the asserted condition holds and let $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, since $\mathrm{ThFam}^\natural(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. Since, however, $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get $T = \widetilde{T} \leq \widetilde{T'} = T'$. Thus, $\mathcal{I}$ is narrowly family reflective.

(b) Suppose that $\mathcal{I}$ is narrowly left reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then $\widetilde{T}, \widetilde{T'} \in \mathrm{ThFam}^\natural(\mathcal{I})$ and, by Proposition 369, $\Omega(\widetilde{T}) \leq \Omega(\widetilde{T'})$. Thus, by hypothesis, $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$.

Assume, conversely, that the asserted condition holds and let $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by hypothesis, $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$. Since, however, $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get $\overleftarrow{T} = \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}} = \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is narrowly left reflective.

(c) Suppose that $\mathcal{I}$ is narrowly right reflective and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\Omega(\overleftarrow{\widetilde{T}}) \leq \Omega(\overleftarrow{\widetilde{T'}})$. Since $\widetilde{T}, \widetilde{T'} \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$.

Assume, conversely, that the asserted condition holds and let $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Then, since $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get $\Omega(\overleftarrow{\widetilde{T}}) = \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) = \Omega(\overleftarrow{\widetilde{T'}})$. Now, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$ and, therefore, $T \leq T'$. We conclude that $\mathcal{I}$ is narrowly right reflective.

(d) Suppose $\mathcal{I}$ is narrowly system reflective and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T}, \widetilde{T'} \in \mathrm{ThSys}(\mathcal{I})$ and $\Omega(T) \leq \Omega(T')$. Then $\widetilde{T}, \widetilde{T'} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$ and, by Proposition 369, $\Omega(\widetilde{T}) = \Omega(T) \leq \Omega(T') = \Omega(\widetilde{T'})$. Thus, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$.

Assume, conversely, that the asserted condition holds and let $T, T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, since $T, T' \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we get $\widetilde{T} = T, \widetilde{T'} = T' \in \mathrm{ThSys}(\mathcal{I})$ and, therefore, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. But this gives $T = \widetilde{T} \leq \widetilde{T'} = T'$. Thus, $\mathcal{I}$ is narrowly system reflective. ∎

As was shown in Lemma 401, narrow right injectivity implies exclusive systemicity. In the next lemma, we show that narrow family reflectivity also implies exclusive systemicity.

Lemma 439 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is narrowly family reflective, then it is exclusively systemic.*

Proof: Assume $\mathcal{I}$ is narrowly family reflective and let $T \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$. By Proposition 20, $\Omega(T) \leq \Omega(\overleftarrow{T})$. Thus, by hypothesis, $T \leq \overleftarrow{T}$. Since, by Proposition 2, the reverse inclusion always holds, we get $\overleftarrow{T} = T$. Thus, $\mathcal{I}$ is exclusively systemic. ∎

Lemma 405 also has the following direct consequence.

Corollary 440 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is narrowly right reflective, then it is narrowly stable.*

Proof: Since narrow right reflectivity implies narrow right injectivity, this follows directly from Lemma 405. ∎

We establish, next the *narrow reflectivity hierarchy*. The following proposition forms an analog of Proposition 406, which established the narrow injectivity hierarchy.

Proposition 441 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is narrowly right reflective, then it is narrowly family reflective;*

(b) If $\mathcal{I}$ *is narrowly family reflective, then it is narrowly left reflective;*

(c) If $\mathcal{I}$ *is narrowly left reflective, then it is narrowly system reflective.*

Proof:

(a) Suppose that $\mathcal{I}$ is narrowly right reflective and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. By Corollary 440, $\mathcal{I}$ is narrowly stable. Now we obtain $\Omega(\overleftarrow{T}) = \Omega(T) \leq \Omega(T') = \Omega(\overleftarrow{T'})$. Hence, by narrow right reflectivity, $T \leq T'$. Hence, $\mathcal{I}$ is narrowly family reflective.

(b) Suppose that $\mathcal{I}$ is narrowly family reflective and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by hypothesis, $T \leq T'$, whence, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$. Thus, $\mathcal{I}$ is narrowly left reflective.

(c) Suppose that $\mathcal{I}$ is narrowly left reflective and let $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by hypothesis, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. Therefore, since T, T' are theory systems, $T \leq T'$ and, hence, $\mathcal{I}$ is narrowly system reflective.

■

We have now established the following **narrow reflectivity hierarchy** of π-institutions.

Narrowly R Reflective

$\downarrow$

Narrowly F Reflective

$\downarrow$

Narrowly L Reflective

$\downarrow$

Narrowly S Reflective

We give an additional result pertaining to the hierarchy of narrow reflectivity properties depicted in the diagram. The following proposition may be viewed as an analog of Proposition 407.

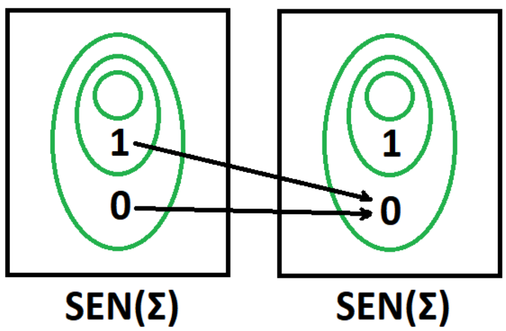
Proposition 442 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly system reflective and narrowly systemic, then it is narrowly right reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly system reflective and narrowly systemic. Let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. By narrow systemicity, $T = \overleftarrow{T}$ and $T' = \overleftarrow{T'}$. Hence, on the one hand $\Omega(T) \leq \Omega(T')$ and, on the other, $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$. Thus, by narrow system reflectivity, $T \leq T'$. Thus, $\mathcal{I}$ is narrowly right reflective. ■

We present three examples to show that all inclusions established between the narrow reflectivity classes and shown in the preceding diagram are indeed proper inclusions. The first example depicts a π-institution which is narrowly family reflective but not narrowly right reflective. This shows that the class of narrowly right reflective π-institutions constitutes a proper subclass of the class of narrowly family reflective π-institutions.

Example 443 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

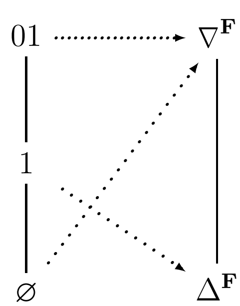
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ *has three theory families,* $\varnothing$*,* $\{\{1\}\}$ *and* $\{\{0,1\}\}$*, but only two theory systems,* $\varnothing$ *and* $\{\{0,1\}\}$*. The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since the Leibniz operator is an isomorphism on $\mathrm{ThFam}^{\lightning}(\mathcal{I})$*,* $\mathcal{I}$ *is narrowly family reflective. On the other hand,* $\{\{1\}\}, \{\{0,1\}\} \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$ *and*

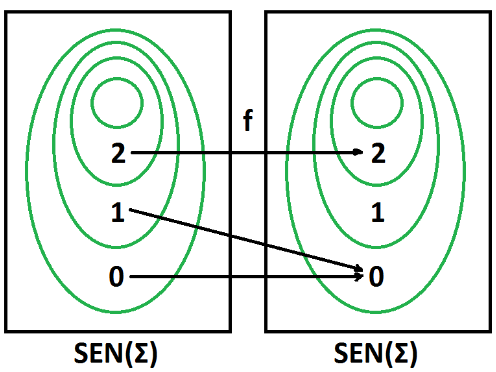
$$\Omega(\overleftarrow{\{\{1\}\}}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} = \Omega(\{\{0,1\}\}) = \Omega(\overleftarrow{\{\{0,1\}\}}),$$

but $\{\{1\}\} \neq \{\{0,1\}\}$. *Therefore,* $\mathcal{I}$ *is not narrowly right injective and, a fortiori, it fails to be narrowly right reflective.*

The next example depicts a π-institution which is narrowly left reflective but not narrowly family reflective. This shows that the class of narrowly family reflective π-institutions is a proper subclass of the class of narrowly left reflective π-institutions.

Example 444 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

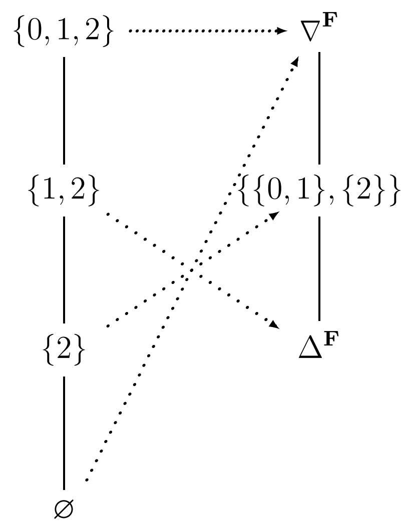
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families, but only three theory systems, namely* $\varnothing$, $\{2\}$ *and* $\{0,1,2\}$. *Moreover, clearly,* $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \{\{2\},\{1,2\},\{0,1,2\}\}$. *The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:*



There are three pairs (T, T'), *with* $T, T' \in \mathrm{ThFam}^{\natural}(\mathcal{I})$ *and* $T \neq T'$, *such that* $\Omega(T) \leq \Omega(T')$, *namely,*

$$(\{1,2\},\{0,1,2\}), \quad (\{2\},\{0,1,2\}), \quad (\{1,2\},\{2\}).$$

For all three, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. *Thus,* $\mathcal{I}$ *is narrowly left reflective. On the other hand, for* $T = \{1,2\}$ *and* $T' = \{2\}$, *even though* $\Omega(T) \leq \Omega(T')$, *we get* $T \nleq T'$, *whence* $\mathcal{I}$ *fails to be narrowly family reflective.*

We finish the sequence of examples by presenting a narrowly system reflective π-institution which fails to be narrowly left reflective. This example shows that narrowly left reflective π-institutions form a proper subclass of the class of narrowly system reflective π-institutions.

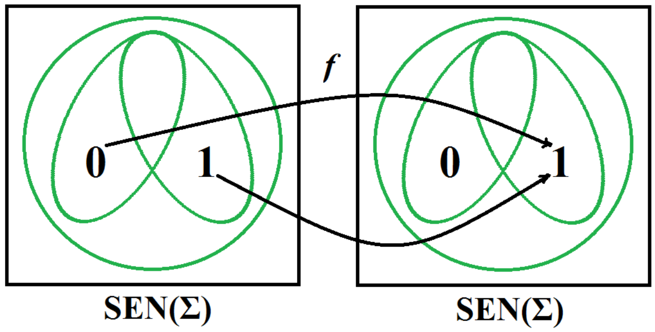
Example 445 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 1$ *and* $\mathrm{SEN}^\flat(f)(1) = 1$;
- $N^\flat$ *is the trivial clone.*

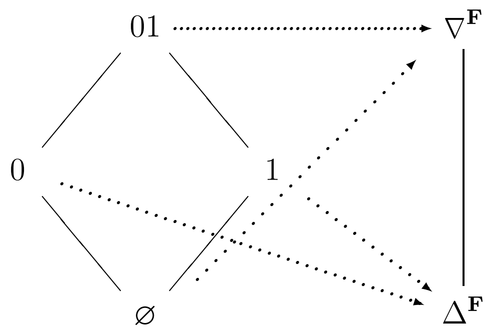
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{1\}, \{0,1\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$.

T	$\overleftarrow{T}$
$\varnothing$	$\varnothing$
$\{0\}$	$\varnothing$
$\{1\}$	$\{1\}$
$\{0,1\}$	$\{0,1\}$



The lattice of theory families and the corresponding Leibniz congruence systems are depicted below.



It is obvious from the diagram that the Leibniz operator is an isomorphism on $\mathrm{ThSys}^{\nmid}(\mathcal{I})$. *Therefore,* $\mathcal{I}$ *is narrowly system reflective. On the other hand, for* $T = \{\{0\}\}$, $T' = \{\{1\}\}$, *both members of* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$, *we have* $\Omega(T) = \Omega(T') = \Delta^{\mathbf{F}}$, *whereas* $\overleftarrow{T} = \{\varnothing\} \neq \{\{1\}\} = \overleftarrow{T'}$. *Therefore,* $\mathcal{I}$ *is not narrowly left injective and, a fortiori, it fails to be narrowly left reflective.*

We turn now to the relationships between corresponding classes of the rough reflectivity and the narrow reflectivity hierarchies. These parallel the ones already established between the rough injectivity and narrow injectivity classes in Section 6.5.

Using the characterization in Part (a) of Proposition 438, we can immediately see that the two types of family reflectivity coincide.

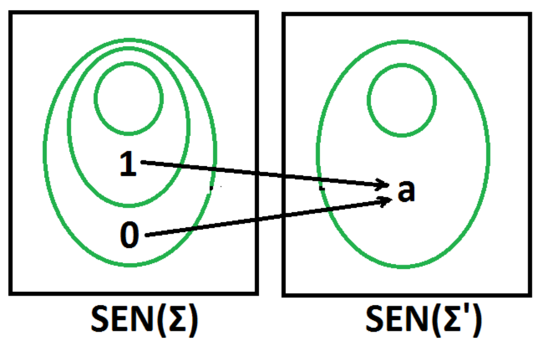
Corollary 446 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly family reflective if and only if it is narrowly family reflective.*

Proof: Part (a) of Proposition 438. ∎

As was the case with rough and narrow injectivity properties, the relationships between the remaining classes are not so straightforward, due to the necessity of investigating the mode of interaction between rough equivalence and the $\leftarrow$ operator. Starting with the two left reflectivity classes, we show that the class of narrow left reflective π-institutions is not included in the class of roughly left reflective π-institutions. This is accomplished by constructing a π-institution which is narrowly left reflective but not roughly left reflective.

Example 447 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

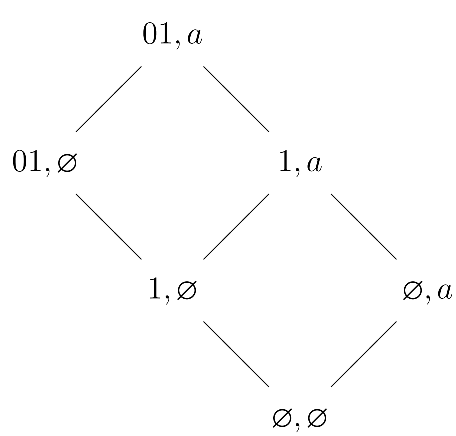
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$

Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$*, only four of which are theory systems, and only two of which are in* $\mathrm{ThFam}^{\lightning}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



The only pair (T,T'), *with* $T,T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $T \neq T'$ *and* $\Omega(T) \leq \Omega(T')$ *is* $(\{1,a\},\ \{01,a\})$, *Since,* $\overleftarrow{\{1,a\}} = \{1,a\} \leq \{01,a\} = \overleftarrow{\{01,a\}}$, *it follows that* $\mathcal{I}$ *is narrowly left reflective.*

On the other hand, consider $T = \{1,\varnothing\}$ *and* $T' = \{1,a\}$. *We have* $\Omega(1,\varnothing) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(1,a)$, *but*

$$\overleftarrow{\widetilde{1,\varnothing}} = \widetilde{\varnothing,\varnothing} = \{01,a\} \nleq \{1,a\} = \widetilde{1,a} = \overleftarrow{\widetilde{1,a}}.$$

This proves that $\mathcal{I}$ *is not roughly left reflective.*

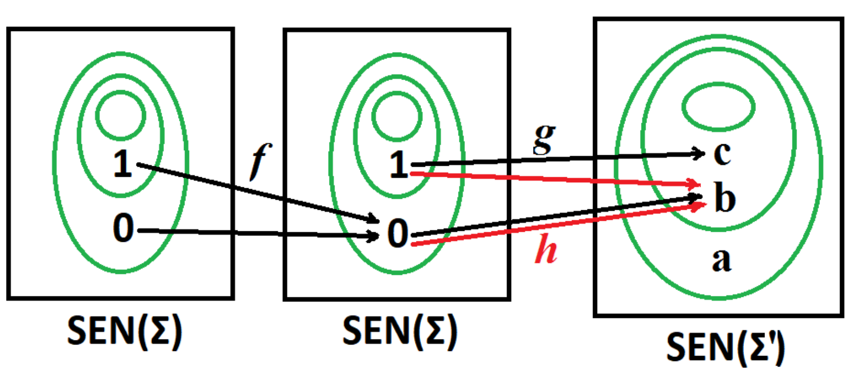
We exhibit, next a π-institution that is roughly left reflective, while it fails to be narrowly left reflective. Combined with Example 447, this will show that the two left reflectivity classes, rough and narrow, are incomparable from the point of view of inclusion.

Example 448 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and three nonidentity morphisms* $f : \Sigma \to \Sigma$ *and* $g, h : \Sigma \to \Sigma'$, *such that* $f \circ f = f$, $g \circ f = h$ *and* $h \circ f = h$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(g)(0) = b$, $\mathrm{SEN}^\flat(g)(1) = c$ *and* $\mathrm{SEN}^\flat(h)(0) = \mathrm{SEN}^\flat(h)(1) = b$;
- $N^\flat$ *is the clone generated by a single binarry natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$, *whose components are defined by the following tables:*

$\sigma^\flat_\Sigma$	0	1
0	0	1
1	1	1

$\sigma^\flat_{\Sigma'}$	a	b	c
a	a	a	c
b	a	b	c
c	c	c	c



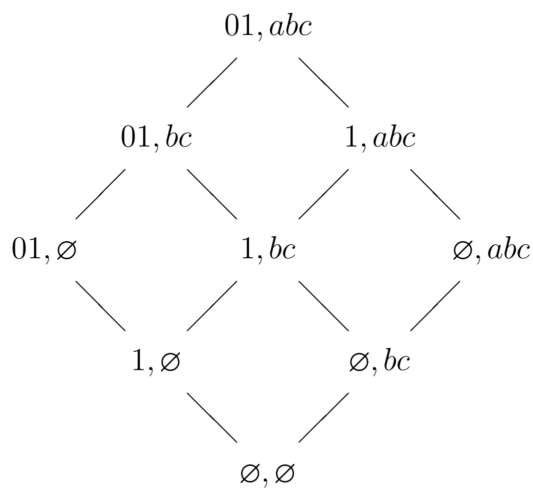
It is not difficult, albeit slightly tedious, to check that this is a well-defined natural transformation. We summarize the checking in the accompanying table.

(x,y)	$f(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_\Sigma(f(x),f(y))$	$g(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_{\Sigma'}(g(x),g(y))$	$h(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_{\Sigma'}(h(x),h(y))$
$(0,0)$	$0=0$	$b=b$	$b=b$
$(0,1)$	$0=0$	$c=c$	$b=b$
$(1,0)$	$0=0$	$c=c$	$b=b$
$(1,1)$	$0=0$	$c=c$	$b=b$

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing,\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing,\{b,c\},\{a,b,c\}\}.$$

Clearly, there are nine theory families in $\mathrm{ThFam}(\mathcal{I})$*, five of which are theory systems, and four of which are in* $\mathrm{ThFam}^{\lightning}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



The action of $\overleftarrow{\ }$ *on theory families is given in the following table.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$01, abc$	$01, abc$	$\varnothing, abc$	$\varnothing, abc$
$01, bc$	$01, bc$	$1, \varnothing$	$\varnothing, \varnothing$
$1, abc$	$\varnothing, abc$	$\varnothing, bc$	$\varnothing, bc$
$01, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$
$1, bc$	$\varnothing, bc$		

The table below provides the Leibniz congruence systems associated with the theory families of $\mathcal{I}$.

T	$\Omega(T)$
$\{01,abc\},\{01,\varnothing\},\{\varnothing,abc\},\{\varnothing,\varnothing\}$	$\nabla^{\mathbf{F}}$
$\{1,abc\},\{1,\varnothing\}$	$\{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{01,bc\},\{1,bc\},\{\varnothing,bc\}$	$\Delta^{\mathbf{F}}$

To see that $\mathcal{I}$ is roughly left reflective, suppose that $\Omega(T) \le \Omega(T')$. We separate cases depending on $\Omega(T')$.

- *If $\Omega(T') = \Delta^{\mathbf{F}}$, then $T, T' \in \{\{01, bc\}, \{1, bc\}, \{\varnothing, b\}\}$, whence $\widetilde{\overleftarrow{T}} = \{01, bc\} = \widetilde{\overleftarrow{T'}}$;*
- *If $\Omega(T') = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}$ or $\Omega(T') = \nabla^{\mathbf{F}}$, then $\widetilde{\overleftarrow{T}} \le \{01, abc\} = \widetilde{\overleftarrow{T'}}$.*

On the other hand, for $T = \{01, bc\}$ and $T' = \{1, bc\}$, we get $\Omega(T) = \Delta^{\mathbf{F}} = \Omega(T')$, whereas $\overleftarrow{T} = \{01, bc\} \nleq \{\varnothing, bc\} = \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is not narrowly left reflective.

We turn, next to the relationship between the two kinds of right reflectivity. We show, first, that rough right reflectivity implies narrow right reflectivity.

Proposition 449 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly right reflective, then it is narrowly right reflective.*

Proof: Suppose $\mathcal{I}$ is roughly right reflective and let $T, T' \in \mathrm{ThFam}^{\natural}(\mathcal{I})$, such that $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. By rough right reflectivity, we get that $\widetilde{T} \le \widetilde{T'}$. Since, however, $T, T' \in \mathrm{ThFam}^{\natural}(\mathcal{I})$, we get $T = \widetilde{T} \le \widetilde{T'} = T'$. Therefore, $\mathcal{I}$ is narrowly right reflective. ∎

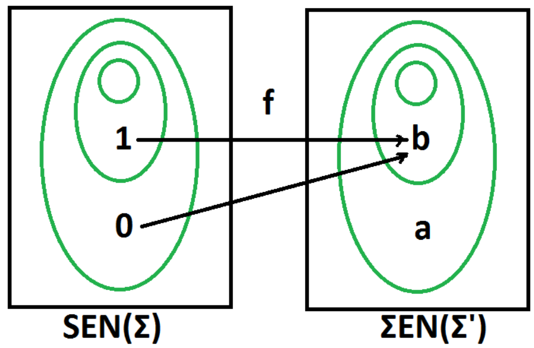
The converse, on the other hand, does not hold in general, as the following example demonstrates.

Example 450 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ be the algebraic system defined as follows:*

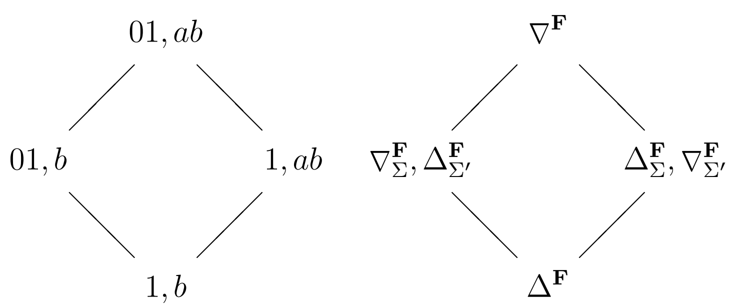
- $\mathbf{Sign}^{\flat}$ *is the category with objects Σ and Σ' and a unique morphism $f : \Sigma \to \Sigma'$;*
- $\mathrm{SEN}^{\flat} : \mathbf{Sign}^{\flat} \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^{\flat}(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^{\flat}(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^{\flat}(f)(0) = b$, $\mathrm{SEN}^{\flat}(f)(1) = b$;
- *$N^{\flat}$ is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_{\Sigma} = \{\varnothing, \{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$



Clearly, there are only four theory families in $\mathrm{ThFam}^{\sharp}(\mathcal{I})$*, all of which are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*



From this diagram and the fact that all theory families in $\mathrm{ThFam}^{\sharp}(\mathcal{I})$ *are theory systems, we see that, for all* $T, T' \in \mathrm{ThFam}^{\sharp}(\mathcal{I})$*,*

$$\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{iff} \quad \Omega(T) \leq \Omega(T') \quad \textit{iff} \quad T \leq T'.$$

Therefore, $\mathcal{I}$ *is indeed narrowly right reflective.*

On the other hand, consider $T = \{01, ab\}$ *and* $T' = \{1, \varnothing\}$*. Then we have*

$$\Omega(\overleftarrow{T}) = \Omega(01, ab) = \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing}) = \Omega(\overleftarrow{T'}),$$

whereas $\widetilde{01, ab} = \{01, ab\} \nleq \{1, ab\} = \widetilde{1, \varnothing}$*. This shows that* $\mathcal{I}$ *is not roughly right reflective.*

Finally, we look at system reflectivity. We show that rough system reflectivity implies narrow system reflectivity, but that the converse implication fails in general.

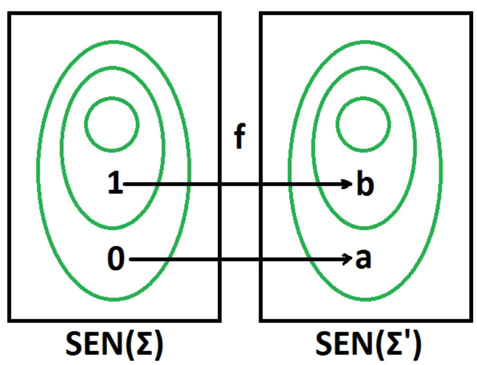
Proposition 451 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly system reflective, then it is narrowly system reflective.*

Proof: Suppose $\mathcal{I}$ is roughly system reflective and let $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, such that $\Omega(T) \leq \Omega(T')$. Then, by rough system reflectivity, $\widetilde{T} \leq \widetilde{T'}$. However, since $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, we get $T = \widetilde{T} \leq \widetilde{T'} = T'$. Therefore, $\mathcal{I}$ is narrowly system reflective. ■

And now we present an example of a π-institution that is narrowly system reflective but not roughly system reflective. This, combined with Proposition 451, shows that the class of narrowly system reflective π-institutions properly contains the class of roughly system reflective π-institutions.

Example 452 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

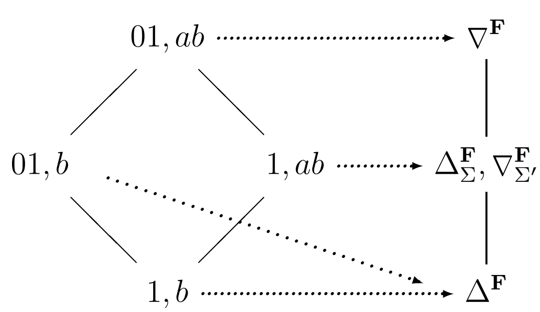
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$

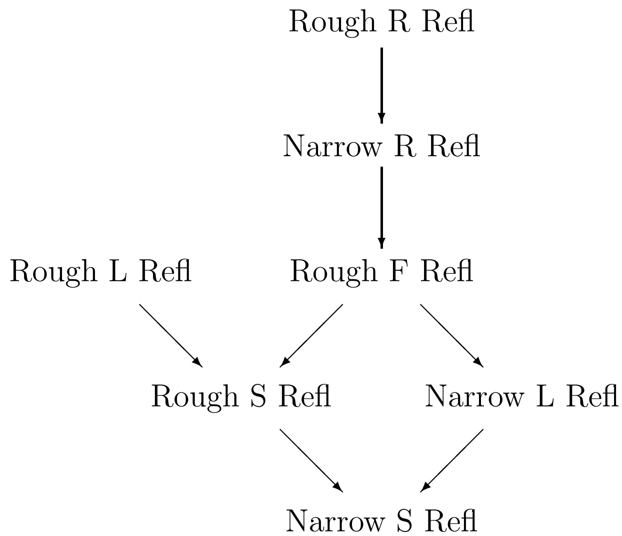
There are only four theory families in $\mathrm{ThFam}^{\lightning}(\mathcal{I})$*, all of which except for* $\{01, b\}$ *are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*



From this diagram we see that for all $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$*, we get* $\Omega(T) \leq \Omega(T')$ *if and only if* $T \leq T'$*. Therefore,* $\mathcal{I}$ *is narrowly system reflective.*

On the other hand, consider $T = \{\varnothing, b\}$*,* $T' = \{1, b\} \in \mathrm{ThSys}(\mathcal{I})$*. Even though* $\widetilde{T} = \{01, b\} \nleq \{1, b\} = \widetilde{T}'$*, we have* $\Omega(T) = \Delta^{\mathbf{F}} = \Omega(T')$*. Hence,* $\mathcal{I}$ *is not roughly system reflective.*

The results obtained and the counterexamples presented, thus far, reveal the following mixed hierarchy of rough and narrow reflectivity classes of π-institutions, paralleling the one presented for rough and narrow injectivity properties.



As far as narrow injectivity versus narrow reflectivity properties, it is easy to show that a narrow reflectivity property implies the corresponding narrow injectivity property. (In fact, this observation, formalized in Proposition 453, has already been used before, e.g., in the proof of Part (a) of Proposition 441.)

Proposition 453 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is narrowly family reflective, then it is narrowly family injective;*

(b) If $\mathcal{I}$ *is narrowly left reflective, then it is narrowly left injective;*

(c) If $\mathcal{I}$ *is narrowly right reflective, then it is narrowly right injective;*

(d) If $\mathcal{I}$ *is narrowly system reflective, then it is narrowly system injective.*

Proof: We only deal with the family case, since the other three implications are equally straightforward to prove.

Assume that $\mathcal{I}$ is narrowly family reflective and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Since this implies that $\Omega(T) \leq \Omega(T')$ and that

$\Omega(T') \leq \Omega(T)$, we get, by applying narrow family reflectivity, that $T \leq T'$ and $T' \leq T$. Therefore, $T = T'$ and, hence, $\mathcal{I}$ is narrowly family injective. ■

Turning to the relationships between narrow reflectivity classes and corresponding reflectivity classes, we prove a theorem, analogous to Theorem 418, asserting that ordinary reflectivity is equivalent to narrow reflectivity in the presence of theorems.

Theorem 454 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is family reflective if and only if it is narrowly family reflective and has theorems;*

(b) $\mathcal{I}$ *is left reflective if and only if it is narrowly left reflective and has theorems;*

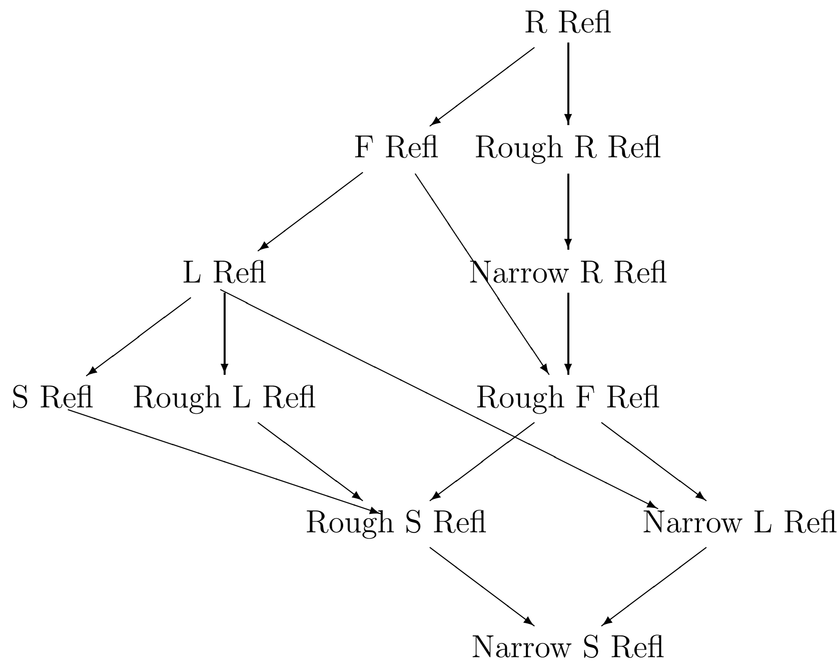
(c) $\mathcal{I}$ *is right reflective if and only if it is narrowly right reflective and has theorems;*

(d) $\mathcal{I}$ *is system reflective if and only if it is narrowly system reflective and has theorems.*

Proof: By Theorem 432, if $\mathcal{I}$ has one of the four reflectivity properties, then it has theorems. Moreover, by the same theorem, a reflectivity property implies the corresponding rough reflectivity property and, by Corollary 446, Proposition 449 and Proposition 451, each implies the corresponding narrow reflectivity property except in the case of left reflectivity, where (as actually in all other cases, as well) one can easily see directly that left reflectivity implies narrow left reflectivity, since the defining condition of the latter is a special case of that of the former.

All converses are also easily verified, since, in the presence of theorems, $\mathrm{ThFam}^{\natural}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$ and $\mathrm{ThSys}^{\natural}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, which makes the four defining conditions for the narrow classes identical with the corresponding conditions for the ordinary reflectivity classes. ■

We now have the following hierarchy.



The narrow reflectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems. This result forms an analog of Theorem 419, which applied to narrow injectivity classes.

Theorem 455 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is narrowly right reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $T \leq T'$*;*

(b) $\mathcal{I}$ *is narrowly family reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $T \leq T'$*;*

(c) $\mathcal{I}$ *is narrowly left reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\overleftarrow{T} \leq \overleftarrow{T'}$*;*

(d) $\mathcal{I}$ *is narrowly system reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}\nmid}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $T \leq T'$*.*

Proof: The proof follows the steps of the proofs of the various parts of Theorem 419. We do Part (a) in detail to give a flavor of what is involved.

The "if" follows by considering the **F**-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{F})$, by Lemmas 51 and 376.

For the "only if", suppose that $\mathcal{I}$ is narrowly right reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an **F**-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\Omega(\alpha^{-1}(\overleftarrow{T})) \leq \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Hence, by Lemma 6, $\Omega(\overleftarrow{\alpha^{-1}(T)}) \leq \Omega(\overleftarrow{\alpha^{-1}(T')})$. Since, by Lemmas 51 and 376, $\alpha^{-1}(T), \alpha^{-1}(T') \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we get, by applying narrow right reflectivity, $\alpha^{-1}(T) \leq \alpha^{-1}(T')$. This yields, taking into account the surjectivity of $\langle F, \alpha \rangle$, $T \leq T'$. ■

We finally recast narrow reflectivity in terms of the order reflectivity of mappings from posets of theory or filter families/systems into posets of congruence systems. The following results form analogs of Propositions 420 and 421, respectively, addressing reflectivity instead of injectivity properties.

Proposition 456 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* **F**. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly family reflective;*

(b) $\Omega : \mathrm{ThFam}^{\nmid}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* **F**-*algebraic system* $\mathcal{A}$.

Similarly, for system reflectivity, we have

Proposition 457 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* **F**. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly system reflective;*

(b) $\Omega : \mathrm{ThSys}^{\nmid}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}\nmid}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is order reflecting, for every* **F**-*algebraic system* $\mathcal{A}$.

6.8 Rough Complete Reflectivity

In this section we study classes of π-institutions defined using complete reflectivity properties of the Leibniz operator applied on rough equivalence classes.

Definition 458 (Rough c-Reflectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* **F**.

- $\mathcal{I}$ *is called* **roughly family completely reflective**, *or* **roughly family c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{T} \le \widetilde{T'}.$$

- $\mathcal{I}$ *is called* **roughly left completely reflective**, *or* **roughly left c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}} \le \overleftarrow{\widetilde{T'}}.$$

- $\mathcal{I}$ *is called* **roughly right completely reflective**, *or* **roughly right c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{T} \le \widetilde{T'}.$$

- $\mathcal{I}$ *is called* **roughly system completely reflective**, *or* **roughly system c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} \widetilde{T} \le \widetilde{T'}.$$

As was shown to be the case with rough right reflectivity in Lemma 423, we show that rough right c-reflectivity implies rough systemicity and, hence, by Theorem 370, stability.

Lemma 459 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly right completely reflective, then it is roughly systemic.*

Proof: This is a consequence of Lemma 423, since rough right c-reflectivity implies trivially rough right reflectivity. ∎

Next we establish the *rough c-reflectivity hierarchy* of π-institutions.

Proposition 460 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) *If* $\mathcal{I}$ *is roughly right c-reflective, then it is roughly family c-reflective;*

(b) *If* $\mathcal{I}$ *is roughly family c-reflective, then it is roughly system c-reflective;*

(c) *If* $\mathcal{I}$ *is roughly left c-reflective, then it is roughly system c-reflective.*

Proof:

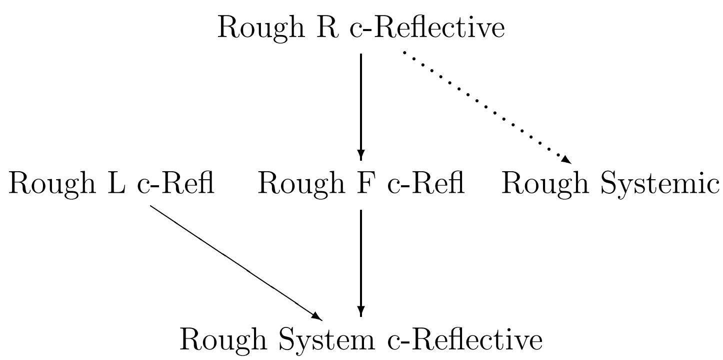
(a) Suppose $\mathcal{I}$ is roughly right c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. By Lemma 459, $\mathcal{I}$ is roughly systemic, whence $\overleftarrow{T} \sim T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} \sim T'$. Thus, by Theorem 370, we get
$$\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) = \bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T') = \Omega(\overleftarrow{T'}).$$
Now applying rough right c-reflectivity, we get $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$. This proves that $\mathcal{I}$ is roughly family c-reflective.

(b) Suppose $\mathcal{I}$ is roughly family c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by rough family c-reflectivity, we get $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$, whence, $\mathcal{I}$ is roughly system c-reflective.

(c) Suppose $\mathcal{I}$ is roughly left c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. By rough left c-reflectivity, we conclude that $\bigcap_{T\in\mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$. However, since $\mathcal{T} \cup \{T'\}$ consists of theory systems, we have $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$. Hence we get $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$ and, hence, $\mathcal{I}$ is roughly system reflective.

■

We have now established the following **rough complete reflectivity hierarchy** of π-institutions.



We formulate two additional properties concerning the relationships between rough c-reflectivity classes. First, rough right c-reflectivity turns out to be equivalent to rough system c-reflectivity combined with rough systemicity.

Proposition 461 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly right c-reflective if and only if it is roughly system c-reflective and roughly systemic.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly right c-reflective. Then, by Lemma 459, it is roughly systemic and by Proposition 460 it is roughly system c-reflective.

Suppose, conversely, that $\mathcal{I}$ is roughly system c-reflective and roughly systemic and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. By rough system c-reflectivity and Proposition 42, we get $\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. Hence, by rough systemicity, $\bigcap_{T\in\mathcal{T}}\widetilde{T} = \bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}} = \widetilde{T'}$. Thus, $\mathcal{I}$ is roughly right c-reflective. ■

Second, we show that rough system c-reflectivity together with stability imply rough left c-reflectivity.

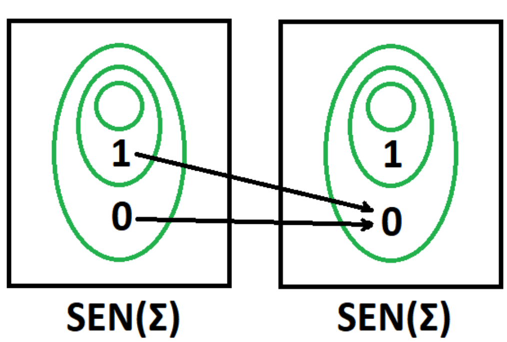
Proposition 462 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is roughly system c-reflective and stable, then it is roughly left c-reflective.*

Proof: Suppose that $\mathcal{I}$ is roughly system c-reflective and stable and consider $\mathcal{T}\cup\{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}}\Omega(T) \leq \Omega(T')$. Then, by stability $\bigcap_{T\in\mathcal{T}}\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Hence, since $\{\overleftarrow{T} : T\in\mathcal{T}\}\cup\{\overleftarrow{T'}\} \subseteq \mathrm{ThSys}(\mathcal{I})$, by rough system c-reflectivity, $\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. This shows that $\mathcal{I}$ is roughly left c-reflective. ■

We present three examples to show that all inclusions established between rough c-reflectivity classes and depicted in the diagram above are proper inclusions. The first example will show that the class of roughly right c-reflective π-institutions is a proper subclass of the class of roughly family c-reflective π-institutions.

Example 463 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

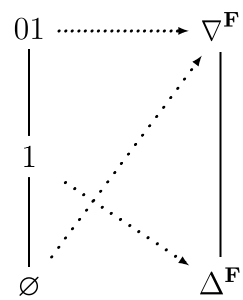
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f:\Sigma\to\Sigma$, *such that* $f\circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;
- $N^\flat$ *is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ has three theory families $\{\varnothing\}$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\{\varnothing\}$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



It is easy to see that $\mathcal{I}$ is roughly family c-reflective. Suppose that for $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T')$.

- *If $\Omega(T') = \Delta^{\mathbf{F}}$, then $\bigcap_{T \in \mathcal{T}} \Omega(T) = \Delta^{\mathbf{F}}$, whence $T' = \{\{1\}\}$ and $\{\{1\}\} \in \mathcal{T}$. Thus, $\bigcap_{T \in \mathcal{T}} \widetilde{T} \le \{\{1\}\} = \widetilde{T'}$.*

- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \{\varnothing\}$ or $T' = \{\{0,1\}\}$. In either case, $\bigcap_{T \in \mathcal{T}} \widetilde{T} \le \{\{0,1\}\} = \widetilde{T'}$.*

On the other hand, for $T = \{\{1\}\}$, we get $\widetilde{T} = \{\{1\}\} \ne \{\{0,1\}\} = \widetilde{\{\varnothing\}} = \widetilde{\overleftarrow{T}}$, whence $T \not\approx \overleftarrow{T}$ and, hence, $\mathcal{I}$ is not roughly systemic. Therefore, by Lemma 459, $\mathcal{I}$ is not roughly right c-reflective.

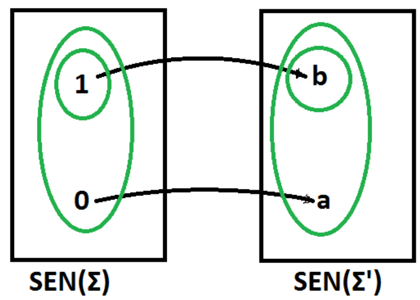
The second example shows that there exists a roughly left c-reflective π-institution that is not roughly family c-reflective.

Example 464 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with objects Σ and Σ' and a unique (non-identity) morphism $f : \Sigma \to \Sigma'$;*

- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ and $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;*

- *$N^\flat$ is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

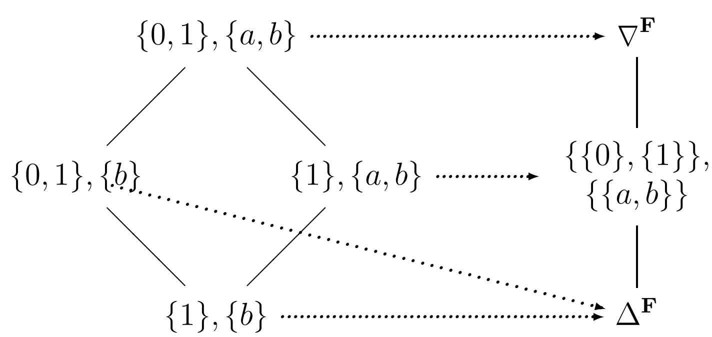
$$\mathcal{C}_\Sigma = \{\{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a,b\}\}.$$

Again, since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on ThFam$(\mathcal{I})$*.*

The following table shows the action of $\overleftarrow{\ }$ on theory families.

T	$\{1,b\}$	$\{01,b\}$	$\{1,ab\}$	$\{01,ab\}$
$\overleftarrow{T}$	$\{1,b\}$	$\{1,b\}$	$\{1,ab\}$	$\{01,ab\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



We show, first, that $\mathcal{I}$ is roughly left c-reflective. Suppose $\mathcal{T} \cup \{T'\} \subseteq$ ThFam$(\mathcal{I})$*, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$.*

- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \{\{0,1\},\{a,b\}\}$, whence*

$$\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \{\{0,1\},\{a,b\}\} = \overleftarrow{T'}$$

and, hence, $\bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$.

- *If* $\Omega(T') = \{\{\{0\},\{1\}\},\{\{a,b\}\}\}$*, then* $T' = \{\{1\},\{a,b\}\}$ *and one of* $\{\{0,1\},\{b\}\}$ *or* $\{\{1\},\{a,b\}\}$ *or* $\{\{1\},\{b\}\}$ *must belong to* $\mathcal{T}$*. In either case*
$$\bigcap_{T\in\mathcal{T}}\overleftarrow{T} \le \{\{1\},\{a,b\}\} = \overleftarrow{T'}$$
and, hence, $\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \le \widetilde{\overleftarrow{T'}}$.

- *If* $\Omega(T') = \Delta^{\mathbf{F}}$*, then* T' *must be either* $\{\{0,1\},\{b\}\}$ *or* $\{\{1\},\{b\}\}$ *and, moreover,* $\{\{0,1\},\{b\}\}$ *or* $\{\{1\},\{b\}\}$ *is in* $\mathcal{T}$*. Thus, we get*
$$\bigcap_{T\in\mathcal{T}}\overleftarrow{T} \le \{\{1\},\{b\}\} = \overleftarrow{T'}$$
and, hence, $\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \le \widetilde{\overleftarrow{T'}}$.

On the other hand, we have $\Omega(\{\{0,1\},\{b\}\}) \le \Omega(\{\{1\},\{b\}\})$*, but, clearly,* $\{\{0,1\},\{b\}\} \not\le \{\{1\},\{b\}\}$*. Thus, since rough equivalence is the identity on* $\mathrm{ThFam}(\mathcal{I})$*, we conclude that* $\mathcal{I}$ *is not roughly family c-reflective.*

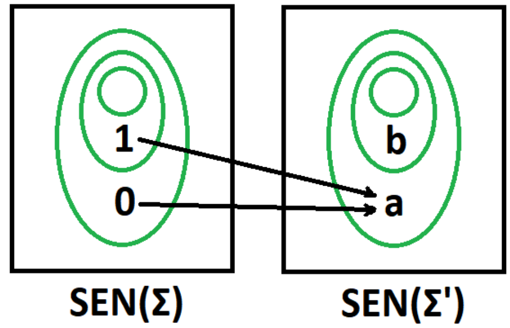
The third example shows that there exists a roughly family c-reflective π-institution that is not roughly left c-reflective. Combined with the preceding example, it has the effect of establishing the following facts:

- The classes of roughly family c-reflective and roughly left c-reflective π-institutions are incomparable.
- The class of roughly family c-reflective π-institutions is properly contained in the class of roughly system c-reflective π-institutions.
- Similarly, the class of roughly left c-reflective π-institutions is a proper subclass of the class of roughly system c-reflective π-institutions.

Example 465 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*

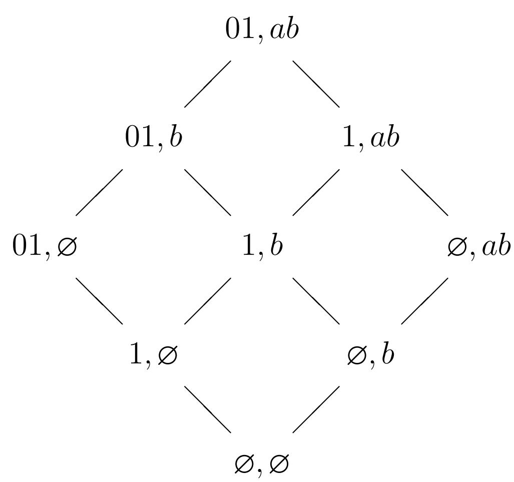
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*
$$\mathcal{C}_\Sigma = \{\varnothing,\{1\},\{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing,\{b\},\{a,b\}\}.$$



There are nine theory families, but only five theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$\varnothing, \varnothing$	$\varnothing, \varnothing$	$\varnothing, ab$	$\varnothing, ab$
$1, \varnothing$	$\varnothing, \varnothing$	$01, b$	$\varnothing, b$
$\varnothing, b$	$\varnothing, b$	$1, ab$	$1, ab$
$01, \varnothing$	$\varnothing, \varnothing$	$01, ab$	$01, ab$
$1, b$	$\varnothing, b$		

The lattice of theory families of $\mathcal{I}$ *is shown in the diagram.*



We show that $\mathcal{I}$ *is roughly family c-reflective. The following table summarizes the theory families together with their associated Leibniz congruence systems.*

T	$\Omega(T)$
$\{\varnothing, \varnothing\}, \{01, \varnothing\}, \{\varnothing, ab\}, \{01, ab\}$	$\nabla^{\mathbf{F}}$
$\{\varnothing, b\}, \{01, b\}$	$\{\nabla^{\mathbf{F}}_{\Sigma}, \Delta^{\mathbf{F}}_{\Sigma'}\}$
$\{1, \varnothing\}, \{1, ab\}$	$\{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{1, b\}$	$\Delta^{\mathbf{F}}$

Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*, such that* $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$*.*

- *If* $\Omega(T') = \nabla^{\mathbf{F}}$*, then* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \{01, ab\} = \widetilde{T}'$.
- *If* $\Omega(T') = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}$*, then* $\mathcal{T}$ *must include one of the theory families* $\{1, \varnothing\}$, $\{1, ab\}$, $\{1, b\}$. *Hence,* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \{1, ab\} = \widetilde{T}'$.
- *If* $\Omega(T') = \{\nabla^{\mathbf{F}}_{\Sigma}, \Delta^{\mathbf{F}}_{\Sigma'}\}$*, then* $\mathcal{T}$ *must include one of the theory families* $\{\varnothing, b\}$, $\{01, b\}$, $\{1, b\}$. *Hence,* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \{01, b\} = \widetilde{T}'$.
- *If* $\Omega(T') = \Delta^{\mathbf{F}}$*, then* $\bigcap_{T\in\mathcal{T}} \Omega(T) = \Delta^{\mathbf{F}}$ *and* $\widetilde{T}' = \widetilde{\{1, b\}} = \{1, b\}$.
  - *If* $\{1, b\} \in \mathcal{T}$*, then* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \{1, b\} = \widetilde{T}'$;
  - *If* $\{1, b\} \notin \mathcal{T}$*, then* $\mathcal{T}$ *must include at least one member of each of the pairs*
  $$\{\varnothing, b\},\ \{01, b\} \quad \text{and} \quad \{1, \varnothing\},\ \{1, ab\}.$$
  Thus, $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \{01, b\} \cap \{1, ab\} = \{1, b\} = \widetilde{T}'$.

On the other hand, consider $T = \{1, \varnothing\}$ *and* $T' = \{1, ab\}$. *We have*

$$\Omega(T) = \Omega(\{1, \varnothing\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(\{1, ab\}) = \Omega(T'),$$

whereas

$$\overleftarrow{\widetilde{T}} = \widetilde{\{\varnothing, \varnothing\}} = \{01, ab\} \nleq T' = \widetilde{T}' = \overleftarrow{\widetilde{T}'}.$$

hence, $\mathcal{I}$ *is not roughly left c-reflective.*

We look, next, at the connections between rough c-reflectivity and rough reflectivity classes. Membership in a rough c-reflectivity class implies, in a straightforward way, membership in the corresponding rough reflectivity class.

Theorem 466 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is roughly right c-reflective, then it is roughly right reflective;*

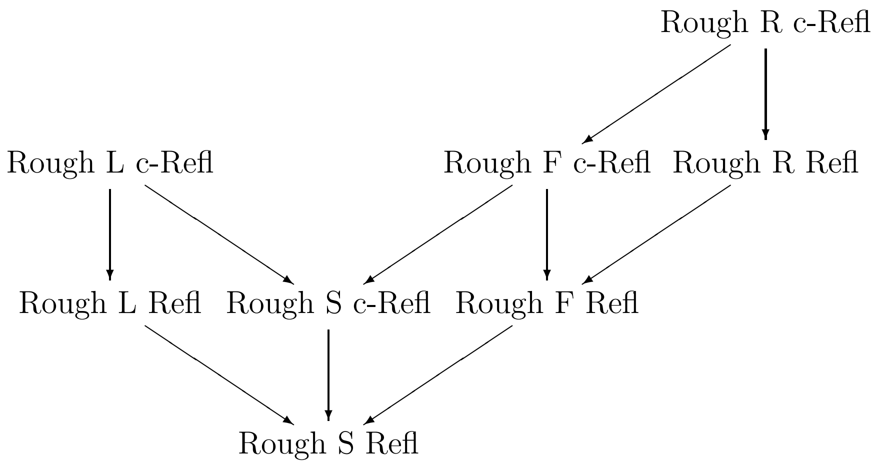
(b) If $\mathcal{I}$ *is roughly family c-reflective, then it is roughly family reflective;*

(c) If $\mathcal{I}$ *is roughly left c-reflective, then it is roughly left reflective;*

(d) If $\mathcal{I}$ *is roughly system c-reflective, then it is roughly system reflective.*

Proof: The property of being, e.g., roughly right reflective is a specialization of the property of being roughly right c-reflective, where one replaces the class $\mathcal{T}$ of theory families by the singleton $\{T\}$. The same holds for the remaining three types of rough reflectivity and rough c-reflectivity, respectively. ■

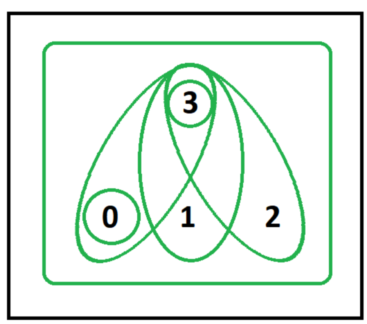
Theorem 466 establishes the mixed rough hierarchy depicted in the diagram.



To see that all classes in the hierarchy are different, we give an example of a π-institution satisfying all four rough reflectivity properties, which is not, however, roughly system c-reflective and, therefore, a fortiori, belongs to none of the four rough c-reflectivity classes.

Example 467 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$*;*
- $N^\flat$ *is the trivial clone.*



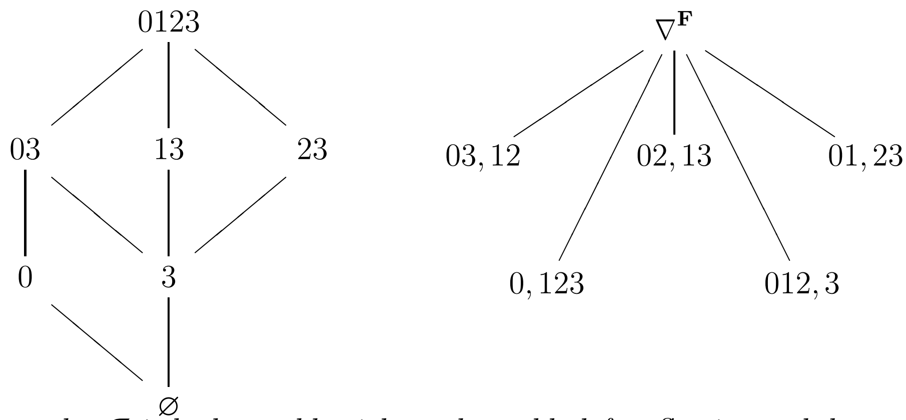
SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{3\}, \{0,3\}, \{1,3\}, \{2,3\}, \{0,1,2,3\}\}.$$

$\mathcal{I}$ *has seven theory families all of which are theory systems. It follows that the action of* $\overleftarrow{\ }$ *is trivial. Moreover, the only non-singleton rough equivalence class is the one consisting of* $\{\varnothing\}$ *and* $\{\{0,1,2,3\}\}$*.*

The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



We show that $\mathcal{I}$ is both roughly right and roughly left reflective and, hence, belongs to all four classes in the rough reflectivity hierarchy. Note that, since $\mathcal{I}$ is systemic, both rough reflectivity properties boil down to showing that, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \widetilde{T} \leq \widetilde{T'}.$$

- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \{\varnothing\}$ or $T' = \{\{0,1,2,3\}\}$. Therefore, $\widetilde{T} \leq \{\{0,1,2,3\}\} = \widetilde{T'}$;*
- *If $\Omega(T') \neq \nabla^{\mathbf{F}}$, then, since $\Omega(T) \leq \Omega(T')$, we must have $T = T'$ and, hence, $\widetilde{T} \leq \widetilde{T'}$.*

On the other hand, we have

$$\Omega(\{03\}) \cap \Omega(\{3\}) = \{03, 12\} \cap \{012, 3\} = \{0, 12, 3\} \leq \{0, 123\} = \Omega(\{\{0\}\}),$$

whereas

$$\widetilde{\{03\}} \cap \widetilde{\{3\}} = \{03\} \cap \{3\} = \{3\} \nleq \{0\} = \widetilde{\{0\}}.$$

Hence, $\mathcal{I}$ is not roughly system c-reflective and, therefore, it belongs to none of the four rough c-reflectivity classes.

We explore, next, the connections between rough c-reflectivity and c-reflectivity classes. By analogy with the case of reflectivity and rough reflectivity (Theorem 432), we get that membership in a c-reflectivity class implies membership in the corresponding rough c-reflectivity class and, also, possession of theorems. Conversely, membership in a rough c-reflectivity class plus possession of theorems entails membership in the corresponding c-reflectivity class.

Theorem 468 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) *$\mathcal{I}$ is right/family c-reflective if and only if it is roughly right c-reflective and has theorems;*

(b) *$\mathcal{I}$ is right/family c-reflective if and only if it is roughly family c-reflective and has theorems;*

(c) *$\mathcal{I}$ is left c-reflective if and only if it is roughly left c-reflective and has theorems;*

(d) *$\mathcal{I}$ is system c-reflective if and only if it is roughly system c-reflective and has theorems.*

Proof:

(a) Suppose that $\mathcal{I}$ is right c-reflective. Then, by Proposition 243, it is right reflective. Hence, by Theorem 432, it has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Then, by right c-reflectivity, $\bigcap_{T\in\mathcal{T}} T \leq T'$. Since $\mathcal{I}$ has theorems, $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Therefore, $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$ and $\mathcal{I}$ is roughly right c-reflective.

Assume, conversely, that $\mathcal{I}$ is roughly right c-reflective and has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Then, by rough right c-reflectivity, we get $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$. On the other hand, since $\mathcal{I}$ has theorems, $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Therefore, $\bigcap_{T\in\mathcal{T}} T \leq T'$ and $\mathcal{I}$ is right c-reflective.

(b) Suppose that $\mathcal{I}$ is family c-reflective. Then, by Proposition 243, it is family reflective. Hence, by Theorem 432, it has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by family c-reflectivity, $\bigcap_{T\in\mathcal{T}} T \leq T'$. Since $\mathcal{I}$ has theorems, $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Therefore, $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$ and $\mathcal{I}$ is roughly family c-reflective.

Assume, conversely, that $\mathcal{I}$ is roughly family c-reflective and has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by rough family c-reflectivity, we get $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$. On the other hand, since $\mathcal{I}$ has theorems, $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Therefore, $\bigcap_{T\in\mathcal{T}} T \leq T'$ and $\mathcal{I}$ is family c-reflective.

(c) Suppose that $\mathcal{I}$ is left c-reflective. Then, by Proposition 243, it is left reflective. Hence, by Theorem 432, it has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by left reflectivity, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Since $\mathcal{I}$ has theorems, $\overleftarrow{\widetilde{T}} = \overleftarrow{T}$, for all $T \in \mathcal{T}$, and $\overleftarrow{\widetilde{T'}} = \overleftarrow{T'}$. Therefore, $\bigcap_{T\in\mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$ and $\mathcal{I}$ is roughly left c-reflective.

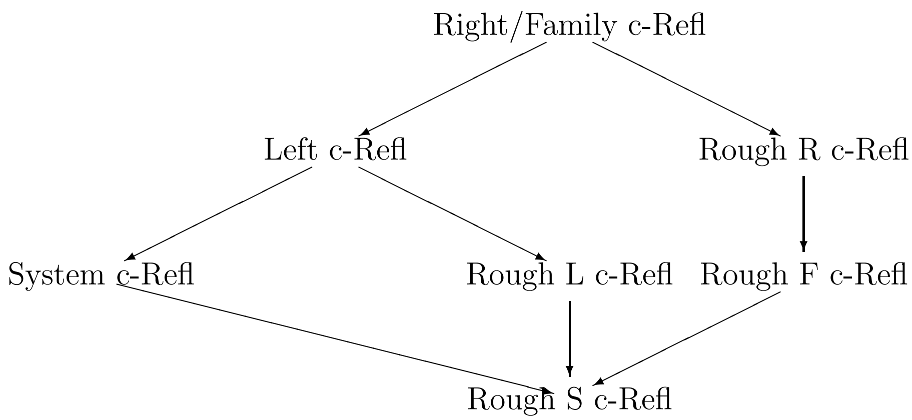
Assume, conversely, that $\mathcal{I}$ is roughly left c-reflective and has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by rough left c-reflectivity, we get $\bigcap_{T\in\mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$. On the other hand, since

$\mathcal{I}$ has theorems, $\widetilde{\overleftarrow{T}} = \overleftarrow{T}$, for all $T \in \mathcal{T}$, and $\widetilde{\overleftarrow{T'}} = \overleftarrow{T'}$. Therefore, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$ and $\mathcal{I}$ is left c-reflective.

(d) Similar to Part (b).

■

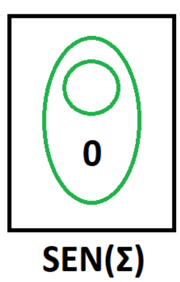
The work in Chapter 3, together with the work done in the present section and Theorem 468, reveal a hierarchy of c-reflectivity and rough c-reflectivity classes shown in the accompanying diagram.



To complete the demonstration that all classes in the depicted hierarchy are distinct we provide an example of a π-institution which belongs to all steps in the rough c-reflectivity hierarchy but possesses none of the four (gentle) c-reflectivity properties.

Example 469 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

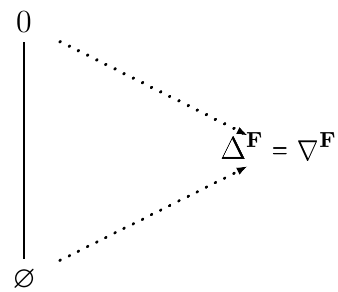
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



Note that $\widetilde{\{\{0\}\}} = \widetilde{\{\varnothing\}} = \{\{0\}\}$*, whence, trivially,* $\mathcal{I}$ *is both roughly right and roughly left c-reflective.*

On the other hand, since $\Omega(\{\{0\}\}) = \nabla^{\mathbf{F}} = \Omega(\{\varnothing\})$*, whereas* $\{\{0\}\} \nleq \{\varnothing\}$*,* $\mathcal{I}$ *is not system c-reflective and, hence, a fortiori,* $\mathcal{I}$ *has none of the four c-reflectivity properties.*

As was shown to be the case with the rough reflectivity properties in Theorem 434, the rough c-reflectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 470 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is roughly right c-reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$ *implies* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$*;*

(b) $\mathcal{I}$ *is roughly family c-reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$*;*

(c) $\mathcal{I}$ *is roughly left c-reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*,* $\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\bigcap_{T\in\mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$*;*

(d) $\mathcal{I}$ *is roughly system c-reflective if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $\mathcal{T} \cup \{T'\} \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*,* $\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ *implies* $\bigcap_{T\in\mathcal{T}} \widetilde{T} \leq \widetilde{T'}$*.*

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that, by Lemma 51, $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$.

For the "only if", suppose that $\mathcal{I}$ is roughly right c-reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}) \le \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})) \le \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$, whence, $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) \le \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\bigcap_{T \in \mathcal{T}} \Omega(\alpha^{-1}(\overleftarrow{T})) \le \Omega(\alpha^{-1}(\overleftarrow{T'}))$. By Lemma 6,

$$\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{\alpha^{-1}(T)}) \le \Omega(\overleftarrow{\alpha^{-1}(T')}).$$

Since, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by applying rough right c-reflectivity,

$$\bigcap_{T \in \mathcal{T}} \widetilde{\alpha^{-1}(T)} \le \widetilde{\alpha^{-1}(T')}.$$

Thus, by Theorem 377, $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\widetilde{T}) \le \alpha^{-1}(\widetilde{T'})$, i.e., $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \widetilde{T}) \le \alpha^{-1}(\widetilde{T'})$. Therefore, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\bigcap_{T \in \mathcal{T}} \widetilde{T} \le \widetilde{T'}$.

(b) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly family c-reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. Then we get $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$, whence, $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\bigcap_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T)) \le \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51,

$$\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I}),$$

we get, by applying rough family c-reflectivity, $\bigcap_{T \in \mathcal{T}} \widetilde{\alpha^{-1}(T)} \le \widetilde{\alpha^{-1}(T')}$. Thus, by Theorem 377, $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\widetilde{T}) \le \alpha^{-1}(\widetilde{T'})$, i.e., $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \widetilde{T}) \le \alpha^{-1}(\widetilde{T'})$. Therefore, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\bigcap_{T \in \mathcal{T}} \widetilde{T} \le \widetilde{T'}$.

(c) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly left c-reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \le \Omega^{\mathcal{A}}(T')$. Then $\alpha^{-1}(\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$, whence, $\bigcap_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \le \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. So, by Proposition 24, $\bigcap_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T)) \le \Omega(\alpha^{-1}(T'))$. Since, by Lemma 51,

$$\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I}),$$

we get, by applying rough left c-reflectivity, $\bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{\alpha^{-1}(T)}} \le \overleftarrow{\widetilde{\alpha^{-1}(T')}}$. Thus, by Lemma 6, $\bigcap_{T \in \mathcal{T}} \widetilde{\alpha^{-1}(\overleftarrow{T})} \le \widetilde{\alpha^{-1}(\overleftarrow{T'})}$. Hence, by Theorem 377,

$\bigcap_{T\in\mathcal{T}}\alpha^{-1}(\widetilde{\overleftarrow{T}}) \le \alpha^{-1}(\widetilde{\overleftarrow{T'}})$, i.e., $\alpha^{-1}(\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}}) \le \alpha^{-1}(\widetilde{\overleftarrow{T'}})$. Therefore, taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that $\bigcap_{T\in\mathcal{T}}\widetilde{\overleftarrow{T}} \le \widetilde{\overleftarrow{T'}}$.

(d) Similar to Part (b).

■

Finally, we may recast the rough c-reflectivity classes in terms of complete order reflectivity of mappings from posets of classes of theory or filter families/systems into posets of congruence systems.

Recall that the collections $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$ may be ordered by setting, respectively, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{\lceil T\rceil} \le \widetilde{\lceil T'\rceil} \quad \text{iff} \quad \widetilde{T} \le \widetilde{T'}$$

and, for all $T,T' \in \mathrm{ThSys}(\mathcal{I})$,

$$\widetilde{\lfloor T\rfloor} \le \widetilde{\lfloor T'\rfloor} \quad \text{iff} \quad \widetilde{T} \le \widetilde{T'},$$

and that the corresponding ordered sets are denoted by $\widetilde{\mathbf{ThFam}}(\mathcal{I})$ and $\widetilde{\mathbf{ThSys}}(\mathcal{I})$, respectively.

Proposition 471 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. The following statements are equivalent:*

(a) $\mathcal{I}$ is roughly family c-reflective;

(b) $\Omega : \widetilde{\mathbf{ThFam}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ is completely order reflecting;

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiFam}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is completely order reflecting, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

Similarly, for system c-reflectivity, we have

Proposition 472 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. The following statements are equivalent:*

(a) $\mathcal{I}$ is roughly system c-reflective;

(b) $\Omega : \widetilde{\mathbf{ThSys}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ is completely order reflecting;

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiSys}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is completely order reflecting, for every $\mathbf{F}$-algebraic system $\mathcal{A}$.

6.9 Narrow Complete Reflectivity

In this section we study classes of π-institutions defined using complete reflectivity properties of the Leibniz operator restricted to $\mathrm{ThFam}^{\nleq}(\mathcal{I})$. We call those *narrow complete reflectivity* properties in analogy with the terminology adopted when differentiating rough reflectivity and narrow reflectivity classes.

Definition 473 (Narrow c-Reflectivity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **narrowly family completely reflective***, or* **narrowly family c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T';$$
- $\mathcal{I}$ *is called* **narrowly left completely reflective***, or* **narrowly left c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'};$$
- $\mathcal{I}$ *is called* **narrowly right completely reflective***, or* **narrowly right c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T';$$
- $\mathcal{I}$ *is called* **narrowly system completely reflective***, or* **narrowly system c-reflective** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$,
$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \textit{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

The narrow complete reflectivity properties have the following characterizations, paralleling those given for the narrow reflectivity classes, given in Proposition 438.

Proposition 474 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is narrowly family c-reflective if and only if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ *implies* $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}$;

(b) $\mathcal{I}$ *is narrowly left c-reflective if and only if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ *implies* $\bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$;

(c) *$\mathcal{I}$ is narrowly right c-reflective if and only if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{\widetilde{T}}) \leq \Omega(\overleftarrow{\widetilde{T'}})$ implies $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}$;*

(d) *$\mathcal{I}$ is narrowly system c-reflective if and only if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\{\widetilde{T} : T \in \mathcal{T}\} \cup \{\widetilde{T'}\} \subseteq \mathrm{ThSys}(\mathcal{I})$, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ implies $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T'}$.*

Proof: The proofs of the various parts mimic those of the corresponding parts for the narrow reflectivity properties, presented in detail in Proposition 438. Thus, we only do Part (b) in detail here, trusting that the reader may easily reproduce the other proofs.

Suppose that $\mathcal{I}$ is narrowly left c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then $\{\widetilde{T} : T \in \mathcal{T}\} \cup \{\widetilde{T'}\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$ and, by Proposition 369, $\bigcap_{T \in \mathcal{T}} \Omega(\widetilde{T}) \leq \Omega(\widetilde{T'})$. Thus, by hypothesis, $\bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{\widetilde{T}}} \leq \overleftarrow{\widetilde{\widetilde{T'}}}$.

Assume, conversely, that the asserted condition holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by hypothesis, $\bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{\widetilde{T}}} \leq \overleftarrow{\widetilde{\widetilde{T'}}}$. Since, however, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get

$$\bigcap_{T \in \mathcal{T}} \overleftarrow{T} = \bigcap_{T \in \mathcal{T}} \overleftarrow{\widetilde{\widetilde{T}}} \leq \overleftarrow{\widetilde{\widetilde{T'}}} = \overleftarrow{T'}.$$

Therefore, $\mathcal{I}$ is narrowly left c-reflective. ∎

As was shown in Lemma 439, narrow family reflectivity implies exclusive systemicity. Since narrow family c-reflectivity implies narrow family reflectivity, it follows that it also implies exclusive systemicity.

Corollary 475 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly family c-reflective, then it is exclusively systemic.*

Proof: If $\mathcal{I}$ is narrowly family c-reflective, then it is, a fortiori, narrow family reflective, whence, by Lemma, 439, it is exclusively systemic. ∎

Similarly, the fact that narrow right c-reflectivity strengthens narrow right reflectivity, implies immediately the following

Corollary 476 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly right c-reflective, then it is narrowly stable.*

Proof: Since narrow right c-reflectivity implies narrow right reflectivity, this follows from Corollary 440. ∎

We establish, next the *narrow c-reflectivity hierarchy*. The following proposition forms an analog of Proposition 441, which dealt with the narrow reflectivity hierarchy.

Proposition 477 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(c) If $\mathcal{I}$ *is narrowly right c-reflective, then it is narrowly family c-reflective;*

(b) If $\mathcal{I}$ *is narrowly family c-reflective, then it is narrowly left c-reflective;*

(c) If $\mathcal{I}$ *is narrowly left c-reflective, then it is narrowly system c-reflective.*

Proof:

(a) Suppose that $\mathcal{I}$ is narrowly right c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nsim}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. By Corollary 476, $\mathcal{I}$ is narrowly stable. Now we obtain $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) = \bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') = \Omega(\overleftarrow{T'})$. Hence, by narrow right c-reflectivity, $\bigcap \mathcal{T} \leq T'$. Hence, $\mathcal{I}$ is narrowly family c-reflective.

(b) Suppose that $\mathcal{I}$ is narrowly family c-reflective and consider $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nsim}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by hypothesis, $\bigcap_{T \in \mathcal{T}} T \leq T'$, whence, by Lemma 1, $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \overleftarrow{T'}$. Thus, by Lemma 3, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Thus, $\mathcal{I}$ is narrowly left c-reflective.

(c) Suppose that $\mathcal{I}$ is narrowly left c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nsim}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by hypothesis, we get $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Therefore, since $\mathcal{T} \cup \{T'\}$ is a collection of theory systems, $\bigcap_{T \in \mathcal{T}} T \leq T'$ and, hence, $\mathcal{I}$ is narrowly system c-reflective.

■

We have now established the following **narrow complete reflectivity hierarchy** of π-institutions.

Narrowly R c-Reflective

↓

Narrowly F c-Reflective

↓

Narrowly L c-Reflective

↓

Narrowly S c-Reflective

We give an additional result pertaining to the hierarchy of narrow complete reflectivity properties depicted in the diagram. It forms an analog of Proposition 442, establishing a similar result for the narrow reflectivity hierarchy.

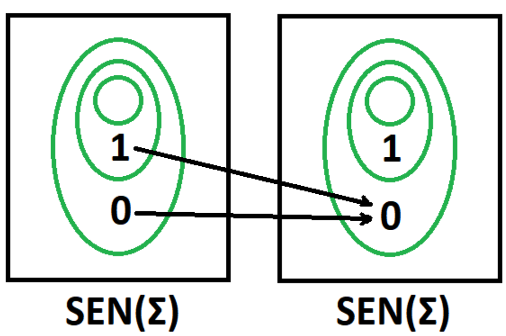
Proposition 478 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly system c-reflective and narrowly systemic, then it is narrowly right c-reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly system c-reflective and narrowly systemic. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. By narrow systemicity, $T = \overleftarrow{T}$, for all $T \in \mathcal{T}$, and $T' = \overleftarrow{T'}$. Hence, on the one hand, $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$ and, on the other, $\{T : T \in \mathcal{T}\} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nmid}(\mathcal{I})$. Thus, by narrow system c-reflectivity, $\bigcap_{T \in \mathcal{T}} T \leq T'$. Thus, $\mathcal{I}$ is narrowly right c-reflective. ■

We present three examples to show that all inclusions established between the narrow c-reflectivity classes and shown in the preceding diagram are indeed proper inclusions. The first example depicts a π-institution which is narrowly family c-reflective but not narrowly right c-reflective. This shows that the class of narrowly right c-reflective π-institutions constitutes a proper subclass of the class of narrowly family c-reflective π-institutions.

Example 479 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

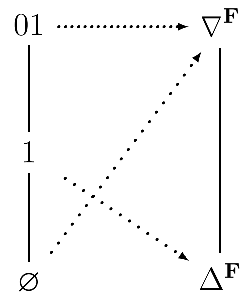
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ *has three theory families,* $\varnothing$*,* $\{\{1\}\}$ *and* $\{\{0, 1\}\}$*, but only two theory systems,* $\varnothing$ *and* $\{\{0, 1\}\}$*. The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since the Leibniz operator is an isomorphism on $\mathrm{ThFam}^{\nmid}(\mathcal{I})$, $\mathcal{I}$ *is narrowly family c-reflective. On the other hand,* $\{\{1\}\},\{\{0,1\}\} \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$ *and*

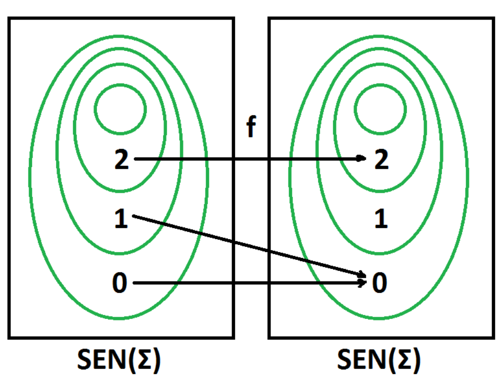
$$\Omega(\overleftarrow{\{\{1\}\}}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} = \Omega(\{\{0,1\}\}) = \Omega(\overleftarrow{\{\{0,1\}\}}),$$

but $\{\{1\}\} \neq \{\{0,1\}\}$. *Therefore,* $\mathcal{I}$ *is not narrowly right injective and, a fortiori, it fails to be narrowly right c-reflective.*

The next example depicts a π-institution which is narrowly left c-reflective but not narrowly family c-reflective. This shows that the class of narrowly family c-reflective π-institutions is a proper subclass of the class of narrowly left c-reflective π-institutions.

Example 480 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

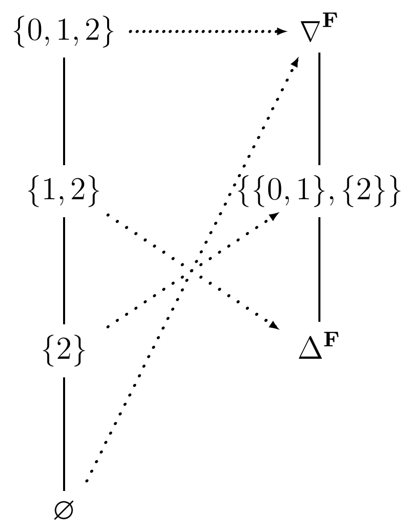
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has four theory families, but only three theory systems, namely $\varnothing$, $\{2\}$ and $\{0,1,2\}$. Moreover, clearly, $\mathrm{ThFam}^{\not\natural}(\mathcal{I}) = \{\{2\},\{1,2\},\{0,1,2\}\}$. The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



To show that $\mathcal{I}$ is narrowly left c-reflective, let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\not\natural}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \le \Omega(T')$. We distinguish the following cases, based on the value of $\Omega(T')$:

- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \mathrm{SEN}^\flat$. Hence, we get*
$$\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \le \mathrm{SEN}^\flat = \overleftarrow{\mathrm{SEN}^\flat} = \overleftarrow{T'};$$
- *If $\Omega(T') = \{\{0,1\},\{2\}\}$, then $T' = \{2\}$. Then, by hypothesis, $\{2\} \in \mathcal{T}$ or $\{1,2\} \in \mathcal{T}$. Hence, in either case, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \le \{2\} = T' = \overleftarrow{T'}$;*
- *If $\Omega(T') = \Delta^{\mathbf{F}}$, then $T' = \{1,2\}$ and, by hypothesis, $\{1,2\} \in \mathcal{T}$. Hence, in this case as well, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \le \overleftarrow{\{1,2\}} = \overleftarrow{T'}$.*

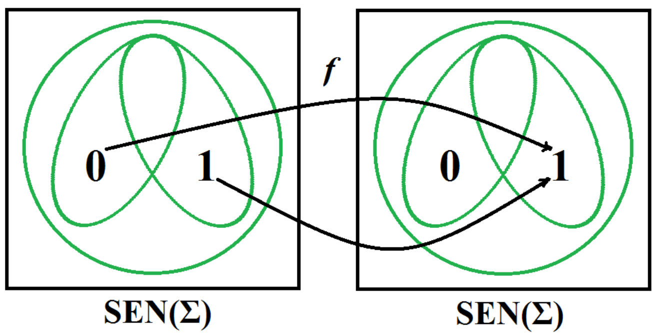
Thus, $\mathcal{I}$ is narrowly left c-reflective.

On the other hand, for $T = \{1,2\}$ and $T' = \{2\}$, even though $\Omega(T) \le \Omega(T')$, we get $T \nleq T'$, whence $\mathcal{I}$ fails to be narrowly family reflective and, hence, a fortiori, it is not narrow family c-reflective.

We finish the sequence of examples by presenting a narrowly system c-reflective π-institution which fails to be narrowly left c-reflective. This example shows that narrowly left c-reflective π-institutions form a proper subclass of the class of narrowly system c-reflective π-institutions.

Example 481 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 1$ *and* $\mathrm{SEN}^\flat(f)(1) = 1$;
- $N^\flat$ *is the trivial clone.*

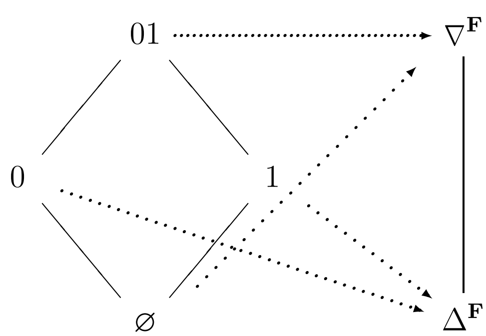


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\varnothing, \{0\}, \{1\}, \{0,1\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$.

T	$\overleftarrow{T}$
$\varnothing$	$\varnothing$
$\{0\}$	$\varnothing$
$\{1\}$	$\{1\}$
$\{0,1\}$	$\{0,1\}$

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below.



It is obvious from the diagram that the Leibniz operator is an isomorphism on $\mathrm{ThSys}^{\nmid}(\mathcal{I})$*. Therefore,* $\mathcal{I}$ *is narrowly system c-reflective. On the other hand, for* $T = \{\{0\}\}$*,* $T' = \{\{1\}\}$*, both members of* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*, we have* $\Omega(T) = \Omega(T') = \Delta^{\mathbf{F}}$*, whereas* $\overleftarrow{T} = \{\varnothing\} \neq \{\{1\}\} = \overleftarrow{T'}$*. Therefore,* $\mathcal{I}$ *is not narrowly left injective and, a fortiori, it fails to be narrowly left c-reflective.*

We turn now to the relationships between corresponding classes of the rough complete reflectivity and the narrow complete reflectivity hierarchies. These parallel the ones already established between the rough reflectivity and narrow reflectivity classes.

Using the characterization in Part (a) of Proposition 474, we can immediately see that the two types of family complete reflectivity coincide.

Corollary 482 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly family c-reflective if and only if it is narrowly family c-reflective.*

Proof: Part (a) of Proposition 474. ■

As was the case with rough and narrow reflectivity properties, the relationships between the remaining classes are more involved. Starting with the two left complete reflectivity classes, we show that the class of narrowly left c-reflective π-institutions is not included in the class of roughly left c-reflective π-institutions. This is accomplished by constructing a π-institution which is narrowly left c-reflective but not roughly left c-reflective.

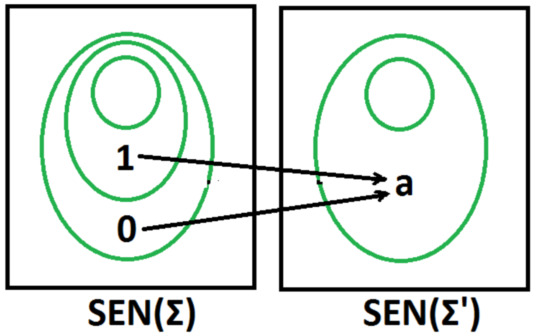
Example 483 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*

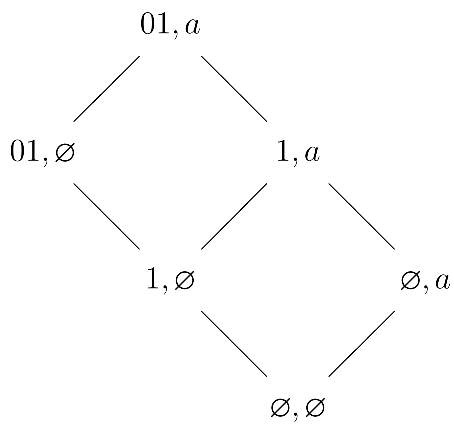
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$

Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$*, only four of which are theory systems, and only two of which are in* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*. The lattice of*



theory families is shown in the diagram:



To see that $\mathcal{I}$ is narrowly left c-reflective, let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\not\,}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$. We reasons by cases, depending on the value of $\Omega(T')$:

- *If $\Omega(T') = \nabla^{\mathbf{F}}$, then $T' = \mathrm{SEN}^\flat$. So we get $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \mathrm{SEN}^\flat = \overleftarrow{\mathrm{SEN}^\flat} = \overleftarrow{T'}$;*
- *If $\Omega(T') = \Delta^{\mathbf{F}}$, then $T' = \{1, a\}$ and, by hypothesis, we must have $T' \in \mathcal{T}$. Thus, $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$.*

We conclude that $\mathcal{I}$ is narrowly left c-reflective.

On the other hand, consider $T = \{1, \varnothing\}$ and $T' = \{1, a\}$. We have $\Omega(1, \varnothing) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(1, a)$, but

$$\overleftarrow{\widetilde{1,\varnothing}} = \widetilde{\varnothing,\varnothing} = \{01, a\} \not\leq \{1, a\} = \widetilde{1,a} = \overleftarrow{\widetilde{1,a}}.$$

This proves that $\mathcal{I}$ is not roughly left reflective and, hence, a fortiori, it fails to be roughly left c-reflective.

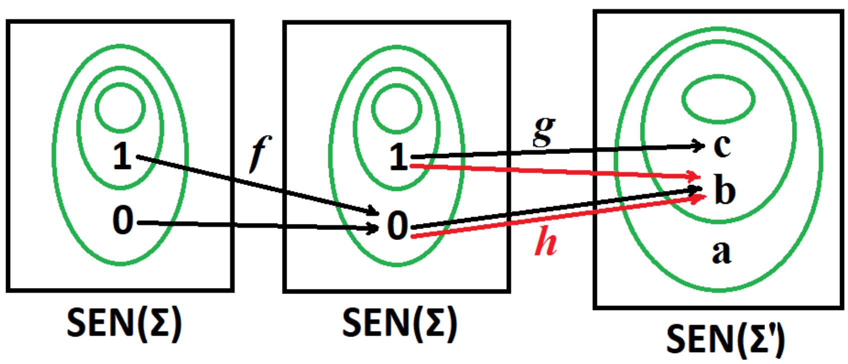
We exhibit, next a π-institution that is roughly left c-reflective, while it fails to be narrowly left c-reflective. Combined with Example 483, this will show that the two left complete reflectivity classes, rough and narrow, are incomparable from the point of view of inclusion.

Example 484 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and three nonidentity morphisms* $f : \Sigma \to \Sigma$ *and* $g, h : \Sigma \to \Sigma'$, *such that* $f \circ f = f$, $g \circ f = h$ *and* $h \circ f = h$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b, c\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$, $\mathrm{SEN}^\flat(g)(0) = b$, $\mathrm{SEN}^\flat(g)(1) = c$ *and* $\mathrm{SEN}^\flat(h)(0) = \mathrm{SEN}^\flat(h)(1) = b$;
- $N^\flat$ *is the clone generated by a single binarry natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$, *whose components are defined by the following tables:*

$\sigma^\flat_\Sigma$	0	1
0	0	1
1	1	1

$\sigma^\flat_{\Sigma'}$	a	b	c
a	a	a	c
b	a	b	c
c	c	c	c



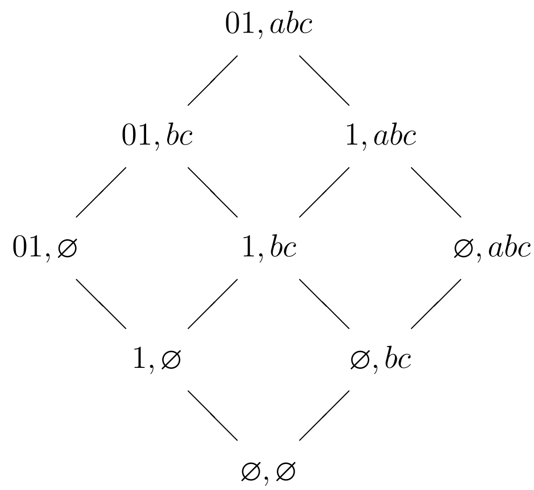
It is not difficult, albeit slightly tedious, to check that this is a well-defined natural transformation. We summarize the checking in the accompanying table.

(x, y)	$f(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_\Sigma(f(x), f(y))$	$g(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_{\Sigma'}(g(x), g(y))$	$h(\sigma^\flat_\Sigma(x,y)) = \sigma^\flat_{\Sigma'}(h(x), h(y))$
$(0,0)$	$0 = 0$	$b = b$	$b = b$
$(0,1)$	$0 = 0$	$c = c$	$b = b$
$(1,0)$	$0 = 0$	$c = c$	$b = b$
$(1,1)$	$0 = 0$	$c = c$	$b = b$

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b, c\}, \{a, b, c\}\}.$$

Clearly, there are nine theory families in $\mathrm{ThFam}(\mathcal{I})$*, five of which are theory systems, and four of which are in* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



The action of $\overleftarrow{\ }$ *on theory families is given in the following table.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$01, abc$	$01, abc$	$\varnothing, abc$	$\varnothing, abc$
$01, bc$	$01, bc$	$1, \varnothing$	$\varnothing, \varnothing$
$1, abc$	$\varnothing, abc$	$\varnothing, bc$	$\varnothing, bc$
$01, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$	$\varnothing, \varnothing$
$1, bc$	$\varnothing, bc$		

The table below provides the Leibniz congruence systems associated with the theory families of $\mathcal{I}$*.*

T	$\Omega(T)$
$\{01, abc\}, \{01, \varnothing\}, \{\varnothing, abc\}, \{\varnothing, \varnothing\}$	$\nabla^{\mathbf{F}}$
$\{1, abc\}, \{1, \varnothing\}$	$\{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}$
$\{01, bc\}, \{1, bc\}, \{\varnothing, bc\}$	$\Delta^{\mathbf{F}}$

To see that $\mathcal{I}$ *is roughly left c-reflective, suppose that* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*, such that* $\bigcap_{T \in \mathcal{T}} \Omega(T) \le \Omega(T')$*. We separate cases depending on* $\Omega(T')$*.*

- *If* $\Omega(T') = \Delta^{\mathbf{F}}$*, then, by hypothesis, at least one among* $\{01, bc\}$*,* $\{1, bc\}$*,* $\{\varnothing, b\}$ *must be in* $\mathcal{T}$*. But, then, we get* $\bigcap_{T \in \mathcal{T}} \widetilde{\overleftarrow{T}} \le \{01, bc\} = \widetilde{\overleftarrow{T'}}$*;*

- *If* $\Omega(T') = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}$ *or* $\Omega(T') = \nabla^{\mathbf{F}}$*, then* $\bigcap_{T \in \mathcal{T}} \widetilde{\overleftarrow{T}} \le \{01, abc\} = \widetilde{\overleftarrow{T'}}$*.*

On the other hand, for $T = \{01, bc\}$ *and* $T' = \{1, bc\}$*, we get* $\Omega(T) = \Delta^{\mathbf{F}} = \Omega(T')$*, whereas* $\overleftarrow{T} = \{01, bc\} \nleq \{\varnothing, bc\} = \overleftarrow{T'}$*. Therefore,* $\mathcal{I}$ *is not narrowly left c-reflective.*

We turn, next to the relationship between the two kinds of right c-reflectivity. We show, first, that rough right c-reflectivity implies narrow right c-reflectivity, a direct analog of Proposition 449, which established the corresponding result for the two right reflectivity classes.

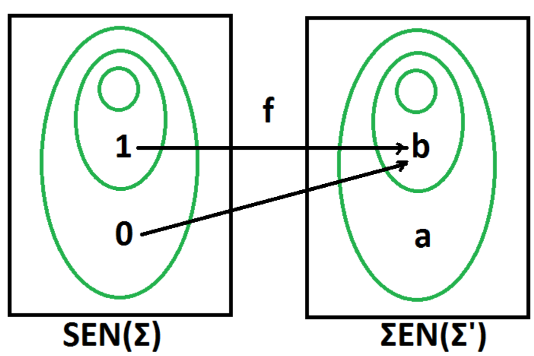
Proposition 485 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly right c-reflective, then it is narrowly right c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly right reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. By rough right reflectivity, we get that $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T}'$. Since, however, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we get $\bigcap_{T \in \mathcal{T}} T = \bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T}' = T'$. Therefore, $\mathcal{I}$ is narrowly right c-reflective. ■

The converse, on the other hand, does not hold in general, as the following example demonstrates.

Example 486 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

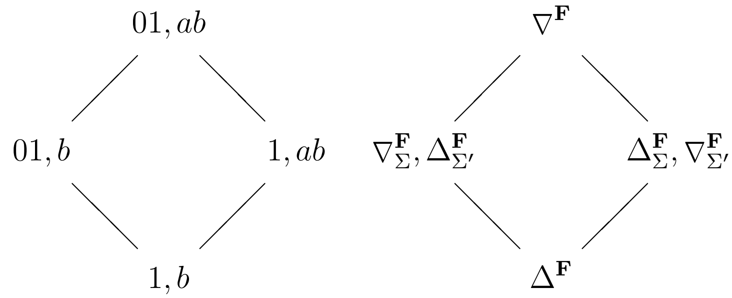
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = b$*,* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$

Clearly, there are only four theory families in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*, all of which are theory systems. Their lattice together with the associated Leibniz congruence* *systems are shown in the diagram:*



From this diagram and the fact that all theory families in $\mathrm{ThFam}^{\nmid}(\mathcal{I})$ *are theory systems, we see that, for all* $T, T' \in \mathrm{ThFam}^{\nmid}(\mathcal{I})$,

$$\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}) \quad \textit{iff} \quad \Omega(T) \leq \Omega(T') \quad \textit{iff} \quad T \leq T'.$$

Therefore, $\mathcal{I}$ *is indeed narrowly right c-reflective.*

On the other hand, consider $T = \{01, ab\}$ *and* $T' = \{1, \varnothing\}$*. Then we have*

$$\Omega(\overleftarrow{T}) = \Omega(01, ab) = \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing}) = \Omega(\overleftarrow{T'}),$$

whereas $\widetilde{01, ab} = \{01, ab\} \nleq \{1, ab\} = \widetilde{1, \varnothing}$. *This shows that* $\mathcal{I}$ *is not roughly right reflective and, hence, a fortiori, it fails to be roughly right c-reflective.*

Finally, we look at system complete reflectivity. We show that rough system c-reflectivity implies narrow system c-reflectivity, but that the converse implication fails in general.

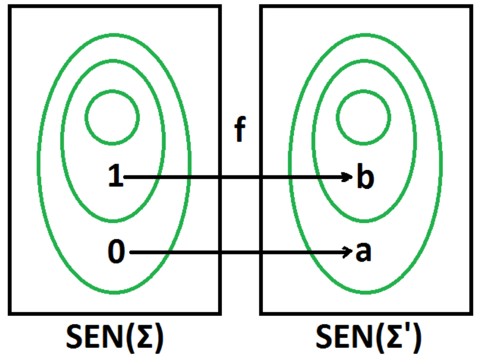
Proposition 487 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is roughly system c-reflective, then it is narrowly system c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly system c-reflective and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nmid}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, by rough system c-reflectivity, $\bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T}'$. However, since $\mathcal{T} \cup \{T'\} \in \mathrm{ThSys}^{\nmid}(\mathcal{I})$, we get $\bigcap_{T \in \mathcal{T}} T = \bigcap_{T \in \mathcal{T}} \widetilde{T} \leq \widetilde{T}' = T'$. Therefore, $\mathcal{I}$ is narrowly system c-reflective. ■

We present an example of a π-institution that is narrowly system c-reflective but not roughly system c-reflective. This, combined with Proposition 487, shows that the class of narrowly system c-reflective π-institutions properly contains the class of roughly system c-reflective π-institutions.

Example 488 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$;

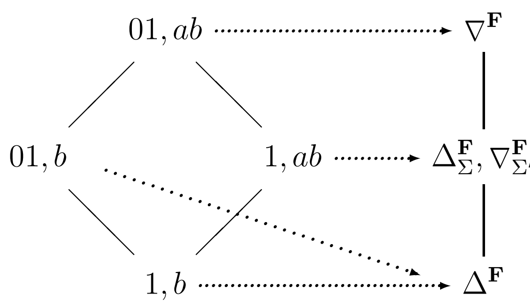


- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;
- $N^\flat$ *is the trivial clone.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are only four theory families in $\mathrm{ThFam}^{\nleq}(\mathcal{I})$*, all of which except for* $\{01,b\}$ *are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*

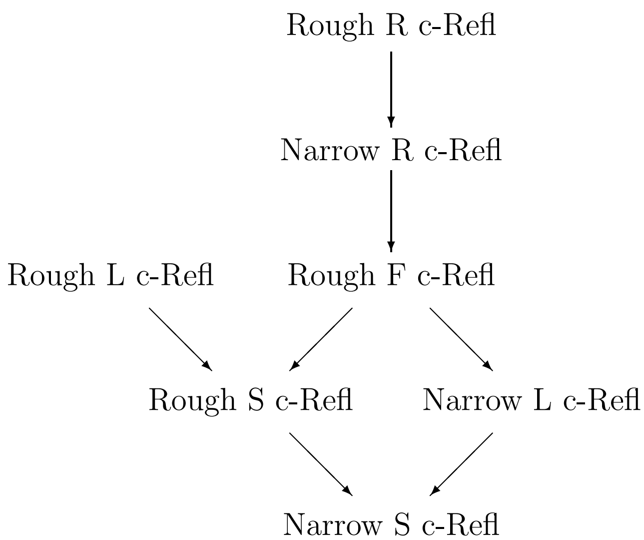


To see that $\mathcal{I}$ *is narrowly system c-reflective, let* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$*, such that* $\bigcap_{T\in\mathcal{T}} \Omega(T) \leq \Omega(T')$*. We distinguish three cases, depending on the value of* $\Omega(T')$*:*

- *If* $\Omega(T') = \nabla^{\mathbf{F}}$*, then* $T' = \mathrm{SEN}^\flat$*. Hence,* $\bigcap_{T\in\mathcal{T}} T \leq \mathrm{SEN}^\flat = T'$*;*
- *If* $\Omega(T') = \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\}$*, then* $T' = \{1, ab\}$*, whence, by hypothesis,* $T' \in \mathcal{T}$ *or* $\{1,b\} \in \mathcal{T}$*. In either case,* $\bigcap_{T\in\mathcal{T}} T \leq \{1,ab\} = T'$*;*
- *If* $\Omega(T') = \Delta^{\mathbf{F}}$*, then* $T' = \{1,b\}$ *and, hence, by hypothesis,* $T' \in \mathcal{T}$*, which shows that* $\bigcap_{T\in\mathcal{T}} T \leq T'$*.*

On the other hand, consider $T = \{\varnothing, b\}$*,* $T' = \{1,b\} \in \mathrm{ThSys}(\mathcal{I})$*. Even though* $\widetilde{T} = \{01,b\} \nleq \{1,b\} = \widetilde{T}'$*, we have* $\Omega(T) = \Delta^{\mathbf{F}} = \Omega(T')$*. Hence,* $\mathcal{I}$ *is not roughly system reflective and, hence, a fortiori, it is not roughly system c-reflective.*

The results obtained and the counterexamples presented, thus far, reveal the following mixed hierarchy of rough and narrow c-reflectivity classes of π-institutions, paralleling the one presented for rough and narrow reflectivity properties.



We have already used in the context of the preceding examples the fact that a narrow c-reflectivity property implies the corresponding narrow reflectivity property, since the latter is a special case of the former in which $\mathcal{T}$ is taken to be a singleton. These observations are formalized in the following

Proposition 489 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is narrowly family c-reflective, then it is narrowly family reflective;*

(b) If $\mathcal{I}$ *is narrowly left c-reflective, then it is narrowly left reflective;*

(c) If $\mathcal{I}$ *is narrowly right c-reflective, then it is narrowly right reflective;*

(d) If $\mathcal{I}$ *is narrowly system c-reflective, then it is narrowly system reflective.*

Proof: All four reflectivity properties are special cases of the corresponding c-reflectivity properties, in which $\mathcal{T}$ is taken to be a singleton collection of theory families. ∎

Turning to the relationships between narrow c-reflectivity classes and corresponding c-reflectivity classes, we prove a theorem, analogous to Theorem 454, asserting that ordinary c-reflectivity is equivalent to narrow c-reflectivity in the presence of theorems.

Theorem 490 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is family c-reflective if and only if it is narrowly family c-reflective and has theorems;*

(b) $\mathcal{I}$ *is left c-reflective if and only if it is narrowly left c-reflective and has theorems;*

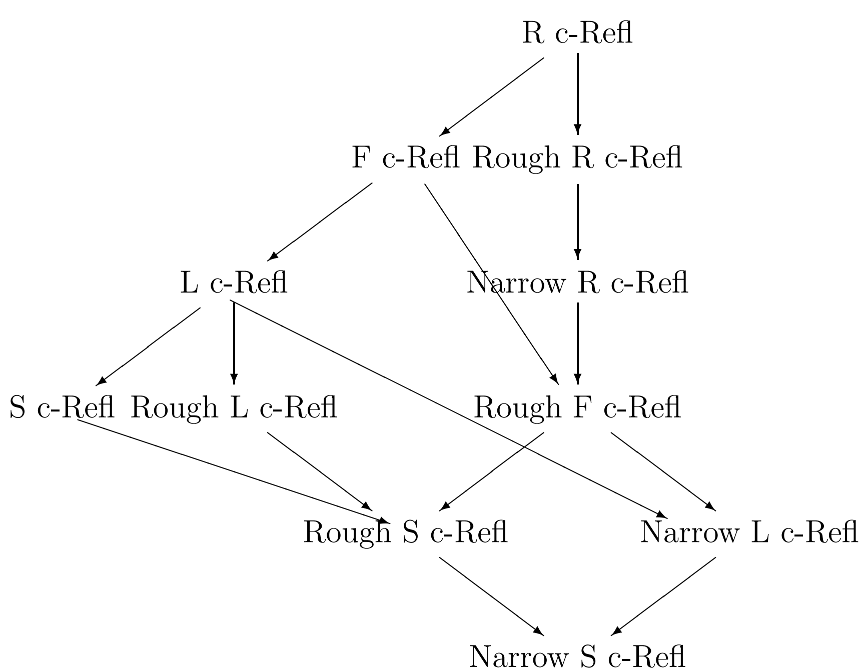
(c) $\mathcal{I}$ *is right c-reflective if and only if it is narrowly right c-reflective and has theorems;*

(d) $\mathcal{I}$ *is system c-reflective if and only if it is narrowly system c-reflective and has theorems.*

Proof: By Theorem 468, if $\mathcal{I}$ has one of the four complete reflectivity properties, then it has theorems. Moreover, by the same theorem, a complete reflectivity property implies the corresponding rough complete reflectivity property and, by Corollary 482, Proposition 485 and Proposition 487, each implies the corresponding narrow complete reflectivity property except in the case of left complete reflectivity, where (as actually in all other cases, as well) one can easily see directly, that left c-reflectivity implies narrow left c-reflectivity, since the defining condition of the latter is a special case of that of the former.

All converses are also easily verified, since, in the presence of theorems, $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$ and $\mathrm{ThSys}^{\nmid}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, which makes the four defining conditions for the narrow c-reflectivity classes identical with the corresponding conditions for the ordinary c-reflectivity classes. ■

We now have the following hierarchy, paralleling the mixed reflectivity and narrow reflectivity hierarchy, given previously.



The narrow complete reflectivity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems. This result forms an analog of Theorem 455, which applied to narrow reflectivity classes.

Theorem 491 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is narrowly right c-reflective if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$ implies $\bigcap_{T\in\mathcal{T}} T \leq T'$;

(b) $\mathcal{I}$ is narrowly family c-reflective if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap_{T\in\mathcal{T}} T \leq T'$;

(c) $\mathcal{I}$ is narrowly left c-reflective if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$;

(d) $\mathcal{I}$ is narrowly system c-reflective if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiSys}^{\mathcal{I}\nmid}(\mathcal{A})$, $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $\bigcap_{T\in\mathcal{T}} T \leq T'$.

Proof: The proof follows the steps of the proofs of the various parts of Theorem 455. We do Part (a) in detail to give a flavor of what is involved.

The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$ and taking into account that $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{F})$, by Lemmas 51 and 376.

For the "only if", suppose that $\mathcal{I}$ is narrowly right c-reflective and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nmid}(\mathcal{A})$, such that $\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Then $\alpha^{-1}(\bigcap_{T\in\mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. Thus, $\bigcap_{T\in\mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$. So, by Proposition 24, $\bigcap_{T\in\mathcal{T}} \Omega(\alpha^{-1}(\overleftarrow{T})) \leq \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Hence, by Lemma 6, $\bigcap_{T\in\mathcal{T}} \Omega(\overleftarrow{\alpha^{-1}(T)}) \leq \Omega(\overleftarrow{\alpha^{-1}(T')})$. Since, by Lemmas 51 and 376, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}^{\nmid}(\mathcal{I})$, we get, by applying narrow right c-reflectivity, $\bigcap_{T\in\mathcal{T}} \alpha^{-1}(T) \leq \alpha^{-1}(T')$ or, equivalently, $\alpha^{-1}(\bigcap_{T\in\mathcal{T}} T) \leq \alpha^{-1}(T')$. This yields, taking into account the surjectivity of $\langle F, \alpha\rangle$, $\bigcap_{T\in\mathcal{T}} T \leq T'$. ∎

We finally recast narrow complete reflectivity in terms of the complete order reflectivity of mappings from posets of theory or filter families/systems into posets of congruence systems. The following results form analogs of Propositions 456 and 457, respectively, addressing complete reflectivity instead of reflectivity properties.

Proposition 492 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly family c-reflective;*

(b) $\Omega : \mathrm{ThFam}^{\nleq}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is completely order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Similarly, for system c-reflectivity, we have

Proposition 493 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly system c-reflective;*

(b) $\Omega : \mathrm{ThSys}^{\nleq}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is completely order reflecting;*

(c) $\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}\nleq}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely order reflecting, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

6.10 Availability of Theorems

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that, by convention, if $\mathcal{I}$ has theorems, then, for every $\Sigma \in |\mathbf{Sign}^\flat|$, $\mathcal{I}$ has a Σ-theorem, i.e., there exists $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in C_\Sigma(\varnothing)$.

Recall, also, from our work in the present chapter, that all levels of the injectivity, reflectivity and complete reflectivity hierarchies imply the existence of theorems and that, moreover, any rough injectivity, rough reflectivity or rough complete reflectivity property, complemented with the existence of theorems, implies the corresponding (gentle) injectivity, reflectivity or complete reflectivity property, respectively. In other words, insisting on existence of theorems causes all pairs of rough and gentle properties to collapse to a single class.

In this section, due to the importance of the property of "having theorems", we give a few more results characterizing that property.

It turns out that existence of theorems is tantamount to the injectivity of the local Frege operator λ.

Theorem 494 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *has theorems if and only if* λ *is injective.*

Proof: Suppose, first, that $\mathcal{I}$ has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\lambda(T) = \lambda(T')$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Since $\mathcal{I}$ has theorems, there exists $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. Then $t \in T_\Sigma$ and, therefore, $\langle \phi, t \rangle \in \lambda_\Sigma(T)$. By hypothesis, $\langle \phi, t \rangle \in \lambda_\Sigma(T')$. But, clearly, $t \in T'_\Sigma$. Hence

$\phi \in T'_\Sigma$. We conclude that $T \leq T'$ and, by symmetry, $T = T'$. Thus, λ is injective.

Assume, conversely, that $\mathcal{I}$ does not have theorems. Then, we have $\varnothing, \mathrm{SEN}^\flat \in \mathrm{ThFam}(\mathcal{I})$, with $\varnothing \neq \mathrm{SEN}^\flat$, whereas $\lambda(\varnothing) = \lambda(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$. Therefore, λ is not injective. ■

It turns out that existence of theorems is also equivalent to both the injectivity and the c-reflectivity of the local Lindenbaum operator $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ on all $\mathbf{F}$-algebraic systems.

Theorem 495 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following conditions are equivalent:*

(i) $\mathcal{I}$ *has theorems;*

(ii) $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ *is injective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*;*

(iii) $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ *is completely reflective, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proof:

(i)⇒(iii) Assume that $\mathcal{I}$ has theorems and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that

$$\bigcap_{T \in \mathcal{T}} \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T) \leq \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(T').$$

Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathrm{SEN}(\Sigma)$, such that $\phi \in \bigcap_{T \in \mathcal{T}} T_\Sigma$. By hypothesis and the surjectivity of $\langle F, \alpha \rangle$, there exists $t \in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)$. Then, we have

$$C^{\mathcal{I},\mathcal{A}}_\Sigma(\bigcap_{T \in \mathcal{T}} T_\Sigma, \phi) = C^{\mathcal{I},\mathcal{A}}_\Sigma(\bigcap_{T \in \mathcal{T}} T_\Sigma) = C^{\mathcal{I},\mathcal{A}}_\Sigma(\bigcap_{T \in \mathcal{T}} T_\Sigma, t).$$

Thus, we get

$$\langle \phi, t \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(\bigcap_{T \in \mathcal{T}} T) \leq \bigcap_{T \in \mathcal{T}} \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T) \leq \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T').$$

We conclude that

$$\begin{array}{lll} \phi & \in & C^{\mathcal{I},\mathcal{A}}_\Sigma(T'_\Sigma, \phi) \quad \text{(inflationarity)} \\ & = & C^{\mathcal{I},\mathcal{A}}_\Sigma(T'_\Sigma, t) \quad (\langle \phi, t \rangle \in \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}_\Sigma(T')) \\ & = & T'_\Sigma. \quad (t \in C^{\mathcal{I},\mathcal{A}}_\Sigma(\varnothing)) \end{array}$$

Therefore, $\bigcap_{T \in \mathcal{T}} T \leq T'$ and $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ is completely reflective.

(iii)⇒(ii) Complete reflectivity implies injectivity.

(ii)⇒(i) Finally, suppose that $\mathcal{I}$ does not have theorems. We let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be the trivial $\mathbf{F}$-algebraic system, with single signature object $*$ and singleton $\mathrm{SEN}(*) = \{0\}$. Since $\mathcal{I}$ does not have theorems, both $\varnothing$ and SEN are $\mathcal{I}$-filter families of $\mathcal{A}$. Now we have

$$\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\varnothing) = \widetilde{\lambda}^{\mathcal{I},\mathcal{A}}(\mathrm{SEN}) = \nabla^{\mathcal{A}}.$$

Hence, the Leibniz operator $\widetilde{\lambda}^{\mathcal{I},\mathcal{A}}$ is not injective.

■

The property of having theorems clearly transfers from a π-institution to all its gmatrix families.

Theorem 496 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *has theorems if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T \neq \overline{\varnothing}$.

Proof: The right-to-left inclusion follows by considering the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. For the converse, assume $\mathcal{I}$ has theorems and let $\mathcal{A}$ be an $\mathbf{F}$-algebraic system and $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let $\Sigma \in |\mathbf{Sign}^\flat|$. Then, there exists $t \in \mathrm{Thm}_\Sigma(\mathcal{I})$. By definition, $\alpha_\Sigma(t) \in T_{F(\Sigma)}$. Hence, $T \neq \overline{\varnothing}$. ■

Note that an alterrnative way of expressing the assertion of Theorem 496 is to say that $\mathcal{I}$ has theorems if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the π-institution $\langle \mathbf{A}, C^{\mathcal{I},\mathcal{A}} \rangle$ has theorems.

Chapter 7

The Semantic Leibniz Hierarchy: Under the Bottom II

7.1 Introduction

In this chapter we continue the study of properties lying below properties in the bottom half of the classical Leibniz hierarchy [64, 86]. The underlying motivation is identical to that presented in the Introduction to, and governing the studies presented in, Chapter 6. Briefly, we note that, when one studies protoalgebraicity, no π-institution that is not almost inconsistent and does not have theorems can be considered. This is because such a π-institution has a theory family $T \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$, i.e., with all its components nonempty, for which $\overline{\varnothing} \leq T$, whereas $\Omega(T) \leq \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing})$. Consequently, to incorporate nontrivial π-institutions without theorems in studies involving monotonicity properties of the Leibniz operator, one would have to devise ways to bypass, or otherwise suitably handle, theory families with one or more empty components. For properties involving reflectivity, which were handled in Chapter 6, this was done in the context of sentential logics in [87] (see, also, [89]). Here, we undertake a study similar to that presented in Chapter 6, but, instead of injectivity, reflectivity and complete reflectivity properties, we focus on monotonicity and complete monotonicity (c-monotonicity) properties.

In Section 7.2, we introduce some weakened versions of stability which serve in formalizing some of the properties studied later in the chapter. Recall from Section 3.2 that a π-institution $\mathcal{I}$ is *stable* if, for every theory family T of $\mathcal{I}$, $\Omega(\overleftarrow{T}) = \Omega(T)$. A first weakening is obtained by restricting the scope of the quantifier to theory families with all components nonempty. The ensuing property is termed *narrow stability*. A further weakening applies the condition only to those theory families T with all components nonempty which, in addition, satisfy that $\overleftarrow{T}$ has all its components nonempty. The resulting concept is termed *exclusive stability*. By definition, stability implies narrow stability, which implies exclusive stability and, as it turns out, both implications are actually strict.

In Section 7.3, we study *rough monotonicity properties*. These are the product of combining monotonicity properties with rough equivalence, introduced in Section 6.2. Rough equivalence formalizes an attempt at overcoming the hurdle imposed by theory families with empty components. Recall that two theory families are *roughly equivalent* if, whenever they differ at some signature Σ, one has Σ-component $\varnothing$ and the other $\mathrm{SEN}^\flat(\Sigma)$. Recall, also, that, given a theory family T, $\widetilde{T}$ denotes its *rough companion*, which results from T by replacing each of its empty Σ-components by $\mathrm{SEN}^\flat(\Sigma)$. Clearly $\widetilde{T}$ is roughly equivalent to T and, moreover, it is the largest theory family in the rough equivalence class $\widetilde{[T]}$ of T. All roughly equivalent theory families have identical Leibniz congruence systems. A π-institution $\mathcal{I}$ is called *roughly family monotone* if, for all theory families $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega(T) \leq \Omega(T')$. *Rough left monotonicity* results by replacing T and T' in the hypothesis by $\overleftarrow{T}$ and $\overleftarrow{T'}$, respectively. *Rough right monotonicity* is the result of the same replacement performed in the conclusion instead. *Rough system monotonicity* stipulates that $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega(T) \leq \Omega(T')$ hold for all theory systems T and T'. Rough left monotonicity implies both rough family and rough right monotonicity, and each of the latter two implies the system version. Additionally, rough left monotonicity is equivalent to the conjunction of rough system monotonicity and stability. Protoalgebraicity (which, recall from Section 3.3, names the equivalent notions of left and family monotonicity) implies rough left monotonicity. Prealgebraicity (naming the equivalent notions of right and system monotonicity), on the other hand, implies rough right monotonicity. But these interrelationships may be tied further, subject to some additional mild hypotheses. Namely, for non-almost inconsistent π-institutions, protoalgebraicity is equivalent to rough left or rough family monotonicity, coupled with availability of theorems. Moreover, for π-institutions possessing a theory family $T \neq \mathrm{SEN}^\flat$, with $\overleftarrow{T} \neq \overline{\varnothing}$, prealgebraicity is equivalent to rough right or rough system monotonicity, couple with availability of theorems. All four rough monotonicity properties transfer. E.g., a π-institution $\mathcal{I}$ is roughly right monotone if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$ and all $\mathcal{I}$-filter families $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$. Finally, it is possible to recast rough family and rough system monotonicity in terms of the Leibniz operator viewed as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$. The property one imposes is monotonicity, where, for rough equivalence classes $\widetilde{[T]}$, $\widetilde{[T']}$ in $\widetilde{\mathrm{ThFam}}(\mathcal{I})$, e.g., the order $\widetilde{[T]} \leq \widetilde{[T']}$ is the one induced by comparing the maximum elements $\widetilde{T} \leq \widetilde{T'}$ in the complete lattice of theory families of $\mathcal{I}$.

In Section 7.4, we look at *narrow monotonicity properties*. Narrowness is an alternative approach to roughness in dealing with theory families having one or more empty components. It literally bypasses theory families with empty components by altogether ignoring them and applying the relevant monotonicity conditions on the collections $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$ of theory families and systems, respectively, all of whose components are nonempty. Accordingly, we say that a π-institution $\mathcal{I}$ is *narrowly family monotone* if, for all $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$. In *narrow left monotonicity* T, T' in the hypothesis, are replaced by $\overleftarrow{T}$, $\overleftarrow{T'}$, respectively, and the same substitution is applied in the conclusion, instead, for *narrow right monotonicity*. *Narrow system monotonicity* imposes the same condition as the family version, but restricts its scope to $T, T' \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$. Narrow left monotonicity implies narrow family monotonicity, which, in turn, implies narrow system monotonicity. The latter is also a consequence of narrow right monotonicity. The left version also implies exclusive stability, whereas the weakest version, i.e., narrow system monotonicity, supplemented by narrow systemicity, introduced in Section 6.3, implies both the left and right versions. Protoalgebraicity implies narrow left monotonicity and prealgebraicity implies narrow right monotonicity. As in the case of rough monotonicity properties, these connections may be strengthened under some fairly mild hypotheses. More precisely, for non almost inconsistent π-institutions, protoalgebraicity is equivalent to narrow left or narrow family monotonicity, augmented by existence of theorems. Similarly, for π-institutions possessing a theory system different from $\overline{\varnothing}$ and $\mathrm{SEN}^\flat$, prealgebraicity is equivalent to narrow right or narrow system monotonicity, coupled with existence of theorems. Of course, having introduced two seemingly different approaches to handling empty theory family components, it is of central importance to investigate the relations between rough monotonicity and narrow monotonicity classes. Narrow family monotonicity turns out to be equivalent to rough family monotonicity, whereas, with regards to the three remaining versions, each of the rough properties implies the corresponding narrow property. All four narrow monotonicity properties transfer. The section concludes with characterizations of narrow family and narrow system monotonicity in terms of the Leibniz operator viewed as a mapping from $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

In Section 7.5, we look at *rough complete monotonicity* (c-monotonicity) properties. These concepts, in analogy with the extension of monotonicity to the c-monotonicity properties of Section 3.4, extend rough monotonicity properties by allowing arbitrary unions on the right-hand side of the relevant inequalities. A π-institution $\mathcal{I}$ is called *roughly family c-monotone* if, for every collection $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ implies $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. In *rough left c-monotonicity* the hypothesis is replaced by $\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}}$ and, in *rough right c-monotonicity*, the conclusion is replaced by $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. The *system version* imposes the same condition as the family version, but restricts it on collections $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$. Here, the only inclusions are those establishing that each of the rough left, family and right c-monotonicity classes form a subclass of the class of roughly system c-monotone π-institutions. Rough left c-monotonicity is equivalent to rough system c-monotonicity plus stability. Under stability, rough family c-monotonicity and rough right c-monotonicity are equivalent and, furthermore, under rough systemicity, the entire hierarchy collapses to a single class. From the definitions, it is obvious that each version of rough c-monotonicity implies the corresponding version of rough monotonicity, since, the definition of the latter specializes that of the former. Moreover, each version of c-monotonicity implies the corresponding version of rough c-monotonicity. As far as closer ties, analogous to those detailed for rough monotonicity classes in Section 7.3, for non almost inconsistent π-institutions, $\mathcal{I}$ is family (left, respectively) c-monotone if and only if it is rough;y family (left, respectively) c-monotone and has theorems. Along similar lines, for $\mathcal{I}$ having a theory family $T \neq \mathrm{SEN}^\flat$, such that $\overleftarrow{T} \neq \overline{\varnothing}$, $\mathcal{I}$ is system (right, respectively) c-monotone if and only if it is roughly system (right, respectively) c-monotone and has theorems. All four rough c-monotonicity properties transfer and, as was the case with rough monotonicity, the family and system versions have characterizations in terms of Ω seen as a mapping from $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

The same extension that led from rough monotonicity to rough c-monotonicity properties may be applied to narrow monotonicity properties and leads to *narrow c-monotonicity* properties, which constitute the objects of study in Section 7.6. A π-institution $\mathcal{I}$ is called *narrowly family c-monotone* if, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$, $T' \leq \bigcup_{T \in \mathcal{T}} T$ implies $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. Once more, the *left version* results by replacing in the hypothesis all theory families by their arrow counterparts, and, similarly for the *right version*, except that the replacement is applied in the conclusion of the implication instead. The *system version* applies the same condition as the family version, but restricts its scope on collections of theory systems in $\mathrm{ThSys}^{\nleq}(\mathcal{I})$. As was the case with rough c-monotonicity in Section 7.5, the only three implications assert that each of the narrow left, family and right c-monotonicity properties implies narrow system c-monotonicity. Each version of c-monotonicity implies its narrow c-monotonicity counterpart. It turns out that rough family c-monotonicity is equivalent to narrow family c-monotonicity. On the other hand, for the remaining three versions, each rough c-monotonicity variant implies the corresponding narrow c-monotonicity variant. Of course, due to the specializations in the relevant definitions, each narrow c-monotonicity property implies the corresponding narrow monotonicity property. All four narrow c-monotonicity properties transfer. Finally, it is the case here as well, that the family and the system versions can be characterized in terms of the Leibniz operator viewed as a mapping from $\mathrm{ThFam}^{\nleq}(\mathcal{I})$ and $\mathrm{ThSys}^{\nleq}(\mathcal{I})$, respectively, to $\mathrm{ConSys}^*(\mathcal{I})$.

7.2 Narrow and Exclusive Stability

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is called *stable* if, for all $T \in \mathrm{ThFam}(\mathcal{I})$,

$$\Omega(\overleftarrow{T}) = \Omega(T).$$

Recall, also, that, in Section 6.5, we defined *narrow stability*, a concept that proved handy in demonstrating that the narrow right properties studied there implied the corresponding narrow family properties. We recall that definition and look at an additional concept weakening stability. These two notions aim at bypassing theory families with empty components.

Definition 497 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **narrowly stable** *if, for all* $T \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$,

$$\Omega(\overleftarrow{T}) = \Omega(T);$$

- $\mathcal{I}$ *is* **exclusively stable** *if, for all* $T \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$*, such that* $\overleftarrow{T} \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$*,*
$$\Omega(\overleftarrow{T}) = \Omega(T).$$

It is clear that stability is the strongest of the three properties followed by narrow stability and exclusive stability, which is the weakest of the three.

Proposition 498 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is stable, then it is narrowly stable;*

(b) If $\mathcal{I}$ *is narrowly stable, then it is exclusively stable.*

Proof: It suffices to note that each property is a specialization of the one immediately dominating it in strength. ■

Thus, the following linear **stability hierarchy** is established.

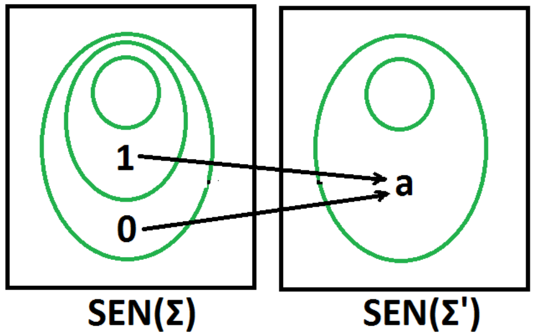
$$\begin{array}{c} \text{Stable} \\ \downarrow \\ \text{Narrowly Stable} \\ \downarrow \\ \text{Exclusively Stable} \end{array}$$

It is not difficult to see that all three classes are different. The following example provides a π-institution that is narrowly stable but not stable, showing that stable π-institutions form a proper subclass of the class consisting of the narrowly stable ones.

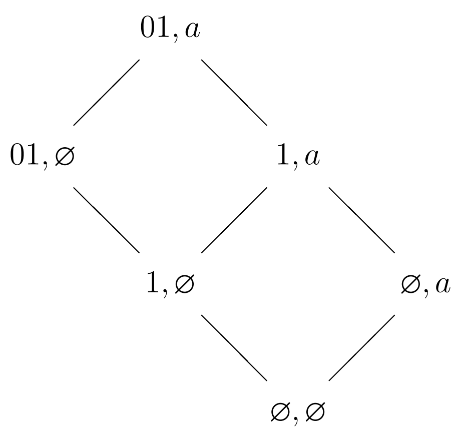
Example 499 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*
$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{a\}\}.$$



Clearly, there are six theory families in $\mathrm{ThFam}(\mathcal{I})$*, only four of which are theory systems, and only two of which are in* $\mathrm{ThFam}^{\nmid}(\mathcal{I})$*. The lattice of theory families is shown in the diagram:*



Since $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \{\{1, a\}, \{01, a\}\}$ *and* $\overleftarrow{\{1, a\}} = \{1, a\}$ *and* $\overleftarrow{\{01, a\}} = \{01, a\}$*, we get that* $\mathcal{I}$ *is narrowly systemic and, hence, a fortiori, also narrowly stable. On the other hand, consider* $T = \{\{1\}, \varnothing\}$*. We have*

$$\Omega(\overleftarrow{\{1, \varnothing\}}) = \Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} \neq \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(\{1, \varnothing\}),$$

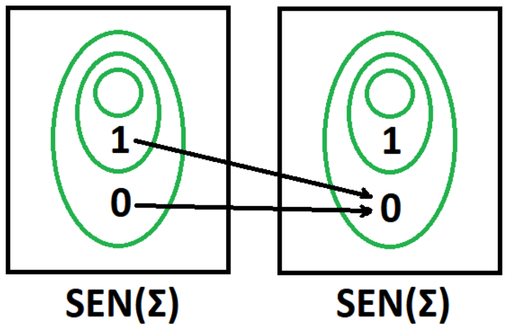
whence $\mathcal{I}$ *is not stable.*

Finally, we give an example of an exclusively stable π-institution which, however, fails to be narrowly stable. This shows that the inclusion of the class of narrowly stable π-institutions into the class of exclusively stable ones is also proper.

Example 500 *Let* $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat} \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^{\flat}$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

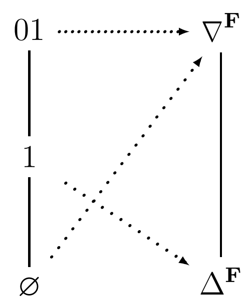
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ *has three theory families* $\{\varnothing\}$, $\{\{1\}\}$ *and* $\{\{0,1\}\}$, *but only two theory systems,* $\{\varnothing\}$ *and* $\{\{0,1\}\}$. *The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



The only theory family $T \in \mathrm{ThFam}^{\sharp}(\mathcal{I})$, *such that* $\overleftarrow{T} \in \mathrm{ThSys}^{\sharp}(\mathcal{I})$ *is* $\{\{0,1\}\}$. *Moreover,* $\overleftarrow{\{0,1\}} = \{0,1\}$, *whence we get that* $\mathcal{I}$ *is exclusively stable. On the other hand, for* $\{\{1\}\} \in \mathrm{ThFam}^{\sharp}(\mathcal{I})$, *we get*

$$\Omega(\overleftarrow{\{1\}}) = \Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} \neq \Delta^{\mathbf{F}} = \Omega(\{1\}).$$

Therefore, $\mathcal{I}$ *is not narrowly stable.*

7.3 Rough Monotonicity

In this section we exploit the notion of rough equivalence, which was studied in some detail in Section 6.2, to introduce and study classes of π-institutions defined using monotonicity properties of the Leibniz operator applied on rough equivalence classes.

Definition 501 (Rough Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **roughly family monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*
$$\widetilde{T} \leq \widetilde{T'} \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$
- $\mathcal{I}$ *is called* **roughly left monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*
$$\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}} \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$
- $\mathcal{I}$ *is called* **roughly right monotone** *if, for all* $T, T' \in \mathrm{ThFam}(\mathcal{I})$*,*
$$\widetilde{T} \leq \widetilde{T'} \quad \textit{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$
- $\mathcal{I}$ *is called* **roughly system monotone** *if, for all* $T, T' \in \mathrm{ThSys}(\mathcal{I})$*,*
$$\widetilde{T} \leq \widetilde{T'} \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$

Next we look into establishing the *rough monotonicity hierarchy* of π-institutions. We show, first, that rough left monotonicity implies stability.

Lemma 502 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly left monotone, then it is stable.*

Proof: Suppose $\mathcal{I}$ is roughly left monotone and let $T \in \mathrm{ThFam}(\mathcal{I})$. Since $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$, we get that $\widetilde{\overleftarrow{\overleftarrow{T}}} = \widetilde{\overleftarrow{T}}$. Thus, by rough left monotonicity, $\Omega(\overleftarrow{T}) = \Omega(T)$. Hence, $\mathcal{I}$ is stable. ■

Lemma 502 leads to the conclusion that, under rough left monotonicity, the properties of rough family monotonicity and rough right monotonicity are equivalent.

Corollary 503 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly left monotone, then it is roughly family monotone if and only if it is roughly right monotone.*

Proof: Suppose $\mathcal{I}$ is roughly left monotone. Then, by Lemma 502, it is stable. Now note that rough family monotonicity is equivalent to the condition that, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{T} \leq \widetilde{T'} \quad \text{implies} \quad \Omega(T) \leq \Omega(T'),$$
which, by stability, is equivalent to, for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{T} \leq \widetilde{T'} \quad \text{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}),$$
and this is equivalent, by definition, to rough right monotonicity. ■

Next we show that rough left monotonicity implies rough family monotonicity.

Proposition 504 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly left monotone, then it is roughly family monotone.*

Proof: Suppose $\mathcal{I}$ is roughly left monotone, i.e., for all $T, T' \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$ implies $\Omega(T) \leq \Omega(T')$. Let $X, Y \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{X} \leq \widetilde{Y}$. If $\overleftarrow{\widetilde{X}} \leq \overleftarrow{\widetilde{Y}}$, then, by rough left monotonicity, $\Omega(X) \leq \Omega(Y)$. So, assume that $\overleftarrow{\widetilde{X}} \nleq \overleftarrow{\widetilde{Y}}$, that is, that there exists $P \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{\widetilde{X}}_P \nsubseteq \overleftarrow{\widetilde{Y}}_P$. At the same time, since $\widetilde{X} \leq \widetilde{Y}$, we have that $\widetilde{X}_P \subseteq \widetilde{Y}_P$. This implies that $X_P \subseteq Y_P$ or $Y_P = \varnothing$. However, if $Y_P = \varnothing$, then, we would also have $\overleftarrow{Y}_P = \varnothing$, whence $\overleftarrow{\widetilde{X}}_P \subseteq \mathrm{SEN}^\flat(P) = \overleftarrow{\widetilde{Y}}_P$, contradicting our assumption. Hence, we conclude that $X_P \subseteq Y_P$. Now, based on $\overleftarrow{\widetilde{X}}_P \nsubseteq \overleftarrow{\widetilde{Y}}_P$, we distinguish two possibilities, $\overleftarrow{X}_P \nsubseteq \overleftarrow{Y}_P$ or $\overleftarrow{X}_P = \varnothing$.

- Suppose $X_P \subseteq Y_P$ and $\overleftarrow{X}_P \nsubseteq \overleftarrow{Y}_P$. Then, there exists $Q \in |\mathbf{Sign}^\flat|$ and $P \stackrel{f}{\to} Q$, such that $X_Q \nsubseteq Y_Q$. Since, however, $\widetilde{X}_Q \subseteq \widetilde{Y}_Q$, we would have $Y_Q = \varnothing$. This, combined with the fact that $\overleftarrow{\widetilde{X}}_P \nsubseteq \overleftarrow{\widetilde{Y}}_P$ implies that $\overleftarrow{Y}_P \neq \varnothing$, yield that there cannot exist $f : P \to Q$, a contradiction.

- So it must be the case that $X_P \subseteq Y_P$ and $\overleftarrow{X}_P = \varnothing$. Since $\overleftarrow{\widetilde{X}}_P \nsubseteq \overleftarrow{\widetilde{Y}}_P$, we must have $\overleftarrow{Y}_P \neq \varnothing$ and $\overleftarrow{Y}_P \neq \mathrm{SEN}^\flat(P)$. Note that it is not possible to have both $X_P = \overleftarrow{X}_P$ and $Y_P = \overleftarrow{Y}_P$. If that had been the case, we would have $X_P = \varnothing$ and $Y_P \neq \varnothing$ or $\mathrm{SEN}^\flat(P)$, whence $\widetilde{X}_P \nsubseteq \widetilde{Y}_P$, which contradicts the hypothesis. So, we must have $\varnothing = \overleftarrow{X}_P \subsetneq X_P$ or $\overleftarrow{Y}_P \subsetneq Y_P$.

  - Assume, first, that $\varnothing = \overleftarrow{X}_P \subsetneq X_P \subseteq Y_P \neq \mathrm{SEN}^\flat(P)$. Define $Z = \{Z_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

  $$Z_\Sigma = \begin{cases} \varnothing, & \text{if } \Sigma \neq P \\ X_P, & \text{if } \Sigma = P \end{cases}.$$

    Then, we have $Z \leq X$, whence $\overleftarrow{Z} \leq \overleftarrow{X}$ and, hence, $\overleftarrow{Z} = \overline{\varnothing} = \overleftarrow{\overline{\varnothing}}$. So, whereas $\overleftarrow{\widetilde{Z}} = \overleftarrow{\widetilde{\overline{\varnothing}}}$, $\Omega(Z) \neq \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing})$. This contradicts rough right monotonicity.

  - Suppose, next, that $\varnothing = \overleftarrow{X}_P = X_P$ and $\overleftarrow{Y}_P \subsetneq Y_P$. We already know that $\overleftarrow{Y}_P \neq \varnothing$. Moreover, since $\widetilde{X}_P \subseteq \widetilde{Y}_P$, we must have $Y_P = \mathrm{SEN}^\flat(P)$. Now we define $Z = \{Z_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting

  $$Z_\Sigma = \begin{cases} \varnothing, & \text{if } \Sigma \neq P \\ \overleftarrow{Y}_P, & \text{if } \Sigma = P \end{cases}.$$

If there had been no morphism of the form $P \xrightarrow{f} Q$, with $Q \neq P$, in $\mathbf{Sign}^\flat$, then, since $Y_P = \mathrm{SEN}^\flat(P)$, we would have $\overleftarrow{Y}_P = \mathrm{SEN}^\flat(P)$, contradicting our assumption. The existence of such a morphism implies that $\overleftarrow{\overline{Z}} = \overline{\varnothing} = \overleftarrow{\overline{\varnothing}}$. However, $\Omega(Z) \neq \nabla^{\mathbf{F}} = \Omega(\overline{\varnothing})$, which contradicts rough left monotonicity.

We conclude that $\mathcal{I}$ must be roughly family monotone. ∎

We now have a picture of the rough monotonicity hierarchy.

Proposition 505 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is roughly left monotone, then it is both roughly family and roughly right monotone;*

(b) If $\mathcal{I}$ *is roughly family or roughly right monotone, then it is roughly system monotone.*

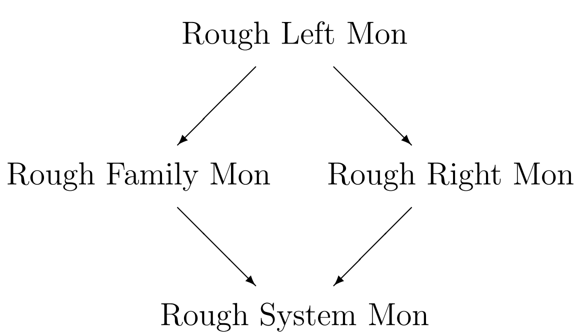
Proof:

(a) Suppose $\mathcal{I}$ is roughly left monotone. By Proposition 504, $\mathcal{I}$ is roughly family monotone. Therefore, by Corollary 503, it is also roughly right monotone.

(b) If $\mathcal{I}$ is roughly family monotone, then it is, a fortiori, roughly system monotone, since the condition defining the latter notion is a specialization of that defining the former. So, suppose $\mathcal{I}$ is roughly right monotone and let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \leq \widetilde{T'}$. Then, by rough right monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Since T, T' are theory systems, $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$, whence $\Omega(T) \leq \Omega(T')$ and, hence, $\mathcal{I}$ is roughly system monotone.

∎

We have now established the following **rough monotonicity hierarchy** of π-institutions.



It is not difficult to see that being roughly left monotone is equivalent to being roughly system monotone and stable.

Proposition 506 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is roughly left monotone if and only if it is roughly system monotone and stable.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left monotone. Then, by Proposition 505, it is roughly system monotone. Moreover, by Lemma 502, $\mathcal{I}$ is stable.

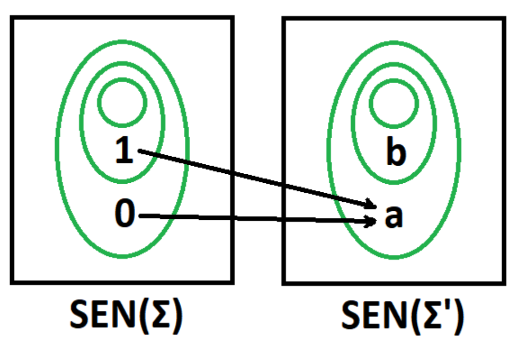
Assume, conversely, that $\mathcal{I}$ is stable and roughly system monotone. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{\overleftarrow{T}} \leq \overleftarrow{\overleftarrow{T'}}$. Then, since $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}(\mathcal{I})$, we get, by rough system monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Thus, by stability, $\Omega(T) \leq \Omega(T')$. We conclude that $\mathcal{I}$ is roughly left monotone. ■

By Proposition 506, under stability, the rough monotonicity hierarchy collapses to a single class. Moreover, by Lemma 383, the same happens, a fortiori, under rough systemicity.

We present two examples to show that all four rough monotonicity classes depicted in the diagram above are different. The first example gives a roughly family monotone π-institution that is not roughly right monotone. It shows that the inclusions represented in the diagram by the two southwest pointing arrows are proper inclusions.

Example 507 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = a$*;*
- $N^\flat$ *is the trivial clone.*



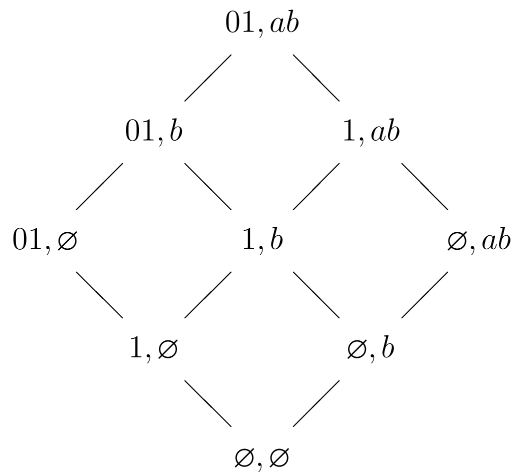
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a, b\}\}.$$

There are nine theory families, but only five theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$	T	$\overleftarrow{T}$
$\varnothing,\varnothing$	$\varnothing,\varnothing$	$\varnothing,ab$	$\varnothing,ab$
$1,\varnothing$	$\varnothing,\varnothing$	$01,b$	$\varnothing,b$
$\varnothing,b$	$\varnothing,b$	$1,ab$	$1,ab$
$01,\varnothing$	$\varnothing,\varnothing$	$01,ab$	$01,ab$
$1,b$	$\varnothing,b$		

The lattice of theory families of $\mathcal{I}$ *is shown in the diagram.*



We show that $\mathcal{I}$ *is roughly family monotone. To this end, suppose* $\widetilde{T} \le \widetilde{T'}$.

- *If* $\widetilde{T'} = \{01,ab\}$, *then* $T' = \{\varnothing,\varnothing\}$ *or* $\{01,\varnothing\}$ *or* $\{\varnothing,ab\}$ *or* $\{01,ab\}$. *In all cases* $\Omega(T) \le \nabla^{\mathbf{F}} = \Omega(T')$;
- *If* $\widetilde{T'} = \{01,b\}$, *then* $T' = \{\varnothing,b\}$ *or* $\{01,b\}$ *and* $\widetilde{T} = \widetilde{T'}$ *or* $\widetilde{T} = \{1,b\} = T$, *whence* $\Omega(T) \le \{\nabla^{\mathbf{F}}_\Sigma, \Delta^{\mathbf{F}}_{\Sigma'}\} = \Omega(T')$;
- *If* $\widetilde{T'} = \{1,ab\}$, *then* $T' = \{1,\varnothing\}$ *or* $\{1,ab\}$ *and* $\widetilde{T} = \widetilde{T'}$ *or* $\widetilde{T} = \{1,b\} = T$, *whence* $\Omega(T) \le \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(T')$;
- *If* $\widetilde{T'} = \{1,b\}$, *then* $\widetilde{T} = \{1,b\}$, *whence* $T = T' = \{1,b\}$ *and* $\Omega(T) = \Omega(T')$.

Therefore, $\mathcal{I}$ *is indeed roughly family monotone.*

On the other hand, we have $\widetilde{\{1,b\}} = \{1,b\} \le \{1,ab\} = \widetilde{\{1,ab\}}$, *whereas*

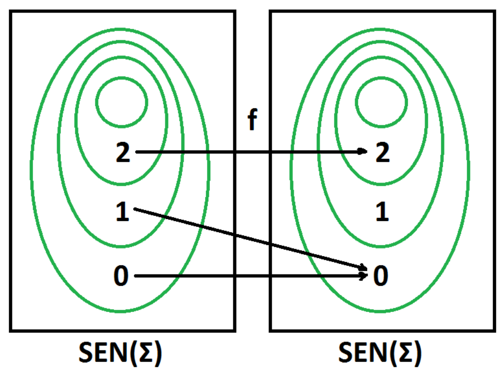
$$\Omega(\overleftarrow{\{1,b\}}) = \Omega(\{\varnothing,b\}) = \{\nabla^{\mathbf{F}}_\Sigma, \Delta^{\mathbf{F}}_{\Sigma'}\} \nleq \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(\{1,ab\}) = \Omega(\overleftarrow{\{1,ab\}}).$$

Therefore, $\mathcal{I}$ *is not roughly right monotone.*

The second example shows that there exists a roughly right monotone π-institution that is not roughly family monotone. This has the effect of establishing that the inclusions represented by the two southeast arrows in the hierarchy diagram are also proper inclusions.

Example 508 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

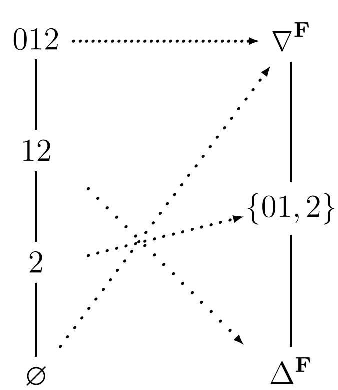
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families, but only three theory systems, namely* $\overline{\varnothing}$, $\{\{2\}\}$ *and* $\{\{0,1,2\}\}$. *The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:*



We show that $\mathcal{I}$ *is roughly right monotone. Suppose* $T, T' \in \mathrm{ThFam}(\mathcal{I})$, *such that* $\widetilde{T} \leq \widetilde{T'}$.

- *If $T' = \{\varnothing\}$ or $T' = \{\{0,1,2\}\}$, i.e., if $\widetilde{T'} = \{\{0,1,2\}\}$, $\Omega(\overleftarrow{T}) \le \nabla^{\mathbf{F}} = \Omega(\overleftarrow{T'})$;*
- *If $T' = \{\{1,2\}\}$, then $T = \{\{2\}\}$ or $T = \{\{1,2\}\}$. So $\Omega(\overleftarrow{T}) = \Omega(\{\{2\}\}) = \Omega(\overleftarrow{T'})$;*
- *If $T' = \{\{2\}\}$, i.e., if $\widetilde{T'} = \{1\}$, then $T = \{\{2\}\}$, and the conclusion is trivial.*

Thus, $\mathcal{I}$ is indeed roughly right monotone.

On the other hand, setting $T = \{\{2\}\}$ and $T' = \{\{1,2\}\}$, we get $\widetilde{T} \le \widetilde{T'}$, but $\Omega(T) = \{\{0,1\},\{2\}\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$. Therefore, $\mathcal{I}$ is not roughly family monotone.

We conclude, after these two examples, that the structure of the rough monotonicity hierarchy is, in fact, exactly as depicted in the diagram and no two classes are identical.

We look, next, at the connections between rough monotonicity and monotonicity classes. It turns out that protoalgebraicity (i.e., family/left monotonicity, by Proposition 171) is strong enough to ensure membership in all classes of the rough monotonicity hierarchy, whereas prealgebraicity (i.e., system/right monotonicity, by Proposition 173) is only sufficiently strong to yield corresponding rough monotonicity properties, i.e., implies rough right monotonicity and, a fortiori, rough system monotonicity.

Theorem 509 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is protoalgebraic, then it is roughly left monotone;

(b) If $\mathcal{I}$ is prealgebraic, then it is roughly right monotone.

Proof:

(a) Suppose that $\mathcal{I}$ is protoalgebraic. By Lemma 170, this implies that $\mathcal{I}$ is stable. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{\overleftarrow{T}} \le \overleftarrow{\overleftarrow{T'}}$. Then, by protoalgebraicity, $\Omega(\overleftarrow{\overleftarrow{T}}) \le \Omega(\overleftarrow{\overleftarrow{T'}})$. Hence, by Proposition 369, $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$. Thus, by stability, $\Omega(T) \le \Omega(T')$. Therefore, $\mathcal{I}$ is roughly left monotone.

(b) Suppose that $\mathcal{I}$ is prealgebraic. If $\mathrm{ThSys}(\mathcal{I})$ consists of a single rough equivalence class, then $\mathcal{I}$ is trivially roughly right monotone. Otherwise, since $\mathcal{I}$ is prealgebraic and $\Omega(\overline{\varnothing}) = \Omega(\mathrm{SEN}^\flat) = \nabla^{\mathbf{F}}$, $\mathcal{I}$ must have theorems. Therefore, rough equivalence is the identity relation on $\mathrm{ThFam}(\mathcal{I})$. Thus, for $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T} \le \widetilde{T'}$, we get $T \le T'$, whence, by Lemma 1, $\overleftarrow{T} \le \overleftarrow{T'}$. Thus, by prealgebraicity, $\Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'})$, showing that $\mathcal{I}$ is roughly right monotone.

■

Moreover, the following additional relations hold.

Theorem 510 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a non-almost inconsistent* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is protoalgebraic if and only if it has theorems and is roughly family or roughly left monotone.*

Proof: Suppose $\mathcal{I}$ is protoalgebraic. Since, by hypothesis, it is not almost inconsistent, it must have theorems. Moreover, by Theorem 509 and Proposition 505, it is both roughly left and roughly family monotone.

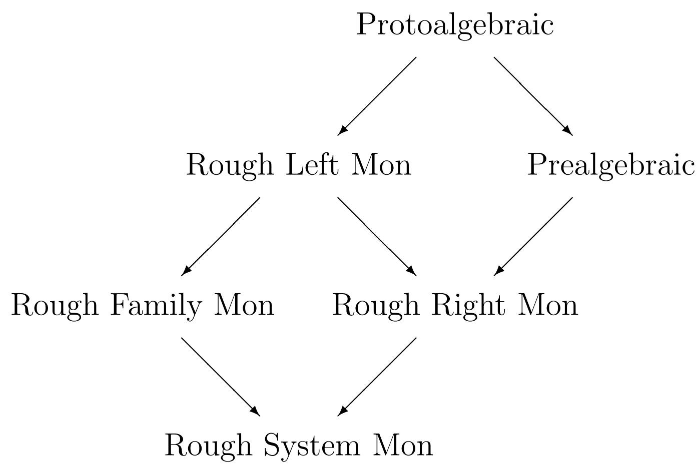
Assume, conversely, that $\mathcal{I}$ is roughly family or roughly left monotone and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. Since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$, whence, we get both $\widetilde{T} \leq \widetilde{T'}$ and $\overleftarrow{\widetilde{T}} \leq \overleftarrow{\widetilde{T'}}$. Using either rough family or rough left monotonicity, as the case requires, we obtain $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is protoalgebraic. ■

Theorem 511 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, that has a theory family* $T \neq \mathrm{SEN}^\flat$ *such that* $\overleftarrow{T} \neq \overline{\varnothing}$. $\mathcal{I}$ *is prealgebraic if and only if it has theorems and it is roughly right or roughly system monotone.*

Proof: Suppose $\mathcal{I}$ is prealgebraic. Since, by hypothesis, it has a theory system $\overleftarrow{T} \neq \mathrm{SEN}^\flat, \overline{\varnothing}$, it must have theorems. Moreover, by Theorem 509, it is roughly right monotone and, hence, by Proposition 505, it is roughly system monotone.

Assume, conversely, that $\mathcal{I}$ is roughly right or roughly system monotone and has theorems. By Proposition 505, it is roughly system monotone and has theorems. Let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$. Since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$, whence, we get $\widetilde{T} \leq \widetilde{T'}$. By rough system monotonicity, we obtain $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is prealgebraic. ■

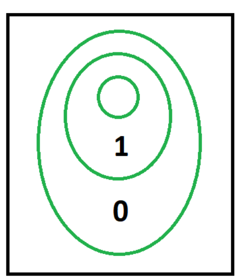
Theorem 509, together with Theorem 175 and Proposition 505, establish the mixed monotonicity and rough monotonicity hierarchy depicted in the diagram.



To see that all classes in the hierarchy are different, we give an example of a π-institution satisfying all four rough monotonicity properties, which is not, however, prealgebraic and, therefore, a fortiori, it is not protoalgebraic either.

Example 512 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial clone.*



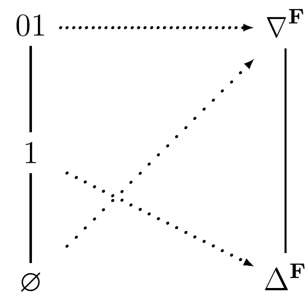
SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ has three theory families $\{\varnothing\}$ *and* $\{\{1\}\}$ *and* $\{\{0, 1\}\}$*, all of which are theory systems.*

The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



$\mathcal{I}$ belongs to all four classes of the rough monotonicity hierarchy. Indeed, since it is systemic, all four rough monotonicity conditions boil down to checking that, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega(T) \leq \Omega(T')$.

- *If $\widetilde{T'} = \{\{0,1\}\}$, then $T' = \{\varnothing\}$ or $T' = \{\{0,1\}\}$, whence $\Omega(T) \leq \nabla^{\mathbf{F}} = \Omega(T')$;*
- *If $\widetilde{T'} = \{\{1\}\}$, then $\widetilde{T} = \{\{1\}\}$ and, hence, $T = T' = \{\{1\}\}$. Thus, the implication holds trivially.*

On the other hand, we have $\{\varnothing\} \leq \{\{1\}\}$, whereas $\Omega(\{\varnothing\}) \nleq \Omega(\{\{1\}\})$, whence $\mathcal{I}$ is not prealgebraic.

The rough monotonicity properties transfer from the theory families/ systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems.

Theorem 513 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is roughly family monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T,T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;

(b) $\mathcal{I}$ is roughly left monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T,T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\overset{\leftleftarrows}{T} \leq \overset{\leftleftarrows}{T'}$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;

(c) $\mathcal{I}$ is roughly right monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T,T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$;

(d) $\mathcal{I}$ is roughly system monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ and all $T,T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T} \leq \widetilde{T'}$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that, by Lemma 51, $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$.

For the "only if", suppose that $\mathcal{I}$ is roughly family monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{T} \leq \widetilde{T'}$. Then $\alpha^{-1}(\widetilde{T}) \leq \alpha^{-1}(\widetilde{T'})$. By Theorem 377, $\widetilde{\alpha^{-1}(T)} \leq \widetilde{\alpha^{-1}(T')}$. Since, by Lemma 51, both $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$ are theory families of $\mathcal{I}$, we get, by rough family monotonicity, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Hence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

(b) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly left monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$. Then $\alpha^{-1}(\widetilde{\overleftarrow{T}}) \leq \alpha^{-1}(\widetilde{\overleftarrow{T'}})$. By Theorem 377, $\widetilde{\alpha^{-1}(\overleftarrow{T})} \leq \widetilde{\alpha^{-1}(\overleftarrow{T'})}$. Hence, by Lemma 6, $\widetilde{\overleftarrow{\alpha^{-1}(T)}} \leq \widetilde{\overleftarrow{\alpha^{-1}(T')}}$. Since, by Lemma 51, $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$ are theory families, we get, by rough left monotonicity, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$, whence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Thus, by the surjectivity of $\langle F, \alpha \rangle$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

(c) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly right monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{T} \leq \widetilde{T'}$. Then $\alpha^{-1}(\widetilde{T}) \leq \alpha^{-1}(\widetilde{T'})$ and, hence, by Theorem 377, $\widetilde{\alpha^{-1}(T)} \leq \widetilde{\alpha^{-1}(T')}$. Since, by Lemma 51, $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$ are theory families, we get, by rough right monotonicity, $\Omega(\overleftarrow{\alpha^{-1}(T)}) \leq \Omega(\overleftarrow{\alpha^{-1}(T')})$. Thus, by Lemma 6, $\Omega(\alpha^{-1}(\overleftarrow{T})) \leq \Omega(\alpha^{-1}(\overleftarrow{T'}))$. Now, by Proposition 24, we get $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T})) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'}))$, whence, by the surjectivity of $\langle F, \alpha \rangle$, $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$.

(d) Similar to Part (a).

■

Finally, we may recast the rough monotonicity classes in terms of the monotonicity of mappings from posets of classes of theory or filter families/systems into posets of congruence systems.

Recall the orderings of the collections $\widetilde{\mathrm{ThFam}}(\mathcal{I})$ and $\widetilde{\mathrm{ThSys}}(\mathcal{I})$: For all $T, T' \in \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{[T]} \leq \widetilde{[T']} \quad \text{iff} \quad \widetilde{T} \leq \widetilde{T'}$$

and, for all $T, T' \in \mathrm{ThSys}(\mathcal{I})$,

$$\widetilde{[T]} \leq \widetilde{[T']} \quad \text{iff} \quad \widetilde{T} \leq \widetilde{T'}$$

and the notation $\widetilde{\mathbf{ThFam}}(\mathcal{I}) = \langle \widetilde{\mathrm{ThFam}}(\mathcal{I}), \leq \rangle$ and $\widetilde{\mathbf{ThSys}}(\mathcal{I}) = \langle \widetilde{\mathrm{ThSys}}(\mathcal{I}), \leq \rangle$ for the corresponding ordered sets.

Proposition 514 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly family monotone;*

(b) $\Omega : \widetilde{\mathbf{ThFam}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^\mathcal{A} : \widetilde{\mathbf{FiFam}}^\mathcal{I}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Similarly, for rough system monotonicity, we have

Proposition 515 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly system monotone;*

(b) $\Omega : \widetilde{\mathbf{ThSys}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^\mathcal{A} : \widetilde{\mathbf{FiSys}}^\mathcal{I}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

7.4 Narrow Monotonicity

We now introduce and study classes of π-institutions defined using, once more, monotonicity properties of the Leibniz operator, but applied only on theory families with all components nonempty. This is one of the ways used already in Chapter 6 to bypass theory families with empty components that may cause lack of monotonicity.

Definition 516 (Narrow Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is called* **narrowly family monotone** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$*,*
$$T \leq T' \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$
- $\mathcal{I}$ *is called* **narrowly left monotone** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$*,*
$$\overleftarrow{T} \leq \overleftarrow{T'} \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$
- $\mathcal{I}$ *is called* **narrowly right monotone** *if, for all* $T, T' \in \mathrm{ThFam}^{\not\emptyset}(\mathcal{I})$*,*
$$T \leq T' \quad \textit{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$

- *$\mathcal{I}$ is called* **narrowly system monotone** *if, for all $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$,*

$$T \leq T' \quad \textit{implies} \quad \Omega(T) \leq \Omega(T').$$

We establish now the *narrow monotonicity hierarchy* of π-institutions.

Proposition 517 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is narrowly left monotone, then it is narrowly family monotone;

(b) If $\mathcal{I}$ is narrowly family monotone, then it is narrowly system monotone;

(c) If $\mathcal{I}$ is narrowly right monotone, then it is narrowly system monotone.

Proof:

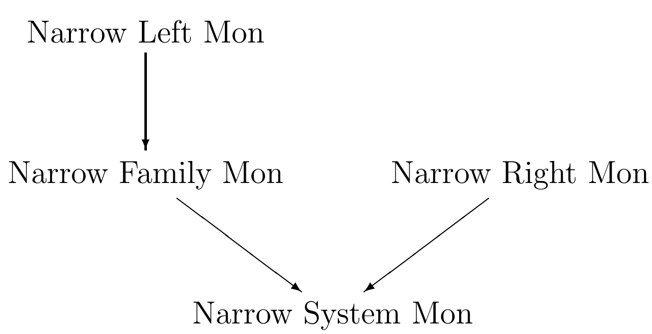
(a) Suppose that $\mathcal{I}$ is narrowly left monotone and let $T, T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$, whence, by narrow left monotonicity, $\Omega(T) \leq \Omega(T')$. Hence $\mathcal{I}$ is narrow family monotone.

(b) Suppose $\mathcal{I}$ is narrow family monotone. Then it is a fortiori narrow system monotone, since the condition defining the latter is a specialization of the one defining the former.

(c) Suppose $\mathcal{I}$ is narrowly right monotone and let $T, T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, such that $T \leq T'$. Then, by narrow right monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$. Since T, T' are theory systems, $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$, whence $\Omega(T) \leq \Omega(T')$ and, hence, $\mathcal{I}$ is narrowly system monotone.

■

We have now established the following **narrow monotonicity hierarchy** of π-institutions.



Some additional relationships may be established between the narrow monotonicity classes. More precisely, we show that narrow left monotonicity implies exclusive stability, whereas narrow system monotonicity together with narrow systemicity, yield both narrow left and narrow right monotonicity.

Proposition 518 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly left monotone, then it is exclusively stable.*

Proof: Suppose that $\mathcal{I}$ is narrowly left monotone and let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^\natural(\mathcal{I})$. Since $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$ and $T, \overleftarrow{T} \in \mathrm{ThFam}^\natural(\mathcal{I})$, we get, by narrow left monotonicity, $\Omega(\overleftarrow{T}) = \Omega(T)$. Thus, $\mathcal{I}$ is exclusively stable. ■

Proposition 519 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is narrowly system monotone and narrowly systemic, then it is both narrowly left and narrowly right monotone.*

Proof: Suppose that $\mathcal{I}$ is narrowly system monotone and narrowly systemic and let $T, T' \in \mathrm{ThFam}^\natural(\mathcal{I})$.

- Assume that $\overleftarrow{T} \leq \overleftarrow{T'}$. By narrow systemicity, $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$, whence $T, T' \in \mathrm{ThSys}^\natural(\mathcal{I})$. Thus, by narrow system monotonicity, $\Omega(T) \leq \Omega(T')$ and, therefore, $\mathcal{I}$ is narrowly left monotone.
- Assume that $T \leq T'$. Again, by narrow systemicity, $\overleftarrow{T} = T$ and $\overleftarrow{T'} = T'$, which yields that $\overleftarrow{T}, \overleftarrow{T'} \in \mathrm{ThSys}^\natural(\mathcal{I})$. Hence, by narrow system monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$, showing that $\mathcal{I}$ is narrowly right monotone.

■

By Propositions 517 and 519, under narrow systemicity, the narrow monotonicity hierarchy collapses to a single class.

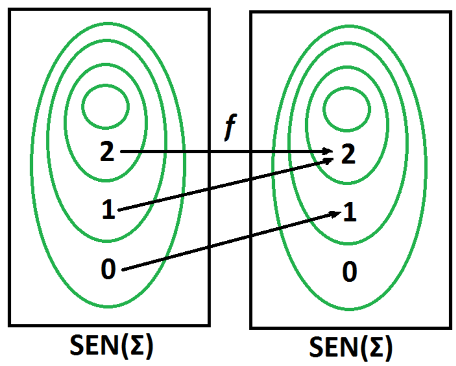
We present three examples to show that all four narrow monotonicity classes depicted in the diagram above are different. The first example gives a narrowly family monotone π-institution which is not narrowly left monotone. Thus, it shows that the class of narrowly left monotone π-institutions is properly contained in the class of narrowly family monotone π-institutions.

Example 520 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and four non-identity morphisms* $f, z, o, t : \Sigma \to \Sigma$*, whose composition table is the following:*

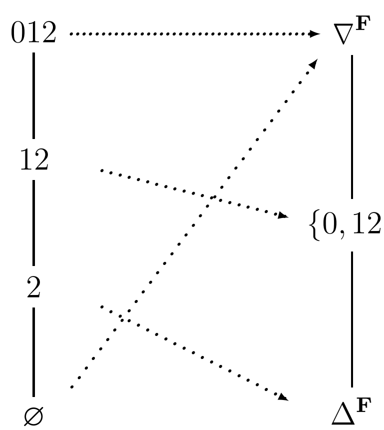
$\circ$	f	z	o	t
f	t	o	t	t
z	z	z	z	z
o	o	o	o	o
t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, *with*
$$\mathrm{SEN}^\flat(f)(0) = 1, \quad \mathrm{SEN}^\flat(f)(1) = 2, \quad \mathrm{SEN}^\flat(f)(2) = 2,$$
whereas $\mathrm{SEN}^\flat(z)(x) = 0$, $\mathrm{SEN}^\flat(o)(x) = 1$ *and* $\mathrm{SEN}^\flat(t)(x) = 2$, *for all* $x \in \mathrm{SEN}^\flat(\Sigma)$;
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*
$$C_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families* $\varnothing$, $\{\{2\}\}$, $\{\{1,2\}\}$ *and* $\{\{0,1,2\}\}$, *but only two theory systems,* $\varnothing$ *and* $\{\{0,1,2\}\}$. *The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since $\mathrm{ThFam}^{\sharp}(\mathcal{I}) = \{\{\{2\}\}, \{\{1,2\}\}, \mathrm{SEN}^\flat\}$, *it is clear that* $\mathcal{I}$ *is narrowly family monotone.*

On the other hand, for $T = \{\{1,2\}\}$ *and* $T' = \{\{2\}\}$, *we get* $\overleftarrow{T} = \overline{\varnothing} = \overleftarrow{T'}$, *whereas* $\Omega(T) = \{0,12\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$. *Therefore,* $\mathcal{I}$ *is not narrowly left monotone.*

The second example shows that there exists a narrowly family monotone π-institution that is not narrowly right monotone, thus showing, on the one hand, that the class of narrowly right monotone π institutions is properly included in the class of narrowly system monotone π-institutions and, on the other, that narrowly family monotone π-institutions do not form a subclass of narrowly right monotone π-institutions.

Example 521 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and four non-identity morphisms* $f, g, o, t : \Sigma \to \Sigma$*, whose composition table is the following:*

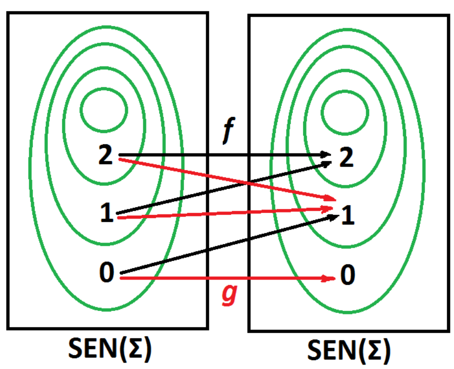
$\circ$	f	g	o	t
f	t	f	t	t
g	o	g	o	o
o	o	o	o	o
t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*, with*

$$\begin{array}{lll} \mathrm{SEN}^\flat(f)(0) = 1, & \mathrm{SEN}^\flat(f)(1) = 2, & \mathrm{SEN}^\flat(f)(2) = 2; \\ \mathrm{SEN}^\flat(g)(0) = 0, & \mathrm{SEN}^\flat(g)(1) = 1, & \mathrm{SEN}^\flat(g)(2) = 1, \end{array}$$

whereas $\mathrm{SEN}^\flat(o)(x) = 1$ *and* $\mathrm{SEN}^\flat(t)(x) = 2$*, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*;*

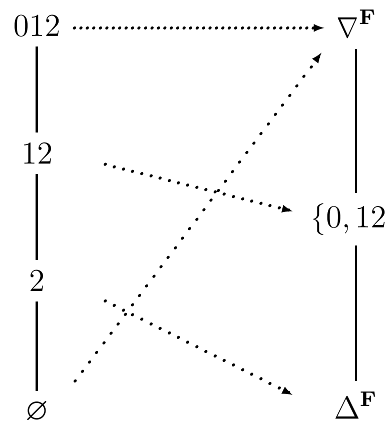
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *has four theory families* $\varnothing$, $\{\{2\}\}$, $\{\{1, 2\}\}$ *and* $\{\{0, 1, 2\}\}$*, but only three theory systems,* $\varnothing$, $\{\{1, 2\}\}$ *and* $\{\{0, 1, 2\}\}$*. The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since $\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \{\{\{2\}\}, \{\{1,2\}\}, \mathrm{SEN}^\flat\}$*, it is clear that* $\mathcal{I}$ *is narrowly family monotone.*

On the other hand, for $T = \{\{2\}\}$ *and* $T' = \{\{1,2\}\}$*, we get* $T \le T'$*, whereas* $\Omega(\overleftarrow{T}) = \Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} \not\le \{0,12\} = \Omega(T') = \Omega(\overleftarrow{T'})$*. Therefore,* $\mathcal{I}$ *is not narrowly right monotone.*

The third example shows that there exists a narrowly right monotone π-institution that is not narrowly family monotone. Combined with the preceding examples, it has the effect of establishing the following facts:

- The classes of narrowly family monotone and narrowly right monotone π-institutions are pairwise incomparable.
- The class of narrowly family monotone π-institutions is properly contained in the class of narrowly system monotone π-institutions.

Example 522 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

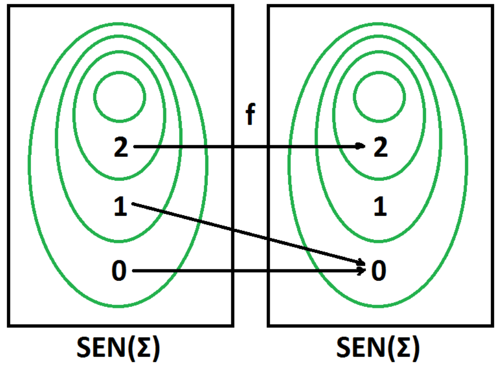
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*,* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

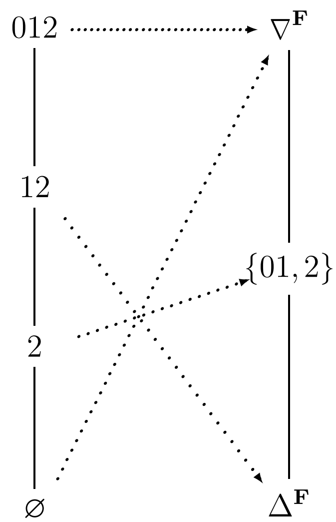
$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families, but only three theory systems, namely* $\overline{\varnothing}$*,* $\{\{2\}\}$ *and* $\{\{0,1,2\}\}$*. Moreover, clearly,*

$$\mathrm{ThFam}^{\nmid}(\mathcal{I}) = \{\{\{2\}\}, \{\{1,2\}\}, \{\{0,1,2\}\}\}.$$



The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



We have

$$\begin{array}{rcl}\Omega(\overleftarrow{2}) & = & \Omega(2) = \{01,2\};\\ \Omega(\overleftarrow{12}) & = & \Omega(2) = \{01,2\};\\ \Omega(\overleftarrow{012}) & = & \Omega(012) = \nabla^{\mathbf{F}}.\end{array}$$

Thus, we get $\Omega(\overleftarrow{2}) \leq \Omega(\overleftarrow{12}) \leq \Omega(\overleftarrow{012})$ *and, therefore,* $\mathcal{I}$ *is narrowly right monotone.*

On the other hand, for $T = \{\{2\}\}$ *and* $T' = \{\{1,2\}\}$*, we get* $T \leq T'$*, whereas* $\Omega(T) = \{01,2\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$*. Thus,* $\mathcal{I}$ *is not narrowly family monotone.*

We conclude that the structure of the narrow monotonicity hierarchy is, in fact, exactly as depicted in the diagram and no two classes are identical.

We look, next, at the connections between narrow monotonicity and monotonicity classes. Once more, as was the case with monotonicity and rough monotonicity in Section 7.3, protoalgebraicity (i.e., family/left monotonicity, by Proposition 171) is strong enough to ensure membership in all classes of the narrow monotonicity hierarchy, whereas prealgebraicity (i.e., system/right monotonicity, by Proposition 173) is only sufficiently strong to yield corresponding narrow monotonicity properties, i.e., implies narrow right monotonicity and, a fortiori, narrow system monotonicity.

Theorem 523 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is protoalgebraic, then it is narrowly left monotone;*

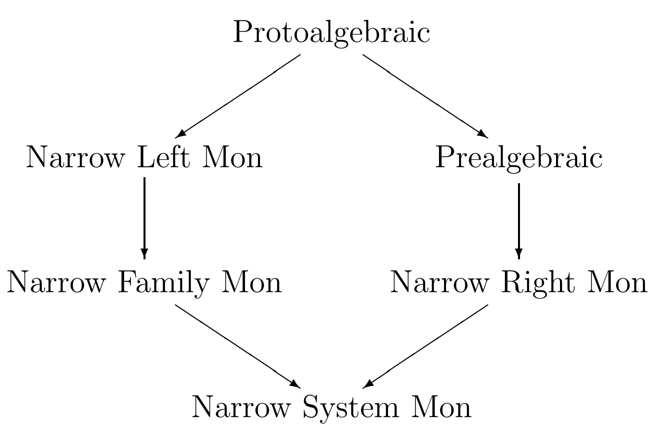
(b) If $\mathcal{I}$ *is prealgebraic, then it is narrowly right monotone.*

Proof:

(a) Suppose that $\mathcal{I}$ is protoalgebraic. By Proposition 171, it is left monotone, whence, it is, a fortiori, narrowly left monotone, since the condition defining the latter is a specialization of that defining the former.

(b) Suppose that $\mathcal{I}$ is prealgebraic. By Proposition 173, it is right monotone, whence, it is, a fortiori, narrowly right monotone, since the condition defining the latter is a specialization of that defining the former. ■

Thus, the following mixed monotonicity and narrow monotonicity hierarchy emerges.



We also have the following additional relations, paralleling the ones established between monotonicity and rough monotonicity classes in Theorems 510 and 511.

Theorem 524 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a non-almost inconsistent* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is protoalgebraic if and only if it has theorems and is narrowly left or narrowly family monotone.*

Proof: Suppose $\mathcal{I}$ is protoalgebraic. Since, by hypothesis, it is not almost inconsistent, it must have theorems. Moreover, by Theorem 523 and Proposition 517, it is both narrowly left and narrowly family monotone.

Assume, conversely, that $\mathcal{I}$ is narrowly left or narrowly family monotone and has theorems. Let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, since $\mathcal{I}$ has theorems, $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$ and, moreover, by Lemma 1, we get $\overleftarrow{T} \leq \overleftarrow{T'}$. Using either narrow family or narrow left monotonicity, as the case requires, we obtain $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is protoalgebraic. ■

Theorem 525 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, that has a theory system* $T \neq \overline{\varnothing}, \mathrm{SEN}^\flat$*.* $\mathcal{I}$ *is prealgebraic if and only if it has theorems and it is narrowly right or narrowly system monotone.*

Proof: Suppose $\mathcal{I}$ is prealgebraic. Since, by hypothesis, it has a theory system $T \neq \overline{\varnothing}, \mathrm{SEN}^\flat$, it must have theorems. Moreover, by Theorem 523, it is narrowly right monotone and, hence, by Proposition 517, it is narrowly system monotone.

Assume, conversely, that $\mathcal{I}$ is narrowly right or narrowly system monotone and has theorems. By Proposition 517, it is narrowly system monotone and has theorems. Let $T, T' \in \mathrm{ThSys}(\mathcal{I})$, such that $T \leq T'$. Since $\mathcal{I}$ has theorems, $T, T' \in \mathrm{ThSys}^{\nleq}(\mathcal{I})$. By narrow system monotonicity, we obtain $\Omega(T) \leq \Omega(T')$. Therefore, $\mathcal{I}$ is prealgebraic. ■

To see that all classes in the hierarchy are different, we give an example of a π-institution satisfying all four narrow monotonicity properties, which is not, however, prealgebraic and, therefore, a fortiori, it is not protoalgebraic either.

Example 526 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

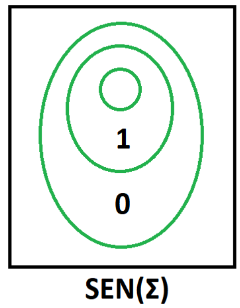
- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial clone.*

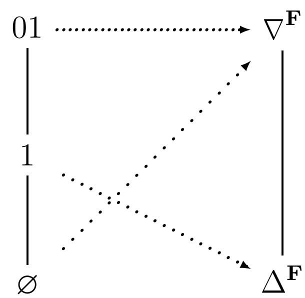
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ *has three theory families* $\{\varnothing\}$ *and* $\{\{1\}\}$ *and* $\{\{0, 1\}\}$*, all of which are theory systems.*

The lattice of theory families of $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*





$\mathcal{I}$ belongs to all four classes of the narrow monotonicity hierarchy. Indeed, since it is systemic, all four narrow monotonicity conditions boil down to checking that, for all $T,T' \in \mathrm{ThFam}^{\not\downarrow}(\mathcal{I})$, $T \leq T'$ implies $\Omega(T) \leq \Omega(T')$. This is obvious, since the only $T,T' \in \mathrm{ThFam}^{\not\downarrow}(\mathcal{I})$, with $T \lneq T'$, are $T = \{\{1\}\}$ and $T' = \{\{0,1\}\}$ and $\Omega(T) = \Delta^{\mathbf{F}} \leq \nabla^{\mathbf{F}} = \Omega(T')$.

On the other hand, we have $\{\varnothing\} \leq \{\{1\}\}$, whereas $\Omega(\{\varnothing\}) \nleq \Omega(\{\{1\}\})$, whence $\mathcal{I}$ is not prealgebraic.

We look, next, at relationships between narrow monotonicity and rough monotonicity classes. We show that the two family versions coincide and that, for the remaining three properties, each of the rough versions implies the corresponding narrow version.

Theorem 527 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ if roughly family monotone iff it is narrowly family monotone;

(b) If $\mathcal{I}$ is roughly left monotone, then it is narrowly left monotone;

(c) If $\mathcal{I}$ is roughly right monotone, then it is narrowly right monotone;

(d) If $\mathcal{I}$ is roughly system monotone, then it is narrowly system monotone.

Proof:

(a) Suppose that $\mathcal{I}$ is roughly family monotone and let $T,T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $T \leq T'$. Since $T,T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, $\widetilde{T} = T$ and $\widetilde{T'} = T'$, whence, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. Thus, by rough family monotonicity, $\Omega(T) \leq \Omega(T')$ and, therefore, $\mathcal{I}$ is narrowly family monotone. Suppose, conversely, that $\mathcal{I}$ is narrowly family monotone and let $T,T' \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T} \leq \widetilde{T'}$. Since $\widetilde{T},\widetilde{T'} \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by narrow family monotonicity, $\Omega(\widetilde{T}) \leq \Omega(\widetilde{T'})$. Therefore, by Proposition 369, $\Omega(T) \leq \Omega(T')$ and, hence, $\mathcal{I}$ is roughly family monotone.

(b) Suppose that $\mathcal{I}$ is roughly left monotone, i.e., that, for all $T,T' \in \mathrm{ThFam}(\mathcal{I})$, $\widetilde{\overleftarrow{T}} \leq \widetilde{\overleftarrow{T'}}$ implies $\Omega(T) \leq \Omega(T')$. Assume, for the sake of obtaining a contradiction, that $\mathcal{I}$ is not narrowly left monotone. Then, there exist $X,Y \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $\overleftarrow{X} \leq \overleftarrow{Y}$ and $\Omega(X) \nleq \Omega(Y)$.

First, observe that, if there existed $Z \in \mathrm{ThFam}(\mathcal{I})$ and $P \in |\mathbf{Sign}^\flat|$, such that $Z_P \neq \varnothing$ and $\overleftarrow{Z}_P = \varnothing$, then, setting $Z' = \{Z_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$Z'_\Sigma = \begin{cases} \varnothing, & \text{if } \Sigma \neq P \\ Z_P, & \text{if } \Sigma = P \end{cases},$$

we would have $\widetilde{\overleftarrow{Z'}} = \widetilde{\overleftarrow{\overline{\varnothing}}}$, but $\Omega(Z') \neq \Omega(\overline{\varnothing})$, which contradicts rough left monotonicity. Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma \neq \varnothing$ implies $\overleftarrow{T}_\Sigma \neq \varnothing$.

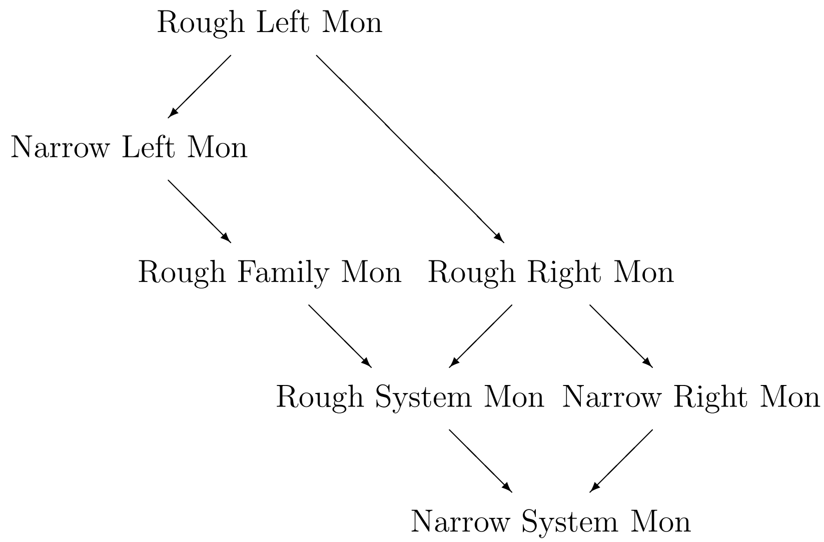
Continuing with the proof, by hypothesis, $\overleftarrow{X} \leq \overleftarrow{Y}$ and $\Omega(X) \nleq \Omega(Y)$. Hence, by rough left monotonicity, $\widetilde{\overleftarrow{X}} \nleq \widetilde{\overleftarrow{Y}}$. Thus, there exists $P \in |\mathbf{Sign}^\flat|$, such that $\widetilde{\overleftarrow{X}}_P \nsubseteq \widetilde{\overleftarrow{Y}}_P$, whereas $\overleftarrow{X}_P \subseteq \overleftarrow{Y}_P$. But this gives $\overleftarrow{X}_P = \varnothing$, whence, by the preceding observation, $X_P = \varnothing$, which contradicts $X \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$. Therefore, $\mathcal{I}$ must be narrowly left monotone.

(c) Suppose that $\mathcal{I}$ is roughly right monotone and let $T,T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, such that $T \leq T'$. Since $T,T' \in \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get $\widetilde{T} = T$ and $\widetilde{T'} = T'$, whence, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. By rough right monotonicity, $\Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'})$, whence $\mathcal{I}$ is narrowly right monotone.

(d) Suppose that $\mathcal{I}$ is roughly system monotone and let $T,T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, such that $T \leq T'$. Since $T,T' \in \mathrm{ThSys}^{\lightning}(\mathcal{I})$, $\widetilde{T} = T$ and $\widetilde{T'} = T'$, whence, by hypothesis, $\widetilde{T} \leq \widetilde{T'}$. Thus, by rough system monotonicity, $\Omega(T) \leq \Omega(T')$ and, therefore, $\mathcal{I}$ is narrowly system monotone.

∎

Thus, the following mixed rough monotonicity and narrow monotonicity hierarchy emerges.



To see that all classes in the hierarchy are different, we must find examples that separate the class of rough monotone from the class of narrow monotone π-institutions for each of the three allegedly distinct types, subject to the inclusions established in Theorem 527.

First, we provide an example of a narrowly left monotone π-institution that is not roughly left monotone. This proves that the class of roughly left monotone π-institutions is a proper subclass of the class of narrowly left monotone ones.

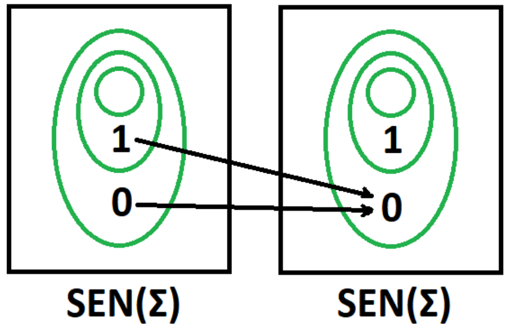
Example 528 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

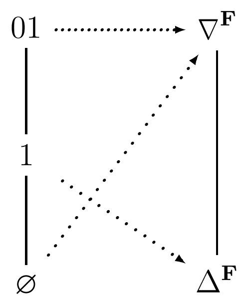
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$*;*
- $N^\flat$ *is the trivial clone, consisting of the projections only.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ *has three theory families* $\{\varnothing\}$, $\{\{1\}\}$ *and* $\{\{0,1\}\}$*, but only two theory systems,* $\{\varnothing\}$ *and* $\{\{0,1\}\}$*. The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*





To see that $\mathcal{I}$ is narrowly left monotone, note that the only two different theory families in $\mathrm{ThFam}^{\not\, \sharp}(\mathcal{I})$ *are* $\{\{1\}\}$ *and* $\{\{0,1\}\}$ *and we have*

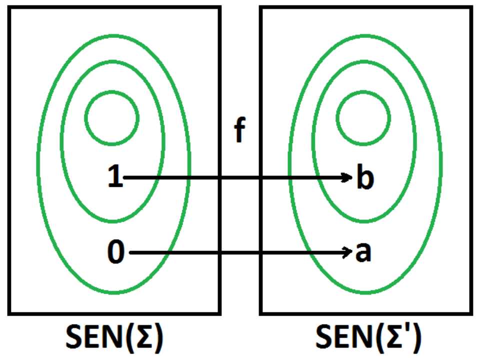
$$\overleftarrow{\{\{1\}\}} = \{\varnothing\} \le \{\{0,1\}\} = \overleftarrow{\{\{0,1\}\}} \quad \text{and} \quad \Omega(\{\{1\}\}) = \Delta^{\mathbf{F}} \le \nabla^{\mathbf{F}} = \Omega(\{\{0,1\}\}).$$

On the other hand, $\mathcal{I}$ is not roughly left monotone, since $\widetilde{\overleftarrow{\{\varnothing\}}} = \{\{0,1\}\} = \widetilde{\overleftarrow{\{\{1\}\}}}$*, but* $\Omega(\{\varnothing\}) \not\le \Omega(\{\{1\}\})$*.*

Next we exhibit a narrowly right monotone but not roughly right monotone π-institution, showing that the class of roughly right monotone π-institutions is a proper subclass of that of the narrowly right monotone ones.

Example 529 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

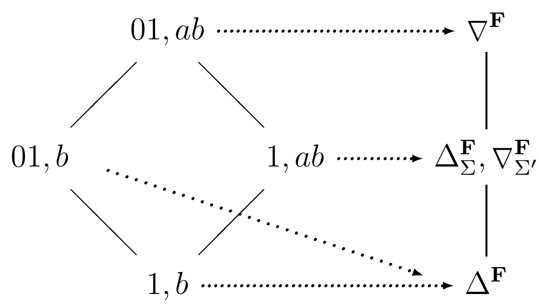
- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

There are only four theory families in $\mathrm{ThFam}^{\natural}(\mathcal{I})$*, all of which except for* $\{01, b\}$ *are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*



To see that $\mathcal{I}$ *is narrowly right monotone, we check all cases comparing theory families in* $\mathrm{ThFam}^{\natural}(\mathcal{I})$*:*

$$\begin{array}{ll}
\{1,b\} \leq \{01,b\}, & \Omega(\overleftarrow{\{1,b\}}) = \Omega(\{1,b\}) = \Omega(\overleftarrow{\{01,b\}});\\
\{1,b\} \leq \{1,ab\}, & \Omega(\overleftarrow{\{1,b\}}) = \Delta^{\mathbf{F}} \leq \Omega(\overleftarrow{\{1,ab\}});\\
\{01,b\} \leq \{01,ab\}, & \Omega(\overleftarrow{\{01,b\}}) \leq \nabla^{\mathbf{F}} = \Omega(\overleftarrow{\{01,ab\}});\\
\{1,ab\} \leq \{01,ab\}, & \Omega(\overleftarrow{\{1,ab\}}) \leq \nabla^{\mathbf{F}} = \Omega(\overleftarrow{\{01,ab\}}).
\end{array}$$

On the other hand, since $\widetilde{\{1,\varnothing\}} \leq \widetilde{\{1,ab\}}$*, but*

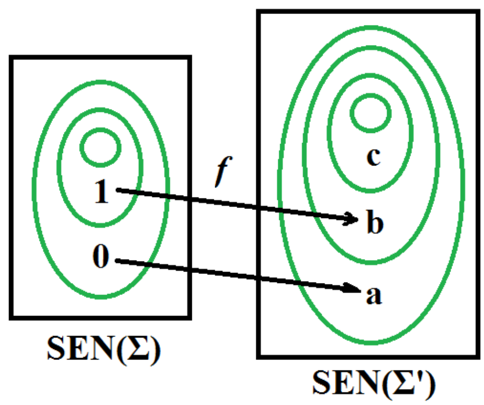
$$\Omega(\overleftarrow{\{1,\varnothing\}}) = \Omega(\{\varnothing,\varnothing\}) \nleq \Omega(\{1,ab\}) = \Omega(\overleftarrow{\{1,ab\}}),$$

$\mathcal{I}$ *is not roughly right monotone.*

Finally, we present an example of a narrowly system monotone π-institution which fails to be roughly system monotone, thereby establishing that the class of roughly system monotone π-institutions is properly contained in the class of narrowly system monotone ones.

Example 530 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two object* Σ, Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$, *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$;
- $N^\flat$ *is the trivial clone.*



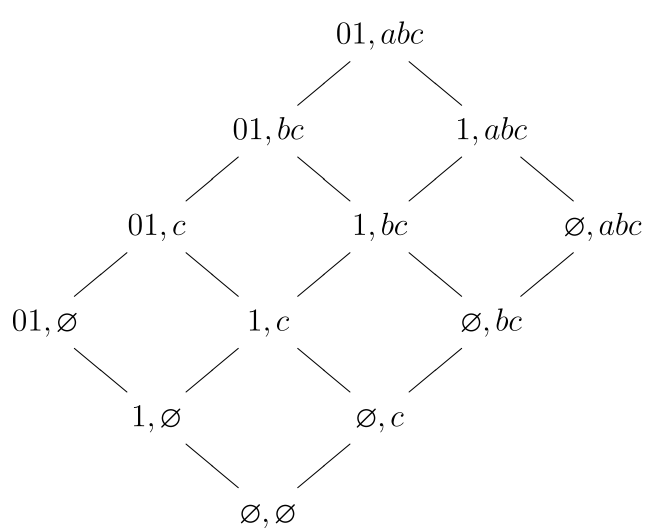
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{c\}, \{b,c\}, \{a,b,c\}\}.$$

$\mathcal{I}$ *has twelve theory families, but only seven theory systems. These are*

$$\overline{\varnothing}, \{\varnothing, c\}, \{\varnothing, bc\}, \{\varnothing, abc\}, \{1, bc\}, \{1, abc\}, \{01, abc\}.$$

The following diagram shows the structure of the lattice of theory families.



To see that $\mathcal{I}$ is narrow system monotone, note that there are only three theory systems in $\mathrm{ThSys}^{\nleq}(\mathcal{I})$*, namely,* $\{1, bc\}$*,* $\{1, abc\}$ *and* $\{01, abc\}$ *and we have* $\{1, bc\} \leq \{1, abc\} \leq \{01, abc\}$ *and, also,*

$$\begin{aligned}\Omega(\{1, bc\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \{a, bc\}\} \\ \leq \Omega(\{1, abc\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\} \\ \leq \Omega(\{01, abc\}) = \nabla^{\mathbf{F}}.\end{aligned}$$

On the other hand, setting $T = \{\varnothing, c\}$ *and* $T' = \{\varnothing, bc\}$*, which are both theory systems, we get*

$$\widetilde{T} = \{01, c\} \leq \{01, bc\} = \widetilde{T}',$$

whereas

$$\Omega(T) = \{\nabla^{\mathbf{F}}_{\Sigma}, \{ab, c\}\} \nleq \{\Delta^{\mathbf{F}}_{\Sigma}, \{a, bc\}\} = \Omega(T').$$

Therefore, $\mathcal{I}$ is not roughly system monotone.

The narrow monotonicity properties transfer from the theory families/systems of a π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ to all $\mathcal{I}$-filter families/systems on arbitrary $\mathbf{F}$-algebraic systems. Recall the notations $\mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$ and $\mathrm{FiSys}^{\mathcal{I}\nleq}(\mathcal{A})$ for the collections of $\mathcal{I}$-filter families and $\mathcal{I}$-filter systems, respectively, of an $\mathbf{F}$-algebraic system $\mathcal{A}$ all of whose components are nonempty.

Theorem 531 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is narrowly family monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$*,* $T \leq T'$ *implies* $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$*;*

(b) $\mathcal{I}$ is narrowly left monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$*,* $\overleftarrow{T} \leq \overleftarrow{T'}$ *implies* $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$*;*

(c) $\mathcal{I}$ is narrowly right monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$*,* $T \leq T'$ *implies* $\Omega^{\mathcal{A}}(\overleftarrow{T}) \leq \Omega^{\mathcal{A}}(\overleftarrow{T'})$*;*

(d) $\mathcal{I}$ is narrowly system monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$ *and all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}\nleq}(\mathcal{A})$*,* $T \leq T'$ *implies* $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$*.*

Proof:

(a) The "if" follows by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account that, by Lemma 51, $\mathrm{ThFam}(\mathcal{I}) = \mathrm{FiFam}^{\mathcal{I}}(\mathcal{F})$.

For the "only if", suppose that $\mathcal{I}$ is narrowly family monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{A})$, such that $T \leq T'$. Then $\alpha^{-1}(T) \leq \alpha^{-1}(T')$. Since, by Lemmas 51 and 376, both $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$ are in $\mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by narrow family monotonicity, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$. Hence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

(b) The "if" follows as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is narrowly left monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $T, T' \in \mathrm{FiFam}^{\mathcal{I}\lightning}(\mathcal{A})$, such that $\overleftarrow{T} \leq \overleftarrow{T'}$. Then $\alpha^{-1}(\overleftarrow{T}) \leq \alpha^{-1}(\overleftarrow{T'})$. By Lemma 6, $\overleftarrow{\alpha^{-1}(T)} \leq \overleftarrow{\alpha^{-1}(T')}$. Since, by Lemmas 51 and 376, $\alpha^{-1}(T)$ and $\alpha^{-1}(T')$ are in $\mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by narrow left monotonicity, $\Omega(\alpha^{-1}(T)) \leq \Omega(\alpha^{-1}(T'))$, whence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T)) \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T'))$. Thus, by the surjectivity of $\langle F, \alpha \rangle$, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$.

Parts (c) and (d) may be proved similarly. ■

Finally, in analogs of Propositions 514 and 515, we recast the narrow monotonicity properties in terms of the monotonicity of mappings from posets of theory or filter families/systems into posets of congruence systems.

Proposition 532 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly family monotone;*

(b) $\Omega : \mathbf{ThFam}^{\lightning}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Similarly, for narrow system monotonicity, we have

Proposition 533 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly system monotone;*

(b) $\Omega : \mathbf{ThSys}^{\lightning}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is monotone;*

(c) $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

7.5 Rough Complete Monotonicity

In this section we study classes of π-institutions defined using complete monotonicity properties of the Leibniz operator applied on rough equivalence classes.

Definition 534 (Rough c-Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **roughly family completely monotone**, *or* **roughly family c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T} \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is called* **roughly left completely monotone**, *or* **roughly left c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}} \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is called* **roughly right completely monotone**, *or* **roughly right c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T} \quad \textit{implies} \quad \Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T}).$$
- $\mathcal{I}$ *is called* **roughly system completely monotone**, *or* **roughly system c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$,
$$\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T} \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$

We start with an analog of Corollary 503 applying to rough complete monotonicity properties.

Corollary 535 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is roughly left monotone, then it is roughly family c-monotone if and only if it is roughly right c-monotone.*

Proof: Suppose $\mathcal{I}$ is roughly left monotone. Then, by Lemma 502, it is stable. Now note that rough family c-monotonicity is equivalent to the condition that, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,
$$\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T} \quad \text{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T),$$

which, by stability, is equivalent to, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$,

$$\widetilde{T'} \le \bigcup_{T \in \mathcal{T}} \widetilde{T} \quad \text{implies} \quad \Omega(\overleftarrow{T'}) \le \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T}),$$

and this is equivalent, by definition, to rough right c-monotonicity. ∎

We establish a rough complete monotonicity hierarchy analogous to the one obtained in Proposition 505 for rough monotonicity.

Proposition 536 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is roughly family c-monotone, then it is roughly system c-monotone;*

(b) If $\mathcal{I}$ *is roughly left c-monotone, then it is roughly system c-monotone;*

(c) If $\mathcal{I}$ *is roughly right c-monotone, then it is roughly system c-monotone.*

Proof:

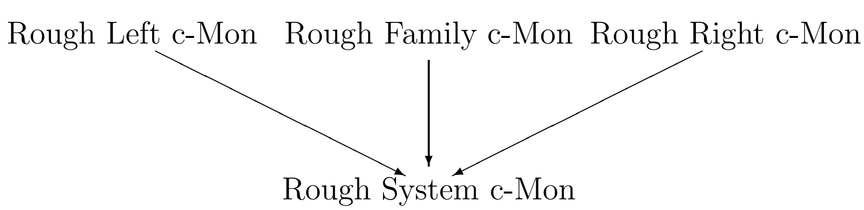
(a) The definition of rough system c-monotonicity is a specialization of that of rough family c-monotonicity, in which the universal quantification is restricted over theory systems.

(b) Suppose $\mathcal{I}$ is roughly left c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T'} \le \bigcup_{T \in \mathcal{T}} \widetilde{T'}$. Since $\mathcal{T} \cup \{T'\}$ consists of theory systems, $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$. Hence, we get $\widetilde{\overleftarrow{T'}} \le \bigcup_{T \in \mathcal{T}} \widetilde{\overleftarrow{T}}$. Thus, by rough left monotonicity, we get $\Omega(T') \le \bigcup_{T \in \mathcal{T}} \Omega(T)$. Therefore, $\mathcal{I}$ is roughly system c-monotone.

(c) Suppose $\mathcal{I}$ is roughly right monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T'} \le \bigcup_{T \in \mathcal{T}} \widetilde{T}$. Then, by rough right monotonicity, $\Omega(\overleftarrow{T'}) \le \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. Since $\mathcal{T} \cup \{T'\}$ consists of theory systems, $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$, whence $\Omega(T') \le \bigcup_{T \in \mathcal{T}} \Omega(T)$ and, hence, $\mathcal{I}$ is roughly system c-monotone.

∎

We have now established the following **rough c-monotonicity hierarchy** of π-institutions.



In an analog of Proposition 506, it is shown that being roughly left c-monotone is equivalent to being roughly system c-monotone and stable.

Proposition 537 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is roughly left c-monotone if and only if it is roughly system c-monotone and stable.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left c-monotone. Then, by Proposition 536, it is roughly system c-monotone. Moreover, it is, a fortiori, roughly left monotone and, hence, by Lemma 502, it is stable.

Assume, conversely, that $\mathcal{I}$ is stable and roughly system c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{\overleftarrow{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\overleftarrow{T}}$. Then, since $\{\overleftarrow{T} : T \in \mathcal{T}\} \cup \{\overleftarrow{T'}\} \subseteq \mathrm{ThSys}(\mathcal{I})$, we get, by rough system c-monotonicity, $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. Thus, by stability, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. We conclude that $\mathcal{I}$ is roughly left c-monotone. ∎

We show, next, that the rough complete monotonicity hierarchy collapses to two classes under stability and to a single class under rough systemicity.

Proposition 538 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is stable and roughly system c-monotone, then it is roughly left c-monotone.*

(b) If $\mathcal{I}$ *is stable, then it is roughly family c-monotone if and only if it is roughly right c-monotone.*

Proof:

(a) By Proposition 537.

(b) Suppose that $\mathcal{I}$ is stable. Then, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\Omega(\overleftarrow{T}) = \Omega(T)$, $T \in \mathcal{T}$, and $\Omega(\overleftarrow{T'}) = \Omega(T')$, whence the conditions defining rough family c-monotonicity and rough right c-monotonicity become identical. Therefore, under stability, roughly family and roughly right c-monotone π-institutions coincide.

∎

By Proposition 538, under stability, we get the reduced hierarchy

Rough Family/Right c-Monotonicity

↓

Rough System/Left c-Monotonicity

We also get that rough systemicity causes the further collapse of the entire hierarchy into a single class.

Proposition 539 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. For roughly systemic* π*-institutions, all four rough c-monotonicity classes coincide.*

Proof: Since rough systemicity implies stability, by Proposition 538, it suffices to show that, if $\mathcal{I}$ is roughly system c-monotone and roughly systemic, then it is roughly family c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. By rough systemicity, $\overleftarrow{\widetilde{T}} = \widetilde{T}$, for all $T \in \mathcal{T}$, and $\overleftarrow{\widetilde{T'}} = \widetilde{T'}$. Therefore, $\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}}$. Thus, since $\{\overleftarrow{T} : T \in \mathcal{T}\} \cup \{\overleftarrow{T'}\}$ consists of theory systems, by rough system c-monotonicity, $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. Since rough systemicity implies stability, $\Omega(\overleftarrow{T}) = \Omega(T)$, for all $T \in \mathcal{T}$, and $\Omega(\overleftarrow{T'}) = \Omega(T')$. Thus, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. We conclude that $\mathcal{I}$ is roughly family c-monotone. ■

We present several examples to show that all four rough complete monotonicity classes depicted in the diagram above are different and that the hierarchy is exactly as shown.

The first example gives a roughly left c-monotone π-institution which is not roughly family c-monotone. Thus, it shows that the class of roughly family c-monotone π-institutions is properly contained in the class of roughly system c-monotone π-institutions and that, moreover, the class of roughly left c-monotone π-institutions is not a subclass of the class of roughly family c-monotone π-institutions.

Example 540 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

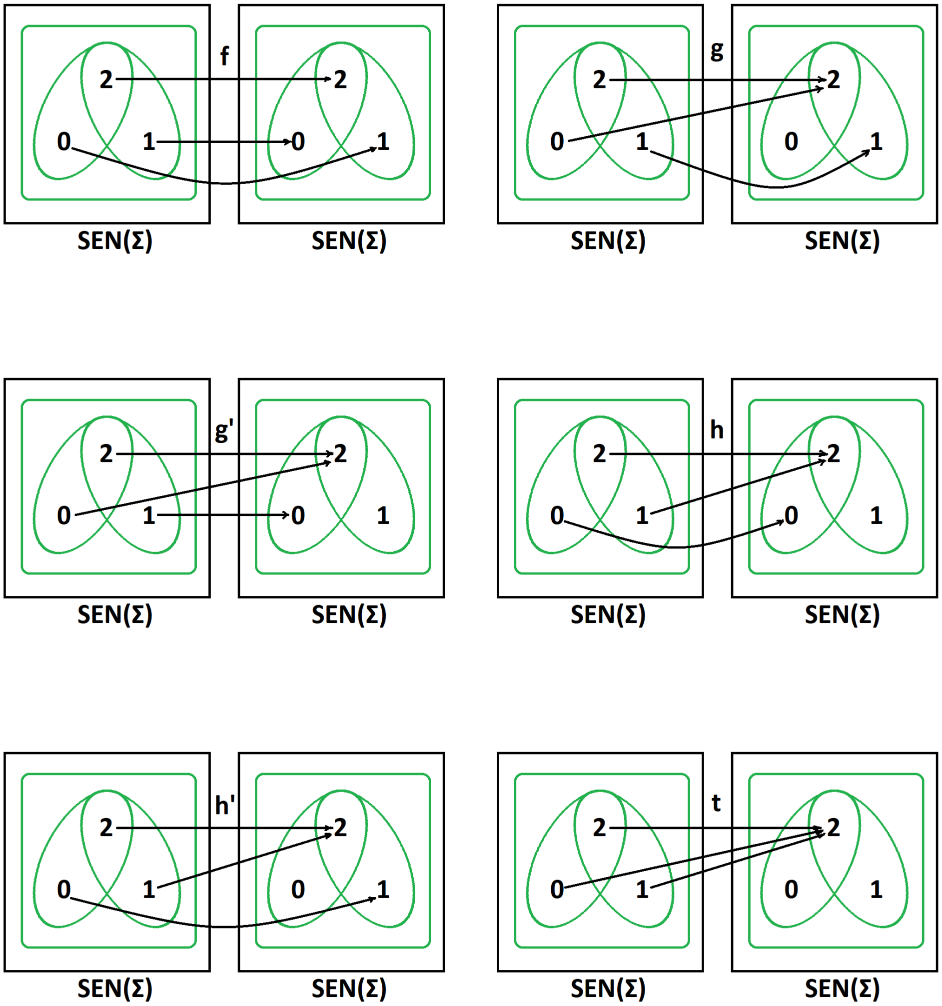
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and six non-identity morphisms* $f, g, g', h, h', t : \Sigma \to \Sigma$*, in which composition is defined by the following table, whose entry in row* k *and column* ℓ *is the result of the composition* $\ell \circ k$*:*

$\circ$	f	g	g'	h	h'	t
f	f	h'	h	g'	g	t
g	g'	g	g'	t	t	t
g'	g	t	t	g'	g	t
h	h'	t	t	h	h'	t
h'	h	h'	h	t	t	t
t	t	t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given, on objects, by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and, on morphisms, by the following table, whose entries in column* k *give the values of the function* $\mathrm{SEN}^\flat(k) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma)$*:*

x	f	g	g'	h	h'	t
0	1	2	2	0	1	2
1	0	1	0	2	2	2
2	2	2	2	2	2	2

- *$N^\flat$ is the trivial clone.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

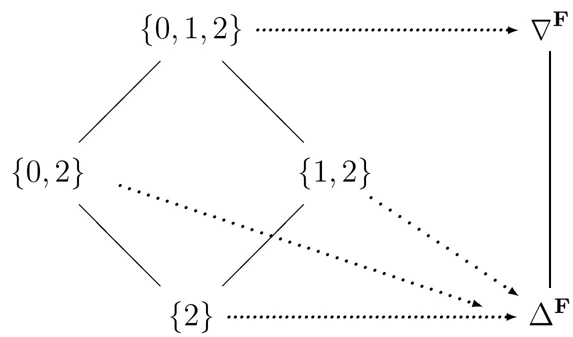
$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

Note that since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on ThFam$(\mathcal{I})$*.*

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{0,2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ has only two theory systems, $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$*, and* $\mathrm{SEN} = \{\{0,1,2\}\}$.

To show that $\mathcal{I}$ is (roughly) left c-monotone, assume that, for some $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$.

- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{0,1,2\}\}$, then $\{\{0,1,2\}\} \in \mathcal{T}$ and, hence,*
$$\Omega(T') \leq \nabla^{\mathbf{F}} = \Omega(\{\{0,1,2\}\}) \leq \bigcup_{T\in\mathcal{T}} \Omega(T);$$
- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{2\}\}$, then $T' \neq \{\{0,1,2\}\}$, whence*
$$\Omega(T') = \Delta^{\mathbf{F}} \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$

Thus, in any case, $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$ and $\mathcal{I}$ is roughly left c-monotone.

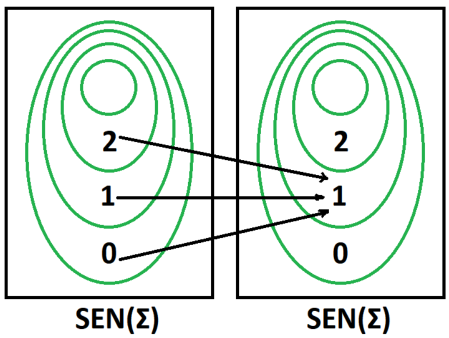
On the other hand, we have
$$\{\{0,1,2\}\} \leq \{\{0,2\}\} \cup \{\{1,2\}\},$$
whereas
$$\Omega(\{\{0,1,2\}\}) = \nabla^{\mathbf{F}} \nleq \Delta^{\mathbf{F}} = \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\}).$$
Therefore, $\mathcal{I}$ is not roughly family c-monotone.

An additional conclusion obtained from Example 540, combined with the statement of Corollary 535, is that the class of roughly left c-monotone π-institutions is not a subclass of the class of roughly right c-monotone π-institutions either, since that inclusion would imply that the former is also a subclass of the class of roughly family c-monotone π-institutions, contradicting Example 540.

The second example shows that there exists a roughly family c-monotone π-institution that is not roughly right c-monotone, thus showing, on the one hand, that the class of roughly right c-monotone π-institutions is properly included in the class of roughly system c-monotone π-institutions and, on the other, that roughly family c-monotone π-institutions do not form a subclass of roughly right c-monotone π-institutions.

Example 541 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = \mathrm{SEN}^\flat(f)(2) = 1$;
- $N^\flat$ *is the clone generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by* $\sigma^\flat_\Sigma(0) = 2$, $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 2$.



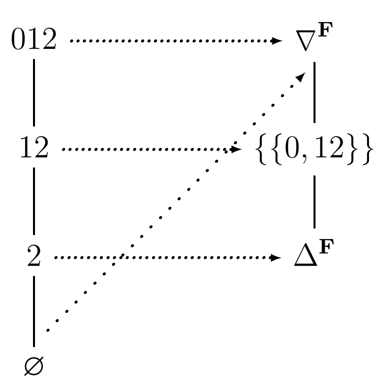
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

There are four theory families, but only three theory systems. The action of $\overleftarrow{\ }$ *on theory families is given in the table below.*

T	$\overleftarrow{T}$
$\{\varnothing\}$	$\{\varnothing\}$
$\{2\}$	$\{\varnothing\}$
$\{12\}$	$\{12\}$
$\{012\}$	$\{012\}$

The lattice of theory families of $\mathcal{I}$ *together with the Leibniz congruence systems are shown in the diagram.*



We show that $\mathcal{I}$ is roughly family c-monotone. To this end, suppose $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T\in\mathcal{T}} \widetilde{T}$.

- *If $\widetilde{T'} = \{012\}$, then we must have $\{\varnothing\} \in \mathcal{T}$ or $\{012\} \in \mathcal{T}$. Hence, we get $\Omega(T') = \nabla^{\mathbf{F}} = \bigcup_{T\in\mathcal{T}} \Omega(T)$;*
- *If $\widetilde{T'} = \{12\}$, then $\mathcal{T}$ must include one of $\{12\}$, $\{\varnothing\}$ or $\{012\}$. Hence, we get $\Omega(T') = \{\{0,12\}\} \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$;*
- *If $\widetilde{T'} = \{2\}$, then $T' = \{2\}$ and, hence, $\Omega(T') = \Delta^{\mathbf{F}} \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$.*

Therefore, $\mathcal{I}$ is indeed roughly family c-monotone.

On the other hand, we have $\widetilde{\{2\}} = \{2\} \leq \{12\} = \widetilde{\{12\}}$, whereas

$$\Omega(\overleftarrow{\{2\}}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}} \nleq \{\{0,12\}\} = \Omega(\{12\}) = \Omega(\overleftarrow{\{12\}}).$$

Therefore, $\mathcal{I}$ is not roughly right c-monotone.

An additional conclusion obtained from Example 541, combined with the statement of Corollary 535, is that the class of roughly family c-monotone π-institutions is not a subclass of the class of roughly left c-monotone π-institutions. Otherwise, by Corollary 535, rough family c-monotonicity would imply rough right c-monotonicity, contradicting Example 541.

The third example shows that there exists a roughly right c-monotone π-institution that is not roughly left c-monotone. It establishes that the class of roughly left c-monotone π-institutions is properly contained in the class of roughly system c-monotone π-institutions and, also, that the class of roughly right c-monotone π-institutions does not form a subclass of the class consisting of the roughly left c-monotone ones.

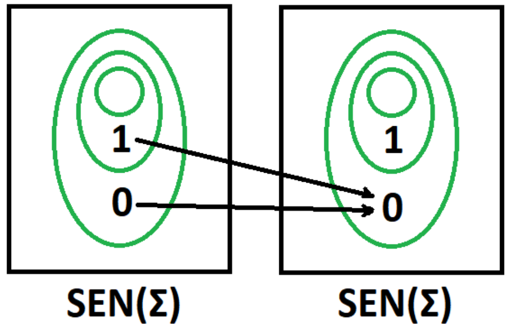
Example 542 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be the algebraic system defined as follows:*

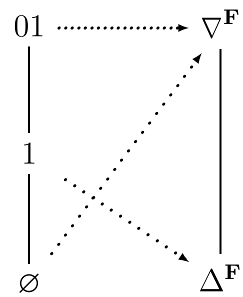
- *$\mathbf{Sign}^\flat$ is the category with the single object Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ and $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;*
- *$N^\flat$ is the trivial clone, consisting of the projections only.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ has three theory families $\varnothing$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\varnothing$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.





We show that $\mathcal{I}$ is roughly right c-monotone. Suppose $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. Since, for all $T \in \mathcal{T}$, we have $\overleftarrow{T} = \{\varnothing\}$ or $\overleftarrow{T} = \{01\}$, we have, trivially,

$$\Omega(\overleftarrow{T'}) \leq \nabla^{\mathbf{F}} = \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T}).$$

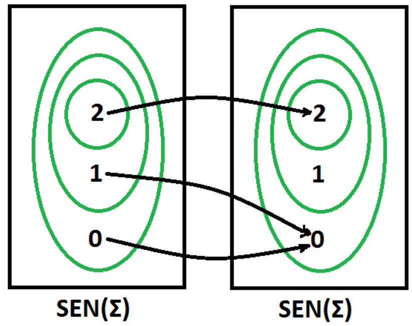
Thus, $\mathcal{I}$ is indeed roughly right monotone.

On the other hand, we have $\widetilde{\overleftarrow{\{\varnothing\}}} = \{01\} = \widetilde{\{\varnothing\}} = \widetilde{\overleftarrow{\{1\}}}$, but $\Omega(\{\varnothing\}) \nleq \Omega(\{1\})$. Therefore, $\mathcal{I}$ is not roughly left c-monotone.

The last example in this series depicts a roughly right c-monotone π-institution, which is not roughly family c-monotone. This shows that the class of roughly right c-monotone π-institutions does not form a subclass of the class of roughly family c-monotone ones.

Example 543 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

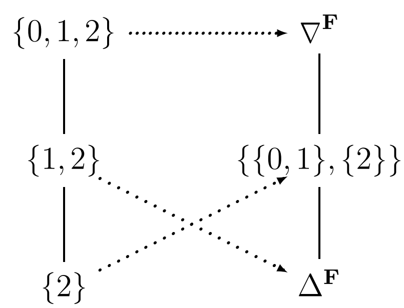


Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$. Since $\mathcal{I}$ has theorems, rough equivalence on ThFam$(\mathcal{I})$ *coincides with the identity relation.*

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



We show that $\mathcal{I}$ is roughly right c-monotone. Suppose $\mathcal{T} \cup \{T'\} \subseteq$ ThFam$(\mathcal{I})$*, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$.*

- *If $T' = \{012\}$, then $T' \in \mathcal{T}$, whence we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$;*
- *If $T' = \{12\}$, then $\{12\} \in \mathcal{T}$ or $\{012\} \in \mathcal{T}$. In either case $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$;*
- *If $T' = \{2\}$, then $\mathcal{T} \neq \varnothing$ and, since $\overleftarrow{\{12\}} = \{2\}$, we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$.*

Therefore, $\mathcal{I}$ is roughly right c-monotone. On the other hand, since $\{2\} \leq \{12\}$, but $\Omega(\{2\}) = \{\{01,2\}\} \nleq \Delta^{\mathbf{F}} = \Omega(\{12\})$, $\mathcal{I}$ is not roughly family c-monotone.

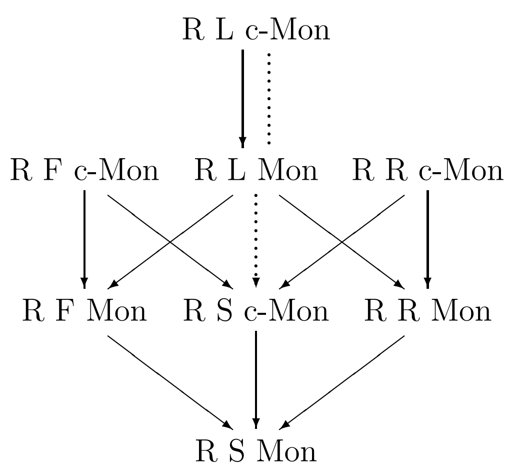
We conclude, after these four examples, that the structure of the rough complete monotonicity hierarchy is exactly as depicted in the diagram and no two classes are identical.

We look, next at the connections between the classes in the rough monotonicity and rough complete monotonicity hierarchies. We have a straightforward

Proposition 544 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is roughly family (respectively, left, right, system) c-monotone, then it is roughly family (respectively, left, right, system) monotone.*

Proof: The condition defining a rough monotonicity class is a special case of the condition defining the respective rough c-monotonicity class, where the collection $\mathcal{T}$, in that definition, is taken to be a singleton. ■

Proposition 544, in view of Propositions 505 and 536, establishes the hierarchy depicted in the diagram (the dotted line and arrow represent jointly a single arrow signifying the inclusion of the class of roughly left c-monotone into the class of roughly system c-monotone π-institutions).



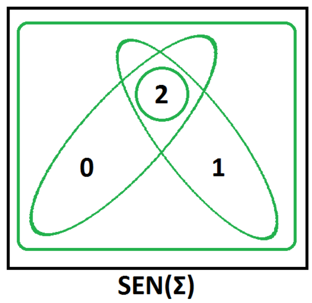
We present an example to show that the two hierarchies are separated. It shows a π-institution, which belongs to all steps of the rough monotonicity hierarchy but to none of the four rough complete monotonicity classes.

Example 545 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*

- *$N^\flat$ is the clone generated by the unary natural transformation $\sigma^\flat$: $\mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$, given by*

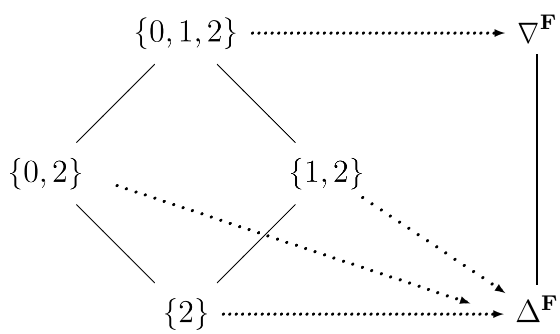
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	1
1	2
2	0



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

It is easy to see that the lattices of theory families and corresponding Leibniz congruence systems are as given in the diagram.



Since $\mathbf{Sign}^\flat$ *is trivial, $\mathcal{I}$ is systemic and, since $\mathcal{I}$ has theorems, rough equivalence is the identity relation on* $\mathrm{FiFam}(\mathcal{I})$. *We conclude that all four rough monotonicity properties for $\mathcal{I}$ coincide and, moreover, they are identical with both monotonicity properties, which they also coincide, due to systemicity. The same holds for c-monotonicity. All four rough c-monotonicity properties coincide and they, in turn, are identical with all c-monotonicity conditions.*

From the diagram one can verify immediately that $\mathcal{I}$ is (roughly left, right and family) monotone, On the other hand, we have $\{\{0,1,2\}\} \le \{\{0,2\}\} \cup \{\{1,2\}\}$, but, obviously, $\Omega(\{\{0,1,2\}\}) \nleq \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\})$. Taking into account that $\mathcal{I}$ is systemic, we conclude that $\mathcal{I}$ fails to be roughly system c-monotone.

We turn, next, our attention to the relations between the classes in the rough c-monotonicity hierarchy and those in the c-monotonicity hierarchy. We start by showing that possessing any type of c-monotonicity forces a π-institution to either have theorems or, else, to have only one theory system rough equivalence class.

Proposition 546 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is left c-monotone without theorems, then* $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| = 1$*.*

(b) If $\mathcal{I}$ *is system c-monotone without theorems, then* $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| = 1$*.*

Proof:

(a) Suppose that $\mathcal{I}$ is left c-monotone and does not have theorems. If $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| > 1$, then there exists $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T} \neq \mathrm{SEN}^\flat$. Thus, we get

$$\overleftarrow{\overline{\varnothing}} = \overline{\varnothing} \leq \overleftarrow{T} \quad \text{and} \quad \Omega(\overline{\varnothing}) \nleq \Omega(T).$$

Therefore, $\mathcal{I}$ is not left c-monotone, a contradiction. Thus, we must have $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| = 1$, as claimed.

(b) Suppose that $\mathcal{I}$ is system c-monotone and does not have theorems. If $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| > 1$, then there exists $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T} \neq \mathrm{SEN}^\flat$. Thus, we get

$$\overline{\varnothing} < T \quad \text{and} \quad \Omega(\overline{\varnothing}) \nleq \Omega(T).$$

Therefore, $\mathcal{I}$ is not system c-monotone, a contradiction. Thus, we must have $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| = 1$, as claimed.

■

We can establish the following relations between c-monotonicity and rough c-monotonicity classes.

Proposition 547 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is left c-monotone, then it is roughly left c-monotone;*

(b) If $\mathcal{I}$ *is family c-monotone, then it is roughly family c-monotone;*

(c) If $\mathcal{I}$ *is right c-monotone, then it is roughly right c-monotone;*

(d) If $\mathcal{I}$ *is system c-monotone, then it is roughly system c-monotone.*

Proof:

(a) Suppose that $\mathcal{I}$ is left c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\overleftarrow{\overleftarrow{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\overleftarrow{T}}$. If $\mathcal{I}$ has theorems, then $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$, for all $T \in \mathcal{T}$, and $\overleftarrow{\overleftarrow{T'}} = \overleftarrow{T'}$, whence $\overleftarrow{T'} \leq \bigcup_{t \in \mathcal{T}} \overleftarrow{T}$. Thus, by left c-monotonicity, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. On the other hand, if $\mathcal{I}$ does not have theorems, then, by Proposition 546, $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| = 1$, whence, by Theorem 370, $\Omega(T') = \bigcup_{T \in \mathcal{T}} \Omega(T)$.

(b) Suppose that $\mathcal{I}$ is family c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. If $\mathcal{I}$ has theorems, then we get $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Thus, $T' \leq \bigcup_{T \in \mathcal{T}} T$. By family c-monotonicity, we now get $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. On the other hand, if $\mathcal{I}$ does not have theorems, then, by Propositions 186 and 546, $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| = 1$, whence, by Theorem 370, $\Omega(T') = \bigcup_{T \in \mathcal{T}} \Omega(T)$.

(c) Suppose that $\mathcal{I}$ is right c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. If $\mathcal{I}$ has theorems, then we get $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Thus, $T' \leq \bigcup_{T \in \mathcal{T}} T$. By right c-monotonicity, we now get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$. On the other hand, if $\mathcal{I}$ does not have theorems, then, by Propositions 187 and 546, $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| = 1$, whence, by Theorem 370, $\Omega(\overleftarrow{T'}) = \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$.

(d) Suppose that $\mathcal{I}$ is system c-monotone. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. If $\mathcal{I}$ has theorems, then we get $\widetilde{T} = T$, for all $T \in \mathcal{T}$, and $\widetilde{T'} = T'$. Thus, $T' \leq \bigcup_{T \in \mathcal{T}} T$. By system c-monotonicity, we now get $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. On the other hand, if $\mathcal{I}$ does not have theorems, then, by Proposition 546, $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| = 1$, whence, by Theorem 370, $\Omega(T') = \bigcup_{T \in \mathcal{T}} \Omega(T)$.

■

We can now prove the following additional, and more precise, relations.

Theorem 548 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a non-almost inconsistent* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family (left, respectively) c-monotone if and only if it is roughly family (left, respectively) c-monotone and has theorems.*

Proof: Suppose $\mathcal{I}$ is family or left c-monotone. Since, by hypothesis, it is not almost inconsistent, $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| > 1$. Thus, by Proposition 546, $\mathcal{I}$ has theorems. Moreover, by Theorem 547, it is roughly family or left c-monotone, respectively.

Assume, conversely, that $\mathcal{I}$ is roughly family (or left c-monotone) and has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$ (or $\overleftarrow{T'} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$, respectively). Since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$, whence, we get $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ (or $\overleftarrow{\overleftarrow{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\overleftarrow{T}}$). Using rough family (or left, respectively) c-monotonicity, we obtain $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. Therefore, $\mathcal{I}$ is family (or left) c-monotone. ■

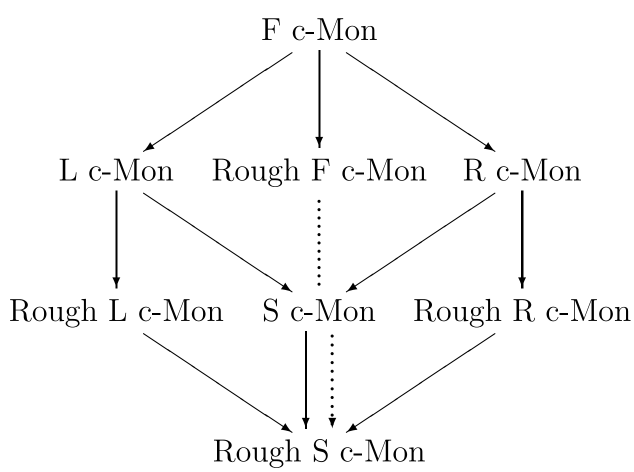
Analogously, for the cases of system and right c-monotonicity, we get the following

Theorem 549 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, that has a theory family* $T \neq \mathrm{SEN}^\flat$ *such that* $\overleftarrow{T} \neq \overline{\varnothing}$*.* $\mathcal{I}$ *is system (right, respectively) c-monotone if and only if it roughly system (right, respectively) c-monotone and has theorems.*

Proof: Suppose $\mathcal{I}$ is system or right c-monotone. Since, by hypothesis, it has a theory system $\overleftarrow{T} \neq \mathrm{SEN}^\flat, \overline{\varnothing}$, we get $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| > 1$. Thus, by Proposition 546, $\mathcal{I}$ must have theorems. Moreover, by Theorem 547, it is roughly system or right c-monotone, respectively.

Assume, conversely, that $\mathcal{I}$ is roughly system (or right) c-monotone and has theorems. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}(\mathcal{I})$ (or $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, respectively), such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. Since $\mathcal{I}$ has theorems, rough equivalence coincides with the identity relation on $\mathrm{ThFam}(\mathcal{I})$, whence, we get $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. By rough system (or right, respectively) c-monotonicity, we obtain $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$ (or $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$, respectively). Therefore, $\mathcal{I}$ is system (or right) c-monotone. ∎

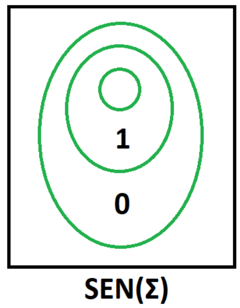
The preceding propositions allow us to draw the following hierarchical diagram concerning the complete monotonicity and the rough complete monotonicity classes.



To see that the rough c-monotonicity classes are separated from the c-monotonicity classes, we give an example. A π-institution is presented which belongs to all four rough c-monotonicity classes, but fails to be system c-monotone and, therefore, belongs to none of the four c-monotonicity classes. The secret lies, of course, in the absence of theorems.

Example 550 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*;*
- $N^\flat$ *is the trivial clone.*

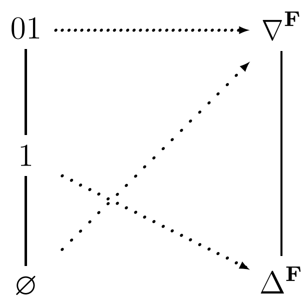


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ *has three theory families* $\{\varnothing\}$ *and* $\{\{1\}\}$ *and* $\{\{0, 1\}\}$*, all of which are theory systems.*

The lattice of theory families of $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



$\mathcal{I}$ *belongs to all four classes of the rough c-monotonicity hierarchy. Indeed, since it is systemic, all four rough monotonicity conditions boil down to checking that, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$*,* $\widetilde{T'} \le \bigcup_{T \in \mathcal{T}} \widetilde{T}$ *implies* $\Omega(T') \le \bigcup_{T \in \mathcal{T}} \Omega(T)$*.*

- *If* $\bigcup_{T \in \mathcal{T}} \widetilde{T} = \{01\}$*, then* $\mathcal{T}$ *must include* $\{\varnothing\}$ *or* $\{01\}$*, whence* $\Omega(T') \le \nabla^{\mathbf{F}} = \bigcup_{T \in \mathcal{T}} \Omega(T)$*;*
- *If* $\bigcup_{T \in \mathcal{T}} \widetilde{T} = \{1\}$*, then* $\widetilde{T'} = \{1\}$ *and, hence,* $\mathcal{T} = \{\{1\}\}$ *and* $T' = \{1\}$*. Thus, the implication holds trivially.*

Since $\bigcup_{T \in \mathcal{T}} \widetilde{T} = \{\varnothing\}$ *cannot occur, we get that* $\mathcal{I}$ *is roughly family c-monotone.*

On the other hand, we have $\{\varnothing\} \le \{1\}$*, whereas* $\Omega(\{\varnothing\}) \nleq \Omega(\{1\})$*, whence* $\mathcal{I}$ *is not system c-monotone.*

Next, we turn to transfer theorems for the rough c-monotonicity classes.

Theorem 551 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is roughly family c-monotone if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$;

(b) $\mathcal{I}$ *is roughly left c-monotone if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}}$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$;

(c) $\mathcal{I}$ *is roughly right c-monotone if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ *implies* $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})$;

(d) $\mathcal{I}$ *is roughly system c-monotone if and only if, for all* $\mathbf{F}$*-algebraic systems* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ *and all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$ *implies* $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

Proof:

(a) The "if" results by applying the hypothesis to the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$.

For the "only if", suppose that $\mathcal{I}$ is roughly family c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. Then we get $\alpha^{-1}(\widetilde{T'}) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \widetilde{T})$, whence $\alpha^{-1}(\widetilde{T'}) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\widetilde{T})$. Thus, by Theorem 377, $\widetilde{\alpha^{-1}(T')} \leq \bigcup_{T \in \mathcal{T}} \widetilde{\alpha^{-1}(T)}$. Since, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by rough family c-monotonicity, $\Omega(\alpha^{-1}(T')) \leq \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T))$. Hence, by Proposition 24, we get $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

(b) The "if" is obtained as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly left c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}}$. Then we get $\alpha^{-1}(\overleftarrow{\widetilde{T'}}) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}})$, whence $\alpha^{-1}(\overleftarrow{\widetilde{T'}}) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\overleftarrow{\widetilde{T}})$. Thus, by Theorem 377, $\widetilde{\alpha^{-1}(\overleftarrow{T'})} \leq \bigcup_{T \in \mathcal{T}} \widetilde{\alpha^{-1}(\overleftarrow{T})}$. Hence, by Lemma 6, we get $\overleftarrow{\widetilde{\alpha^{-1}(T')}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{\alpha^{-1}(T)}}$. Since, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by rough left c-monotonicity, $\Omega(\alpha^{-1}(T')) \leq \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T))$. Hence, by Proposition 24, we get $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq$

$\alpha^{-1}(\bigcup_{T\in\mathcal{T}}\Omega^{\mathcal{A}}(T))$. Taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T\in\mathcal{T}}\Omega^{\mathcal{A}}(T)$.

(c) The "if" is obtained as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is roughly right c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T}\cup\{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\widetilde{T'} \leq \bigcup_{T\in\mathcal{T}}\widetilde{T}$. Then we get $\alpha^{-1}(\widetilde{T'}) \leq \alpha^{-1}(\bigcup_{T\in\mathcal{T}}\widetilde{T})$, whence $\alpha^{-1}(\widetilde{T'}) \leq \bigcup_{T\in\mathcal{T}}\alpha^{-1}(\widetilde{T})$. Thus, by Theorem 377, $\widetilde{\alpha^{-1}(T')} \leq \bigcup_{T\in\mathcal{T}}\widetilde{\alpha^{-1}(T)}$. Since, by Lemma 51, $\{\alpha^{-1}(T) : T \in \mathcal{T}\}\cup\{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}(\mathcal{I})$, we get, by rough right c-monotonicity, $\Omega(\overleftarrow{\alpha^{-1}(T')}) \leq \bigcup_{T\in\mathcal{T}}\Omega(\overleftarrow{\alpha^{-1}(T)})$. Thus, by Lemma 6, $\Omega(\alpha^{-1}(\overleftarrow{T'})) \leq \bigcup_{T\in\mathcal{T}}\Omega(\alpha^{-1}(\overleftarrow{T}))$. Hence, by Proposition 24, we get $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \leq \bigcup_{T\in\mathcal{T}}\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T}))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \leq \alpha^{-1}(\bigcup_{T\in\mathcal{T}}\Omega^{\mathcal{A}}(\overleftarrow{T}))$. Taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}}\Omega^{\mathcal{A}}(\overleftarrow{T})$.

(d) Similar to Part (a).

■

We close this section by giving two characterizations concerning the rough family and rough system c-monotonicity classes, based on mappings between posets satisfying the complete monotonicity property.

Proposition 552 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly family c-monotone;*

(b) $\Omega : \widetilde{\mathbf{ThFam}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is completely monotone;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiFam}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

Proposition 553 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. The following statements are equivalent:*

(a) $\mathcal{I}$ *is roughly system c-monotone;*

(b) $\Omega : \widetilde{\mathbf{ThSys}}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is completely monotone;*

(c) $\Omega^{\mathcal{A}} : \widetilde{\mathbf{FiSys}}^{\mathcal{I}}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$*.*

7.6 Narrow Complete Monotonicity

In this section we revisit classes of π-institutions defined using complete monotonicity properties of the Leibniz operator. However, complete monotonicity is only applied on theory systems/families all of whose components are nonempty.

Definition 554 (Narrow c-Monotonicity) *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is called* **narrowly family completely monotone**, *or* **narrowly family c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$,
$$T' \leq \bigcup_{T \in \mathcal{T}} T \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is called* **narrowly left completely monotone**, *or* **narrowly left c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$,
$$\overleftarrow{T'} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{T} \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$
- $\mathcal{I}$ *is called* **narrowly right completely monotone**, *or* **narrowly right c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$,
$$T' \leq \bigcup_{T \in \mathcal{T}} T \quad \textit{implies} \quad \Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T}).$$
- $\mathcal{I}$ *is called* **narrowly system completely monotone**, *or* **narrowly system c-monotone** *for short, if, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\lightning}(\mathcal{I})$,
$$T' \leq \bigcup_{T \in \mathcal{T}} T \quad \textit{implies} \quad \Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T).$$

We establish a narrow complete monotonicity hierarchy analogous to the one obtained in Proposition 536 for rough complete monotonicity.

Proposition 555 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

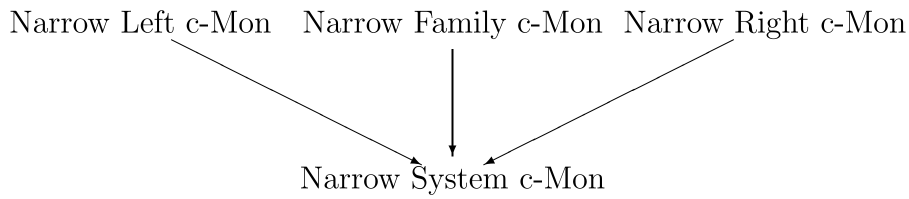
(a) If $\mathcal{I}$ *is narrowly left c-monotone, then it is narrowly system c-monotone;*

(b) If $\mathcal{I}$ *is narrowly family c-monotone, then it is narrowly system c-monotone;*

(c) If $\mathcal{I}$ *is narrowly right c-monotone, then it is narrowly system c-monotone.*

Proof: We sketch a proof that works for all three cases. Suppose that $\mathcal{I}$ is narrowly left (family or right) c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^\natural(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. Since $\mathcal{T} \cup \{T'\}$ consists of theory systems, we have $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$. Thus, by hypothesis, $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$. Now we apply narrow left (narrow family or narrow right) c-monotonicity to get $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$ ($\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$ or $\Omega(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$). However, in all three cases, we conclude that $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$. Therefore, $\mathcal{I}$ is narrowly system c-monotone. ■

We have now established the following **narrow c-monotonicity hierarchy** of π-institutions.



We may establish some additional relationships between those classes once various types of stability and monotonicity are allowed into the mix. First, we show that narrow left c-monotonicity implies exclusive stability and that, under narrow stability, narrow family c-monotonicity and narrow right c-monotonicity coincide.

Proposition 556 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is narrowly left c-monotone, then it is exclusively stable.

(b) If $\mathcal{I}$ is narrowly stable, then it is narrowly family c-monotone if and only if it is narrowly right c-monotone.

Proof:

(a) Suppose $\mathcal{I}$ is narrowly left c-monotone. Let $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, such that $\overleftarrow{T} \in \mathrm{ThSys}^\natural(\mathcal{I})$. Then, since $\overleftarrow{\overleftarrow{T}} = \overleftarrow{T}$, we get, by applying narrow left c-monotonicity, $\Omega(\overleftarrow{T}) = \Omega(T)$. Thus, $\mathcal{I}$ is exclusively stable.

(b) Suppose $\mathcal{I}$ is narrowly stable. Then, for all $T \in \mathrm{ThFam}^\natural(\mathcal{I})$, we have $\Omega(\overleftarrow{T}) = \Omega(T)$. Thus, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^\natural(\mathcal{I})$, the condition $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$ is equivalent to the condition $\Omega(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$. Therefore, the condition defining narrow family c-monotonicity is identical to that defining narrow right c-monotonicity.

■

Finally, under narrow systemicity, all four narrow complete monotonicity classes collapse into a single class.

Proposition 557 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is narrowly systemic and narrowly system c-monotone, then it has all four narrow c-monotonicity properties.*

Proof: Suppose that $\mathcal{I}$ is narrowly systemic and narrowly system c-monotone.

- Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$, such that $\overleftarrow{T'} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$. By narrow systemicity, $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$, whence $T' \leq \bigcup_{T \in \mathcal{T}} T$ and, moreover, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$. Thus, by narrow system c-monotonicity, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. This proves that $\mathcal{I}$ is narrowly left c-monotone.

- Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. By narrow systemicity, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$. Thus, by narrow system c-monotonicity, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. This proves that $\mathcal{I}$ is narrowly family c-monotone.

- Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. By narrow systemicity, $\overleftarrow{T} = T$, for all $T \in \mathcal{T}$, and $\overleftarrow{T'} = T'$, and, thus, $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^{\nleq}(\mathcal{I})$. Thus, by narrow system c-monotonicity, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. But, then, we get $\Omega(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{T})$, whence $\mathcal{I}$ is also narrowly right c-monotone. ■

We reuse some examples to show that all four rough complete monotonicity classes depicted in the diagram above are different and that no inclusions hold among the three top classes.

The first example gives a narrowly left c-monotone π-institution which is neither narrowly family nor narrowly right c-monotone. Thus, it shows that the classes of narrowly family and of narrowly right c-monotone π-institutions are properly contained in the class of narrowly system c-monotone π-institutions and that, moreover, the class of narrowly left c-monotone π-institutions is not a subclass of either the class of narrowly family or the class of narrowly right c-monotone π-institutions.

Example 558 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

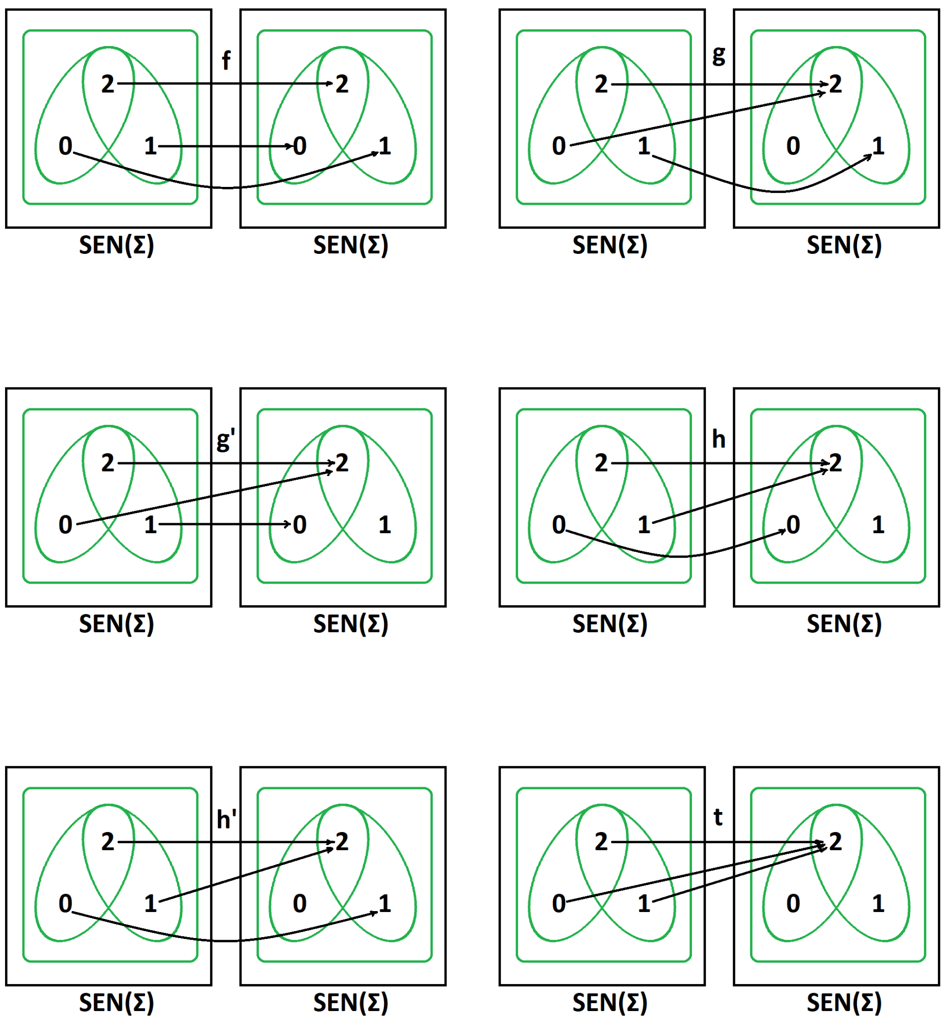
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and six non-identity morphisms* $f, g, g', h, h', t : \Sigma \to \Sigma$, *in which composition is defined by the following table, whose entry in row* k *and column* ℓ *is the result of the composition* $\ell \circ k$:

$\circ$	f	g	g'	h	h'	t
f	f	h'	h	g'	g	t
g	g'	g	g'	t	t	t
g'	g	t	t	g'	g	t
h	h'	t	t	h	h'	t
h'	h	h'	h	t	t	t
t	t	t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given, on objects, by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and, on morphisms, by the following table, whose entries in column* k *give the values of the function* $\mathrm{SEN}^\flat(k) : \mathrm{SEN}^\flat(\Sigma) \to \mathrm{SEN}^\flat(\Sigma)$*:*

x	f	g	g'	h	h'	t
0	1	2	2	0	1	2
1	0	1	0	2	2	2
2	2	2	2	2	2	2

- $N^\flat$ *is the trivial clone.*



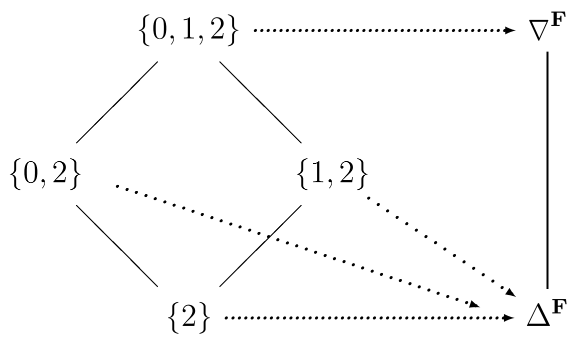
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{0,2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ *has only two theory systems,* $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$, *and* $\mathrm{SEN} = \{\{0,1,2\}\}$.

Since $\mathcal{I}$ has theorems, narrow left c-monotonicity coincides with left c-monotonicity. To show that $\mathcal{I}$ is left c-monotone, assume that, for some $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T'} \leq \bigcup_{T\in\mathcal{T}} \overleftarrow{T}$.

- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{0,1,2\}\}$, then $\{\{0,1,2\}\} \in \mathcal{T}$ and, hence,*

$$\Omega(T') \leq \nabla^{\mathbf{F}} = \Omega(\{\{0,1,2\}\}) \leq \bigcup_{T\in\mathcal{T}} \Omega(T);$$

- *If $\bigcup_{T\in\mathcal{T}} \overleftarrow{T} = \{\{2\}\}$, then $T' \neq \{\{0,1,2\}\}$, whence*

$$\Omega(T') = \Delta^{\mathbf{F}} \leq \bigcup_{T\in\mathcal{T}} \Omega(T).$$

Thus, in any case, $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$ and $\mathcal{I}$ is left completely monotone.

On the other hand, we have

$$\{\{0,1,2\}\} \leq \{\{0,2\}\} \cup \{\{1,2\}\},$$

whereas

$$\begin{aligned} \Omega(\overleftarrow{\{\{0,1,2\}\}}) &= \Omega(\{\{0,1,2\}\}) = \nabla^{\mathbf{F}} \\ &\nleq \Delta^{\mathbf{F}} \\ &= \Omega(\{\{2\}\}) \cup \Omega(\{\{2\}\}) \\ &= \Omega(\overleftarrow{\{\{0,2\}\}}) \cup \Omega(\overleftarrow{\{\{1,2\}\}}). \end{aligned}$$

Therefore, $\mathcal{I}$ is not (narrowly) right c-monotone. Using the same theory families, we also get $\{\{0,1,2\}\} \leq \{\{0,2\}\} \cup \{\{1,2\}\}$, whereas $\Omega(\{\{0,1,2\}\}) = \nabla^{\mathbf{F}} \nleq \Delta^{\mathbf{F}} = \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\})$, whence $\mathcal{I}$ is not (narrowly) family c-monotone either.

The second example shows that there exists a narrowly family c-monotone π-institution that is not narrowly right c-monotone, thus showing that narrowly family c-monotone π-institutions do not form a subclass of the class of narrowly right c-monotone π-institutions.

Example 559 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with the single object Σ and four non-identity morphisms $f, g, o, t : \Sigma \to \Sigma$, whose composition table is the following:*

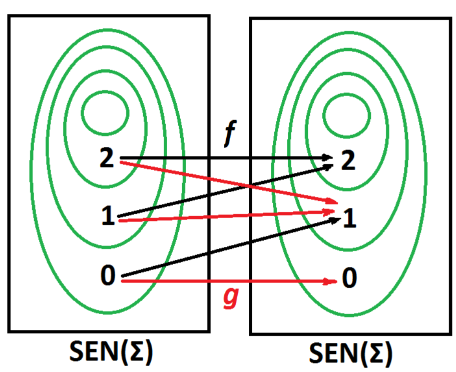
$\circ$	f	g	o	t
f	t	f	t	t
g	o	g	o	o
o	o	o	o	o
t	t	t	t	t

- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, with*

$$\begin{array}{lll} \mathrm{SEN}^\flat(f)(0) = 1, & \mathrm{SEN}^\flat(f)(1) = 2, & \mathrm{SEN}^\flat(f)(2) = 2; \\ \mathrm{SEN}^\flat(g)(0) = 0, & \mathrm{SEN}^\flat(g)(1) = 1, & \mathrm{SEN}^\flat(g)(2) = 1, \end{array}$$

  whereas $\mathrm{SEN}^\flat(o)(x) = 1$ and $\mathrm{SEN}^\flat(t)(x) = 2$, for all $x \in \mathrm{SEN}^\flat(\Sigma)$;

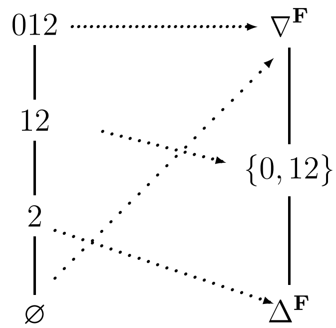
- *$N^\flat$ is the trivial clone, consisting of the projections only.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has four theory families $\varnothing$, $\{\{2\}\}$, $\{\{1,2\}\}$ and $\{\{0,1,2\}\}$, but only three theory systems, $\varnothing$, $\{\{1,2\}\}$ and $\{\{0,1,2\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



Since, as shown in the diagram, $\Omega : \mathrm{ThFam}^{\nleq}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an order isomorphism, $\mathcal{I}$ is narrowly family c-monotone.

On the other hand, for $T = \{\{2\}\}$ and $T' = \{\{1,2\}\}$, we get $T \le T'$, whereas $\Omega(\overleftarrow{T}) = \Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} \nleq \{0,12\} = \Omega(T') = \Omega(\overleftarrow{T'})$. Therefore, $\mathcal{I}$ is not narrowly right c-monotone.

The third example gives a narrowly right c-monotone π-institution which is neither narrowly family nor narrowly left c-monotone. Thus, it shows that the classes of narrowly family and of narrowly left c-monotone π-institutions are properly contained in the class of narrowly system c-monotone π-institutions and that, moreover, the class of narrowly right c-monotone π-institutions is not a subclass of either the class of narrowly family or the class of narrowly left c-monotone π-institutions.

Example 560 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

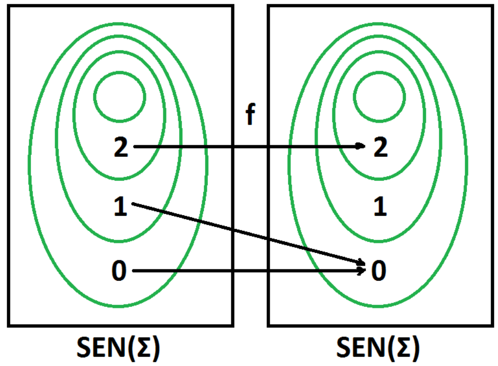
- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a unique (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(f)(0) = \mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial clone.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

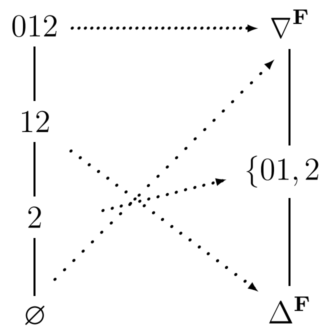
$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ has four theory families, but only three theory systems, namely $\overline{\varnothing}$, $\{\{2\}\}$ and $\{\{0,1,2\}\}$. Moreover, clearly,

$$\mathrm{ThFam}^{\nleq}(\mathcal{I}) = \{\{\{2\}\}, \{\{1,2\}\}, \{\{0,1,2\}\}\}.$$



The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



To see that $\mathcal{I}$ is narrowly right c-monotone, suppose $\mathcal{T}\cup\{T'\}\subseteq \mathrm{ThFam}^{\natural}(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. Then,

- *if $T' = \{\{0,1,2\}\}$, we must have $\{\{0,1,2\}\} \in \mathcal{T}$, whence $\Omega(\overleftarrow{T'}) = \nabla^{\mathbf{F}} = \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$;*
- *if $T' \neq \{\{0,1,2\}\}$, then $\Omega(\overleftarrow{T'}) \leq \{\{01,2\}\} \leq \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$.*

Therefore, $\mathcal{I}$ is narrowly right c-monotone.

On the other hand, for $T = \{\{2\}\}$ and $T' = \{\{1,2\}\}$, we get $T \leq T'$, whereas $\Omega(T) = \{01,2\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$. Thus, $\mathcal{I}$ is not narrowly family c-monotone. Moreover, for the same theory families, $\overleftarrow{T} = \{\{2\}\} = \overleftarrow{T'}$, whereas $\Omega(T) = \{01,2\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$. Thus, $\mathcal{I}$ is not narrowly left c-monotone.

The last example shows that there exists a narrowly family c-monotone π-institution that is not narrowly left c-monotone, thus showing that narrowly family c-monotone π-institutions do not form a subclass of the class of narrowly left c-monotone ones.

Example 561 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and four non-identity morphisms* $f, z, o, t : \Sigma \to \Sigma$, *whose composition table is the following:*

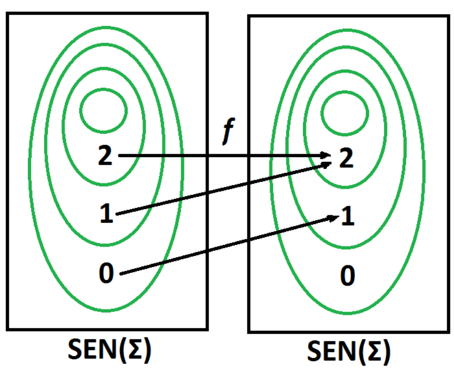
$\circ$	f	z	o	t
f	t	o	t	t
z	z	z	z	z
o	o	o	o	o
t	t	t	t	t

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, *with*

$$\mathrm{SEN}^\flat(f)(0) = 1, \quad \mathrm{SEN}^\flat(f)(1) = 2, \quad \mathrm{SEN}^\flat(f)(2) = 2,$$

whereas $\mathrm{SEN}^\flat(z)(x) = 0$, $\mathrm{SEN}^\flat(o)(x) = 1$ *and* $\mathrm{SEN}^\flat(t)(x) = 2$, *for all* $x \in \mathrm{SEN}^\flat(\Sigma)$;

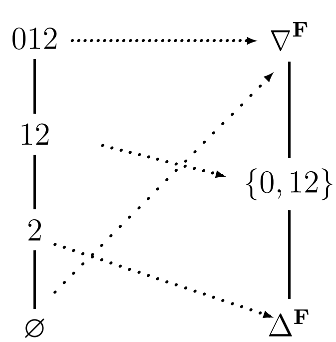
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{2\}, \{1,2\}, \{0,1,2\}\}.$$

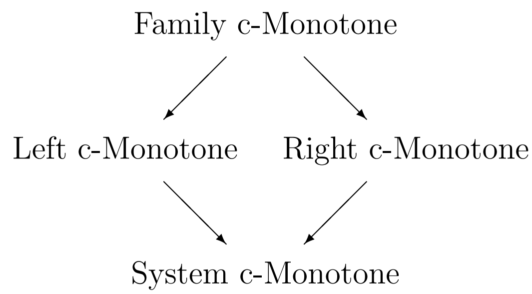
$\mathcal{I}$ *has four theory families* $\varnothing$, $\{\{2\}\}$, $\{\{1,2\}\}$ *and* $\{\{0,1,2\}\}$, *but only two theory systems,* $\varnothing$ *and* $\{\{0,1,2\}\}$. *The lattice of theory families of* $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



Since $\Omega : \mathrm{ThFam}^{\lightning}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is an order isomorphism,* $\mathcal{I}$ *is narrowly family c-monotone. On the other hand, for* $T = \{\{1,2\}\}$ *and* $T' = \{\{2\}\}$*, we get* $\overleftarrow{T} = \overline{\varnothing} = \overleftarrow{T'}$*, whereas* $\Omega(T) = \{0,12\} \nleq \Delta^{\mathbf{F}} = \Omega(T')$*. Therefore,* $\mathcal{I}$ *is not narrowly left c-monotone.*

We conclude, after these examples, that the structure of the narrow complete monotonicity hierarchy is, in fact, exactly as depicted in the diagram and no two classes are identical.

Recall from Chapter 3 that we have the following complete monotonicity hierarchy of π-institutions.



We establish now a combined c-monotonicity and narrow c-monotonicity hierarchy. It is not difficult to see that a c-monotonicity property implies the corresponding narrow c-monotonicity property. Alternatively, these relations can be derived by the relationships governing rough and narrow c-monotonicity classes, on the one hand, and the ones governing rough c-monotonicity and c-monotonicity classes on the other.

Proposition 562 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is family (left, right, system, respectively) c-monotone, then it is narrowly family (narrowly left, narrow right, narrowly system, respectively) c-monotone.*

Proof: If $\mathcal{I}$ has a certain type of c-monotonicity, then it has, a fortiori, the same type of narrow c-monotonicity, since the condition defining the latter is a specialization of that defining the former, in which $\mathcal{T} \cup \{T'\}$ are only allowed to range over theory families or systems, as the case may be, in $\mathrm{ThFam}^{\lightning}(\mathcal{I})$ or $\mathrm{ThSys}^{\lightning}(\mathcal{I})$, respectively. (An alternative way is to combine Proposition 547 with Theorem 566 that follows.) ■

Analogously to Theorems 548 and 549, we also get more precise relationships between c-monotonicity and narrow c-monotonicity classes.

Theorem 563 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a non-almost inconsistent* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is family (left, respectively) c-monotone if and only if it is narrowly family (left, respectively) c-monotone and has theorems.*

Proof: Suppose $\mathcal{I}$ is family or left c-monotone. Since, by hypothesis, it is not almost inconsistent, $|\widetilde{\mathrm{ThFam}}(\mathcal{I})| > 1$. Thus, by Proposition 546, $\mathcal{I}$ has theorems. Moreover, by Proposition 562, it is narrowly family or left c-monotone, respectively.

Assume, conversely, that $\mathcal{I}$ is narrowly family (or left c-monotone) and has theorems. Then, since $\mathrm{ThFam}^{\natural}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$, the condition defining narrow family (left) c-monotonicity coincides with the one defining family (left, respectively) c-monotonicity. ∎

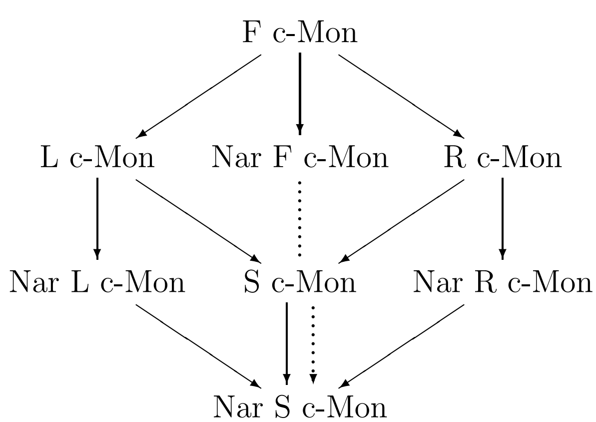
Analogously, for the cases of system and right c-monotonicity, we get the following

Theorem 564 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*, that has a theory family* $T \neq \mathrm{SEN}^\flat$ *such that* $\overleftarrow{T} \neq \overline{\varnothing}$*.* $\mathcal{I}$ *is system (right, respectively) c-monotone if and only if it roughly system (right, respectively) c-monotone and has theorems.*

Proof: Suppose $\mathcal{I}$ is system or right c-monotone. Since, by hypothesis, it has a theory system $\overleftarrow{T} \neq \mathrm{SEN}^\flat, \overline{\varnothing}$, we get $|\widetilde{\mathrm{ThSys}}(\mathcal{I})| > 1$. Thus, by Proposition 546, $\mathcal{I}$ must have theorems. Moreover, by Proposition 562, it is narrowly system or right c-monotone, respectively.

Assume, conversely, that $\mathcal{I}$ is narrowly system (or right) c-monotone and has theorems. Then, since $\mathrm{ThFam}^{\natural}(\mathcal{I}) = \mathrm{ThFam}(\mathcal{I})$ and $\mathrm{ThSys}^{\natural}(\mathcal{I}) = \mathrm{ThSys}(\mathcal{I})$, the condition defining narrow right (system) c-monotonicity coincides with the one defining right (system, respectively) c-monotonicity. ∎

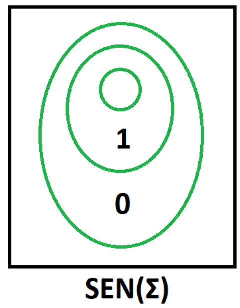
Thus, we have the following mixed hierarchy of c-monotonicity and narrow c-monotonicity properties.



We provide an example of a π-institution which has all four types of narrow c-monotonicity but fails to be system c-monotone and, as a consequence, does not belong to any of the four c-monotonicity classes.

Example 565 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with the single object* Σ;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$;
- $N^\flat$ *is the trivial clone.*

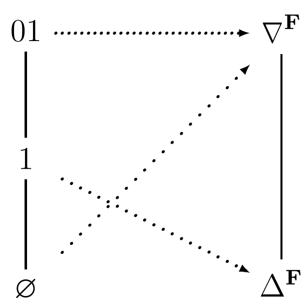


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ *has three theory families* $\{\varnothing\}$ *and* $\{\{1\}\}$ *and* $\{\{0,1\}\}$, *all of which are theory systems.*

The lattice of theory families of $\mathcal{I}$ *and the corresponding Leibniz congruence systems are given in the diagram.*



$\mathcal{I}$ *belongs to all four classes of the narrow c-monotonicity hierarchy. Indeed, since it is systemic, all four narrow c-monotonicity conditions boil down to checking that, for all* $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^\sharp(\mathcal{I})$, $T' \le \bigcup_{T\in\mathcal{T}} T$ *implies* $\Omega(T') \le \bigcup_{T\in\mathcal{T}} \Omega(T)$.

- *If* $T' = \{\{1\}\}$, *then* $\Omega(T') = \Delta^{\mathbf{F}} \le \bigcup_{T\in\mathcal{T}} \Omega(T)$;
- *If* $T' = \mathrm{SEN}^\flat$, *then* $\mathrm{SEN}^\flat \in \mathcal{T}$, *whence* $\Omega(T') \le \nabla^{\mathbf{F}} = \bigcup_{T\in\mathcal{T}} \Omega(T)$.

On the other hand, we have $\{\varnothing\} \le \{\{1\}\}$, *whereas* $\Omega(\{\varnothing\}) \nleq \Omega(\{\{1\}\})$, *whence* $\mathcal{I}$ *is not system c-monotone.*

As far as connections between the rough c-monotonicity and narrow c-monotonicity classes are concerned, we get the following analog of Theorem 527.

Theorem 566 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is roughly family c-monotone if and only if it is narrowly family c-monotone;*

(b) $\mathcal{I}$ *is roughly left c-monotone, then it is narrowly left c-monotone;*

(c) If $\mathcal{I}$ *is roughly right c-monotone, then it is narrowly right c-monotone;*

(d) If $\mathcal{I}$ *is roughly system c-monotone, then it is narrowly system c-monotone.*

Proof:

(a) Suppose $\mathcal{I}$ is roughly family c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^{\nsim}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. Then, by hypothesis, $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$, whence, by rough family c-monotonicity, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$. Thus $\mathcal{I}$ is narrowly family c-monotone.

Assume, conversely, that $\mathcal{I}$ is narrowly family c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\widetilde{T'} \leq \bigcup_{T \in \mathcal{T}} \widetilde{T}$. Since $\{\widetilde{T} : T \in \mathcal{T}\} \cup \{\widetilde{T'}\} \subseteq \mathrm{ThFam}^{\nsim}(\mathcal{I})$, we get, by narrow family c-monotonicity, $\Omega(\widetilde{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\widetilde{T})$. Thus, by Proposition 369, $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T)$, showing that $\mathcal{I}$ is roughly family c-monotone.

(b) Suppose that $\mathcal{I}$ is roughly left c-monotone, i.e., that, for all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{\widetilde{T'}} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\widetilde{T}}$ implies $\Omega(T') \leq \bigcup_{T \in \mathcal{T}} \Omega(T')$. Assume, for the sake of obtaining a contradiction, that $\mathcal{I}$ is not narrowly left c-monotone. Then, there exist $\mathcal{X} \cup \{Y\} \subseteq \mathrm{ThFam}^{\nsim}(\mathcal{I})$, such that $\overleftarrow{Y} \leq \bigcup_{X \in \mathcal{X}} \overleftarrow{X}$ and $\Omega(Y) \nleq \bigcup_{X \in \mathcal{X}} \Omega(X)$.

First, observe that, if there existed $Z \in \mathrm{ThFam}(\mathcal{I})$ and $P \in |\mathbf{Sign}^\flat|$, such that $Z_P \neq \varnothing$ and $\overleftarrow{Z}_P = \varnothing$, then, setting $Z' = \{Z_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, with

$$Z'_\Sigma = \begin{cases} \varnothing, & \text{if } \Sigma \neq P \\ Z_P, & \text{if } \Sigma = P \end{cases},$$

we would have $\overleftarrow{\widetilde{Z'}} = \overleftarrow{\widetilde{\varnothing}}$, but $\Omega(Z') \neq \Omega(\overline{\varnothing})$, which contradicts rough left c-monotonicity. Thus, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma \neq \varnothing$ implies $\overleftarrow{T}_\Sigma \neq \varnothing$.

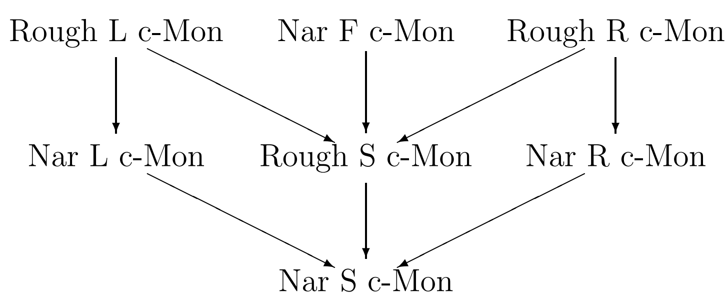
Continuing with the proof, by hypothesis, $\overleftarrow{Y} \leq \bigcup_{X\in\mathcal{X}} \overleftarrow{X}$ and $\Omega(Y) \nleq \bigcup_{X\in\mathcal{X}} \Omega(X)$. Hence, by rough left c-monotonicity, $\overleftarrow{\overleftarrow{Y}} \nleq \bigcup_{X\in\mathcal{X}} \overleftarrow{\overleftarrow{X}}$. Thus, there exists $P \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{\overleftarrow{Y}}_P \nsubseteq \bigcup_{X\in\mathcal{X}} \overleftarrow{\overleftarrow{X}}_P$, whereas $\overleftarrow{Y}_P \subseteq \bigcup_{X\in\mathcal{X}} \overleftarrow{X}_P$. But this gives $\overleftarrow{Y}_P = \varnothing$, whence, by the preceding observation, $Y_P = \varnothing$, which contradicts $Y \in \mathrm{ThFam}^\nmid(\mathcal{I})$. Therefore, $\mathcal{I}$ must be narrowly left c-monotone.

(c) Suppose $\mathcal{I}$ is roughly right c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}^\nmid(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. By hypothesis, $\widetilde{T'} \leq \bigcup_{T\in\mathcal{T}} \widetilde{T}$. Thus, by rough right c-monotonicity, $\Omega(\overleftarrow{T'}) \leq \bigcup_{T\in\mathcal{T}} \Omega(\overleftarrow{T})$. Thus, $\mathcal{I}$ is narrowly right c-monotone.

(d) Suppose $\mathcal{I}$ is roughly system c-monotone and let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThSys}^\nmid(\mathcal{I})$, such that $T' \leq \bigcup_{T\in\mathcal{T}} T$. Then, by hypothesis, $\widetilde{T'} \leq \bigcup_{T\in\mathcal{T}} \widetilde{T}$, whence, by rough system c-monotonicity, $\Omega(T') \leq \bigcup_{T\in\mathcal{T}} \Omega(T)$. Thus $\mathcal{I}$ is narrowly system c-monotone.

■

Theorem 566 gives rise to the following mixed rough and narrow c-monotonicity hierarchy.

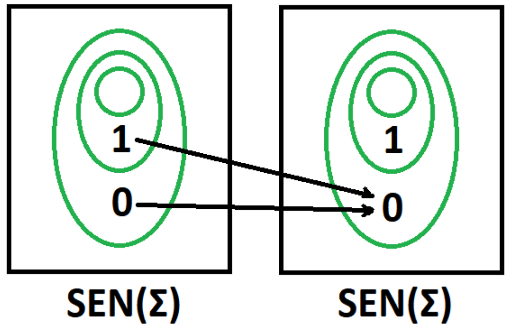


We insert, again, some examples to show that each of the three rough c-monotonicity classes is different from its narrow counterpart.

The first example gives a narrowly left c-monotone π-institution which is not roughly left c-monotone.

Example 567 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

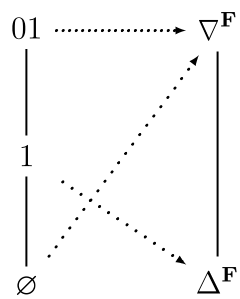
- $\mathbf{Sign}^\flat$ *is the category with the single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$;
- $N^\flat$ *is the trivial clone, consisting of the projections only.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\}.$$

$\mathcal{I}$ has three theory families $\{\varnothing\}$, $\{\{1\}\}$ and $\{\{0,1\}\}$, but only two theory systems, $\{\varnothing\}$ and $\{\{0,1\}\}$. The lattice of theory families of $\mathcal{I}$ and the corresponding Leibniz congruence systems are given in the diagram.



To see that $\mathcal{I}$ is narrowly left c-monotone, note that the only two different theory families in $\mathrm{ThFam}^{\nsubseteq}(\mathcal{I})$ are $\{\{1\}\}$ and $\{\{0,1\}\}$ and we have

$$\overleftarrow{\{\{1\}\}} = \{\varnothing\} \leq \{\{0,1\}\} = \overleftarrow{\{\{0,1\}\}}$$
$$\text{and} \quad \Omega(\{\{1\}\}) = \Delta^{\mathbf{F}} \leq \nabla^{\mathbf{F}} = \Omega(\{\{0,1\}\}).$$

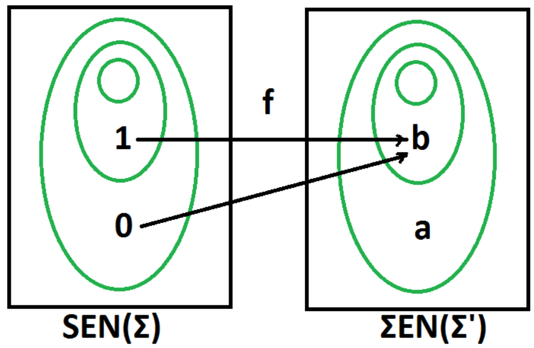
On the other hand, $\mathcal{I}$ is not roughly left c-monotone, since $\overleftarrow{\widetilde{\{\varnothing\}}} = \{\{0,1\}\} = \overleftarrow{\widetilde{\{\{1\}\}}}$, but $\Omega(\{\varnothing\}) \nleq \Omega(\{\{1\}\})$.

The second example shows that there exists a narrowly right c-monotone π-institution that is not roughly right c-monotone.

Example 568 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects Σ and Σ' and a unique morphism $f : \Sigma \to \Sigma'$;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = b$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{b\}, \{a,b\}\}.$$

Clearly, there are only four theory families in $\mathrm{ThFam}^{\nleq}(\mathcal{I})$*, all of which are theory systems. Their lattice together with the associated Leibniz congruence systems are shown in the diagram:*

$$\begin{array}{ccc} & 01, ab & \\ 01, b & & 1, ab \\ & 1, b & \end{array} \qquad \begin{array}{ccc} & \nabla^{\mathbf{F}} & \\ \nabla^{\mathbf{F}}_\Sigma, \Delta^{\mathbf{F}}_{\Sigma'} & & \Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'} \\ & \Delta^{\mathbf{F}} & \end{array}$$

From this diagram and the fact that all theory families depicted are theory systems, we can see that, for all $T, T' \in \mathrm{ThFam}^{\nleq}(\mathcal{I})$*,*

$$T \le T' \quad \textit{iff} \quad \Omega(\overleftarrow{T}) \le \Omega(\overleftarrow{T'}).$$

Therefore, $\mathcal{I}$ *is indeed narrowly right c-monotone.*

On the other hand, consider $T = \{1, \varnothing\}$ *and* $T' = \{1, ab\}$*. Then we have* $\widetilde{T} = \{1, ab\} = \widetilde{T}'$*, whereas*

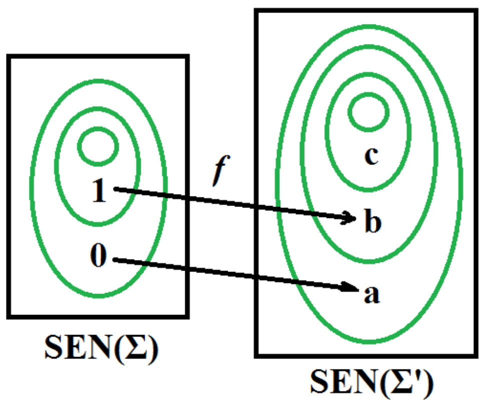
$$\Omega(\overleftarrow{T}) = \Omega(\overline{\varnothing}) = \nabla^{\mathbf{F}} \nleq \{\Delta^{\mathbf{F}}_\Sigma, \nabla^{\mathbf{F}}_{\Sigma'}\} = \Omega(\{1, ab\}) = \Omega(\overleftarrow{T'}).$$

This shows that $\mathcal{I}$ *is not roughly right c-monotone.*

The last example gives a narrowly system c-monotone π-institution which is not roughly system c-monotone.

Example 569 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two object* Σ, Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$, *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial clone.*



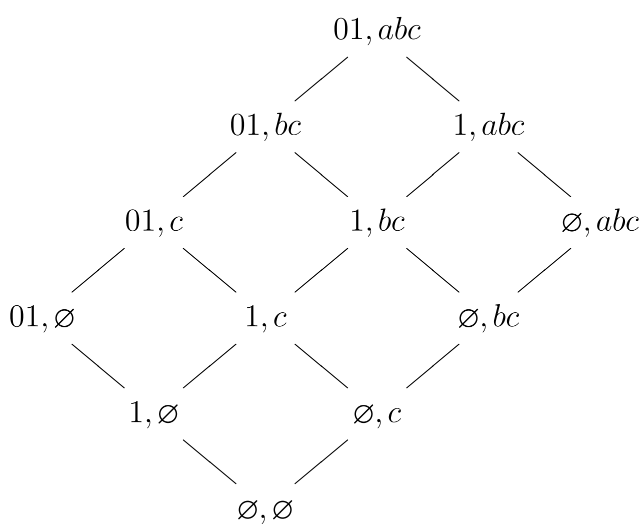
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{1\}, \{0,1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\varnothing, \{c\}, \{b,c\}, \{a,b,c\}\}.$$

$\mathcal{I}$ *has twelve theory families, but only seven theory systems. These are*

$$\overline{\varnothing}, \{\varnothing, c\}, \{\varnothing, bc\}, \{\varnothing, abc\}, \{1, bc\}, \{1, abc\}, \{01, abc\}.$$

The following diagram shows the structure of the lattice of theory families.



To see that $\mathcal{I}$ is narrow system c-monotone, note that there are only three theory systems in $\mathrm{ThSys}^{\nleq}(\mathcal{I})$*, namely,* $\{1,bc\}$, $\{1,abc\}$ *and* $\{01,abc\}$ *and we have* $\{1,bc\} \le \{1,abc\} \le \{01,abc\}$ *and, also,*

$$\begin{aligned}\Omega(\{1,bc\}) &= \{\Delta^{\mathbf{F}}_{\Sigma}, \{a,bc\}\}\\ &\le \Omega(\{1,abc\}) = \{\Delta^{\mathbf{F}}_{\Sigma}, \nabla^{\mathbf{F}}_{\Sigma'}\}\\ &\le \Omega(\{01,abc\}) = \nabla^{\mathbf{F}}.\end{aligned}$$

On the other hand, setting $T = \{\varnothing, c\}$ *and* $T' = \{\varnothing, bc\}$*, which are both theory systems, we get*

$$\widetilde{T} = \{01,c\} \le \{01,bc\} = \widetilde{T'},$$

whereas

$$\Omega(T) = \{\nabla^{\mathbf{F}}_{\Sigma}, \{ab,c\}\} \nleq \{\Delta^{\mathbf{F}}_{\Sigma}, \{a,bc\}\} = \Omega(T').$$

Therefore, $\mathcal{I}$ is not roughly system c-monotone.

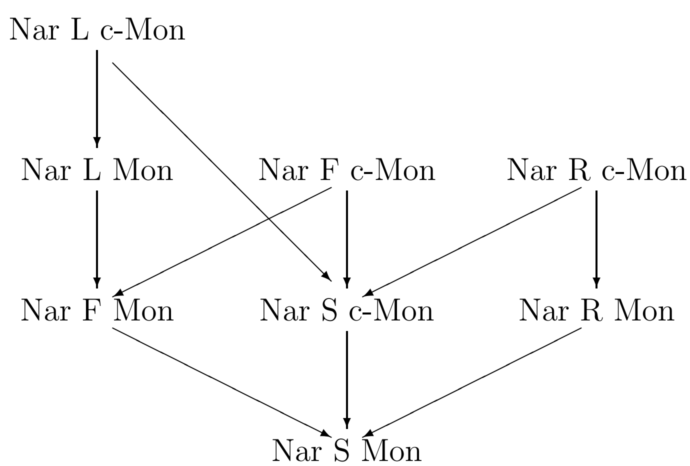
We conclude, after these examples, that the structure of the joint rough and narrow c-monotonicity hierarchy is as depicted in the diagram following Theorem 566, with no two classes being identical.

Finally, we look at some straightforward connections between the classes in the narrow monotonicity and narrow complete monotonicity hierarchies. These follow directly by the definitions involved.

Proposition 570 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$*. If $\mathcal{I}$ is narrowly family (respectively, left, right, system) c-monotone, then it is narrowly family (respectively, left, right, system) monotone.*

Proof: The condition defining a narrow monotonicity class is a special case of the condition defining the corresponding narrow c-monotonicity class, where the collection $\mathcal{T}$, in that definition, is taken to be a singleton. ■

Proposition 570, in view of Propositions 517 and 555, establishes the hierarchy depicted in the diagram.

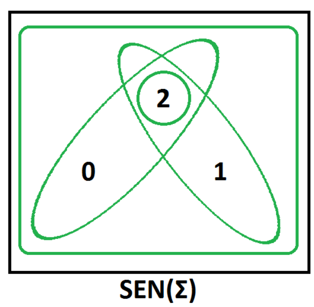


We present an example to show that the two hierarchies are separated. The showcased π-institution belongs to all steps of the narrow monotonicity hierarchy but to none of the four narrow c-monotonicity classes.

Example 571 *Define the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *as follows:*

- $\mathbf{Sign}^\flat$ *is a trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the clone generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, given by*

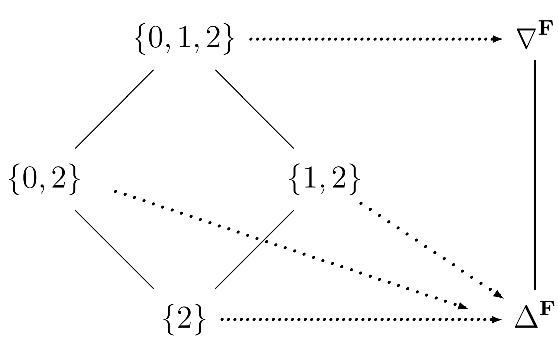
$x \in \mathrm{SEN}^\flat(\Sigma)$	$\sigma^\flat_\Sigma(x)$
0	1
1	2
2	0



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

It is easy to see that the lattices of theory families and corresponding Leibniz congruence systems are as given in the diagram.



Since $\mathbf{Sign}^\flat$ *is trivial,* $\mathcal{I}$ *is systemic and, since* $\mathcal{I}$ *has theorems,* $\mathrm{FiFam}^\sharp(\mathcal{I}) = \mathrm{FiFam}(\mathcal{I})$*. We conclude that all four narrow monotonicity properties for*

$\mathcal{I}$ coincide and, moreover, they are identical with both monotonicity properties, which they also coincide, due to systemicity. The same holds for c-monotonicity. All four narrow c-monotonicity properties coincide and they, in turn, are identical with all c-monotonicity conditions.

From the diagram one can verify immediately that $\mathcal{I}$ is (narrowly left, right and family) monotone, On the other hand, we have

$$\{\{0,1,2\}\} \le \{\{0,2\}\} \cup \{\{1,2\}\},$$

but, obviously, $\Omega(\{\{0,1,2\}\}) \not\le \Omega(\{\{0,2\}\}) \cup \Omega(\{\{1,2\}\})$. Taking into account that $\mathcal{I}$ is systemic, we conclude that $\mathcal{I}$ fails to be narrowly system c-monotone.

Next, we turn to transfer theorems for the various narrow c-monotonicity properties.

Theorem 572 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

- *(a) $\mathcal{I}$ is narrowly family c-monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$, $T' \le \bigcup_{T \in \mathcal{T}} T$ implies $\Omega^{\mathcal{A}}(T') \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$;*
- *(b) $\mathcal{I}$ is narrowly left c-monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$, $\overleftarrow{T'} \le \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$ implies $\Omega^{\mathcal{A}}(T') \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$;*
- *(c) $\mathcal{I}$ is narrowly right c-monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\mathcal{I}\nleq}(\mathcal{A})$, $T' \le \bigcup_{T \in \mathcal{T}} T$ implies $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})$;*
- *(d) $\mathcal{I}$ is narrowly system c-monotone if and only if, for all $\mathbf{F}$-algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiSys}^{\mathcal{I}\nleq}(\mathcal{A})$, $T' \le \bigcup_{T \in \mathcal{T}} T$ implies $\Omega^{\mathcal{A}}(T') \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.*

Proof:

- (a) The "if" results by applying the hypothesis to the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$.

  For the "only if", suppose that $\mathcal{I}$ is narrowly family c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\nleq}(\mathcal{I})$, such that $T' \le \bigcup_{T \in \mathcal{T}} T$. Then we get $\alpha^{-1}(T') \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} T)$, whence $\alpha^{-1}(T') \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(T)$. Since, by Lemmas 51 and 376, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}^{\nleq}(\mathcal{I})$, we get, by narrow family c-monotonicity, $\Omega(\alpha^{-1}(T')) \le \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T))$. Hence, by Proposition 24, $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \le \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \le \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\Omega^{\mathcal{A}}(T') \le \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

(b) The "if" is obtained as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is narrowly left c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\lightning}(\mathcal{I})$, such that $\overleftarrow{T'} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{T}$. Then we get $\alpha^{-1}(\overleftarrow{T'}) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \overleftarrow{T})$, whence $\alpha^{-1}(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\overleftarrow{T})$. By Lemma 6, we get $\overleftarrow{\alpha^{-1}(T')} \leq \bigcup_{T \in \mathcal{T}} \overleftarrow{\alpha^{-1}(T)}$. Since, by Lemmas 51 and 376, it holds $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by narrow left c-monotonicity, that $\Omega(\alpha^{-1}(T')) \leq \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(T))$. Thus, by Proposition 24, we now get $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(T))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(T')) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we obtain $\Omega^{\mathcal{A}}(T') \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T)$.

(c) The "if" is obtained as in Part (a).

For the "only if", suppose that $\mathcal{I}$ is narrowly right c-monotone and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \mathrm{FiFam}^{\lightning}(\mathcal{I})$, such that $T' \leq \bigcup_{T \in \mathcal{T}} T$. Then we get $\alpha^{-1}(T') \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} T)$, whence $\alpha^{-1}(T') \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(T)$. Since, by Lemmas 51 and 376, $\{\alpha^{-1}(T) : T \in \mathcal{T}\} \cup \{\alpha^{-1}(T')\} \subseteq \mathrm{ThFam}^{\lightning}(\mathcal{I})$, we get, by narrow right c-monotonicity, $\Omega(\overleftarrow{\alpha^{-1}(T')}) \leq \bigcup_{T \in \mathcal{T}} \Omega(\overleftarrow{\alpha^{-1}(T)})$. Thus, by Lemma 6, $\Omega(\alpha^{-1}(\overleftarrow{T'})) \leq \bigcup_{T \in \mathcal{T}} \Omega(\alpha^{-1}(\overleftarrow{T}))$. Hence, by Proposition 24, we get $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \leq \bigcup_{T \in \mathcal{T}} \alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T}))$, i.e., $\alpha^{-1}(\Omega^{\mathcal{A}}(\overleftarrow{T'})) \leq \alpha^{-1}(\bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T}))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we obtain $\Omega^{\mathcal{A}}(\overleftarrow{T'}) \leq \bigcup_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(\overleftarrow{T})$.

(d) Similar to Part (a). ■

We close this section by giving two characterizations concerning the narrow family and narrow system c-monotonicity classes, based on mappings between posets satisfying the complete monotonicity property.

Proposition 573 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly family c-monotone;*

(b) $\Omega : \mathbf{ThFam}^{\lightning}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is completely monotone;*

(c) $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Proposition 574 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *The following statements are equivalent:*

(a) $\mathcal{I}$ *is narrowly system c-monotone;*

(b) $\Omega : \mathbf{ThSys}^{\lightning}(\mathcal{I}) \to \mathbf{ConSys}^*(\mathcal{I})$ *is completely monotone;*

(c) $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}\lightning}(\mathcal{A}) \to \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ *is completely monotone, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A}$.

Chapter 8

The Semantic Leibniz Hierarchy: Over the Top I

8.1 Introduction

The prototypical example of an algebraizable deductive system, classical propositional calculus, has the additional distinctive feature of being *1-algebraizable* or *regularly algebraizable* (see, e.g., Chapter 5 of [64], Chapter 3 (p. 66) of [52] and Section 3.4 of [86]). This means that any two theorems are equivalent or, more generally, that any two sentences belonging to a theory T are equivalent relative to T. In this chapter, we undertake the study of regularity, a property that, when added to algebraizability, yields regular algebraizability, featured among the topmost classes in the entire semantic hierarchy discussed in this monograph.

In Section 8.2, we introduce and study the basic *regularity properties*, which form the basis for developing the regular algebraizability classes in Sections 8.4-8.7. A π-institution $\mathcal{I}$ is *family regular* if, for every theory family T of $\mathcal{I}$, all signatures Σ and all Σ-sentences ϕ and ψ, $\phi,\psi \in T_\Sigma$ implies $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$. It is *left regular* if it satisfies the same condition, but with T in the hypothesis replaced by $\overleftarrow{T}$, and *right regular* if T is replaced by $\overleftarrow{T}$ in the conclusion instead. Finally, $\mathcal{I}$ is *system regular* if, in the implication defining family regularity, T is restricted to range only over theory systems, instead of being allowed to range over arbitrary theory families. These four properties form a linear hierarchy, with family regularity being the strongest, followed by right regularity, then by left regularity, with the system version being the weakest of the four. Stability causes the collapse of this hierarchy into two levels, since, under stability, system regularity implies left regularity and right regularity implies family regularity. More transparently, systemicity causes a total collapse of the hierarchy into a single class. The family, left and system versions have characterizations involving the Suszko operator and one of its variants. For a sneak preview, $\mathcal{I}$ is system regular if and only if for every signature Σ and all Σ-sentences ϕ and ψ, $\langle\phi,\psi\rangle \in \widehat{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi,\psi))$, where $\overrightarrow{C}(\phi,\psi)$ is the least theory system of $\mathcal{I}$ containing ϕ and ψ and $\widehat{\Omega}^{\mathcal{I}}$: $\mathrm{ThSys}(\mathcal{I}) \to \mathrm{ConSys}(\mathcal{I})$ gives, for a given theory system T of $\mathcal{I}$, the largest congruence system $\widehat{\Omega}^{\mathcal{I}}(T)$ compatible with every theory system including T. All four regularity properties transfer, e.g., looking at right regularity, it holds for a π-institution $\mathcal{I}$ if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, all $\mathcal{I}$-filter families T of $\mathcal{A}$, all signatures Σ of $\mathcal{A}$ and all Σ-sentences ϕ, ψ, $\phi,\psi \in T_\Sigma$ implies $\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(\overleftarrow{T})$. Finally, the family and system versions have natural characterizations in terms of the form of the filter families/systems, respectively, of the reduced matric families/systems of $\mathcal{I}$. The condition here is that, if $\langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, then T is at most a singleton, i.e., each of its components T_Σ has at most one element.

In Section 8.3, we look at *assertionality*, which is the property ensuing from regularity when existence of theorems is also postulated. Thus, a π-institution $\mathcal{I}$ is *family*, *right*, *left* or *system assertional* if it is family, right, left or system regular, respectively, and has theorems. The hierarchy of regularity properties established in Section 8.2 immediately yields an a priori linear assertionality hierarchy with four classes, the family version implying the right, which, in turn, implies the left version, with the system being the weakest of the four versions. However, it turns out that right assertionality is strong enough to imply systemicity and, as a consequence, the family and right versions are equivalent. Thus, the hierarchy consists of only three distinct classes. The weakest property, system assertionality, coupled with systemicity, is equivalent to the strongest, family assertionality. It is straightforward by the definitions that each asertionality property implies its regularity counterpart. More interestingly, each assertionality property implies the corresponding complete reflectivity (c-reflectivity) property (see Section 3.8). All three versions of assertionality transfer. This follows from the fact that both regularity and existence of theorems transfer. Additionally, based on the characterizations of family and system regularity in terms of reduced matrix families/systems, one may obtain similar characterizations of family/system assertionality. Again, for the sake of preview, the condition characterizing family assertionality is that, for every reduced $\mathcal{I}$-matrix family $\langle\mathcal{A},T\rangle$, T is a singleton, i.e., $|T_\Sigma| = 1$, for all signatures Σ of $\mathcal{A}$.

Having discussed, to some extent, the foundations in Sections 8.2 and 8.3, we embark, in Section 8.4, on the study of algebraizability properties, starting with *regular weak prealgebraizability*. The three classes defined here reflect the type of asssertionality combined with prealgebraicity. Accordingly, a π-institution $\mathcal{I}$ is *regularly weakly family* (RWF) *prealgebraizable* if it is prealgebraic and family assertional. It is *regularly weakly left* (RWL) *prealgebraizable* if it is prealgebraic and left assertional, and it is *regularly weakly system* (RWS) *prealgebraizable* if it is prealgebraic and system assertional. The hierarchy of assertionality properties of Section 8.3 yields that RWF prealgebraizability implies RWL prealgebraizability, which, in turn, implies RWS prealgebraizability. By definition, RWF/L/S prealgebraizability implies, respectively, family/left/system assertionality. More noteworthy, however, is the fact that, since each version of assertionality implies the corresponding c-reflectivity version, RWF/L/S prealgebraizability implies, respectively, WF/L/SC prealgebraizability (see Section 4.2). All three regular weak prealgebraizability properties transfer. This property stems from the transferability of both prealgebraicity and assertionality. It is possible to formulate characterizations of the regular weak prealgebraizability properties in terms of the Leibniz operator viewed as a mapping between ordered sets. E.g., a π-institution $\mathcal{I}$ is RWF prealgebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T)$ is a singleton. The other two characterizations assume similar forms.

In Section 8.5, we switch from regular weak prealgebraizability to *regular weak algebraizability* properties. The former involve prealgebraicity, which, when strengthened to protoalgebraicity, yield the latter. In accordance, a π-institution $\mathcal{I}$ is *regularly weakly family* (RWF) *algebraizable* if it is protoalgebraic and family assertional. It is *regularly weakly left* (RWL) *algebraizable* if it is protoalgebraic and left assertional, and it is *regularly weakly system* (RWS) *algebraizable* if it is protoalgebraic and system assertional. The strengthening of prealgebraicity to protoalgebraicity results in the identification of the left and system versions. Thus, the regular weak algebraizability hierarchy consists of only two distinct classes, that of regularly weakly family algebraizable π-institutions and its proper superclass of regularly weakly system algebraizable π-institutions. Further, in comparing regular weak algebraizability with regular weak prealgebraizability properties, it is revealed that the strongest versions of each, i.e., RWF algebraizability and RWF prealgebraizability, are actually equivalent. In contrast, RWS algebraizability strictly implies RWL prealgebraizability. Again, based on the fact that assertionality implies c-reflectivity, one infers that each regular weak algebraizability property implies the corresponding weak algebraizability property (see Section 4.3). Both regular weak algebraizability properties transfer and both can be characterized in terms of the Leibniz operator seen as a mapping between ordered sets. Clearly, since RWF algebraizability coincides with RWF prealgebraizability, the characterization, given previously, regarding the latter applies to the former as well.

In Section 8.6, we turn to *regular prealgebraizability* properties, which are obtained from the regular weak prealgebraizability properties of Section 8.4, not by strengthening prealgebraicity to protoalgebraicity, as was done in Section 8.5, but, by adding, instead, system extensionality, i.e., by replacing prealgebraicity by preequivalentiality. Consequently, a π-institution $\mathcal{I}$ is *regularly family* (RF) *prealgebraizable* if it is preequivalential (prealgebraic and system extensional) and family assertional. It is *regularly left* (RL) *prealgebraizable* if it is preequivalential and left assertional, and it is *regularly system* (RS) *prealgebraizable* if it is preequivalential and system assertional. RF prealgebraizability implies RL prealgebraizability, which implies RS prealgebraizability, based on the asertionality hierarchy of Section 8.3. Since preequivalentiality implies prealgebraicity, each of the three regular prealgebraizability properties implies the corresponding regular weak prealgebraizability property. Furthermore, since assertionality implies c-reflectivity, each of the regular prealgebraizability properties implies its prealgebraizability counterpart (see Section 5.5). All three regular prealgebraizability properties transfer. In addition, each can be characterized via the use of the Leibniz operator perceived as a mapping between ordered sets. Roughly speaking, these characterizations mimic the ones used in Section 8.4 for regular weak prealgebraizability properties, while adding some form of commutativity with inverse logical extensions, which, by Theorem 327, captures extensionality.

In Section 8.7, the last section of the chapter, we look at *regular algebraizability* properties, which are obtained from the regular prealgebraizability properties of Section 8.6 by strengthening preequivalentiality to equivalentiality or, alternatively, from the regular weak algebraizability properties of Section 8.5 by strengthening protoalgebraicity to equivalentiality. Either point of view leads to defining a π-institution $\mathcal{I}$ being *regularly family* (RF) *algebraizable* if it is equivalential and family assertional, *regularly left* (RL) *algebraizable* if it is equivalential and left assertional, and *regularly system* (RS) *algebraizable* if it is equivalential and system assertional. As transpired with regular weak algebraizability in Section 8.5, the left and system versions are equivalent, and this results in a two-class hierarchy, with RF algebraizability at the top, dominating RS algebraizability. The reasoning naturally leading to the establishment of these classes, permits us to conclude, on the one hand, that each regular algebraizability property implies the corresponding regular prealgebraizability property and, on the other, that each regular algebraizability property implies its regular weak counterpart. But, in addition, in establishing the relations between regular algebraizability and regular prealgebraizability properties, it is seen that the two family versions coincide. A final comparison is made between regular algebraizability and algebraizability (see Section 5.6). Since assertionality implies c-reflectivity, one obtains that each of the two distinct regular algebraizability versions implies the corresponding algebraizability version. Both regular algebraizability properties transfer. Finally, each possesses a characterization via the Leibniz operator, viewed as a mapping between ordered sets, satisfying some additional properties.

8.2 Semantic Regularity

In this chapter, we deal with π-institutions that have theorems and that, in addition, satisfy some form of the *semantic regularity property*, which is detailed in the following

Definition 575 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- $\mathcal{I}$ *is* **family regular** *if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*
$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T);$$
- $\mathcal{I}$ *is* **left regular** *if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*
$$\phi, \psi \in \overleftarrow{T}_\Sigma \quad \text{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T);$$

- $\mathcal{I}$ *is* **right regular** *if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi, \psi \in T_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T});$$

- $\mathcal{I}$ *is* **system regular** *if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi, \psi \in T_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

We establish a hierarchy of regularity properties by looking at the relationships that hold between the properties introduced in Definition 575.

Proposition 576 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) If $\mathcal{I}$ *is family regular, then it is left regular;*

(b) If $\mathcal{I}$ *is family regular, then it is right regular;*

(c) If $\mathcal{I}$ *is left regular, then it is system regular;*

(d) If $\mathcal{I}$ *is right regular, then it is system regular.*

Proof:

(a) Suppose that $\mathcal{I}$ is family regular and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, by Proposition 42, $\phi, \psi \in T_\Sigma$. Thus, by family regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is left regular.

(b) Suppose that $\mathcal{I}$ is family regular and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by family regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, by Proposition 20, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. Thus, $\mathcal{I}$ is right regular.

(c) Suppose that $\mathcal{I}$ is left regular and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since T is a theory system, $\overleftarrow{T} = T$, whence, $\phi, \psi \in \overleftarrow{T}_\Sigma$. Hence, by left regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is system regular.

(d) Suppose that $\mathcal{I}$ is right regular and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by right regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. But T is a theory system, i.e., $\overleftarrow{T} = T$, whence $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Thus, $\mathcal{I}$ is system regular.

■

We now show that, in fact, right regularity implies left regularity. This is a more challenging result that requires a technical lemma.

Lemma 577 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is right regular and not systemic, then, for all* $T \in \mathrm{ThFam}(\mathcal{I}) \backslash \mathrm{ThSys}(\mathcal{I})$ *and all* $\Sigma \in |\mathbf{Sign}^\flat|$*, such that* $\overleftarrow{T}_\Sigma \subsetneq T_\Sigma$*,* $\overleftarrow{T}_\Sigma = \varnothing$*.*

Proof: Suppose that $\mathcal{I}$ is right regular and not systemic and consider $T \in \mathrm{ThFam}(\mathcal{I}) \backslash \mathrm{ThSys}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$, such that $\overleftarrow{T}_\Sigma \subsetneq T_\Sigma$ and $\overleftarrow{T}_\Sigma \neq \varnothing$. Then, on the one hand, there exists $\phi \in T_\Sigma$, such that $\phi \notin \overleftarrow{T}_\Sigma$ and, on the other, there exists $\psi \in \overleftarrow{T}_\Sigma$. Thus, by the compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, we get that $\langle \phi, \psi \rangle \notin \Omega_\Sigma(\overleftarrow{T})$, whereas, since $\overleftarrow{T} \leq T$, $\phi, \psi \in T_\Sigma$. Therefore, $\mathcal{I}$ is not right regular, a contradiction. We conclude that $\overleftarrow{T}_\Sigma = \varnothing$. ■

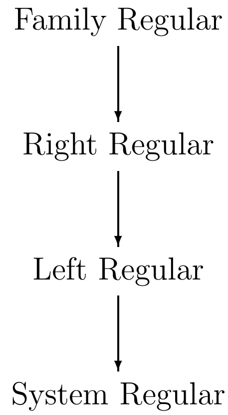
Theorem 578 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is right regular, then it is left regular.*

Proof: Suppose $\mathcal{I}$ is right regular. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, also, $\phi, \psi \in T_\Sigma$.

- If $\mathcal{I}$ is systemic, then, by right regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T}) = \Omega_\Sigma(T)$, whence $\mathcal{I}$ is left regular.
- Suppose, now, that $\mathcal{I}$ is not systemic, whence Lemma 577 applies. Since $\phi, \psi \in \overleftarrow{T}_\Sigma$, by Lemma 577, we must have $\overleftarrow{T}_\Sigma = T_\Sigma$. But then, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ such that $\mathbf{Sign}^\flat(\Sigma, \Sigma') \neq \varnothing$, we get $\overleftarrow{T}_{\Sigma'} \neq \varnothing$, whence $\overleftarrow{T}_{\Sigma'} = T_{\Sigma'}$. Thus, for all $\sigma^\flat$ in $N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, the condition
$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in \overleftarrow{T}_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in \overleftarrow{T}_{\Sigma'}$$
is equivalent to the condition
$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$
Hence, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T}) = \Omega_\Sigma(T)$.

We conclude that $\mathcal{I}$ is left regular. ■

Proposition 576 and Theorem 578 establish the hierarchy depicted in the diagram.



We show, next, that, adding stability to system regularity and to right regularity takes us, respectively, into the classes of left regular and family regular π-institutions.

Proposition 579 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is system regular and stable, then it is left regular;*

(b) If $\mathcal{I}$ *is right regular and stable, then it is family regular.*

Proof:

(a) Suppose $\mathcal{I}$ is system regular and stable. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Since, by Proposition 42, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we may apply system regularity to conclude that $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. Therefore, by stability, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Thus, $\mathcal{I}$ is left regular.

(b) Suppose $\mathcal{I}$ is right regular and stable. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. By right regularity, we get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. Therefore, by stability, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Thus, $\mathcal{I}$ is family regular.

■

Of course, if systemicity is assumed, then all four classes in the regularity hierarchy collapse into a single class.

Proposition 580 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is system regular and systemic, then it is family regular.*

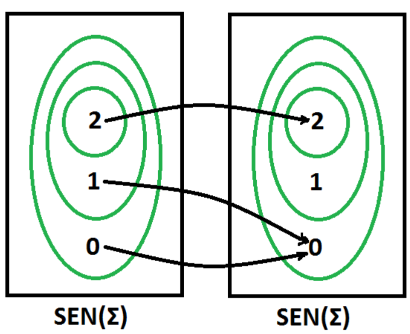
Proof: Under systemicity, all theory families are also theory systems. Hence the conditions defining family and system regularity are identical. ■

To show that all four classes in the hierarchy above are different, we must present some examples that separate them. The first example provides an unstable π-institution which is left regular but not right regular. This accomplishes two goals:

- It shows that the class of right regular π-institutions is a proper subclass of the class of left regular ones;
- It shows that the converse of Part (a) of Proposition 579 does not hold in general, as the π-institution constructed is left regular but fails to be stable.

Example 581 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial category of natural transformations.*

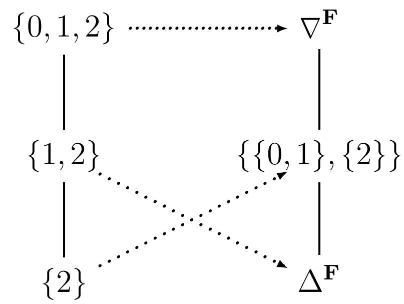


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$*.*

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



Since

$$\Omega(\overleftarrow{\{\{1,2\}\}}) = \Omega(\{\{2\}\}) = \{\{\{0,1\},\{2\}\}\} \neq \Delta^{\mathbf{F}} = \Omega(\{\{1,2\}\}),$$

$\mathcal{I}$ is not stable.

We show that $\mathcal{I}$ is left regular, i.e., that, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, if $\phi, \psi \in \overleftarrow{T}_\Sigma$, then $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$.

- *If $T = \{\{0,1,2\}\}$, then, for all ϕ, ψ, $\langle\phi,\psi\rangle \in \nabla^{\mathbf{F}}_\Sigma = \Omega_\Sigma(\{\{0,1,2\}\})$;*
- *If $T \neq \{\{0,1,2\}\}$, then $\phi, \psi \in \overleftarrow{T}_\Sigma$ implies $\phi = \psi = 2$, whence, $\langle\phi,\psi\rangle \in \Delta^{\mathbf{F}}_\Sigma \subseteq \Omega_\Sigma(T)$.*

On the other hand, for $T = \{\{1,2\}\}$, we have $1, 2 \in T_\Sigma$, but

$$\langle 1,2\rangle \notin \{\{\{0,1\},\{2\}\}\} = \Omega_\Sigma(\{\{2\}\}) = \Omega_\Sigma(\overleftarrow{T}).$$

Therefore, $\mathcal{I}$ is not right regular.

The second example presents a π-institution which is right regular, but fails to be family regular.

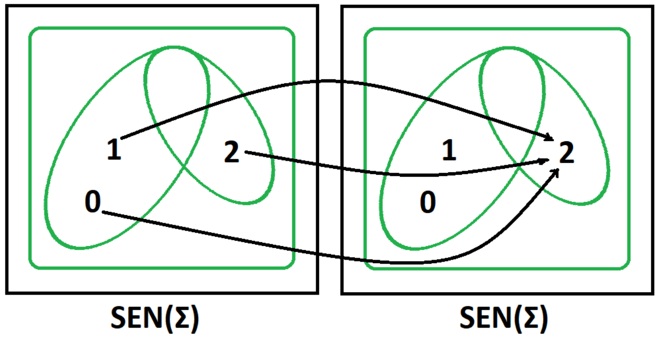
Example 582 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with a single object Σ and a unique (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is defined by $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ and*

  $$\mathrm{SEN}^\flat(f)(0) = 2,\ \mathrm{SEN}^\flat(f)(1) = 2,\ \mathrm{SEN}^\flat(f)(2) = 2;$$

- *$N^\flat$ is the category of natural transformations generated by the unary natural transformation $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ determined by*

  $$\sigma^\flat_\Sigma(0) = 0,\ \sigma^\flat_\Sigma(1) = 2,\ \sigma^\flat_\Sigma(2) = 2.$$



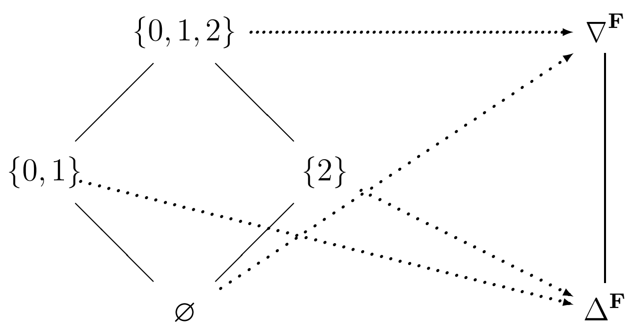
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\varnothing, \{0,1\}, \{2\}, \{0,1,2\}\}.$$

The following table shows the action of $\overleftarrow{}$ *on theory families.*

T	$\varnothing$	$\{0,1\}$	$\{2\}$	$\{0,1,2\}$
$\overleftarrow{T}$	$\varnothing$	$\varnothing$	$\{2\}$	$\{0,1,2\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



We show, first, that $\mathcal{I}$ is right regular, i.e., that it satisfies, for all $T \in$ ThFam$(\mathcal{I})$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi,\psi \in T_\Sigma$ implies $\langle\phi,\psi\rangle \in \Omega_\Sigma(\overleftarrow{T})$.

- *If $T = \{\varnothing\}$, then the conclusion is vacuously true;*
- *If $T = \{\{0,1\}\}$, then, since $\Omega(\overleftarrow{T}) = \Omega(\{\varnothing\}) = \nabla^{\mathbf{F}}$, the conclusion is trivial;*
- *If $T = \{\{2\}\}$, then $\phi,\psi \in T_\Sigma$ implies $\phi = \psi = 2$, whence $\langle\phi,\psi\rangle \in \Delta^{\mathbf{F}}_\Sigma \subseteq \Omega_\Sigma(\overleftarrow{T})$;*
- *If $T = \{\{0,1,2\}\}$, then, since $\Omega(\overleftarrow{T}) = \Omega(T) = \nabla^{\mathbf{F}}$, the conclusion is trivial.*

On the other hand, for $T = \{\{0,1\}\}$, *we have* $0,1 \in T_\Sigma$, *whereas* $\langle 0,1\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$. *We conclude that* $\mathcal{I}$ *is not family regular.*

The last example shows a system regular π-institution which fails to be left regular.

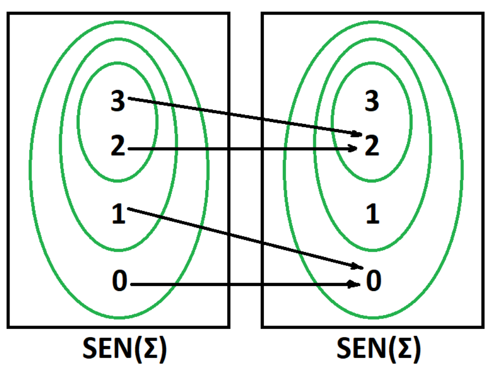
Example 583 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and*

  $$\mathrm{SEN}^\flat(f)(0) = 0,\ \mathrm{SEN}^\flat(f)(1) = 0,\ \mathrm{SEN}^\flat(f)(2) = 2,\ \mathrm{SEN}^\flat(f)(3) = 2;$$

- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *determined by*

x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	0	1	0	1



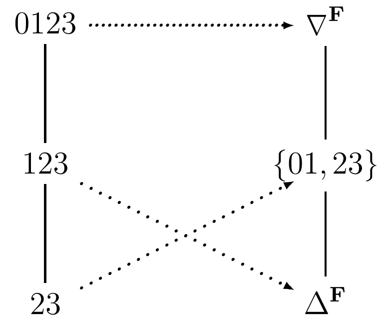
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

The following table shows the action of $\overleftarrow{\ }$ *on theory families.*

T	$\{2,3\}$	$\{1,2,3\}$	$\{0,1,2,3\}$
$\overleftarrow{T}$	$\{2,3\}$	$\{2,3\}$	$\{0,1,2,3\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in *terms of blocks) on the right:*



We show, first, that $\mathcal{I}$ *is system regular, i.e., that it satisfies, for all* $T \in \mathrm{ThSys}(\mathcal{I})$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\phi, \psi \in T_\Sigma$ *implies* $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$.

- *If* $T = \{\{2, 3\}\}$, *then,* $\phi = \psi$ *or* $\{\phi, \psi\} = \{2, 3\}$. *In either case* $\langle \phi, \psi \rangle \in \{\{0, 1\}, \{2, 3\}\} = \Omega_\Sigma(T)$;
- *If* $T = \{\{0, 1, 2, 3\}\}$, *then, since* $\Omega(T) = \nabla^{\mathbf{F}}$, *the conclusion is trivial.*

On the other hand, for $T = \{\{1, 2, 3\}\}$, *we have* $2, 3 \in \{2, 3\} = \overleftarrow{T}_\Sigma$, *whereas* $\langle 2, 3 \rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$. *We conclude that* $\mathcal{I}$ *is not left regular.*

We provide, next, characterizations of three of the four regularity classes in terms of the Suszko operator acting on the theory families of a π-institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. Given a theory system $T \in \mathrm{ThSys}(\mathcal{I})$, we set

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{\Omega(T') : T \leq T' \in \mathrm{ThSys}(\mathcal{I})\},$$

a system version of the Suszko operator on $\mathcal{I}$.

Theorem 584 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is family regular if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi, \psi));$$

(b) $\mathcal{I}$ *is left regular if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi));$$

(c) $\mathcal{I}$ *is system regular if and only if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\langle \phi, \psi \rangle \in \widehat{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)).$$

Proof:

(a) Suppose $\mathcal{I}$ is family regular. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have, by family regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, for all $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\phi, \psi \in T_\Sigma$. Therefore, by the definition of $\widetilde{\Omega}^{\mathcal{I}}$,

$$\begin{array}{lll}\langle \phi, \psi \rangle & \in & \bigcap\{\Omega_\Sigma(T) : T \in \mathrm{ThFam}(\mathcal{I}), \phi, \psi \in T_\Sigma\} \\ & = & \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi, \psi)).\end{array}$$

Assume, conversely, that the displayed condition holds. To show family regularity, let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, $C(\phi, \psi) \leq T$, whence, by the hypothesis and the monotonicity of $\widetilde{\Omega}^{\mathcal{I}}$,

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(C(\phi, \psi)) \subseteq \widetilde{\Omega}^{\mathcal{I}}_\Sigma(T) \subseteq \Omega_\Sigma(T).$$

Hence, $\mathcal{I}$ is family regular.

(b) Suppose $\mathcal{I}$ is left regular. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have, by left regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, for all $T \in \mathrm{ThFam}(\mathcal{I})$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Therefore, by the definition of $\widetilde{\Omega}^{\mathcal{I}}$,

$$\begin{array}{lll}\langle \phi, \psi \rangle & \in & \bigcap\{\Omega_\Sigma(T) : T \in \mathrm{ThFam}(\mathcal{I}), \phi, \psi \in \overleftarrow{T}_\Sigma\} \\ & = & \bigcap\{\Omega_\Sigma(T) : T \in \mathrm{ThFam}(\mathcal{I}), \overrightarrow{\{\phi, \psi\}} \leq T\} \\ & = & \widetilde{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)).\end{array}$$

Assume, conversely, that the displayed condition holds. To show left regularity, let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, $\overrightarrow{\{\phi, \psi\}} \leq T$, whence, by the hypothesis and the monotonicity of $\widetilde{\Omega}^{\mathcal{I}}$,

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)) \subseteq \widetilde{\Omega}^{\mathcal{I}}_\Sigma(T) \subseteq \Omega_\Sigma(T).$$

Hence, $\mathcal{I}$ is left regular.

(c) Suppose $\mathcal{I}$ is system regular. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$. Then, we have, by system regularity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, for all $T \in \mathrm{ThSys}(\mathcal{I})$, such that $\phi, \psi \in T_\Sigma$. Therefore, by the definition of $\widehat{\Omega}^{\mathcal{I}}$,

$$\begin{array}{lll}\langle \phi, \psi \rangle & \in & \bigcap\{\Omega_\Sigma(T) : T \in \mathrm{ThSys}(\mathcal{I}), \phi, \psi \in T_\Sigma\} \\ & = & \bigcap\{\Omega_\Sigma(T) : T \in \mathrm{ThSys}(\mathcal{I}), \overrightarrow{\{\phi, \psi\}} \leq T\} \\ & = & \widehat{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)).\end{array}$$

Assume, conversely, that the displayed condition holds. To show system regularity, let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, $\overrightarrow{\{\phi, \psi\}} \leq T$, whence, by the hypothesis and the monotonicity of $\widehat{\Omega}^{\mathcal{I}}$,

$$\langle \phi, \psi \rangle \in \widehat{\Omega}^{\mathcal{I}}_\Sigma(\overrightarrow{C}(\phi, \psi)) \subseteq \widehat{\Omega}^{\mathcal{I}}_\Sigma(T) \subseteq \Omega_\Sigma(T).$$

Hence, $\mathcal{I}$ is system regular.

■

We show, next, that all four regularity properties transfer from theory families/systems to $\mathcal{I}$-filter families/systems over arbitrary $\mathbf{F}$-algebraic systems.

Theorem 585 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) $\mathcal{I}$ *is family regular if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi, \psi \in T_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T);$$

(b) $\mathcal{I}$ *is right regular if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi, \psi \in T_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(\overleftarrow{T});$$

(c) $\mathcal{I}$ *is left regular if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi, \psi \in \overleftarrow{T}_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T);$$

(d) $\mathcal{I}$ *is system regular if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, all* $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$*, all* $\Sigma \in |\mathbf{Sign}|$ *and all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,*

$$\phi, \psi \in T_\Sigma \quad \textit{implies} \quad \langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T).$$

Proof:

(a) The "if" follows easily by considering the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and recalling from Lemma 51 that $\mathrm{FiFam}^{\mathcal{I}}(\mathcal{F}) = \mathrm{ThFam}(\mathcal{I})$.

Assume, conversely, that $\mathcal{I}$ is family regular and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then, we get $\phi, \psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. By Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, whence, by family regularity, we get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(\alpha^{-1}(T))$. Thus, by Proposition 24, we get $\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T))$. Hence, $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega^{\mathcal{A}}_{F(\Sigma)}(T)$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathrm{SEN}(\Sigma)$, if $\phi, \psi \in T_\Sigma$, then $\langle \phi, \psi \rangle \in \Omega^{\mathcal{A}}_\Sigma(T)$.

(b) The "if" follows as in Part (a).

Assume, conversely, that $\mathcal{I}$ is right regular and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\in T_{F(\Sigma)}$. Then, we get $\phi,\psi\in\alpha_\Sigma^{-1}(T_{F(\Sigma)})$. By Lemma 51, $\alpha^{-1}(T)\in\mathrm{ThFam}(\mathcal{I})$, whence, by right regularity, we get that $\langle\phi,\psi\rangle\in\Omega_\Sigma(\overleftarrow{\alpha^{-1}(T)})$. By Lemma 6, we get $\langle\phi,\psi\rangle\in\Omega_\Sigma(\alpha^{-1}(\overleftarrow{T}))$. Thus, by Proposition 24, we get $\langle\phi,\psi\rangle\in\alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(\overleftarrow{T}))$. Hence, $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle\in\Omega^{\mathcal{A}}_{F(\Sigma)}(\overleftarrow{T})$. Taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that, for all $\Sigma\in|\mathbf{Sign}|$ and all $\phi,\psi\in\mathrm{SEN}(\Sigma)$, if $\phi,\psi\in T_\Sigma$, then $\langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}_\Sigma(\overleftarrow{T})$.

(c) The "if" follows as in Part (a).

Assume, conversely, that $\mathcal{I}$ is left regular and let $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$ be an $\mathbf{F}$-algebraic system, $T\in\mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\phi,\psi\in\mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\in\overleftarrow{T}_{F(\Sigma)}$. Then, we get $\phi,\psi\in\alpha_\Sigma^{-1}(\overleftarrow{T}_{F(\Sigma)})$, i.e., by Lemma 6, $\phi,\psi\in\overleftarrow{\alpha^{-1}(T)}_\Sigma$. By Lemma 51, $\alpha^{-1}(T)\in\mathrm{ThFam}(\mathcal{I})$, whence, by left regularity, we get that $\langle\phi,\psi\rangle\in\Omega_\Sigma(\alpha^{-1}(T))$. Thus, by Proposition 24, we get $\langle\phi,\psi\rangle\in\alpha_\Sigma^{-1}(\Omega^{\mathcal{A}}_{F(\Sigma)}(T))$. Hence, $\langle\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)\rangle\in\Omega^{\mathcal{A}}_{F(\Sigma)}(T)$. Taking into account the surjectivity of $\langle F,\alpha\rangle$, we conclude that, for all $\Sigma\in|\mathbf{Sign}|$ and all $\phi,\psi\in\mathrm{SEN}(\Sigma)$, if $\phi,\psi\in\overleftarrow{T}_\Sigma$, then $\langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}_\Sigma(T)$.

(d) Similar to Part (a). ■

We also have the following characterizations in terms of reduced $\mathcal{I}$-matrix families and $\mathcal{I}$-matrix systems.

Theorem 586 *Let* $\mathbf{F}=\langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ *be an algebraic system and* $\mathcal{I}=\langle\mathbf{F},C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is family regular if and only if, for every* $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$*, with* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$, $\mathbf{A}=\langle\mathbf{Sign},\mathrm{SEN},N\rangle$*, and all* $\Sigma\in|\mathbf{Sign}|$, $|T_\Sigma|\le1$*;*

(b) $\mathcal{I}$ *is system regular if and only if, for every* $\langle\mathcal{A},T\rangle\in\mathrm{MatSys}^*(\mathcal{I})$*, with* $\mathcal{A}=\langle\mathbf{A},\langle F,\alpha\rangle\rangle$, $\mathbf{A}=\langle\mathbf{Sign},\mathrm{SEN},N\rangle$*, and all* $\Sigma\in|\mathbf{Sign}|$, $|T_\Sigma|\le1$.

Proof:

(a) Suppose, first, that $\mathcal{I}$ is family regular. Let $\langle\mathcal{A},T\rangle\in\mathrm{MatFam}^*(\mathcal{I})$, $\Sigma\in|\mathbf{Sign}|$ and $\phi,\psi\in\mathrm{SEN}(\Sigma)$, such that $\phi,\psi\in T_\Sigma$. Then, we have, using Theorem 585 and the fact that $\langle\mathcal{A},T\rangle$ is reduced,

$$\langle\phi,\psi\rangle\in\Omega^{\mathcal{A}}_\Sigma(T)=\Delta^{\mathcal{A}}_\Sigma,$$

whence $\phi=\psi$. Therefore, $|T_\Sigma|\le1$.

Suppose, conversely, that the given condition holds. Let $T\in\mathrm{ThFam}(\mathcal{I})$, $\Sigma\in|\mathbf{Sign}^\flat|$ and $\phi,\psi\in\mathrm{SEN}^\flat(\Sigma)$, such that $\phi,\psi\in T_\Sigma$. Then, $\langle\mathcal{F}/\Omega(T),$

$T/\Omega(T)\rangle$ is reduced and, moreover, $\phi/\Omega_\Sigma(T), \psi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T)$. Hence, by hypothesis, $\phi/\Omega_\Sigma(T) = \psi/\Omega_\Sigma(T)$, i.e., $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$. We conclude that $\mathcal{I}$ is family regular.

(b) Suppose, first, that $\mathcal{I}$ is system regular. Let $\langle\mathcal{A},T\rangle \in \mathrm{MatSys}^*(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi,\psi \in \mathrm{SEN}(\Sigma)$, such that $\phi,\psi \in T_\Sigma$. Then, we have, using Theorem 585 and the fact that $\langle\mathcal{A},T\rangle$ is reduced,

$$\langle\phi,\psi\rangle \in \Omega^{\mathcal{A}}_\Sigma(T) = \Delta^{\mathcal{A}}_\Sigma,$$

whence $\phi = \psi$. Therefore, $|T_\Sigma| \le 1$.

Suppose, conversely, that the given condition holds. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi,\psi \in T_\Sigma$. Then, $\langle\mathcal{F}/\Omega(T), T/\Omega(T)\rangle$ is a reduced $\mathcal{I}$-matrix system. Moreover, we have $\phi/\Omega_\Sigma(T)$, $\psi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T)$. Hence, by hypothesis, $\phi/\Omega_\Sigma(T) = \psi/\Omega_\Sigma(T)$, i.e., $\langle\phi,\psi\rangle \in \Omega_\Sigma(T)$. We conclude that $\mathcal{I}$ is system regular.

■

8.3 Assertionality

In this section, we introduce the *assertionality hierarchy* of π-institutions. The properties defining this hierarchy are obtained simply by adding to the various properties defining the regularity hierarchy the stipulation that $\mathcal{I}$ have theorems.

Definition 587 (Assertionality) *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **family assertional** *if it is family regular and has theorems;*
- $\mathcal{I}$ *is* **left assertional** *if it is left regular and has theorems;*
- $\mathcal{I}$ *is* **right assertional** *if it is right regular and has theorems;*
- $\mathcal{I}$ *is* **system assertional** *if it is system regular and has theorems.*

Definition 587 and Proposition 576 allow us to obtain the following a priori assertionality hierarchy of π-institutions.

Family Assertional

↓

Right Assertional

↓

Left Assertional

↓

System Assertional

However, using the characterizing properties included in the following proposition, we shall see that right assertionality implies systemicity and, hence, the classes of family assertional and right assertional π-institutions coincide.

Proposition 588 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is family assertional if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = t_\Sigma / \Omega_\Sigma(T)$, *for some* $t_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I})$;

(b) $\mathcal{I}$ *is right assertional if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = t_\Sigma / \Omega_\Sigma(\overleftarrow{T})$, *for some* $t_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I})$;

(c) $\mathcal{I}$ *is left assertional if and only if, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $\Sigma \in |\mathbf{Sign}^\flat|$, $\overleftarrow{T}_\Sigma = t_\Sigma / \Omega_\Sigma(T)$, *for some* $t_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I})$;

(d) $\mathcal{I}$ *is system assertional if and only if, for all* $T \in \mathrm{ThSys}(\mathcal{I})$ *and all* $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = t_\Sigma / \Omega_\Sigma(T)$, *for some* $t_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I})$.

Proof: If, in a certain context, a π-institution $\mathcal{I}$ has theorems, we shall use t_Σ to denote an arbitrary Σ-theorem of $\mathcal{I}$, $\Sigma \in |\mathbf{Sign}^\flat|$.

(a) Suppose that $\mathcal{I}$ is family assertional and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. If $\phi \in T_\Sigma$, then $\phi, t_\Sigma \in T_\Sigma$, whence, by family regularity, $\langle \phi, t_\Sigma \rangle \in \Omega_\Sigma(T)$, i.e., $\phi \in t_\Sigma / \Omega_\Sigma(T)$. On the other hand, if $\langle \phi, t_\Sigma \rangle \in \Omega_\Sigma(T)$, then, since $t_\Sigma \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T, $\phi \in T_\Sigma$.

Suppose, conversely, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = t_\Sigma / \Omega_\Sigma(T)$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by hypothesis

$$\phi \ \Omega_\Sigma(T) \ t_\Sigma \ \Omega_\Sigma(T) \ \psi,$$

whence $\mathcal{I}$ is family regular.

(b) Suppose that $\mathcal{I}$ is right assertional and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. If $\phi \in T_\Sigma$, then $\phi, t_\Sigma \in T_\Sigma$, whence, by right regularity, $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(\overleftarrow{T})$, i.e., $\phi \in t_\Sigma/\Omega_\Sigma(\overleftarrow{T})$. On the other hand, if $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(\overleftarrow{T})$, then, since $t_\Sigma \in \overleftarrow{T}_\Sigma$, we get, by the compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, $\phi \in \overleftarrow{T}_\Sigma \subseteq T_\Sigma$.

Suppose, conversely, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $T_\Sigma = t_\Sigma/\Omega_\Sigma(\overleftarrow{T})$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by hypothesis

$$\phi \ \Omega_\Sigma(\overleftarrow{T}) \ t_\Sigma \ \Omega_\Sigma(\overleftarrow{T}) \ \psi,$$

whence $\mathcal{I}$ is right regular.

(c) Suppose that $\mathcal{I}$ is left assertional and let $T \in \mathrm{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^\flat|$. If $\phi \in \overleftarrow{T}_\Sigma$, then $\phi, t_\Sigma \in \overleftarrow{T}_\Sigma$, whence, by left regularity, $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(T)$, i.e., $\phi \in t_\Sigma/\Omega_\Sigma(T)$. On the other hand, if $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(T)$, then, since $\Omega(T) \le \Omega(\overleftarrow{T})$, we get $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(\overleftarrow{T})$. But $t_\Sigma \in \overleftarrow{T}_\Sigma$, whence, by the compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, $\phi \in \overleftarrow{T}_\Sigma$.

Suppose, conversely, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $\overleftarrow{T}_\Sigma = t_\Sigma/\Omega_\Sigma(T)$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, by hypothesis

$$\phi \ \Omega_\Sigma(T) \ t_\Sigma \ \Omega_\Sigma(T) \ \psi,$$

whence $\mathcal{I}$ is left regular.

(d) Similar to Part (a).

∎

Using the characterizations in Proposition 588, we can show that right assertionality implies systemicity.

Proposition 589 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is right assertional, then* $\mathcal{I}$ *is systemic.*

Proof: Suppose that $\mathcal{I}$ is right assertional. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$. Then, by right assertionality and Proposition 588, $\langle\phi, t_\Sigma\rangle \in \Omega_\Sigma(\overleftarrow{T})$, for some $t_\Sigma \in \mathrm{Thm}_\Sigma(\mathcal{I})$. But $t_\Sigma \in \overleftarrow{T}_\Sigma$, whence, by compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, $\phi \in \overleftarrow{T}_\Sigma$. Therefore, $T \le \overleftarrow{T}$ and, hence, $T \in \mathrm{ThSys}(\mathcal{I})$. Thus, $\mathcal{I}$ is systemic. ∎

Proposition 590 *Let* $\mathbf{F} = \langle\mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle\mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is right assertional if and only if* $\mathcal{I}$ *is family assertional.*

Proof: If $\mathcal{I}$ is family assertional, then, by definition, it is family regular and has theorems, whence, by Proposition 576, it is right regular and has theorems and, therefore, by definition, it is right assertional.

Suppose, conversely, that $\mathcal{I}$ is right assertional. Then, by Proposition 589, it is systemic and, hence, a fortiori, stable. Therefore, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, if $\phi, \psi \in T_\Sigma$, then, by right assertionality, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$ and, hence, by stability, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is family regular and, hence, family assertional. ■

We can also show easily that, in case $\mathcal{I}$ is systemic, the entire assertionailty hierarchy collapses into a single class.

Proposition 591 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is family assertional if and only if it is system assertional and systemic.*

Proof: If $\mathcal{I}$ is systemic, the conditions defining family assertionality and system assertionality coincide.

On the other hand, if $\mathcal{I}$ is family assertional, then, by definition, it is family regular and has theorems, whence, by Proposition 576, it is right regular and has theorems. Thus, by definition, $\mathcal{I}$ is right assertional and, hence, by Proposition 589, it is systemic. Moreover, using again Proposition 576, we conclude that $\mathcal{I}$ is also system assertional. ■

Thus, we get, regarding the assertionality hierarchy the following

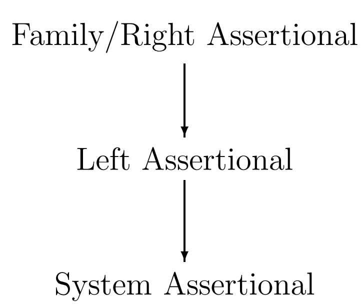
Proposition 592 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ *is family/right assertional, then it is left assertional;*

(b) If $\mathcal{I}$ *is left assertional, then it is system assertional.*

Proof: By Definition 587, Proposition 576 and Proposition 591. ■

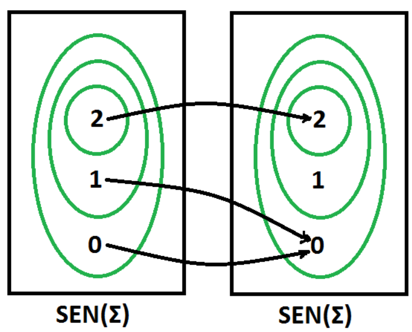
Proposition 592 establishes the **assertionality hierarchy** depicted in the accompanying diagram.



We show, next, that all three classes are different, by constructing two examples to separate them. The first is an example of a left assertional π-institution which fails to satisfy family assertionality.

Example 593 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



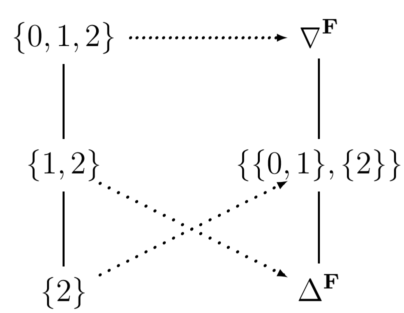
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$*.*

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$*:*

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1, 2\}$	$\{2\}$
$\{0, 1, 2\}$	$\{0, 1, 2\}$

Since $\mathcal{I}$ *is not systemic, then, by Proposition 591, it fails to be family assertional.*

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



Clearly, $\mathcal{I}$ *has theorems. Thus, to show that it is left assertional, it suffices to show, by Proposition 588, that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $\overleftarrow{T}_\Sigma = 2/\Omega_\Sigma(T)$*.*

- $\overleftarrow{\{\{2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{2\}\})$;
- $\overleftarrow{\{\{1,2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{1,2\}\})$;
- $\overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\} = 2/\Omega_\Sigma(\{\{0,1,2\}\})$.

The next example showcases a system assertional π-institution which is not left assertional.

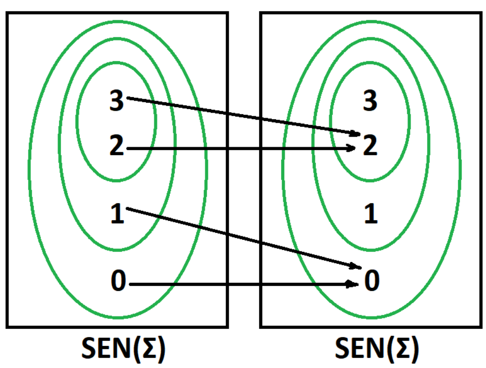
Example 594 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and*

  $$\mathrm{SEN}^\flat(f)(0) = 0,\ \mathrm{SEN}^\flat(f)(1) = 0,\ \mathrm{SEN}^\flat(f)(2) = 2,\ \mathrm{SEN}^\flat(f)(3) = 2;$$

- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *determined by*

x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	0	1	0	1



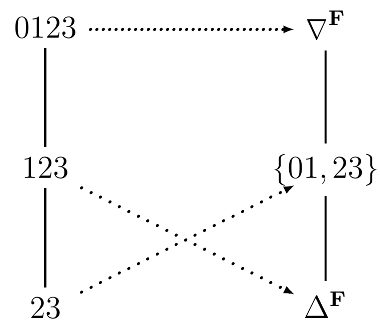
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

The following table shows the action of $\overleftarrow{\ }$ *on theory families.*

T	$\{2,3\}$	$\{1,2,3\}$	$\{0,1,2,3\}$
$\overleftarrow{T}$	$\{2,3\}$	$\{2,3\}$	$\{0,1,2,3\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



Clearly, $\mathcal{I}$ has theorems. To see that $\mathcal{I}$ is system assertional, it suffices to show, by Proposition 588, that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T_\Sigma = 2/\Omega_\Sigma(T)$. We do have indeed:

- $\{2,3\} = 2/\Omega_\Sigma(\{\{2,3\}\})$;
- $\{0,1,2,3\} = 2/\Omega_\Sigma(\{\{0,1,2,3\}\})$.

On the other hand, for $T = \{\{1,2,3\}\}$, we have $2,3 \in \{2,3\} = \overleftarrow{T}_\Sigma$, whereas $\langle 2,3\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$. We conclude that $\mathcal{I}$ is not left regular and, hence, a fortiori, not left assertional either.

We proceed by exploring the relationships that hold between the various classes of the assertionality hierarchy, introduced in the present section, with the classes of the regularity hierarchy, which were introduced in Section 8.2. We have the following straightforward implications, which follow directly from the definitions involved.

Proposition 595 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

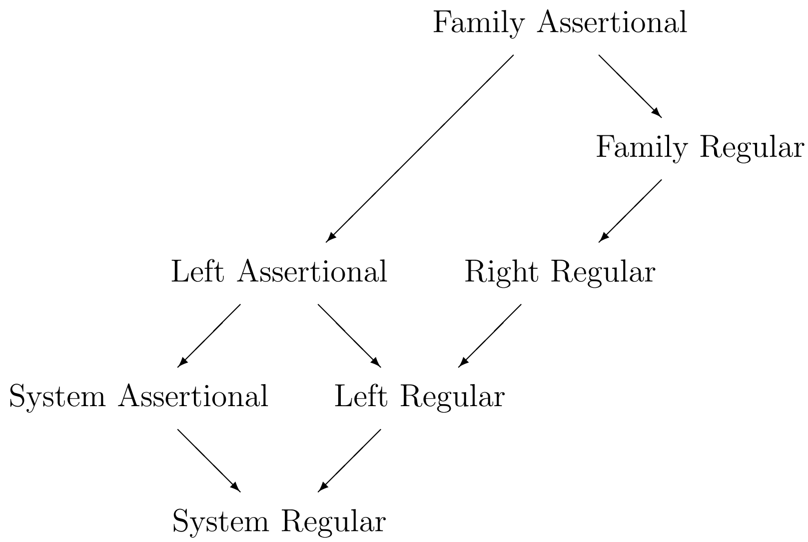
(a) If $\mathcal{I}$ is family assertional, then it is family regular;

(b) If $\mathcal{I}$ is left assertional, then it is left regular;

(c) If $\mathcal{I}$ is system assertional, then it is system regular.

Proof: Directly from Definition 587. ■

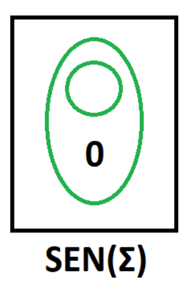
Thus, taking into account Propositions 576 and 592, we have the following mixed assertionality and regularity hierarchy.



An easy example shows that the three southeast arrows from the assertionality classes to the corresponding regularity classes correspond to proper inclusions.

Example 596 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

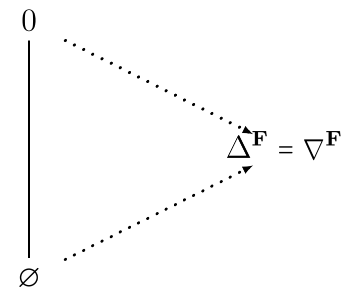
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\varnothing, \{0\}\}.$$

$\mathcal{I}$ is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.



$\mathcal{I}$ is family regular, since, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\langle 0,0\rangle \in \nabla^{\mathbf{F}}_{\Sigma} = \Omega_{\Sigma}(T)$.

On the other hand, since $\mathcal{I}$ does not have theorems, $\mathcal{I}$ does not belong to any of the steps in the assertionality hierarchy.

We examine next, the relationships between the classes in the assertionality hierarchy and those in the complete reflectivity hierarchy.

Theorem 597 *Let $\mathbf{F} = \langle \mathbf{Sign}^{\flat}, \mathrm{SEN}^{\flat}, N^{\flat}\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is family/right assertional, then it is family/right completely reflective;

(b) If $\mathcal{I}$ is left assertional, then it is left completely reflective;

(c) If $\mathcal{I}$ is system assertional, then it is system completely reflective.

Proof:

(a) Suppose that $\mathcal{I}$ is family assertional. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \le \Omega(T')$, $\Sigma \in |\mathbf{Sign}^{\flat}|$ and $\phi \in \bigcap_{T\in\mathcal{T}} T_{\Sigma}$. By assertionality, there exists $t_{\Sigma} \in \mathrm{Thm}_{\Sigma}(\mathcal{I})$, whence, $\phi, t_{\Sigma} \in T_{\Sigma}$, for all $T \in \mathcal{T}$. Thus, by family regularity, $\langle \phi, t_{\Sigma}\rangle \in \Omega_{\Sigma}(T)$, for all $T \in \mathcal{T}$, i.e., $\langle \phi, t_{\Sigma}\rangle \in \bigcap_{T\in\mathcal{T}} \Omega_{\Sigma}(T)$. By hypothesis, $\langle \phi, t_{\Sigma}\rangle \in \Omega_{\Sigma}(T')$. Therefore, since $t_{\Sigma} \in T'_{\Sigma}$, we get, by compatibility of $\Omega(T')$ with T', $\phi \in T'_{\Sigma}$. We conclude that $\bigcap_{T\in\mathcal{T}} T \le T'$ and, hence, that $\mathcal{I}$ is family c-reflective.

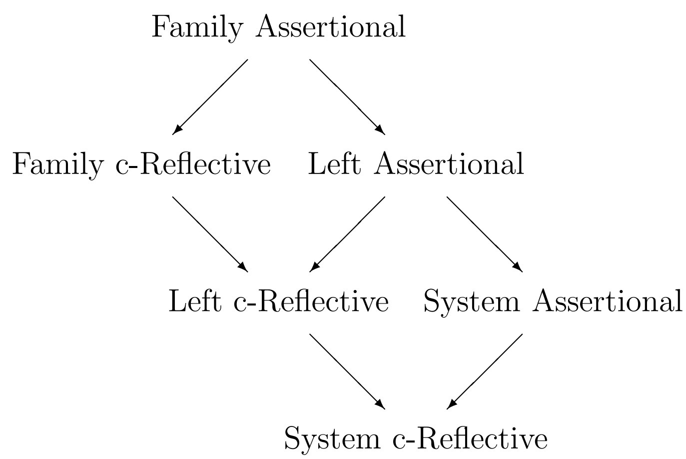
(b) Suppose that $\mathcal{I}$ is left assertional. Let $\mathcal{T} \cup \{T'\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcap_{T\in\mathcal{T}} \Omega(T) \le \Omega(T')$, $\Sigma \in |\mathbf{Sign}^{\flat}|$ and $\phi \in \bigcap_{T\in\mathcal{T}} \overleftarrow{T}_{\Sigma}$. By assertionality, there exists $t_{\Sigma} \in \mathrm{Thm}_{\Sigma}(\mathcal{I})$, whence, $\phi, t_{\Sigma} \in \overleftarrow{T}_{\Sigma}$, for all $T \in \mathcal{T}$. Thus, by left regularity, $\langle \phi, t_{\Sigma}\rangle \in \Omega_{\Sigma}(T)$, for all $T \in \mathcal{T}$, i.e., $\langle \phi, t_{\Sigma}\rangle \in \bigcap_{T\in\mathcal{T}} \Omega_{\Sigma}(T)$. By hypothesis, $\langle \phi, t_{\Sigma}\rangle \in \Omega_{\Sigma}(T') \subseteq \Omega_{\Sigma}(\overleftarrow{T'})$. Therefore, since $t_{\Sigma} \in \overleftarrow{T'}_{\Sigma}$, we get, by compatibility of $\Omega(\overleftarrow{T'})$ with $\overleftarrow{T'}$, $\phi \in \overleftarrow{T'}_{\Sigma}$. We conclude that $\bigcap_{T\in\mathcal{T}} \overleftarrow{T} \le \overleftarrow{T'}$ and, hence, that $\mathcal{I}$ is left c-reflective.

(c) Similar to Part (a).

∎

Alternatively, Theorem 597 may be proven by employing the characterizations provided in Proposition 588.

Based on the complete reflectivity hierarchy, which was established in Section 3.8, on the assertionality hierarchy established in Proposition 592 and on Theorem 597, we get the hierarchy relating assertionality with complete reflectivity classes shown in the diagram.



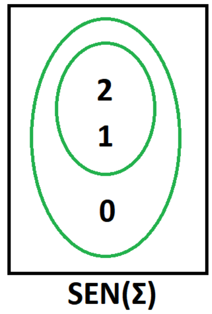
To show that all southwest inclusion arrows, connecting the various assertionality classes with the corresponding c-reflectivity classes, represent proper inclusions we construct an example of a family completely reflective π-institution which fails to be system assertional. Note that, since family c-reflectivity implies family injectivity, any π-institution fulfilling these requirements must have theorems. Therefore, the failure of assertionality must be due to failure of family regularity rather than the absence of theorems.

Example 598 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

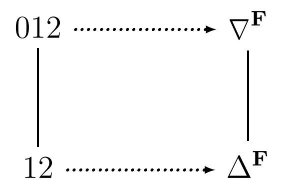
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$*, specified by* $\sigma^\flat_\Sigma(0) = 0$*,* $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 0$*.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1,2\},\{0,1,2\}\}.$$



$\mathcal{I}$ is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.



Since the lattice of theory families of $\mathcal{I}$ is order isomorphic with the lattice of $\mathrm{AlgSys}^*(\mathcal{I})$*-congruence systems, $\mathcal{I}$ is family completely reflective.*

On the other hand, for $T = \{\{2,3\}\}$, we have $2,3 \in T_\Sigma$, but $\langle 2,3\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$, whence $\mathcal{I}$ is not system regular and, hence, a fortiori, belongs to none of the three classes in the assertionality hierarchy.

We show, next, that all assertionality properties transfer from theory families/systems to $\mathcal{I}$-filter families/systems over arbitrary $\mathbf{F}$-algebraic systems. This is a consequence of the facts that, by Theorem 585, all regularity properties transfer and, also, that the property of having theorems carries from the collection of all theory families to the collections of all filter systems over arbitrary algebraic systems, as seen in Lemma 376.

Theorem 599 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is family (respectively, left, system) assertional if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\langle \mathbf{A}, C^{\mathcal{I},\mathcal{A}}\rangle$ is family (respectively, left, system) assertional.*

Proof: Directly from Lemma 376 and Theorem 585. ■

We also have the following characterizations in terms of reduced $\mathcal{I}$-matrix families and $\mathcal{I}$-matrix systems.

Theorem 600 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is family assertional if and only if, for every $\langle \mathcal{A}, T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, and all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$;

(b) *$\mathcal{I}$ is system assertional if and only if, for every $\langle\mathcal{A},T\rangle \in \mathrm{MatSys}^*(\mathcal{I})$, with $\mathcal{A} = \langle\mathbf{A},\langle F,\alpha\rangle\rangle$, $\mathbf{A} = \langle\mathbf{Sign},\mathrm{SEN},N\rangle$, and all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$.*

Proof:

(a) Suppose, first, that $\mathcal{I}$ is family assertional. Then, by definition, it is family regular. Thus, by Theorem 586, for all $\langle\mathcal{A},T\rangle \in \mathrm{MatFam}^*(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^\flat|$, $|T_\Sigma| \leq 1$. However, by family assertionality, $\mathcal{I}$ has theorems, whence, by Lemma 376, $|T_\Sigma| = 1$.

Suppose, conversely, that the given condition holds. Then $\mathcal{I}$ has theorems and, by Lemma 586, it is family regular. Therefore, $\mathcal{I}$ is family assertional.

(b) Similar to Part (a).

■

8.4 Regular Weak Prealgebraizability

We look, next, at those classes of π-institutions that are formed by adding prealgebraicity to the various levels of assertionality.

Definition 601 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$.*

- *$\mathcal{I}$ is* **regularly weakly family prealgebraizable***, or* **RWF prealgebraizable** *for short, if it is prealgebraic and family assertional;*
- *$\mathcal{I}$ is* **regularly weakly left prealgebraizable***, or* **RWL prealgebraizable** *for short, if it is prealgebraic and left assertional;*
- *$\mathcal{I}$ is* **regularly weakly system prealgebraizable***, or* **RWS prealgebraizable** *for short, if it is prealgebraic and system assertional.*

Based on the assertionality hierarchy established in Proposition 592, we have the following

Proposition 602 *Let $\mathbf{F} = \langle\mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle\mathbf{F},C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) *If $\mathcal{I}$ is regularly weakly family prealgebraizable, then it is regularly weakly left prealgebraizable;*

(b) *If $\mathcal{I}$ is regularly weakly left prealgebraizable, then it is regularly weakly system prealgebraizable.*

Proof: Straightforward by combining Definition 601 and Proposition 592. ■

Proposition 602 establishes the **regular weak prealgebraizability hierarchy** depicted in the following diagram.

Regular Weak Family Prealgebraizable

↓

Regular Weak Left Prealgebraizable

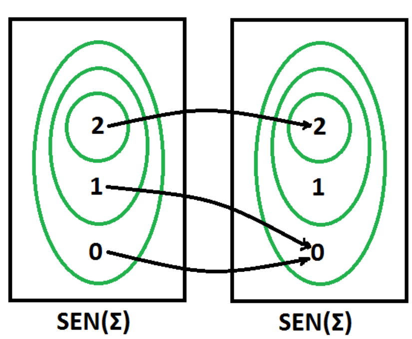
↓

Regular Weak System Prealgebraizable

We reuse two examples to show that all classes in this hierarchy are different, i.e., that the arrows in the diagram represent proper inclusions. The first describes a π-institution that is regularly weakly left prealgebraizable but fails to be regularly weakly family prealgebraizable, thus showing that the family class is properly included in the left class.

Example 603 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$*,* $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



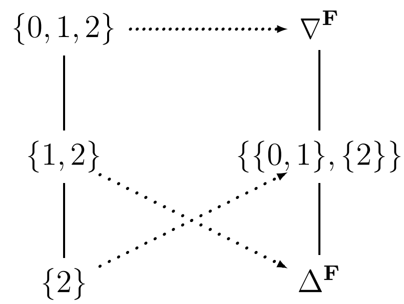
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

Since $\mathcal{I}$ is not systemic, by Proposition 591, it fails to be family assertional and, hence, it is not regularly weakly family prealgebraizable.

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



Since the only theory systems of $\mathcal{I}$ are $\{\{2\}\}$ and $\{\{0,1,2\}\}$, it is clear that Ω is monotone on theory systems and, hence, $\mathcal{I}$ is prealgebraic. Clearly, $\mathcal{I}$ has theorems. Thus, to complete the proof that it is regularly weakly left prealgebraizable, it suffices to show that it is left assertional, i.e., by Proposition 588, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T}_\Sigma = 2/\Omega_\Sigma(T)$.

- $\overleftarrow{\{\{2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{2\}\})$;
- $\overleftarrow{\{\{1,2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{1,2\}\})$;
- $\overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\} = 2/\Omega_\Sigma(\{\{0,1,2\}\})$.

The second example presents a regularly weakly system prealgebraizable π-institution that is not regularly weakly left prealgebraizable.

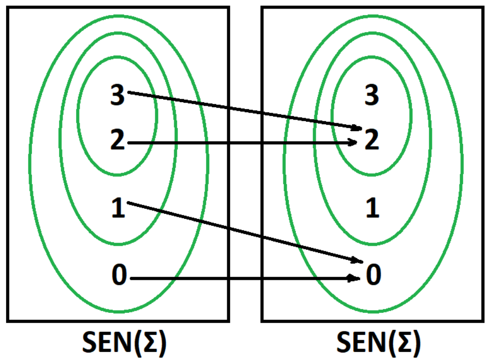
Example 604 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a unique (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and*

  $\mathrm{SEN}^\flat(f)(0) = 0,\ \mathrm{SEN}^\flat(f)(1) = 0,\ \mathrm{SEN}^\flat(f)(2) = 2,\ \mathrm{SEN}^\flat(f)(3) = 2;$

- *$N^\flat$ is the category of natural transformations generated by the unary natural transformation $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ determined by*

x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	0	1	0	1



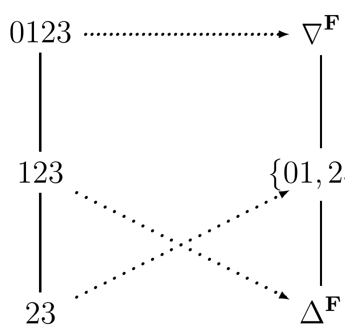
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

The following table shows the action of $\overleftarrow{}$ on theory families.

T	$\{2,3\}$	$\{1,2,3\}$	$\{0,1,2,3\}$
$\overleftarrow{T}$	$\{2,3\}$	$\{2,3\}$	$\{0,1,2,3\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



Since the only theory systems of $\mathcal{I}$ are $\{\{2,3\}\}$ and $\{\{0,1,2,3\}\}$, it is obvious that Ω is monotone on theory systems and, hence, that $\mathcal{I}$ is prealgebraic. Clearly, $\mathcal{I}$ has theorems. To see that $\mathcal{I}$ is regularly weakly system prealgebraizable it suffices to show that it is system assertional, i.e., by Proposition 588, that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, $T_\Sigma = 2/\Omega_\Sigma(T)$. We do have indeed:

- $\{2,3\} = 2/\Omega_\Sigma(\{\{2,3\}\})$;
- $\{0,1,2,3\} = 2/\Omega_\Sigma(\{\{0,1,2,3\}\})$.

On the other hand, for $T = \{\{1,2,3\}\}$*, we have* $2,3 \in \{2,3\} = \overleftarrow{T}_\Sigma$*, whereas* $\langle 2,3\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$*. We conclude that* $\mathcal{I}$ *is not left regular and, hence, a fortiori, it is not regularly weakly left prealgebraizable.*

We investigate, next, the relationships that hold between the various regular weak prealgebraizability classes, introduced in the present section, and the corresponding assertional classes, that were introduced in Section 8.3.

Directly from the definitions involved, we get the following

Proposition 605 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

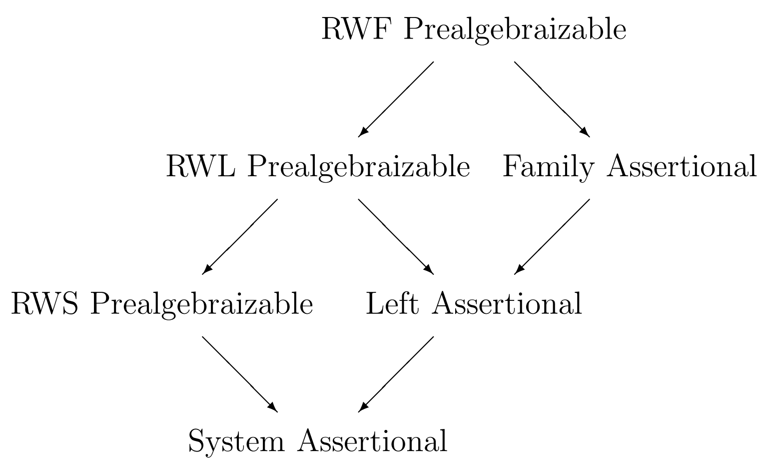
(a) If $\mathcal{I}$ *is regularly weakly family prealgebraizable, then it is family assertional;*

(b) If $\mathcal{I}$ *is regularly weakly left prealgebraizable, then it is left assertional;*

(c) If $\mathcal{I}$ *is regularly weakly system prealgebraizable, then it is system assertional.*

Proof: Directly from Definition 601. ■

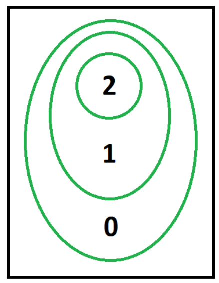
Therefore, we get the mixed regular weak prealgebraizability and assertionality hierarchy depicted in the diagram.



To show that all classes in this hierarchy are different, we provide an example of a π-institution that is family assertional, and, thus, belongs to all three assertionality classes, but fails to be regularly weakly system prealgebraizable, whence it belongs to none of three steps in the regular weak prealgebraizability hierarchy. This example shows that all three southeast arrows represent proper inclusions.

Example 606 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the trivial category of natural transformations.*

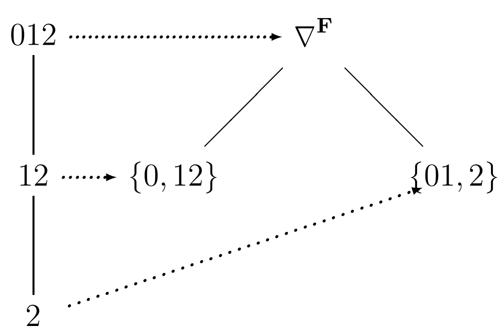


SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



$\mathcal{I}$ *has theorems, whence to show that it is family assertional, it suffices to show that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*,* $T_\Sigma = 2/\Omega_\Sigma(T)$*. Indeed, we have:*

- *For* $T = \{\{2\}\}$*,* $\{2\} = 2/\Omega_\Sigma(\{\{2\}\})$*;*
- *For* $T = \{\{1, 2\}\}$*,* $\{1, 2\} = 2/\Omega_\Sigma(\{\{1, 2\}\})$*;*
- *For* $T = \{\{0, 1, 2\}\}$*,* $\{0, 1, 2\} = 2/\Omega_\Sigma(\{\{0, 1, 2\}\})$*.*

On the other hand, since $\{\{2\}\} \leq \{\{1, 2\}\}$*, but* $\Omega(\{\{2\}\}) \nleq \Omega(\{\{1, 2\}\})$*,* $\mathcal{I}$ *is not prealgebraic and, hence, fails to be regularly weakly system prealgebraizable.*

Turning now to the relationship between the regular weak prealgebraizability hierarchy and the weak prealgebraizability hierarchy, we get the following

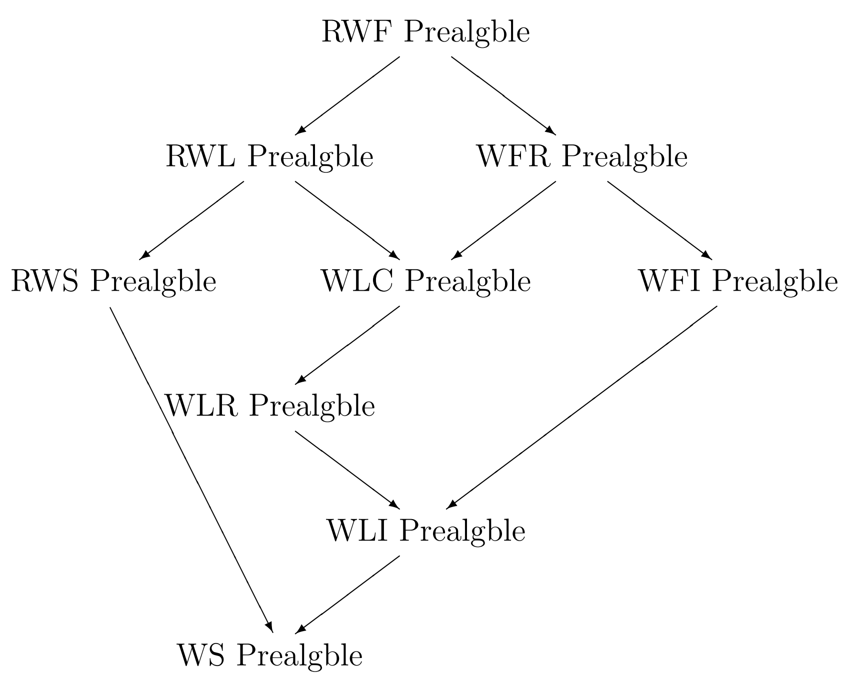
Proposition 607 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- *If* $\mathcal{I}$ *is regularly weakly family prealgebraizable, then it is weakly family (completely) reflective prealgebraizable;*
- *If* $\mathcal{I}$ *is regularly weakly left prealgebraizable, then it is weakly left completely reflective prealgebraizable;*
- *If* $\mathcal{I}$ *is regularly weakly system prealgebraizable, then it is weakly system prealgebraizable.*

Proof: We show Part (a) in detail. The remaining parts can be proved similarly.

Suppose $\mathcal{I}$ is regularly weakly family prealgebraizable. Then, by definition, it is prealgebraic and family assertional. Hence, by Theorem 597, it is prealgebraic and family completely reflective. Thus, by definition, it is weakly family prealgebraizable. ■

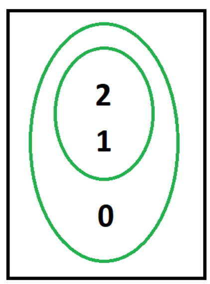
Thus, Proposition 607, together with Proposition 602 and the hierarchy established in Section 4.2, point to the following hierarchy of regularly weakly prealgebraizable and weakly prealgebraizable π-institutions.



Again it is not difficult to see that the classes in the regular weak prealgebraizability hierarchy are different from the classes of weakly prealgebraizable π-institutions. This is accomplished by constructing an example of a π-institution which is weakly family completely reflective prealgebraizable but is not regularly weakly system prealgebraizable.

Example 608 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by* $\sigma^\flat_\Sigma(0) = 0$*,* $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 0$*.*

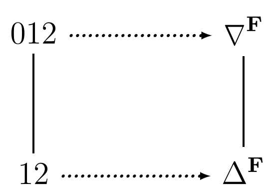


SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



Since the lattice of theory families of $\mathcal{I}$ *is order isomorphic with the lattice of* $\mathrm{AlgSys}^*(\mathcal{I})$*-congruence systems,* $\mathcal{I}$ *is weakly family c-reflective prealgebraizable.*

On the other hand, for $T = \{\{2, 3\}\}$*, we have* $2, 3 \in T_\Sigma$*, but* $\langle 2, 3 \rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$*, whence* $\mathcal{I}$ *is not system regular and, hence, a fortiori, it is not regularly weakly system prealgebraizable either.*

Based on existing results, we can show that all three kinds of regular weak prealgebraizability transfer from theory families/systems to filter families/systems over arbitrary **F**-algebraic systems.

Theorem 609 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

(a) *$\mathcal{I}$ is regularly weakly family prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $T', T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,*

- $T' \leq T''$ *implies* $\Omega^{\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T'')$*;*
- $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*;*

(b) *$\mathcal{I}$ is regularly weakly left prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $T', T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,*

- $T' \leq T''$ *implies* $\Omega^{\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T'')$*;*
- $|\overleftarrow{T}_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*;*

(c) *$\mathcal{I}$ is regularly weakly system prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,*

- $T \leq T'$ *implies* $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$*;*
- $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Combine Theorem 179 with Theorem 599. ■

Finally, we may also adapt previously obtained results characterizing weak prealgebraizability to obtain similar characterizations of regular weak prealgebraizability in terms of mappings between posets of filter families/systems (including theory families/systems) and congruence systems.

Theorem 610 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. $\mathcal{I}$ is regularly weakly family prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly weakly family prealgebraizable. Then it is, by definition, prealgebraic and, moreover, by definition, Proposition 605 and Theorem 597, it is family c-reflective. Therefore, it is WFR prealgebraizable. Thus, the required isomorphism is given by Theorem 268. The expression for T is obtained by applying Theorem 609.

Assume, conversely, that the postulated condition holds. Then, the hypotheses of Theorem 609, Part (a), are satisfied and, therefore, $\mathcal{I}$ is regularly weakly family prealgebraizable. ∎

Theorem 611 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly weakly left prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$, $|\overleftarrow{T}_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$.

Proof: Suppose, first, that $\mathcal{I}$ is regularly weakly left prealgebraizable. Then it is, by definition, prealgebraic and, moreover, by definition, Proposition 605 and Theorem 597, it is left c-reflective. Therefore, it is WLC prealgebraizable. Thus, the required embedding is given by Theorem 276. The expression for T is obtained by applying Theorem 609.

Assume, conversely, that the postulated condition holds. Then, the hypotheses of Theorem 609, Part (b), are satisfied and, therefore, $\mathcal{I}$ is regularly weakly left prealgebraizable. ∎

Theorem 612 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly weakly system prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding, such that, for all $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$.

Proof: Suppose, first, that $\mathcal{I}$ is regularly weakly system prealgebraizable. Then it is, by definition, prealgebraic and, moreover, by definition, Proposition 605 and Theorem 597, it is system c-reflective. Therefore, it is WS prealgebraizable. Thus, the required embedding is given by Theorem 256. The expression for T is obtained by applying Theorem 609.

Assume, conversely, that the postulated condition holds. Then, the hypotheses of Theorem 609, Part (c), are satisfied and, therefore, $\mathcal{I}$ is regularly weakly system prealgebraizable. ∎

8.5 Regular Weak Algebraizability

We look, next, at those classes of π-institutions that are formed by adding protoalgebraicity to the various levels of assertionality.

Definition 613 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **regularly weakly family algebraizable**, *or* **RWF algebraizable** *for short, if it is protoalgebraic and family assertional;*
- $\mathcal{I}$ *is* **regularly weakly left algebraizable**, *or* **RWL algebraizable** *for short, if it is protoalgebraic and left assertional;*
- $\mathcal{I}$ *is* **regularly weakly system algebraizable**, *or* **RWS algebraizable** *for short, if it is protoalgebraic and system assertional.*

Even though there seem to be three classes in the regular weak algebraizability hierarchy, in reality there are only two, since it is easy to see that the classes of regularly weakly left and of regularly weakly system π-institutions coincide.

Proposition 614 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is regularly weakly left algebraizable if and only if it is regularly weakly system algebraizable.*

Proof: The "only if" follows directly by the definition and Proposition 592. For the "if", suppose that $\mathcal{I}$ is regularly weakly system algebraizable. Then it is, a fortiori, protoalgebraic, whence, by Lemma 170, it is stable. Therefore, since $\mathcal{I}$ is system regular and stable, by Proposition 579, it is left regular. We conclude that $\mathcal{I}$ is regularly weakly left algebraizable. ∎

The assertionality hierarchy, established in Proposition 592, and Proposition 614 allow us to establish the following regular weak algebraizability hierarchy.

Proposition 615 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. *If* $\mathcal{I}$ *is regularly weakly family algebraizable, then it is regularly weakly system algebraizable.*

Proof: Straightforward by combining Definition 601 and Proposition 592. ∎

The **regular weak algebraizability hierarchy** is depicted in the following diagram.

Regular Weak Family Algebraizable

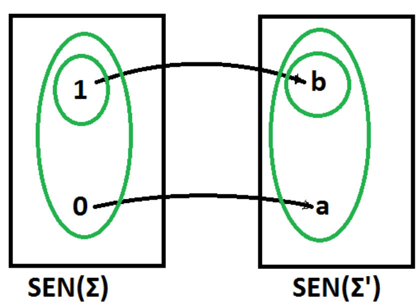
↓

Regular Weak System Algebraizable

We use an example to show that the two classes in this hierarchy are different. Namely, we construct a π-institution that is regularly weakly system algebraizable but fails to be regularly weakly family algebraizable.

Example 616 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$, $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



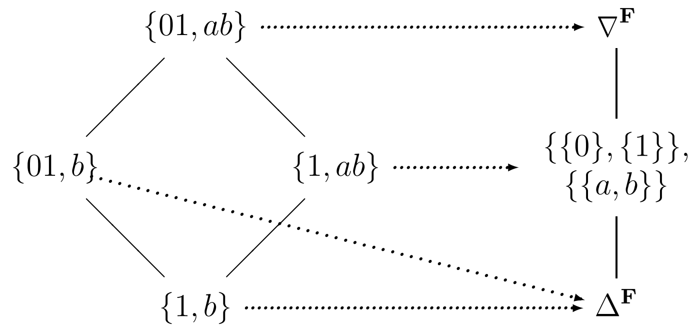
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

The following table shows the action of $\overleftarrow{\ }$ *on theory families, where rows correspond to* T_Σ *and columns to* $T_{\Sigma'}$ *and each entry is written as* $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.

$\leftarrow$	$\{b\}$	$\{a, b\}$
$\{1\}$	$\{1\}, \{b\}$	$\{1\}, \{a, b\}$
$\{0, 1\}$	$\{1\}, \{b\}$	$\{0, 1\}, \{a, b\}$

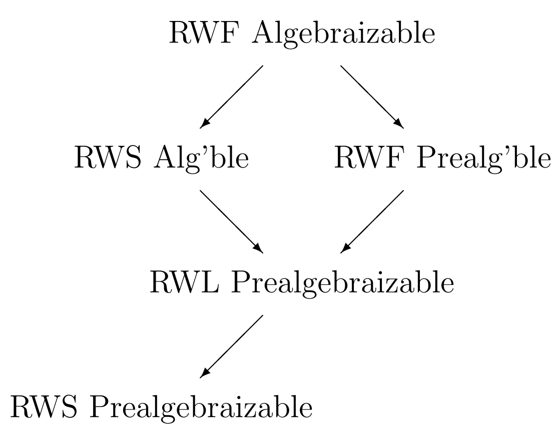
The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in *terms of blocks) on the right:*



The Leibniz operator is monotone on theory families, whence, $\mathcal{I}$ is protoalgebraic. Moreover, $\mathrm{Thm}(\mathcal{I}) = \{\{1\}, \{b\}\}$ *and, for every theory system T, $T_\Sigma = 1/\Omega_\Sigma(T)$ and $T_{\Sigma'} = b/\Omega_{\Sigma'}(T)$. Therefore, $\mathcal{I}$ is system assertional. Thus, $\mathcal{I}$ is regularly weakly system algebraizable.*

On the other hand, for $T = \{\{0, 1\}, \{b\}\} \in \mathrm{ThFam}(\mathcal{I})$, we have $0, 1 \in T_\Sigma$, but $\langle 0, 1\rangle \notin \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ fails to be family regular and, hence, a fortiori, it is not regularly weakly family algebraizable.

We investigate, next, the relationships that hold between the two regular weak algebraizability classes, introduced in the present section, and the three regular weak prealgebraizability classes, that were introduced in Section 8.4. Since, by Theorem 175, protoalgebraicity implies prealgebraicity, we get, a priori, the following mixed hierarchy.



However, we can show that the two top classes of the hierarchies coincide.

Theorem 617 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$. $\mathcal{I}$ is regularly weakly family prealgebraizable if and only if it is regularly weakly family algebraizable.*

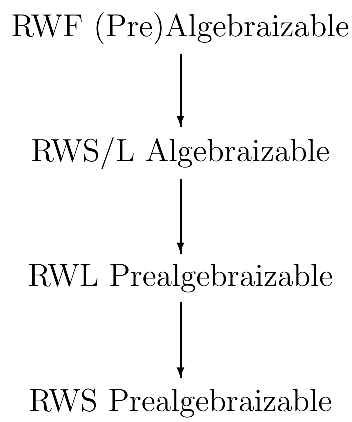
Proof: The "if" follows from the relevant definitions and the fact that, by Theorem 175, protoalgebraicity implies prealgebraicity. For the "only if", it suffices to show that, under family assertionality, prealgebraicity implies protoalgebraicity. By Theorem 175, it suffices, in turn, to show that family assertionality implies stability and, by Proposition 152, that family assertionality implies systemicity. Indeed, by Theorem 597, family assertionality implies family c-reflectivity and, by Proposition 237, we get that $\mathcal{I}$ is systemic. ■

Moreover, from the definitions involved, we get the following

Proposition 618 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is regularly weakly system algebraizable, then it is regularly weakly left prealgebraizable.*

Proof: Suppose $\mathcal{I}$ is regularly weakly system algebraizable. Equivalently, by Proposition 614, it is regularly weakly left algebraizable. Then, by definition, it is protoalgebraic and left assertional. Thus, by Theorem 175, it is prealgebraic and left assertional, i.e., by definition, it is regularly weakly left prealgebraizable. ■

Based on Theorem 617 and Proposition 618, we get the following updated version of the mixed hierarchy shown in the preceding diagram.



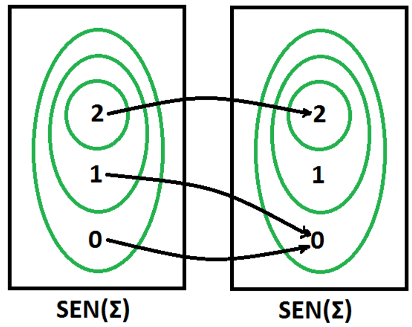
To show that all classes in this hierarchy are different, we provide an example of a π-institution that is regularly weakly left prealgebraizable, but fails to be regularly weakly system algebraizable, i.e., an example that separates the regular weak algebraizability from the regular weak prealgebraizability classes.

Example 619 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;

- $N^\flat$ *is the trivial category of natural transformations.*

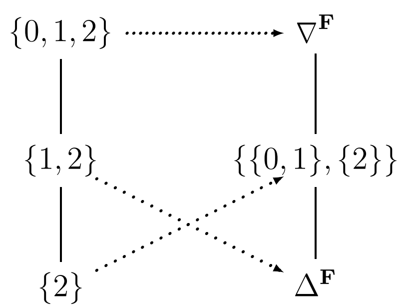


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$.

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below.



Since the only theory systems of $\mathcal{I}$ *are* $\{\{2\}\}$ *and* $\{\{0,1,2\}\}$, *it is clear that* Ω *is monotone on theory systems and, hence,* $\mathcal{I}$ *is prealgebraic. Clearly,* $\mathcal{I}$ *has theorems. Thus, to complete the proof that it is regularly weakly left prealgebraizable, it suffices to show that it is left assertional, i.e., by Proposition 588, that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T}_\Sigma = 2/\Omega_\Sigma(T)$. *Indeed, we get:*

- $\overleftarrow{\{\{2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{2\}\})$;

- $\overleftarrow{\{\{1,2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{1,2\}\})$;

- $\overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\} = 2/\Omega_\Sigma(\{\{0,1,2\}\})$.

On the other hand, since $\{\{2\}\} \leq \{\{1,2\}\}$*, but*

$$\Omega(\{\{2\}\}) = \{\{\{0,1\},\{2\}\}\} \nleq \Delta^{\mathbf{F}} = \Omega(\{\{1,2\}\}),$$

$\mathcal{I}$ *is not protoalgebraic and, hence, it fails to be regularly weakly system algebraizable.*

Turning now to the relationship between regular weak algebraizability and weak algebraizability, we get, by definition

Proposition 620 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

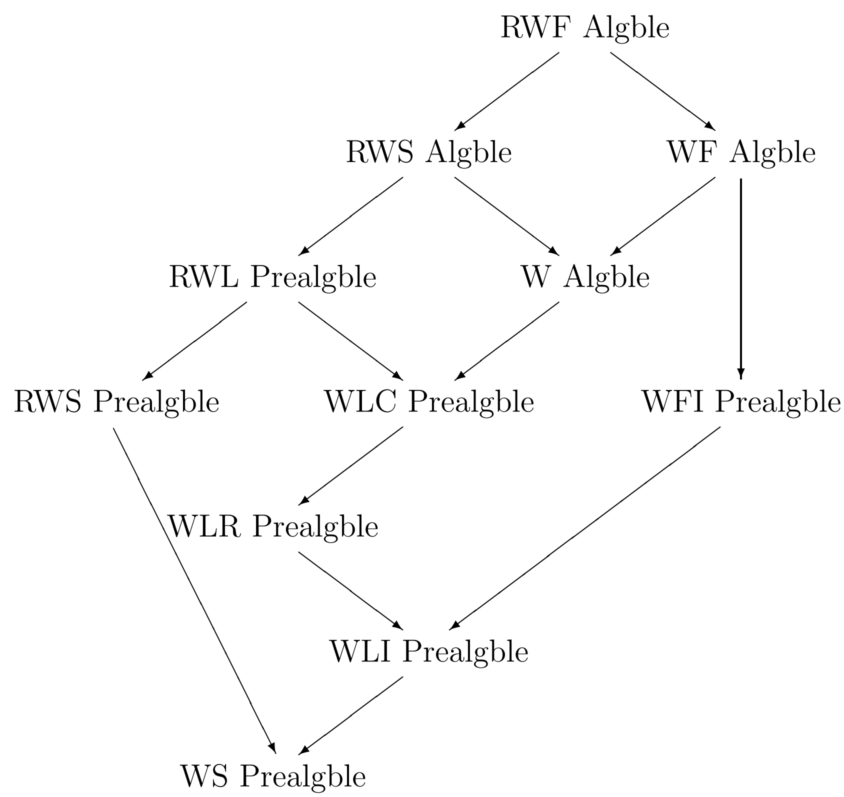
(a) If $\mathcal{I}$ *is regularly weakly family algebraizable, then it is weakly family algebraizable;*

(b) If $\mathcal{I}$ *is regularly weakly system algebraizable, then it is weakly (system/left) algebraizable.*

Proof: For Part (a) note that, by Theorem 617, regular weak family algebraizability coincides with regular weak family prealgebraizability. In turn, by Proposition 607, regular weak family prealgebraizability entails weak family prealgebraizability. But, by Corollary 297, the latter property is identical with weak family algebraizability.

For Part (b), if $\mathcal{I}$ is regularly weakly system algebraizable, then it is, by definition, protoalgebraic and system assertional, whence, by Theorem 597, it is protoalgebraic and system completely reflective. Therefore, it is, by definition, weakly (system or, equivalently, left) algebraizable. ■

Thus, Proposition 620, together with Propositions 607 and 618, point to the following hierarchy of regularly weakly (pre)algebraizable π-institutions and weakly (pre)algebraizable π-institutions.



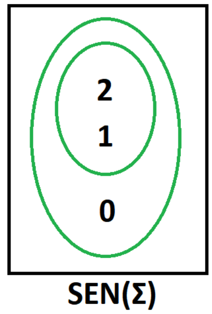
Again it is not difficult to see that the classes in the regular weak algebraizability hierarchy are different from the classes in the weak algebraizability hierarchy. This is accomplished by constructing an example of a π-institution which is weakly family algebraizable but is not regularly weakly system prealgebraizable.

Example 621 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

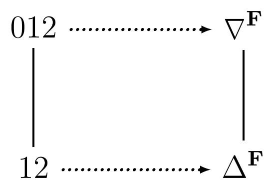
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by* $\sigma^\flat_\Sigma(0) = 0$*,* $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 0$*.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}.$$



$\mathcal{I}$ is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.



Since the lattice of theory families of $\mathcal{I}$ is order isomorphic with the lattice of $\mathrm{AlgSys}^*(\mathcal{I})$*-congruence systems, $\mathcal{I}$ is weakly family algebraizable.*

On the other hand, for $T = \{\{2,3\}\}$, we have $2,3 \in T_\Sigma$, but $\langle 2,3\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$, whence $\mathcal{I}$ is not system regular. Hence, a fortiori, $\mathcal{I}$ is not regularly weakly system prealgebraizable.

As was the case with regular weak prealgebraizability, we can show that both kinds of regular weak algebraizability transfer from theory families/systems to filter families/systems over arbitrary **F**-algebraic systems.

Theorem 622 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is regularly weakly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and all $\Sigma \in |\mathbf{Sign}|$,

- *$T \leq T'$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;*
- *$|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$;*

(b) $\mathcal{I}$ is regularly weakly system algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ and all $\Sigma \in |\mathbf{Sign}|$,

- *$T \leq T'$ implies $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;*
- *$|T''_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$.*

Proof: Combine Theorem 179 with Theorems 599 and 600. ∎

Finally, we may also adapt previously obtained results characterizing weak algebraizability to obtain similar characterizations of regular weak algebraizability in terms of mappings between posets of filter families/ systems and congruence systems.

Corollary 623 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly weakly family algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: By Theorems 617 and 610. ∎

Theorem 624 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly weakly system algebraizable if and only if it is stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism, such that, for all $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly weakly system algebraizable. Then it is, by definition, protoalgebraic and, thus, by Theorem 175, stable. Moreover, by Propositions 618 and 605 and Theorem 597, it is system c-reflective. Therefore, it is weakly algebraizable. Thus, the required isomorphism is given by Theorem 268. The expression for T is obtained by applying Theorem 609.

Assume, conversely, that the postulated condition holds. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since Ω on the collection of theory systems is an order isomorphism, it is monotone and, hence, $\mathcal{I}$ is prealgebraic. Thus, by stability and Theorem 175, $\mathcal{I}$ is protoalgebraic. Moreover, by hypothesis and Theorem 609, $\mathcal{I}$ is system assertional. Thus, by definition, $\mathcal{I}$ is regularly weakly system algebraizable. ∎

8.6 Regular Prealgebraizability

We look, next, at those classes of π-institutions that are formed by adding preequivalentiality to the various levels of assertionality.

Definition 625 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- *$\mathcal{I}$ is* **regularly family prealgebraizable***, or* **RF prealgebraizable** *for short, if it is preequivalential and family assertional;*
- *$\mathcal{I}$ is* **regularly left prealgebraizable***, or* **RL prealgebraizable** *for short, if it is preequivalential and left assertional;*
- *$\mathcal{I}$ is* **regularly system prealgebraizable***, or* **RS prealgebraizable** *for short, if it is preequivalential and system assertional.*

Based on the assertionality hierarchy established in Proposition 592, we have the following

Proposition 626 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is regularly family prealgebraizable, then it is regularly left prealgebraizable;

(b) If $\mathcal{I}$ is regularly left prealgebraizable, then it is regularly system prealgebraizable.

Proof: Straightforward by combining Definition 625 and Proposition 592. ■

Proposition 626 establishes the **regular prealgebraizability hierarchy** depicted in the following diagram.

Regular Family Prealgebraizable

↓

Regular Left Prealgebraizable

↓

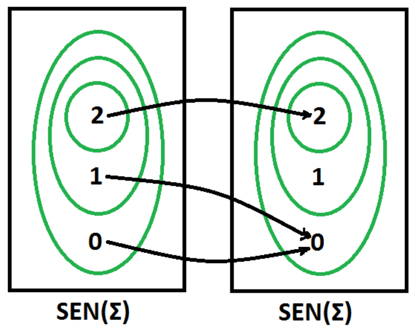
Regular System Prealgebraizable

We give again two examples to show that all classes in this hierarchy are different, i.e., that the arrows in the diagram represent proper inclusions. The first describes a π-institution that is regularly left prealgebraizable but fails to be regularly family prealgebraizable, thus showing that the top arrow stands for a proper inclusion.

Example 627 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- *$\mathbf{Sign}^\flat$ is the category with a single object Σ and a single non-identity morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial category of natural transformations.*



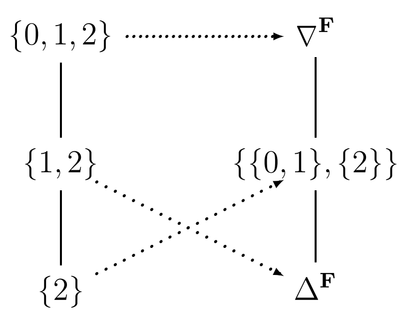
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C\rangle$ by setting $\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}$.

The following table gives the theory families and the theory systems of the π-institution $\mathcal{I}$.

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1,2\}$	$\{2\}$
$\{0,1,2\}$	$\{0,1,2\}$

Since $\mathcal{I}$ is not systemic, by Proposition 591, it fails to be family assertional and, hence, it is not regularly family prealgebraizable.

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



Since the only theory systems of $\mathcal{I}$ are $\{\{2\}\}$ and $\{\{0,1,2\}\}$, it is clear that Ω is monotone on theory systems and, hence, $\mathcal{I}$ is prealgebraic. To see that it is preequivalential, we must also show that it is system extensional. To simplify the process, we note that the only non-trivial proper universes of $\mathbf{F}$ are $\mathbf{X} = \{\{0,1\}\}$ and $\mathbf{Y} = \{\{0,2\}\}$, and the only proper theory system is $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$. *Hence, there are only two cases to check, as shown below (written, as done elsewhere, in shorthand):*

- $\Omega^{\mathbf{X}}(2 \cap \mathbf{X}) = \Omega^{\mathbf{X}}(\varnothing) = \{01\} = \{01,2\} \cap \mathbf{X}^2 = \Omega(2) \cap \mathbf{X}^2$;

- $\Omega^{\mathbf{Y}}(2 \cap \mathbf{Y}) = \Omega^{\mathbf{Y}}(2) = \{0,2\} = \{01,2\} \cap \mathbf{Y}^2 = \Omega(2) \cap \mathbf{Y}^2$.

Clearly, $\mathcal{I}$ has theorems. Thus, to complete the proof that it is regularly left prealgebraizable, it suffices to show that it is left assertional, i.e., by Proposition 588, that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T}_\Sigma = 2/\Omega_\Sigma(T)$.

- $\overleftarrow{\{\{2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{2\}\})$;
- $\overleftarrow{\{\{1,2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{1,2\}\})$;
- $\overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\} = 2/\Omega_\Sigma(\{\{0,1,2\}\})$.

The second example gives a regularly system prealgebraizable π-institution that is not regularly left prealgebraizable.

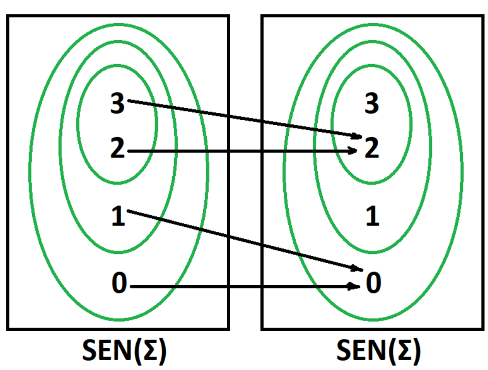
Example 628 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object Σ and a unique (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and*

  $$\mathrm{SEN}^\flat(f)(0) = 0,\ \mathrm{SEN}^\flat(f)(1) = 0,\ \mathrm{SEN}^\flat(f)(2) = 2,\ \mathrm{SEN}^\flat(f)(3) = 2;$$

- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ determined by*

x	0	1	2	3
$\sigma^\flat_\Sigma(x)$	0	1	0	1



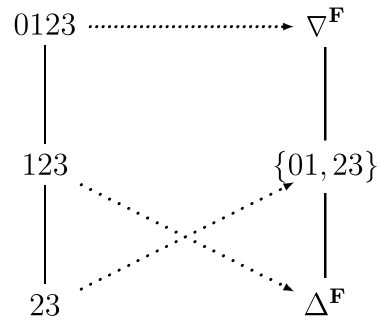
Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{2,3\},\{1,2,3\},\{0,1,2,3\}\}.$$

The following table shows the action of $\overleftarrow{\ }$ *on theory families.*

T	$\{2,3\}$	$\{1,2,3\}$	$\{0,1,2,3\}$
$\overleftarrow{T}$	$\{2,3\}$	$\{2,3\}$	$\{0,1,2,3\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right.



Since the only theory systems of $\mathcal{I}$ *are* $\{\{2,3\}\}$ *and* $\{\{0,1,2,3\}\}$, *it is obvious that* Ω *is monotone on theory systems and, hence, that* $\mathcal{I}$ *is prealgebraic. To see that it is preequivalential, it suffices, thus, to show that it is also system extensional. To simplify the process, we note that the only non-trivial proper universes of* $\mathbf{F}$ *are* $\mathbf{X} = \{\{0,1\}\}$, $\mathbf{Y} = \{\{0,2\}\}$ *and* $\mathbf{Z} = \{\{0,1,2\}\}$, *and the only proper theory system is* $\mathrm{Thm}(\mathcal{I}) = \{\{2,3\}\}$. *Hence, there are three cases to check, as shown below (written, as done elsewhere, in shorthand):*

- $\Omega^{\mathbf{X}}(23 \cap \mathbf{X}) = \Omega^{\mathbf{X}}(\varnothing) = \{01\} = \{01,23\} \cap \mathbf{X}^2 = \Omega(23) \cap \mathbf{X}^2$;
- $\Omega^{\mathbf{Y}}(23 \cap \mathbf{Y}) = \Omega^{\mathbf{Y}}(2) = \{0,2\} = \{01,23\} \cap \mathbf{Y}^2 = \Omega(23) \cap \mathbf{Y}^2$;
- $\Omega^{\mathbf{Z}}(23 \cap \mathbf{Z}) = \Omega^{\mathbf{Z}}(2) = \{01,2\} = \{01,23\} \cap \mathbf{Z}^2 = \Omega(23) \cap \mathbf{Z}^2$.

Clearly, $\mathcal{I}$ *has theorems. To see that* $\mathcal{I}$ *is regularly system prealgebraizable it suffices to show that it is system assertional, i.e., by Proposition 588, that, for all* $T \in \mathrm{ThSys}(\mathcal{I})$, $T_\Sigma = 2/\Omega_\Sigma(T)$. *We do have indeed:*

- $\{2,3\} = 2/\Omega_\Sigma(\{\{2,3\}\})$;
- $\{0,1,2,3\} = 2/\Omega_\Sigma(\{\{0,1,2,3\}\})$.

On the other hand, for $T = \{\{1,2,3\}\}$, *we have* $2,3 \in \{2,3\} = \overleftarrow{T}_\Sigma$, *whereas* $\langle 2,3\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$. *We conclude that* $\mathcal{I}$ *is not left regular and, hence, a fortiori, it is not regularly left prealgebraizable.*

We investigate, next, the relationships that hold between the various regular prealgebraizability classes, introduced in the present section, and the corresponding regular weak prealgebraizability classes, that were introduced in Section 8.4.

Directly from the definitions involved, we get the following

Proposition 629 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

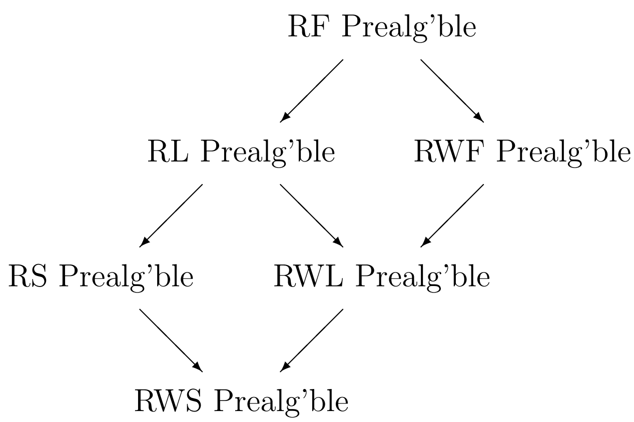
(a) If $\mathcal{I}$ *is regularly family prealgebraizable, then it is regularly weakly family prealgebraizable;*

(b) If $\mathcal{I}$ *is regularly left prealgebraizable, then it is regularly weakly left prealgebraizable;*

(c) If $\mathcal{I}$ *is regularly system prealgebraizable, then it is regularly weakly system prealgebraizable.*

Proof: If $\mathcal{I}$ is regularly family prealgebraizable, then, by definition, it is preequivalential and family assertional. Hence, by Proposition 338, it is prealgebraic and family assertional. Thus, it is, by definition, regularly weakly family prealgebraizable. Parts (b) and (c) can be proven similarly. ■

Therefore, we get the mixed regular prealgebraizability and regular weak prealgebraizability hierarchy depicted in the diagram.



To show that all classes in this hierarchy are different, we provide an example of a π-institution that is regularly weakly family prealgebraizable, and, thus, belongs to all three regular weak prealgebraizability classes, but fails to be regularly system prealgebraizable, whence it belongs to none of three steps in the regular prealgebraizability hierarchy. This example shows that all three southeast arrows represent proper inclusions.

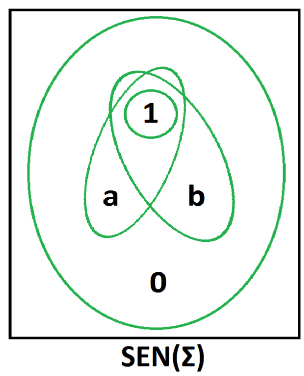
Example 630 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$*;*

- *$N^\flat$ is the category of natural transformations generated by the two binary natural transformations $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by the following tables.*

$\wedge$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

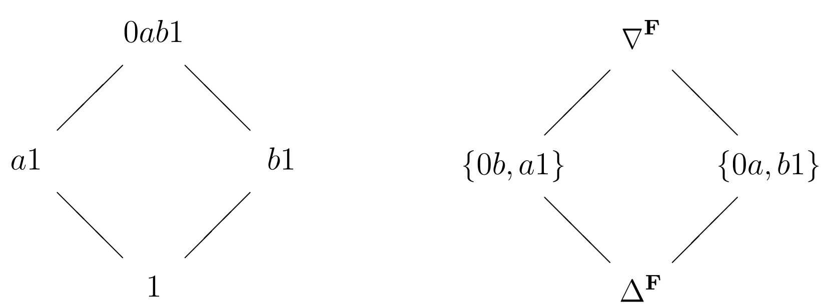


Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution defined by setting

$$\mathcal{C}_\Sigma = \{\{1\}, \{a, 1\}, \{b, 1\}, \{0, a, b, 1\}\}.$$

$\mathcal{I}$ has four theory families, all of which are also theory systems.

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, we can see that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an order isomorphism, whence, $\mathcal{I}$ is weakly family prealgebraizable. Since it has theorems, to show that it is, also, family assertional, it suffices to show that it satisfies, for all $T \in \mathrm{ThFam}(\mathcal{I})$, $T_\Sigma = 1/\Omega_\Sigma(T)$. This is easily checked from the diagram above, giving the Leibniz congruence systems corresponding to the various theory families of $\mathcal{I}$.

On the other hand, for the universe $\mathbf{X} = \{\{0, a, 1\}\}$ *and the theory system* $T = \{\{1\}\}$*, we get*

$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\}, \{a\}, \{1\}\} \subsetneq \{\{0\}, \{a, 1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Thus, $\mathcal{I}$ *is not system extensional and, therefore, it fails to be (system) preequivalential and, a fortiori, it also fails to be regularly system prealgebraizable.*

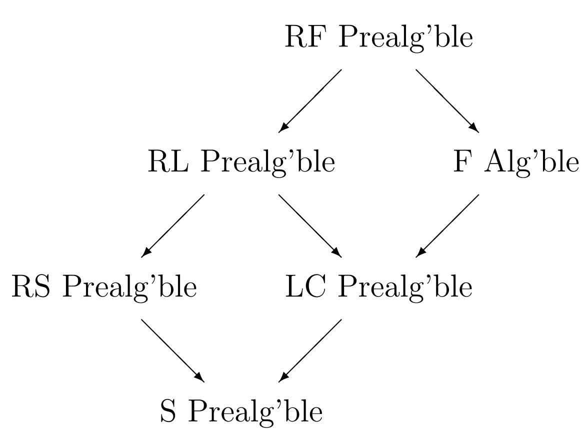
Turning now to the relationship between the regular prealgebraizability hierarchy and the prealgebraizability hierarchy, we get the following

Proposition 631 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.*

- *If* $\mathcal{I}$ *is regularly family prealgebraizable, then it is family (pre)algebraizable;*
- *If* $\mathcal{I}$ *is regularly left prealgebraizable, then it is left completely reflective prealgebraizable;*
- *If* $\mathcal{I}$ *is regularly system prealgebraizable, then it is system prealgebraizable.*

Proof: We show Part (a) in detail. The remaining parts can be proved similarly. Suppose $\mathcal{I}$ is regularly family prealgebraizable. Then, by definition, it is preequivalential and family assertional. Hence, by Theorem 597, it is preequivalential and family completely reflective. Thus, by definition, it is weakly family (pre)algebraizable. ■

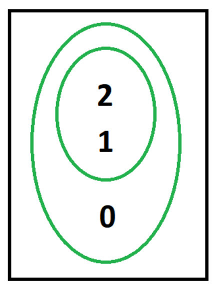
Proposition 631, together with Proposition 626 and the hierarchy established in Section 5.6, point to the following hierarchy of regularly prealgebraizable and (pre)algebraizable π-institutions. Note that the complete hierarchy is larger, but we only show those classes in the (pre)algebraizability hierarchy that are directly related to those in the regular prealgebraizability hierarchy via Theorem 631.



Again it is not difficult to see that the classes in the regular prealgebraizability hierarchy are different from the classes of prealgebraizable π-institutions. This is accomplished by constructing an example of a π-institution which is family completely reflective prealgebraizable (equivalently, family algebraizable), but is not regularly system prealgebraizable.

Example 632 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by* $\sigma^\flat_\Sigma(0) = 0$*,* $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 0$*.*

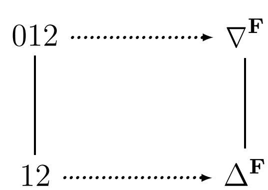


SEN(Σ)

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1,2\},\{0,1,2\}\}.$$

$\mathcal{I}$ *is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.*



Since the lattice of theory families of $\mathcal{I}$ *is order isomorphic with the lattice of* $\mathrm{AlgSys}^*(\mathcal{I})$*-congruence systems,* $\mathcal{I}$ *is weakly family c-reflective prealgebraizable. To see that it is family c-reflective prealgebraizable, it suffices to show that it is also system extensional. The only nontrivial proper universes of* $\mathbf{F}$ *are* $\mathbf{X} = \{\{0,1\}\}$ *and* $\mathbf{Y} = \{\{0,2\}\}$ *and the only proper theory system is* $\{\{1,2\}\}$*. Thus, we only need to check two cases:*

- $\Omega^{\mathbf{X}}(12 \cap \mathbf{X}) = \Omega^{\mathbf{X}}(1) = \{0,1\} = \Delta^{\mathbf{F}} \cap \mathbf{X}^2 = \Omega(12) \cap \mathbf{X}^2$;
- $\Omega^{\mathbf{Y}}(12 \cap \mathbf{Y}) = \Omega^{\mathbf{Y}}(2) = \{0,2\} = \Delta^{\mathbf{F}} \cap \mathbf{Y}^2 = \Omega(12) \cap \mathbf{Y}^2$.

On the other hand, for $T = \{\{1,2\}\}$, *we have* $1,2 \in T_\Sigma$, *but* $\langle 1,2\rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$, *whence* $\mathcal{I}$ *is not system regular and, hence, a fortiori, it is not regularly system prealgebraizable.*

Based on existing results, we can show that all three kinds of regular prealgebraizability transfer from theory families/systems to filter families/systems over arbritrary $\mathbf{F}$-algebraic systems.

Theorem 633 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) $\mathcal{I}$ *is regularly family prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, *every universe* $\mathbf{X} \leq \mathbf{A}$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, *all* $T', T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$,

  - $T' \leq T''$ *implies* $\Omega^{\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T'')$;
  - $\Omega^{\mathbf{X}}(T' \cap \mathbf{X}) \leq \Omega^{\mathcal{A}}(T') \cap \mathbf{X}^2$;
  - $|T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)| = 1$;

(b) $\mathcal{I}$ *is regularly left prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, *every universe* $\mathbf{X} \leq \mathbf{A}$, *all* $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, *all* $T', T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$,

  - $T' \leq T''$ *implies* $\Omega^{\mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T'')$;
  - $\Omega^{\mathbf{X}}(T' \cap \mathbf{X}) \leq \Omega^{\mathcal{A}}(T') \cap \mathbf{X}^2$;
  - $|\overleftarrow{T}_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)| = 1$;

(c) $\mathcal{I}$ *is regularly weakly system prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, *every universe* $\mathbf{X} \leq \mathbf{A}$, *all* $T, T' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$,

  - $T \leq T'$ *implies* $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$;
  - $\Omega^{\mathbf{X}}(T \cap \mathbf{X}) \leq \Omega^{\mathcal{A}}(T) \cap \mathbf{X}^2$;
  - $|T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)| = 1$.

Proof: Combine Theorems 179 and 314 with Theorem 599. ■

Finally, we adapt previously obtained results characterizing prealgebraizability to obtain similar characterizations of regular prealgebraizability in terms of mappings between posets of filter families/ systems (including theory families/systems) and congruence systems.

Theorem 634 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly family prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly family prealgebraizable. Then it is, by definition, preequivalential and, moreover, by definition, Proposition 629, Proposition 605 and Theorem 597, it is family c-reflective. Therefore, it is F (pre)algebraizable. Thus, the required isomorphism is given by Theorem 366. The expression for T is obtained by applying Theorem 600.

Assume, conversely, that the postulated condition holds. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since Ω is an order isomorphism, which commutes with inverse logical extensions, $\mathcal{I}$ is preequivalential. Moreover, by hypothesis and Theorem 600, $\mathcal{I}$ is family assertional. Thus, by definition, $\mathcal{I}$ is regularly family prealgebraizable. ■

Theorem 635 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly left prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding that commutes with inverse logical extensions, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|\overleftarrow{T}_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly left prealgebraizable. Then it is, by definition, preequivalential and, moreover, by definition, Propositions 629 and 605 and Theorem 597, it is left c-reflective. Therefore, it is LC prealgebraizable. Thus, the required embedding is given by Theorem 355. The expression for T is obtained by applying Theorem 600.

Assume, conversely, that the postulated condition holds. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since Ω on the collection of theory systems is an order embedding that commutes with inverse logical extensions, $\mathcal{I}$ is preequivalential. Moreover, by hypothesis and Theorem 600, $\mathcal{I}$ is left assertional. Thus, by definition, $\mathcal{I}$ is regularly left prealgebraizable. ■

Theorem 636 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly system prealgebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding that commutes with inverse logical extensions, such that, for all $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma / \Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly system prealgebraizable. Then it is, by definition, preequivalential and, moreover, by definition, Propositions 629 and 605 and Theorem 597, it is system c-reflective. Therefore, it is system prealgebraizable. Thus, the required embedding is given by Theorem 353. The expression for T is obtained by applying Theorem 600.

Assume, conversely, that the postulated condition holds. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since Ω on the collection of theory systems is an order embedding that commutes with inverse logical extensions, $\mathcal{I}$ is preequivalential. Moreover, by hypothesis and Theorem 600, $\mathcal{I}$ is system assertional. Thus, by definition, $\mathcal{I}$ is regularly system prealgebraizable. ■

8.7 Regular Algebraizability

We look, next, at those classes of π-institutions that are formed by adding equivalentiality to the various levels of assertionality.

Definition 637 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

- $\mathcal{I}$ *is* **regularly family algebraizable**, *or* **RF algebraizable** *for short, if it is equivalential and family assertional;*
- $\mathcal{I}$ *is* **regularly left algebraizable**, *or* **RL algebraizable** *for short, if it is equivalential and left assertional;*
- $\mathcal{I}$ *is* **regularly system algebraizable**, *or* **RS algebraizable** *for short, if it is equivalential and system assertional.*

Even though, there are apparently three classes in the regular algebraizability hierarchy, in reality there are only two, since, as was the case with regular weak algebraizability, the classes of regularly left and of regularly system π-institutions coincide.

Proposition 638 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $\mathcal{I}$ *is regularly left algebraizable if and only if it is regularly system algebraizable.*

Proof: The "only if" follows directly by the definition and Proposition 592. For the "if", suppose that $\mathcal{I}$ is regularly system algebraizable. Then it is, a fortiori, equivalential and, hence, protoalgebraic. Thus, by Lemma 170, it is stable. Therefore, since $\mathcal{I}$ is system regular and stable, by Proposition 579, it is left regular. We conclude that $\mathcal{I}$ is regularly left algebraizable. ■

The assertionality hierarchy, established in Proposition 592, and Proposition 638 allow us to establish the following regular algebraizability hierarchy.

Proposition 639 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is regularly family algebraizable, then it is regularly system algebraizable.*

Proof: Straightforward by combining Definition 637 and Proposition 592, and taking into account Proposition 638. ■

The **regular algebraizability hierarchy** is depicted in the following diagram.

Regular Family Algebraizable

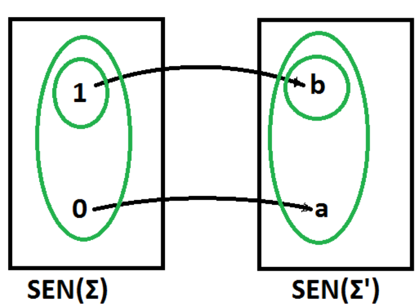
↓

Regular System Algebraizable

We use an example to show that the two classes in this hierarchy are different. Namely, we construct a π-institution that is regularly system algebraizable but fails to be regularly family algebraizable.

Example 640 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with objects* Σ *and* Σ' *and a unique (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a, b\}$ *and* $\mathrm{SEN}^\flat(f)(0) = a$*,* $\mathrm{SEN}^\flat(f)(1) = b$*;*
- $N^\flat$ *is the trivial category of natural transformations.*



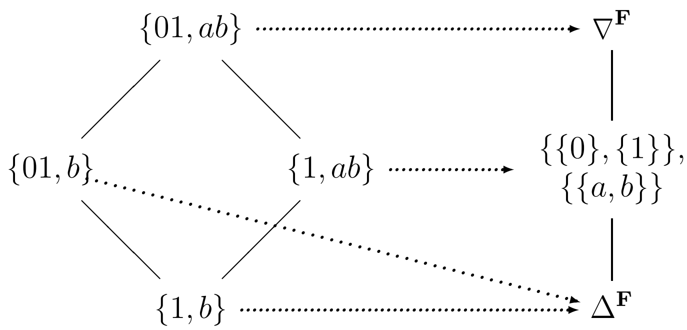
Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by stipulating that*

$$\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{b\}, \{a, b\}\}.$$

The following table shows the action of $^{\leftarrow}$ *on theory families, where rows correspond to* T_Σ *and columns to* $T_{\Sigma'}$ *and each entry is written as* $\overleftarrow{T}_\Sigma, \overleftarrow{T}_{\Sigma'}$.

$\leftarrow$	$\{b\}$	$\{a,b\}$
$\{1\}$	$\{1\},\{b\}$	$\{1\},\{a,b\}$
$\{0,1\}$	$\{1\},\{b\}$	$\{0,1\},\{a,b\}$

The following diagram shows the structure of the lattice of theory families on the left and the structure of the corresponding Leibniz congruence systems (in terms of blocks) on the right:



The Leibniz operator is monotone on theory families, whence, $\mathcal{I}$ *is protoalgebraic. To see that it is equivalential, we must show that it is family extensional. The only non-trivial proper subuniverses of* $\mathbf{F}$ *are* $\mathbf{X} = \{\{0\},\{a,b\}\}$ *and* $\mathbf{Y} = \{\{1\},\{a,b\}\}$. *Moreover, there are only three theory families different from* $\mathrm{SEN}^\flat$. *Thus, we have six cases to examine, accomplished below:*

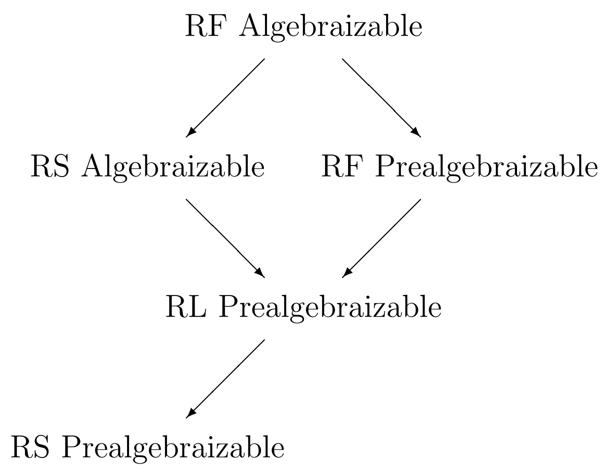
- $\Omega^{\mathbf{X}}(\{1,b\}\cap\mathbf{X}) = \Omega^{\mathbf{X}}(\{\varnothing,b\}) = \{\Delta^{\mathbf{X}}_\Sigma,\nabla^{\mathbf{X}}_{\Sigma'}\} = \Delta^{\mathbf{F}}\cap\mathbf{X}^2 = \Omega(\{1,b\})\cap\mathbf{X}^2$;
- $\Omega^{\mathbf{X}}(\{01,b\}\cap\mathbf{X}) = \Omega^{\mathbf{X}}(\{0,b\}) = \Delta^{\mathbf{X}} = \Delta^{\mathbf{F}}\cap\mathbf{X}^2 = \Omega(\{01,b\})\cap\mathbf{X}^2$;
- $\Omega^{\mathbf{X}}(\{1,ab\}\cap\mathbf{X}) = \Omega^{\mathbf{X}}(\{\varnothing,ab\}) = \nabla^{\mathbf{X}} = \{\Delta^{\mathbf{F}}_\Sigma,\nabla^{\mathbf{F}}_{\Sigma'}\}\cap\mathbf{X}^2 = \Omega(\{1,ab\})\cap\mathbf{X}^2$;
- $\Omega^{\mathbf{Y}}(\{1,b\}\cap\mathbf{Y}) = \Omega^{\mathbf{Y}}(\{1,b\}) = \Delta^{\mathbf{Y}} = \Delta^{\mathbf{F}}\cap\mathbf{Y}^2 = \Omega(\{1,b\})\cap\mathbf{Y}^2$;
- $\Omega^{\mathbf{Y}}(\{01,b\}\cap\mathbf{Y}) = \Omega^{\mathbf{Y}}(\{1,b\}) = \Delta^{\mathbf{Y}} = \Delta^{\mathbf{F}}\cap\mathbf{Y}^2 = \Omega(\{01,b\})\cap\mathbf{Y}^2$;
- $\Omega^{\mathbf{Y}}(\{1,ab\}\cap\mathbf{Y}) = \Omega^{\mathbf{Y}}(\{1,ab\}) = \nabla^{\mathbf{Y}} = \{\Delta^{\mathbf{F}}_\Sigma,\nabla^{\mathbf{F}}_{\Sigma'}\}\cap\mathbf{Y}^2 = \Omega(\{1,ab\})\cap\mathbf{Y}^2$.

We showed that $\mathcal{I}$ *is equivalential. We also have,* $\mathrm{Thm}(\mathcal{I}) = \{\{1\},\{b\}\}$ *and, for every theory system* T, $T_\Sigma = 1/\Omega_\Sigma(T)$ *and* $T_{\Sigma'} = b/\Omega_{\Sigma'}(T)$. *Therefore,* $\mathcal{I}$ *is system assertional. Thus,* $\mathcal{I}$ *is regularly system algebraizable.*

On the other hand, for $T = \{\{0,1\},\{b\}\} \in \mathrm{ThFam}(\mathcal{I})$, *we have* $0,1 \in T_\Sigma$, *but* $\langle 0,1\rangle \notin \Omega_\Sigma(T)$. *Therefore,* $\mathcal{I}$ *fails to be family regular and, hence,* $\mathcal{I}$ *is not regularly family algebraizable.*

We investigate, next, the relationships that hold between the two regular algebraizability classes, introduced in the present section, and the three regular prealgebraizability classes, that were introduced in Section 8.6. Since, by

Proposition 331, equivalentiality implies preequivalentiality, we get, a priori, the following mixed hierarchy.



As was the case with the corresponding weak classes, we can show that the top classes of the regular prealgebraizability and the regular algebraizability hierarchies coincide.

Theorem 641 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly family prealgebraizable if and only if it is regularly family algebraizable.*

Proof: The "if" follows from the relevant definitions and the fact that, by Proposition 331, equivalentiality implies preequivalentiality. For the "only if", it suffices to show that, under family assertionality, preequivalentiality implies equivalentiality. By Proposition 331, it suffices, in turn, to show that family assertionality implies stability and, by Proposition 152, that family assertionality implies systemicity. Indeed, by Theorem 597, family assertionality implies family c-reflectivity and, by Proposition 237, we get that $\mathcal{I}$ is systemic. ∎

Moreover, from the definitions involved, we get the following

Proposition 642 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is regularly system algebraizable, then it is regularly left prealgebraizable.*

Proof: Suppose $\mathcal{I}$ is regularly system algebraizable. Equivalently, by Proposition 638, it is regularly left algebraizable. Then, by definition, it is equivalential and left assertional. Thus, by Proposition 331, it is preequivalential and left assertional, i.e., by definition, it is regularly left prealgebraizable. ∎

Based on Theorem 641 and Proposition 642, we get the following updated version of the mixed hierarchy shown in the preceding diagram.

RF (Pre)Algebraizable

↓

RS Algebraizable

↓

RL Prealgebraizable

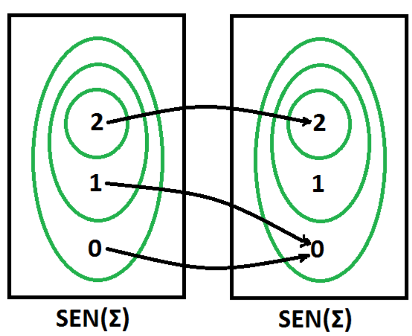
↓

RS Prealgebraizable

To show that all classes in this hierarchy are different, we provide an example of a π-institution that is regularly left prealgebraizable, but fails to be regularly system algebraizable, i.e., an example that separates the regular algebraizability from the regular prealgebraizability classes.

Example 643 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single non-identity morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is given by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f)(0) = 0$, $\mathrm{SEN}^\flat(f)(1) = 0$ *and* $\mathrm{SEN}^\flat(f)(2) = 2$;
- $N^\flat$ *is the trivial category of natural transformations.*

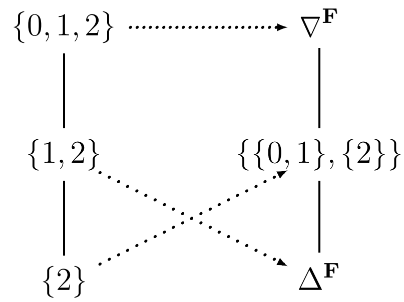


Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting* $\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

The following table gives the theory families and the theory systems of the π*-institution* $\mathcal{I}$:

T	$\overleftarrow{T}$
$\{2\}$	$\{2\}$
$\{1, 2\}$	$\{2\}$
$\{0, 1, 2\}$	$\{0, 1, 2\}$

The lattice of theory families and the corresponding Leibniz congruence systems are depicted below:



Since the only theory systems of $\mathcal{I}$ *are* $\{\{2\}\}$ *and* $\{\{0,1,2\}\}$, *it is clear that* Ω *is monotone on theory systems and, hence,* $\mathcal{I}$ *is prealgebraic. To see that it is preequivalential, we must also show that it is system extensional. To simplify the process, we note that the only non-trivial proper universes of* $\mathbf{F}$ *are* $\mathbf{X} = \{\{0,1\}\}$ *and* $\mathbf{Y} = \{\{0,2\}\}$ *and the only proper theory system is* $\mathrm{Thm}(\mathcal{I}) = \{\{2\}\}$. *Hence, there are two cases to check, as shown below (written, as done elsewhere, in shorthand):*

- $\Omega^{\mathbf{X}}(2 \cap \mathbf{X}) = \Omega^{\mathbf{X}}(\varnothing) = \{01\} = \{01,2\} \cap \mathbf{X}^2 = \Omega(2) \cap \mathbf{X}^2$;
- $\Omega^{\mathbf{Y}}(2 \cap \mathbf{Y}) = \Omega^{\mathbf{Y}}(2) = \{0,2\} = \{01,2\} \cap \mathbf{Y}^2 = \Omega(2) \cap \mathbf{Y}^2$.

Clearly, $\mathcal{I}$ *has theorems. Thus, to complete the proof that it is regularly left prealgebraizable, it suffices to show that it is left assertional, i.e., by Proposition 588, that, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, $\overleftarrow{T}_\Sigma = 2/\Omega_\Sigma(T)$. *Indeed, we get:*

- $\overleftarrow{\{\{2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{2\}\})$;
- $\overleftarrow{\{\{1,2\}\}}_\Sigma = \{2\} = 2/\Omega_\Sigma(\{\{1,2\}\})$;
- $\overleftarrow{\{\{0,1,2\}\}}_\Sigma = \{0,1,2\} = 2/\Omega_\Sigma(\{\{0,1,2\}\})$.

On the other hand, since $\{\{2\}\} \leq \{\{1,2\}\}$, *but*

$$\Omega(\{\{2\}\}) = \{\{\{0,1\},\{2\}\}\} \nleq \Delta^{\mathbf{F}} = \Omega(\{\{1,2\}\}),$$

$\mathcal{I}$ *is not protoalgebraic and, hence, a fortioti, it is not equivalential. As a consequence, it fails to be regularly system algebraizable.*

Turning now to the relationship between regular (pre)algebraizability and regular weak (pre)algebraizability, we complete the picture given in Section 8.6.

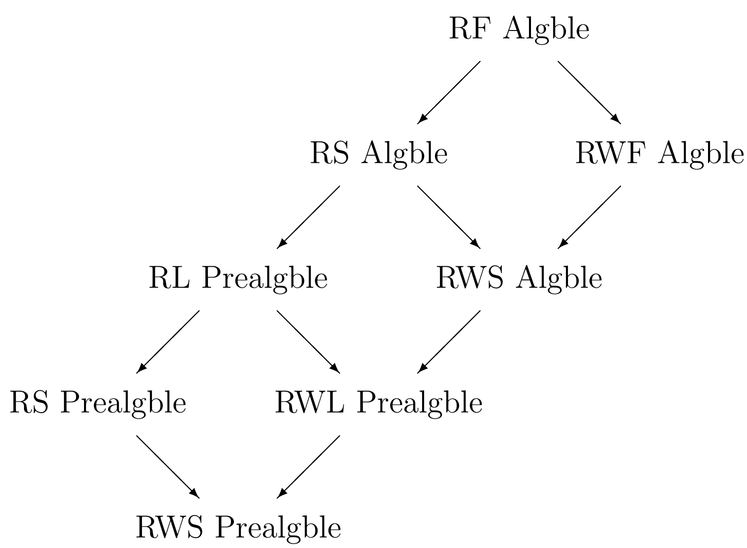
Proposition 644 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$.

(a) If $\mathcal{I}$ is regularly family algebraizable, then it is regularly weakly family algebraizable;

(b) If $\mathcal{I}$ is regularly system algebraizable, then it is regularly weakly system algebraizable.

Proof: By Definition 329, equivalentiality implies protoalgebraicity. From this fact, and Definitions 637 and 613, both implications follow directly. ■

Thus, Proposition 644, together with Propositions 642 and 629, point to the following hierarchy of regularly (pre)algebraizable π-institutions and regularly weakly (pre)algebraizable π-institutions.



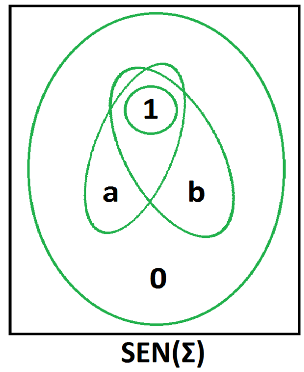
To see that all southeast arrows represent proper inclusions, we give an example of a regularly weakly family algebraizable π-institution which fails to be regularly system prealgebraizable.

Example 645 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with single object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, a, b, 1\}$*;*
- $N^\flat$ *is the category of natural transformations, generated by the two binary natural transformations* $\wedge, \vee : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$*, defined by the following tables:*

$\wedge$	0	a	b	1
0	0	0	0	0
a	0	a	0	a
b	0	0	b	b
1	0	a	b	1

$\vee$	0	a	b	1
0	0	a	b	1
a	a	a	1	1
b	b	1	b	1
1	1	1	1	1

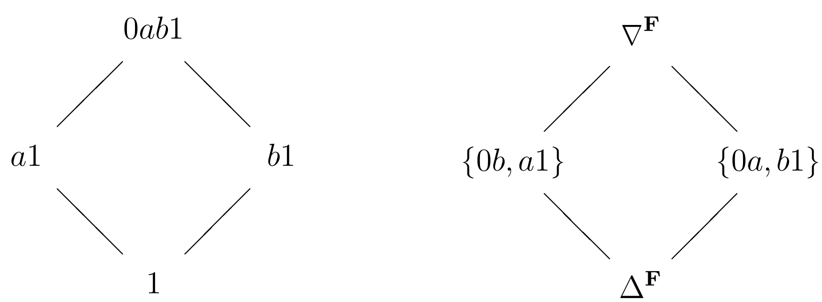


Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be the π-institution, defined by setting

$$\mathcal{C}_\Sigma = \{\{1\}, \{a, 1\}, \{b, 1\}, \{0, a, b, 1\}\}.$$

$\mathcal{I}$ has four theory families, all of which are also theory systems.

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.



From the diagram, we can see that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an order isomorphism, whence, $\mathcal{I}$ is weakly family algebraizable. Since it has theorems, to show that it is, also, family assertional, it suffices to show that it satisfies, for all $T \in \mathrm{Thfam}(\mathcal{I})$, $T_\Sigma = 1/\Omega_\Sigma(T)$. This is easily checked from the diagram above, giving the Leibniz congruence systems corresponding to the various theory families of $\mathcal{I}$.

On the other hand, for the universe $\mathbf{X} = \{\{0, a, 1\}\}$ and the theory system $T = \{\{1\}\}$, we get

$$\Omega(T) \cap \mathbf{X}^2 = \{\{0\}, \{a\}, \{1\}\} \subsetneq \{\{0\}, \{a, 1\}\} = \Omega^{\mathbf{X}}(T \cap \mathbf{X}).$$

Thus, $\mathcal{I}$ is not system extensional and, therefore, it fails to be (system) prequivalential and, a fortiori, it also fails to be regularly system prealgebraizable.

Turning now to the relationship between regular (pre)algebraizability and (pre)algebraizability, we get, by definition,

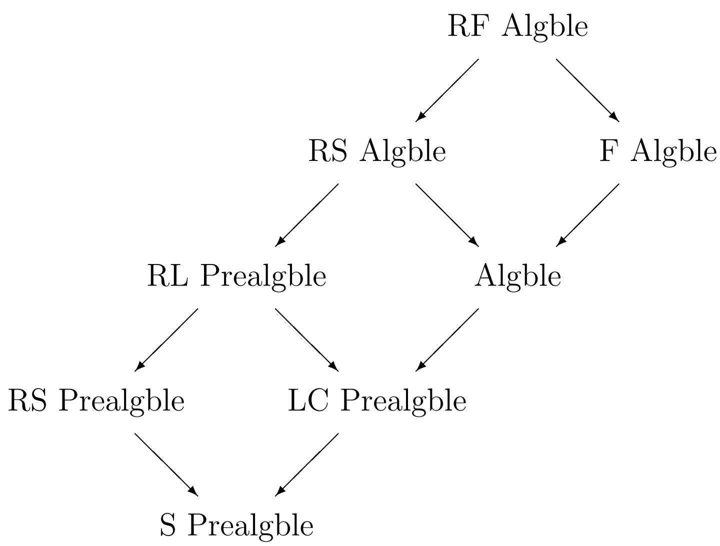
Proposition 646 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a π-institution based on $\mathbf{F}$.*

(a) If $\mathcal{I}$ is regularly family algebraizable, then it is family algebraizable;

(b) If $\mathcal{I}$ is regularly system algebraizable, then it is (system) algebraizable.

Proof: For Part (a) note that, by definition, $\mathcal{I}$ is regularly family algebraizable if and only if it is equivalential and family assertional. Thus, by Theorem 597, it is equivalential and family completely reflective. Thus, by Definition 360, it is family algebraizable. Part (b) follows along similar lines. ■

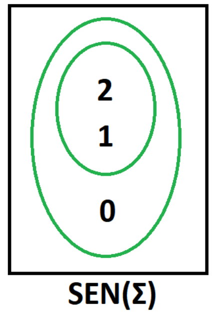
Proposition 646 completes the picture given by Proposition 631 and Proposition 642, establishing the following mixed regular (pre)algebraizability and (pre)algebraizability hierarchies, where, on the prealgebraizability side, only the classes immediately interacting with the regular prealgebraizability classes are shown.



Again it is not difficult to see that the classes in the regular (pre)algebraizability hierarchy are different from the classes in the (pre)algebraizability hierarchy. This is accomplished by constructing an example of a π-institution which is family algebraizable but is not regularly system prealgebraizable.

Example 647 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system defined as follows:*

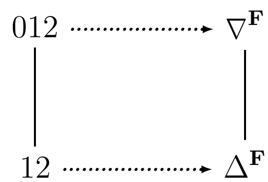
- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$*;*
- $N^\flat$ *is the category of natural transformations generated by the unary natural transformation* $\sigma^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *specified by* $\sigma^\flat_\Sigma(0) = 0$*,* $\sigma^\flat_\Sigma(1) = 1$ *and* $\sigma^\flat_\Sigma(2) = 0$*.*



Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{1,2\}, \{0,1,2\}\}.$$

$\mathcal{I}$ is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.



Since the lattice of theory families of $\mathcal{I}$ is order isomorphic with the lattice of $\mathrm{AlgSys}^*(\mathcal{I})$*-congruence systems, $\mathcal{I}$ is weakly family algebraizable. To see that it is family algebraizable, it suffices to show that it is also family extensional. The only nontrivial proper universes of $\mathbf{F}$ are $\mathbf{X} = \{\{0,1\}\}$ and $\mathbf{Y} = \{\{0,2\}\}$ and the only proper theory family is $\{\{1,2\}\}$. Thus, we only need to check two cases:*

- $\Omega^{\mathbf{X}}(12 \cap \mathbf{X}) = \Omega^{\mathbf{X}}(1) = \{0,1\} = \Delta^{\mathbf{F}} \cap \mathbf{X}^2 = \Omega(12) \cap \mathbf{X}^2$;
- $\Omega^{\mathbf{Y}}(12 \cap \mathbf{Y}) = \Omega^{\mathbf{Y}}(2) = \{0,2\} = \Delta^{\mathbf{F}} \cap \mathbf{Y}^2 = \Omega(12) \cap \mathbf{Y}^2$.

On the other hand, for $T = \{\{2,3\}\}$, we have $2,3 \in T_\Sigma$, but $\langle 2,3 \rangle \notin \Delta^{\mathbf{F}}_\Sigma = \Omega_\Sigma(T)$, whence $\mathcal{I}$ is not system regular and, hence, a fortiori, it is not regularly system prealgebraizable.

As was the case with regular weak algebraizability, we can show that both kinds of regular algebraizability transfer from theory families/ systems to filter families/systems over arbritrary $\mathbf{F}$-algebraic systems.

Theorem 648 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$.*

(a) $\mathcal{I}$ is regularly family algebraizable if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, all $\mathbf{X} \leq \mathbf{A}$, all $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ and all $\Sigma \in |\mathbf{Sign}|$,

– $T \leq T'$ *implies* $\Omega(T) \leq \Omega(T')$*;*
– $\Omega^{\mathbf{X}}(T \cap \mathbf{X}) = \Omega(T) \cap \mathbf{X}^2$*;*
– $|T_\Sigma/\Omega_\Sigma(T)| = 1$*;*

(b) $\mathcal{I}$ *is regularly system algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*, all* $\mathbf{X} \leq \mathbf{A}$*, all* $T, T' \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$*, all* $T'' \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,*

– $T \leq T'$ *implies* $\Omega(T) \leq \Omega(T')$*;*
– $\Omega^{\mathbf{X}}(T \cap \mathbf{X}) = \Omega(T) \cap \mathbf{X}^2$*;*
– $|T''_\Sigma/\Omega_\Sigma(T)| = 1$*.*

Proof: Combine Theorem 334 with Theorem 599. ■

Finally, we obtain characterizations of regular algebraizability in terms of mappings between posets of filter families/ systems and congruence systems.

Corollary 649 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly family algebraizable if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism commuting with inverse logical extensions, such that, for all $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: By Theorems 641 and 634. ■

Theorem 650 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$*.* $\mathcal{I}$ *is regularly system algebraizable if and only if it is stable and, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*,*

$$\Omega^{\mathcal{A}} : \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A}) \to \mathrm{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism commuting with inverse logical extensions, such that, for all $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$ *and all* $\Sigma \in |\mathbf{Sign}|$*,* $|T_\Sigma/\Omega^{\mathcal{A}}_\Sigma(T)| = 1$*.*

Proof: Suppose, first, that $\mathcal{I}$ is regularly system algebraizable. Then it is, by definition, equivalential and, thus, by Proposition 331, stable. Moreover, by Proposition 646, it is algebraizable, whence, the required isomorphism is given by Theorem 365. The expression for T is obtained by applying Theorem 600.

Assume, conversely, that the postulated condition holds. Consider the $\mathbf{F}$-algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since Ω is an order isomorphism that commutes with inverse logical extensions and $\mathcal{I}$ is stable, $\mathcal{I}$ is, by Theorem 365, algebraizable. Hence, $\mathcal{I}$ is, a fortiori, equivalential. Moreover, by hypothesis and Theorem 600, $\mathcal{I}$ is system assertional. Thus, by definition, $\mathcal{I}$ is regularly system algebraizable. ■

Chapter 9

The Semantic Leibniz Hierarchy: Over the Top II

9.1 Introduction

At the apex of the Leibniz hierarchy of sentential logics one finds the class of algebraizable logics [35, 43] (see, also, Chapter 4 of [64] and Sections 3.2 and 6.5 of [86]). The concept was first introduced by Blok and Pigozzi in [35] for finitary logics. It was later generalized to arbitrary sentential logics by Herrmann [43]. Roughly speaking, a sentential logic is *algebraizable* when there exist a class K of algebras, termed the *equivalent algebraic semantics*, and two translations $\delta \approx \varepsilon$ from formulas to equations, called *defining equations*, and Δ from equations to formulas, called *equivalence formulas*, which are interpretations, i.e., preserve and reflect the logical and the equational closures and vice-versa and, in addition, are inverses of one another in a specific sense. For a detailed study of this framework, apart from the original monograph by Blok and Pigozzi [35] and Herrmann's Dissertation [43], one may consult Chapter 4 of [64] and Sections 3.2 and 6.5 of [86]. Partly due to the historical progression, but also due to the intrinsic importance and ubiquity of finitarity, its key role in studies of classical logical systems and a host of advantageous properties associated with it, the finitary aspects of algebraizability have been extensively studied and tight relations between them have been established. A very illuminative and beautifully written summary of these results, as pertaining to algebraizability, appears in Section 3.4 of [86], which constitutes the inspiration and starting point of the investigations presented here.

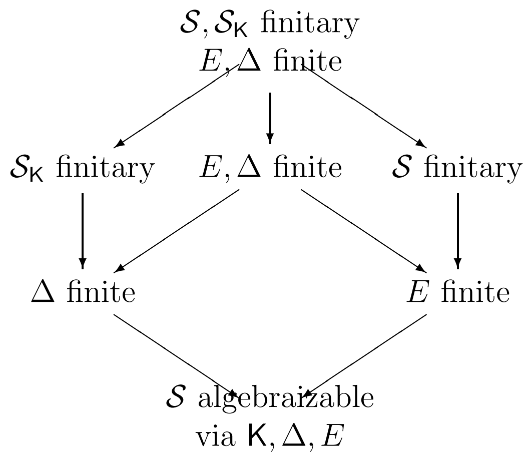
We first give a quick overview of the aforementioned work pertaining to algebraizable sentential logics. We fix an algebraizable sentential logic $\mathcal{S} = \langle \mathcal{L}, \vdash_{\mathcal{S}} \rangle$, with equivalent algebraic semantics the generalized quasivariety K, as witnessed by a set $\delta \approx \varepsilon$ of defining equations and a set Δ of equivalence formulas. Lemma 3.36 of [86] asserts that, in case $\mathcal{S}$ is finitary and has a finite set of equivalence formulas, then every set of equivalence formulas contains a finite subset that also serves as a set of equivalence formulas. Dually, if the equational logic $\mathcal{S}_{\mathsf{K}} = \langle \mathcal{L}, \vDash_{\mathsf{K}} \rangle$ induced by the class K is finitary, i.e., if the class K happens to be a quasivariety, and $\mathcal{S}$ has a finite set of defining equations, then every set of defining equations has a finite subset that also serves in the same capacity. Besides these conditional "finitarization" results, Theorem 3.37 of [86] details some important relationships between the following four conditions: $\mathcal{S}$ finitary; $\mathcal{S}_{\mathsf{K}}$ finitary; $\delta \approx \varepsilon$ finite; and Δ finite. On the one hand, if $\mathcal{S}$ is finitary, $\delta \approx \varepsilon$ may be taken finite, and, dually, if $\mathcal{S}_{\mathsf{K}}$ is finitary, then Δ may be taken to be finite. Moreover, if $\mathcal{S}$ is finitary and has a finite set Δ of equivalence formulas, then $\mathcal{S}_{\mathsf{K}}$ is finitary also, and, dually, if $\mathcal{S}_{\mathsf{K}}$ is finitary and $\mathcal{S}$ has a finite set $\delta \approx \varepsilon$ of defining equations, then $\mathcal{S}$ is finitary also. These implications lead to Corollary 3.38 of [86], which asserts the following three conditional equivalences:

1. If $\delta \approx \varepsilon$ and Δ are both finite, then $\mathcal{S}$ is finitary iff $\mathcal{S}_{\mathsf{K}}$ is finitary.

2. If $\mathcal{S}$ is finitary, then $\mathcal{S}_{\mathsf{K}}$ is finitary iff Δ may be taken finite.

3. If $\mathcal{S}_{\mathsf{K}}$ is finitary, then $\mathcal{S}$ is finitary iff $\delta \approx \varepsilon$ may be taken finite.

These lead to the hierarchy depicted in the diagram shown in Figure 3, p. 137 of [86] and duplicated below.



After outlining the results that lead to the depicted hierarchy, Font gathers pointers to three examples of sentential logics that serve to separate the various classes in the hierarchy. Example 3.41 of [86] revisits Łukasiewicz's infinite valued logic Ł_∞, which is not finitary, has a non-finitary equivalent algebraic semantics, but is algebraized via finite sets of defining equations and equivalence formulas. As a result, it serves to separate classes related by the vertical arrows in the diagram. In Example 3.42 of [86], the so-called Logic of Last Judgement $\mathcal{L}J$, introduced by Herrmann [53], is presented. This is a finitary logic, algebraized by a non-finitary equational consequence, via a single defining equation, but a necessarily infinite set of equivalence formulas. So $\mathcal{L}J$ serves in separating the logics related by the southeast arrows in the diagram. Additional examples that can serve the same purpose were presented by Dellunde [48] and by Lewin, Mikenberg and Schwartze [55]. Finally, in Example 3.43 of [86], Font presents a logic due to Raftery [82]. Raftery's work was motivated by a question posed by Czelakowski in Note 4.5.2 (4) of [64], which was also implicit in Problem 3.18 of [43]. Raftery's logic is not finitary, but is algebraizable, with a finitary equivalent algebraic semantics which is actually a variety, via an infinite set of defining equations and a singleton set of equivalence formulas. It serves in separating the classes of sentential logics connected via the southwest arrows of the diagram. In Section 9.5, we revisit Łukasiewicz's logic and the logics of Dellunde and Raftery in much more detail.

Our own goal in this chapter is to provide analogs of the classes in the finitarity hierarchy of algebraizable sentential logics for logics formalized as π-institutions. The finitarity conditions pertaining to π-institutions remain roughly unchanged. However, keeping in the spirit of dealing with semantically defined classes (i.e., relying on properties of the Leibniz operator) in this part of the monograph, the finitarity conditions regarding $\delta \approx \varepsilon$ and Δ are modified. They are recast as continuity properties of the Leibniz operator and of its inverse. Subject to these modifications, the results obtained for semantically defined finitarity properties pertaining to weakly family algebraizable π-institutions reflect those outlined above for algebraizable sentential logics.

In Section 9.2, we introduce the concept of a π-*structure*, which abstracts that of a π-institution by eliminating the requirement of structurality. That is, a π-structure $\mathcal{I}$ consists of an algebraic system together with a collection of closure operators, one on each of its sentence components, which are not required to satisfy structurality. The *finitary companion* of a π-structure $\mathcal{I}$ is the π-structure obtained by considering the closure family induced by all finite consequences of $\mathcal{I}$. As a consequence, it constitutes the largest finitary π-structure included in $\mathcal{I}$. In addition, it can be shown that it is structural when the given π-structure satisfies structurality, i.e., when it is a π-institution. Finitary companions may also be characterized via their theory families. Namely, a sentence family of a π-institution $\mathcal{I}$ is a theory family of its finitary companion if and only if it is the union of a directed collection of locally finitely generated theory families of $\mathcal{I}$.

In Section 9.3, we focus on some of the fundamental properties that determine the classes in the semantic Leibniz hierarchy and investigate whether they are transferred from a π-institution to its finitary companion and vice-versa, and, if yes, under which conditions. In this vein, protoalgebraicity is shown to hold for a π-institution $\mathcal{I}$ if its finitary companion is protoalgebraic. A similar property holds for family reflectivity. As a consequence, a π-institution is weakly family algebraizable if its finitary companion has the same property. In the opposite direction, for properties of $\mathcal{I}$ to be inherited by its finitary companion, additional provisos are needed. We say that the Leibniz operator of a π-institution is *continuous* if, for every directed collection $\{T^i\}_{i\in I}$ of theory families, such that $\bigcup_{i\in I} T^i$ is also a theory family, $\Omega(\bigcup_{i\in I} T^i) = \bigcup_{i\in I} \Omega(T^i)$. Continuity of the Leibniz operator is a stronger property than, i.e., implies, protoalgebraicity. It turns out that it is also sufficient for the finitary companion of $\mathcal{I}$ to be protoalgebraic, subject to the category of signatures being finite. Along dual lines, we say that the inverse Leibniz operator of a weakly family algebraizable π-institution $\mathcal{I}$ is *continuous* if, for all directed collections $\{\theta^i\}_{i\in I}$ of congruence systems in $\mathrm{ConSys}^*(\mathcal{I})$, such that $\bigcup_{i\in I} \theta^i$ is also a congruence system in $\mathrm{ConSys}^*(\mathcal{I})$, $\Omega^{-1}(\bigcup_{i\in I} \theta^i) = \bigcup_{i\in I} \Omega^{-1}(\theta^i)$. This condition, when supplementing continuity of the Leibniz operator, ensures that weak family algberaizability of a π-institution $\mathcal{I}$, with a finite category of signatures, is inherited by its finitary companion.

Section 9.4 is the main section of the chapter. Here, we establish the semantic finitarity hierarchy of weakly family algebraizable π-institutions, which parallels the hierarchy of sentential logics studied in Section 3.4 of [86] and summarized both in Subsection 1.3.8 and at the beginning of this Introduction. Throughout, the object of study is a weakly family algebraizable π-institution $\mathcal{I}$. Moreover, we denote by $\mathsf{K} \coloneqq \mathrm{AlgSys}(\mathcal{I})$ and by $\mathcal{Q}^{\mathsf{K}}$ the equational π-structure induced by the class K. Note that $\mathcal{I}$ being weakly family algebraizable ensures that the Leibniz operator $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is an isomorphism, whence the inverse Ω^{-1} is well-defined. It is shown, first, that the finitarity of $\mathcal{I}$ ensures the continuity of the inverse Leibniz operator on $\mathrm{ConSys}^*(\mathcal{I})$ and that, dually, the finitarity of $\mathcal{Q}^{\mathsf{K}}$ guarantees that the Leibniz operator itself is continuous on $\mathrm{ThFam}(\mathcal{I})$. Further, if to the finitarity of $\mathcal{I}$ is added the continuity of the Leibniz operator, then the finitarity of $\mathcal{Q}^{\mathsf{K}}$ follows. Dually, if to the finitarity of $\mathcal{Q}^{\mathsf{K}}$ is added the continuity of the inverse Leibniz operator, then $\mathcal{I}$ is also finitary. These results are summarized in three statements, which parallel those governing sentential logics, stated in Corollary 3.38 of [86]. Namely, under continuity of both the Leibniz operator and its inverse, finitarity of $\mathcal{I}$ is equivalent to finitarity of $\mathcal{Q}^{\mathsf{K}}$. Under finitarity of $\mathcal{I}$, finitarity of $\mathcal{Q}^{\mathsf{K}}$ is equivalent to continuity of the Leibniz operator and, dually, under finitarity of $\mathcal{Q}^{\mathsf{K}}$, finitarity of $\mathcal{I}$ is tantamount to continuity of the inverse Leibniz operator.

In Section 9.5, we take a brief detour to present in detail three examples of sentential logics, which serve to separate the classes in the finitarity hierarchy of algebraizable sentential logics, presented in Section 3.4 of [86]. Even though our focus here is not on sentential logics, we showed in Section 1.1 how a sentential logic gives rise to a π-institution in a rather straightforward way. Accordingly, the purpose of presenting these three sentential logics is to construct, based on them, corresponding π-institutions that will serve to separate the classes in the finitarity hierarchy of weakly family algebraizable π-institutions, studied in Section 9.4. The constructions of the π-institutions, based on the sentential logics introduced here, and the separation properties they help establish will be described in some detail in Section 9.6.

The first example is Łukasiewicz's infinite valued logic (see, e.g., Example 3.41 of [86]). It is a logic over a language with three binary connectives $\wedge$, $\vee$, $\to$ and one unary connective $\neg$. It is semantically defined via a logical matrix. It is shown that it is not finitary, but that it is algebraizable via a singleton set of defining equations $E(x) = \{x \approx \top\}$, where $\top \coloneqq x \to x$, and the doubleton set of equivalence formulas $\Delta(x,y) = \{x \to y, y \to x\}$. This logic serves to separate the classes of sentential logics related by vertical arrows in the finitarity hierarchy of algebraizable sentential logics, depicted in the preceding diagram. The second example is a logic introduced by Dellunde in [48]. It is a logic defined over a language with one binary connective $\leftrightarrow$ and one unary connective $\Box$. It is defined via a Hilbert calculus and, as a result, it is finitary. It is shown that it is regularly algebraizable via the infinite set of equivalence formulas $\Delta(x,y) = \{\Box^n x \leftrightarrow \Box^n y : n \in \omega\}$. According to the general theory, regular algebraizability implies that the set of defining equations is the singleton $E(x) = \{x \approx \top\}$, where $\top := x \leftrightarrow x$ defines the unique element in the filter of any reduced matrix of the logic. What is key for our purposes is that there does not exist a finite subset $\Delta_0 \subseteq \Delta$ that also serves as a set of equivalence formulas for this logic. Consequently, this example serves in separating those classes in the hierarchy of sentential logics connected via southeast arrows in the diagram. The last example presented in Section 9.5 is a logic introduced by Raftery [82]. It is a logic defined over a language with one binary connective $\leftrightarrow$ and three unary connectives π_1, π_2 and $\Diamond$. It is semantically defined as a weakening of another logic, which, in turn, is defined using a logical matrix. The weakening, roughly speaking, is obtained by considering an entire variety of algebras to which the underlying algebra of this logical matrix belongs. Raftery shows that neither logic is finitary and that, in addition, the weaker logic, corresponding to the variety, is algebraizable via an infinite set of defining equations and a singleton set of equivalence formulas. As a result, Raftery's logic serves as an example separating the classes related by the southwest arrows in the finitarity hierarchy depicted in the preceding diagram.

In Section 9.6, we use the framework outlined in Section 1.1 to formalize the three sentential logics of Section 9.5 as π-institutions. The resulting examples enable us to separate the classes in the semantic finitarity hierarchy of weakly family algebraizable π-institutions, studied in Section 9.4, in a way that parallels the separation of the classes in the hierarchy of algebraizable sentential logics.

9.2 The Finitary Companion

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. A **π-structure** $\mathcal{I} = \langle \mathbf{F}, D \rangle$, **based on F**, is like a π-institution except that D is a **closure family** on $\mathbf{F}$ instead of a closure system, i.e., the only requirement is that

$$D_\Sigma : \mathcal{P}\mathrm{SEN}^\flat(\Sigma) \to \mathcal{P}\mathrm{SEN}^\flat(\Sigma)$$

be a closure operator on $\mathrm{SEN}^\flat(\Sigma)$, for all $\Sigma \in |\mathbf{Sign}^\flat|$. On the other hand, D is not required to be structural. A heavier use of π-structures will be encountered in Chapter 12, where the concept will be defined anew and more details given. D is called the **closure family of the π-structure** $\mathcal{I}$. Note that π-structures generalize π-institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, D \rangle$ be a π-structure based on $\mathbf{F}$. Define the family

$$D^f = \{D^f_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$$

by letting, for all $\Sigma \in |\mathbf{Sign}^\flat|$,

$$D^f_\Sigma : \mathcal{P}\mathrm{SEN}^\flat(\Sigma) \to \mathcal{P}\mathrm{SEN}^\flat(\Sigma)$$

be given, for all $\Phi \subseteq \mathrm{SEN}^\flat(\Sigma)$, by

$$D^f_\Sigma(\Phi) = \bigcup\{D_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\},$$

where $\subseteq_f$ denotes the finite subset relation.

It is not hard to show that D^f is a finitary closure family on $\mathbf{F}$ and that, moreover, it is a closure system (i.e., structural) in case D itself happens to be structural.

Lemma 651 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, D\rangle$ *a* π*-structure based on* $\mathbf{F}$. *Then* D^f *is a finitary closure family on* $\mathbf{F}$. *Further, if* D *is structural, i.e., if* $\mathcal{I}$ *is a* π*-institution, then* D^f *is also structural.*

Proof: Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in \Phi$. Then $\phi \in D_\Sigma(\phi) \subseteq D^f_\Sigma(\Phi)$. Thus, D^f is inflationary.

Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\Phi \subseteq \Psi$. If $\phi \in D^f_\Sigma(\Phi)$, then there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in D_\Sigma(\Phi')$. But $\Phi' \subseteq_f \Phi \subseteq \Psi$, whence, $\phi \in D^f_\Sigma(\Psi)$. Thus, $D^f_\Sigma(\Phi) \subseteq D^f_\Sigma(\Psi)$ and D^f is also monotone.

Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D^f_\Sigma(D^f_\Sigma(\Phi))$. Then, there exists $\Phi' \subseteq_f D^f_\Sigma(\Phi)$, such that $\phi \in D_\Sigma(\Phi')$. Since $\Phi' \subseteq D^f_\Sigma(\Phi)$, for all $\phi' \in \Phi'$, there exists $\Phi'^{\phi'} \subseteq_f \Phi$, such that $\phi' \in D_\Sigma(\Phi'^{\phi'})$. Hence, we get

$$\phi \in D_\Sigma(\Phi') \subseteq D_\Sigma(\bigcup_{\phi' \in \Phi'} \Phi'^{\phi'}).$$

Since $\bigcup_{\phi' \in \Phi'} \Phi'^{\phi'} \subseteq_f \Phi$, we get, by definition, $\phi \in D^f_\Sigma(\Phi)$. Thus, D^f is also idempotent.

Finally, to show finitarity, let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D^f_\Sigma(\Phi)$. Thus, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in D_\Sigma(\Phi')$. Then, by definition, $\phi \in D^f_\Sigma(\Phi')$. Thus, $D^f_\Sigma(\Phi) = \bigcup_{\Phi' \subseteq_f \Phi} D^f_\Sigma(\Phi')$ and, hence, D^f is a finitary closure family on $\mathbf{F}$.

To prove the last statement concerning structurality, assume that D is structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D^f_\Sigma(\Phi)$. Then, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in D_\Sigma(\Phi')$. Since D is assumed structural, we get $\mathrm{SEN}^\flat(f)(\phi) \in D_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi'))$. But Φ' being a finite subset of Φ, $\mathrm{SEN}^\flat(f)(\Phi')$ is a finite subset of $\mathrm{SEN}^\flat(f)(\Phi)$, whence, $\mathrm{SEN}^\flat(f)(\phi) \in D^f_{\Sigma'}(\mathrm{SEN}^\flat(f)(\Phi))$. This shows that D^f is also structural. ∎

The following proposition provides a characterization of D^f.

Proposition 652 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, D\rangle$ *a* π*-structure based on* $\mathbf{F}$. *Then* D^f *is the largest finitary closure family on* $\mathbf{F}$ *lying below* D *in the* $\leq$ *ordering.*

Proof: By Lemma 651, D^f is a finitary closure family. By its definition and the monotonicity of D, it is clear that $D^f \leq D$. To complete the proof, suppose D' is a finitary closure family on $\mathbf{F}$, such that $D' \leq D$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\Phi \cup \{\phi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in D'_\Sigma(\Phi)$. Since, by hypothesis, D' is finitary, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in D'_\Sigma(\Phi')$. Since, also by hypothesis, $D' \leq D$, we get $\phi \in D_\Sigma(\Phi')$. Thus, since $\Phi' \subseteq_f \Phi$, we get, by definition of D^f, $\phi \in D^f_\Sigma(\Phi)$. Thus, $D' \leq D^f$ and, therefore, D^f is the largest finitary closure family below D. ∎

Corollary 653 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$. *Then* C^f *is the largest finitary closure system on* $\mathbf{F}$ *lying below* C *in the* $\leq$ *ordering.*

Proof: By Proposition 652, C^f is the largest finitary closure family lying below C. But, by Lemma 651, it is a closure system on $\mathbf{F}$. Hence, it is the largest finitary closure system lying below C. ∎

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, D \rangle$ be a π-structure based on $\mathbf{F}$. We call D^f the **finitary companion of** D. Moreover, we set $\mathcal{I}^f = \langle \mathbf{F}, D^f \rangle$ and call it the **finitary companion of** $\mathcal{I}$. Of course, these terms apply, in particular, to the case of π-institutions.

We would like to provide an alternative characterization of the finitary companion that is also very useful in various applications of the notion. With an eye towards this goal, we make the following definitions.

Definition 654 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$ *and* $\mathcal{T} \cup \{T\} \subseteq \mathrm{ThFam}(\mathcal{I})$.

- T *is called* **locally finitely generated** *if, for all* $\Sigma \in |\mathbf{Sign}^\flat|$, *there exists* $\Phi_\Sigma \subseteq_f T_\Sigma$, *such that* $T_\Sigma = C_\Sigma(\Phi_\Sigma)$.
- $\mathcal{T}$ *is* **locally finitely generated** *if all its theory families are locally finitely generated.*

The following proposition provides a characterization of those sentence families of a π-institution $\mathcal{I}$ that are theory families of its finitary companion.

Proposition 655 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on* $\mathbf{F}$ *and* $T \in \mathrm{SenFam}(\mathbf{F})$. *Then* $T \in \mathrm{ThFam}(\mathcal{I}^f)$ *if and only if, there exists a directed locally finitely generated collection* $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, *such that*

$$T = \bigcup_{i \in I} T^i.$$

Proof: Let $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ be a directed locally finitely generated collection. Since it is locally finitely generated, we have, by definition, $T^i \in \mathrm{ThFam}(\mathcal{I}^f)$, for all $i \in I$. But, by Lemma 651, $\mathcal{I}^f$ is finitary. Thus, by Proposition 112, it is continuous. Hence $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I}^f)$.

Suppose, conversely, that $T \in \mathrm{ThFam}(\mathcal{I}^f)$. Set

$$\mathcal{T} = \{C(X) : X \leq_{lf} T\},$$

where $\leq_{lf}$ denotes the locally finite subfamily relation. It is clear, by its definition, that $\mathcal{T}$ is locally finitely generated. Suppose $C(X), C(Y) \in \mathcal{T}$. Then $C(X \cup Y) \in \mathcal{T}$ and, moreover, $C(X), C(Y) \leq C(X \cup Y)$. Hence, $\mathcal{T}$ is also directed. Finally, it is not difficult to see that $T = \bigcup \mathcal{T}$. Thus, the declared characterization holds. ■

9.3 π-Institutions & Companions: Hierarchy

In this section, we study how some of the properties that have been used to build hierarchies of π-institutions are inherited by the finitary companion of a π-institution from the π-institution itself and vice-versa. In some instances the inheritance is immediate, but, in others, additional conditions need to be imposed. We focus on the property of weak family algebraizability. That is the reason of selecting the few properties studied here versus some of the remaining properties introduced previously.

First, we show that protoalgebraicity is passed up to $\mathcal{I}$ from its finitary companion $\mathcal{I}^f$.

Lemma 656 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$ *is protoalgebraic, then so is* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is protoalgebraic. Then, by definition, the Leibniz operator $\Omega : \mathrm{ThFam}(\mathcal{I}^f) \to \mathrm{ConSys}^*(\mathcal{I}^f)$ is monotone. Since $C^f \leq C$, we have $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$. Therefore, the Leibniz operator $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is also monotone. We conclude that $\mathcal{I}$ is protoalgebraic. ■

Similarly, if $\mathcal{I}^f$ is family reflective, then so is $\mathcal{I}$.

Lemma 657 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$ *is family reflective, then so is* $\mathcal{I}$*.*

Proof: Suppose $\mathcal{I}^f$ is family reflective. Then, by definition, the Leibniz operator $\Omega : \mathrm{ThFam}(\mathcal{I}^f) \to \mathrm{ConSys}^*(\mathcal{I}^f)$ is order reflecting. Since $C^f \leq C$, we have $\mathrm{ThFam}(\mathcal{I}) \subseteq \mathrm{ThFam}(\mathcal{I}^f)$. Therefore, a fortiori, the Leibniz operator

$\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is also order reflecting. We conclude that $\mathcal{I}$ is family reflective. ∎

Combining Lemmas 656 and 657, we get that weak family algebraizability for a π-institution is obtained, provided that its finitary companion has the same property.

Proposition 658 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$ is weakly family algebraizable, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is weakly family algebraizable. Then it is protoalgebraic and family reflective. Thus, by Lemmas 656 and 657, respectively, $\mathcal{I}$ is also protoalgebraic and family reflective. Hence, by definition, $\mathcal{I}$ is weakly family algebraizable. ∎

Now we turn to the question of the same properties passing down to $\mathcal{I}^f$ from $\mathcal{I}$. In this direction, additional conditions are needed to ensure inheritance.

Given a directed family $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ it is not, in general, the case that $\bigcup_{i \in I} T^i$ is a theory family of $\mathcal{I}$. However, as we saw in Proposition 112, this is always the case when $\mathcal{I}$ is a finitary π-institution.

Motivated by this consideration, we define the following property of the Leibniz operator:

Definition 659 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. The Leibniz operator*

$$\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$$

is **continuous** *if, for every directed family $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that $\bigcup_{i \in I} T^i \in \mathrm{ThFam}(\mathcal{I})$,*

$$\Omega(\bigcup_{i \in I} T^i) = \bigcup_{i \in I} \Omega(T^i).$$

It is easy to see that continuity implies protoalgebraicity.

Lemma 660 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. If $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous, then $\mathcal{I}$ is protoalgebraic.*

Proof: Suppose Ω is continuous and let $T, T' \in \mathrm{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then $T' = T \cup T'$ and we get

$$\Omega(T) \cup \Omega(T') = \Omega(T \cup T') = \Omega(T').$$

Hence, $\Omega(T) \leq \Omega(T')$ and $\mathcal{I}$ is protoalgebraic. ∎

We saw in Lemma 656 that protoalgebraicity of the finitary companion $\mathcal{I}^f$ of a π-institution $\mathcal{I}$ ensures that $\mathcal{I}$ is also protoalgebraic. We now see that working over finite signature categories and imposing the stronger property of continuity of the Leibniz operator on $\mathcal{I}$ ensure that $\mathcal{I}^f$ is protoalgebraic.

Lemma 661 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*. If* $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is continuous, then* $\mathcal{I}^f$ *is protoalgebraic.*

Proof: Suppose that Ω is continuous on $\mathrm{ThFam}(\mathcal{I})$. Then, by Lemma 660, $\mathcal{I}$ is protoalgebraic. To show that $\mathcal{I}^f$ is protoalgebraic, let $T, T' \in \mathrm{ThFam}(\mathcal{I}^f)$, such that $T \leq T'$. By Proposition 655, there exist directed locally finitely generated collections $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ and $\{T'^j : j \in J\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that

$$T = \bigcup_{i\in I} T^i \quad \text{and} \quad T' = \bigcup_{j\in J} T'^j.$$

Since, by hypothesis, $T \leq T'$, we get, for all $i \in I$, $T^i \leq \bigcup_{j\in J} T'^j$. Since $\mathbf{Sign}^\flat$ is finite, T^i is locally finitely generated and $\{T'^j : j \in J\}$ is directed, there exists $j_i \in J$, such that $T^i \leq T'^{j_i}$, for all $i \in I$. Now we get

$$\begin{array}{rcll}
\Omega(T) & = & \Omega(\bigcup_{i\in I} T^i) & (T = \bigcup_{i\in I} T^i)\\
& = & \bigcup_{i\in I} \Omega(T^i) & (\Omega \text{ continuous})\\
& \leq & \bigcup_{i\in I} \Omega(T'^{j_i}) & (T^i \leq T'^{j_i} \text{ and protoalgebraicity})\\
& \leq & \bigcup_{j\in J} \Omega(T'^j) & (\text{Set Theory})\\
& = & \Omega(\bigcup_{j\in J} T'^j) & (\Omega \text{ continuous})\\
& = & \Omega(T'). & (T' = \bigcup_{j\in J} T'^j)
\end{array}$$

Thus, $\mathcal{I}^f$ is protoalgebraic. ■

Lemma 661 allows us to prove the following result, giving sufficient conditions for weak family algebraizability to be inherited by the finitary companion $\mathcal{I}^f$ from a π-institution $\mathcal{I}$.

Definition 662 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$*. The inverse* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *of the Leibniz operator is* **continuous** *if, for every directed family* $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^*(\mathcal{I})$*, such that* $\bigcup_{i\in I} \theta^i \in \mathrm{ConSys}^*(\mathcal{I})$*,*

$$\Omega^{-1}(\bigcup_{i\in I} \theta^i) = \bigcup_{i\in I} \Omega^{-1}(\theta^i).$$

Theorem 663 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, with* $\mathbf{Sign}^\flat$ *finite, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$*. If*

$$\mathrm{ThFam}(\mathcal{I}) \underset{\Omega^{-1}}{\overset{\Omega}{\rightleftarrows}} \mathrm{ConSys}^*(\mathcal{I})$$

are continuous, then $\mathcal{I}^f$ *is also weakly family algebraizable.*

Proof: By Lemma 661, $\mathcal{I}^f$ is protoalgebraic. Thus, it suffices to show that $\mathcal{I}^f$ is also family injective. To this end, let $T, T' \in \mathrm{ThFam}(\mathcal{I}^f)$, such that $\Omega(T) = \Omega(T')$. By Proposition 655, there exist directed locally finitely generated collections $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ and $\{T'^j : j \in J\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that

$$T = \bigcup_{i\in I} T^i \quad \text{and} \quad T' = \bigcup_{j\in J} T'^j.$$

Now we work as follows:

$$\begin{array}{rcl}
T & = & \bigcup_{i\in I} T^i \\
 & = & \bigcup_{i\in I} \Omega^{-1}(\Omega(T^i)) \\
 & = & \Omega^{-1}(\bigcup_{i\in I} \Omega(T^i)) \\
 & & (\bigcup_{i\in I} \Omega(T^i) \in \mathrm{ConSys}^*(\mathcal{I}) \text{ and } \Omega^{-1} \text{ continuous}) \\
 & = & \Omega^{-1}(\Omega(\bigcup_{i\in I} T^i)) \\
 & & (\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I}) \text{ and } \Omega \text{ continuous}) \\
 & = & \Omega^{-1}(\Omega(\bigcup_{j\in J} T'^j)) \quad (\Omega(T) = \Omega(T')) \\
 & = & \Omega^{-1}(\bigcup_{j\in J} \Omega(T'^j)) \\
 & & (\bigcup_{j\in J} T'^j \in \mathrm{ThFam}(\mathcal{I}) \text{ and } \Omega \text{ continuous}) \\
 & = & \bigcup_{j\in J} \Omega^{-1}(\Omega(T'^j)) \\
 & & (\bigcup_{j\in J} \Omega(T'^j) \in \mathrm{ConSys}^*(\mathcal{I}) \text{ and } \Omega^{-1} \text{ continuous}) \\
 & = & \bigcup_{j\in J} T'^j \\
 & = & T'.
\end{array}$$

Hence, $\mathcal{I}^f$ is family injective and, thus, weakly family algebraizable. ■

9.4 Finitarity and Continuity

In this section, we establish some results pertaining to the finitarity of weakly family algebraizable π-institutions. We stay with semantic notions, using the Leibniz operator, and aim at establishing relations between various aspects of finitarity.

We begin by showing that the finitarity of a weakly family algebraizable π-institution $\mathcal{I}$ entails the continuity of the inverse Leibniz operator on the $\mathcal{I}^*$-congruence systems on $\mathcal{F}$.

Proposition 664 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{I}$ *is finitary, then* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *is continuous.*

Proof: Suppose that $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^*(\mathcal{I})$ is directed, such that $\bigcup_{i\in I} \theta^i \in \mathrm{ConSys}^*(\mathcal{I})$. Since $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^*(\mathcal{I})$, there exist $T^i \in \mathrm{ThFam}(\mathcal{I})$, such that $\theta^i = \Omega(T^i)$, for all $i \in I$. Note that, since, by Theorem 296, Ω is an order isomorphism, $\{T^i : i \in I\}$ is also directed. Moreover, since $\mathcal{I}$ is finitary, we have, by Proposition 112, $\bigvee_{i\in I} T^i = \bigcup_{i\in I} T^i$. Hence, we get

$$\begin{array}{rcll}\bigcup_{i\in I}\theta^i & = & \bigvee_{i\in I}\theta^i & (\bigcup_{i\in I}\theta^i \in \mathrm{ConSys}^*(\mathcal{I}))\\ & = & \bigvee_{i\in I}\Omega(T^i) & (\theta^i = \Omega(T^i))\\ & = & \Omega(\bigvee_{i\in I} T^i) & (\Omega \text{ order isomorphism})\\ & = & \Omega(\bigcup_{i\in I} T^i). & (\mathcal{I} \text{ finitary})\end{array}$$

From this, we get

$$\Omega^{-1}(\bigcup_{i\in I}\theta^i) = \bigcup_{i\in I} T^i = \bigcup_{i\in I}\Omega^{-1}(\theta^i).$$

Hence Ω^{-1} is indeed continuous. ∎

Next, we show that the finitarity of the π-structure $\mathcal{Q}^{\mathsf{K}} = \langle \mathbf{F}, D^{\mathsf{K}}\rangle$, where $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, for a weakly family algebraizable π-institution $\mathcal{I}$, entails the continuity of the Leibniz operator on the collection of theory families of $\mathcal{I}$.

Proposition 665 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a weakly family algebraizable π-institution based on $\mathbf{F}$. If $\mathcal{Q}^{\mathsf{K}}$ is finitary, for $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, then $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous.*

Proof: Suppose that $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ is directed, such that $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I})$. Since $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, $\Omega(T^i) \in \mathrm{ThFam}(\mathcal{Q}^{\mathsf{K}})$, where $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$. Moreover, since, by Theorem 296, Ω is an order isomorphism, $\{\Omega(T^i) : i \in I\}$ is also directed. Hence, since $\mathcal{Q}^{\mathsf{K}}$ is finitary, by Proposition 112, we have $\bigvee_{i\in I}\Omega(T^i) = \bigcup_{i\in I}\Omega(T^i)$. Hence, we get

$$\begin{array}{rcll}\Omega(\bigcup_{i\in I} T^i) & = & \Omega(\bigvee_{i\in I} T^i) & (\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I}))\\ & = & \bigvee_{i\in I}\Omega(T^i) & (\Omega \text{ order isomorphism})\\ & = & \bigcup_{i\in I}\Omega(T^i). & (\mathcal{Q}^{\mathsf{K}} \text{ finitary})\end{array}$$

Hence, Ω is continuous. ∎

We saw in Proposition 664 that finitarity of a weakly family algebraizable π-institution $\mathcal{I}$ entails the continuity of the inverse Leibniz operator. If, to the finitarity of $\mathcal{I}$, we add continuity of the Leibniz operator Ω, then finitarity of $\mathcal{Q}^{\mathsf{K}}$ is ensured, where $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$.

Proposition 666 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C\rangle$ a weakly family algebraizable π-institution based on $\mathbf{F}$. If $\mathcal{I}$ is finitary, and $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous, then $\mathcal{Q}^{\mathsf{K}}$, where $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, is also finitary.*

Proof: Assume that $\mathcal{I}$ is a finitary, weakly family algebraizable π-institution and that Ω is continuous. Let $\{\theta^i : i \in I\} \subseteq \mathrm{ConSys}^*(\mathcal{I})$ be a directed family of congruence systems. Then, there exist $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$, such that

$\Omega(T^i) = \theta^i$, for all $i \in I$. Moreover, since $\{\theta^i : i \in I\}$ is directed and Ω is, by Theorem 296, an order isomorphism, $\{T^i : i \in I\}$ is also directed. Hence, since $\mathcal{I}$ is finitary, by Proposition 112, $\bigvee_{i\in I} T^i = \bigcup_{i\in I} T^i$. Now we have

$$\begin{array}{lll}\bigvee_{i\in I}\theta^i & = & \bigvee_{i\in I}\Omega(T^i) \quad (\Omega(T^i) = \theta^i)\\ & = & \Omega(\bigvee_{i\in I} T^i) \quad (\Omega \text{ order isomorphism})\\ & = & \Omega(\bigcup_{i\in I} T^i) \quad (\mathcal{I} \text{ finitary})\\ & = & \bigcup_{i\in I}\Omega(T^i) \quad (\Omega \text{ continuous})\\ & = & \bigcup_{i\in I}\theta^i. \quad (\Omega(T^i) = \theta^i)\end{array}$$

Thus, $\mathrm{ConSys}^*(\mathcal{I})$ is closed under directed unions and, therefore, by Proposition 112, $\mathcal{Q}^{\mathsf{K}}$ is finitary. ∎

Dually, we have seen in Proposition 665 that if $\mathcal{Q}^{\mathsf{K}}$ is finitary, where $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, then Ω is continuous. If, to the finitarity of $\mathcal{Q}^{\mathsf{K}}$, we add the continuity of Ω^{-1}, then, finitarity of $\mathcal{I}$ is ensured.

Proposition 667 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$*. If* $\mathcal{Q}^{\mathsf{K}}$ *is finitary, where* $\mathsf{K} = \mathrm{AlgSys}^*(\mathcal{I})$*, and* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *is continuous, then* $\mathcal{I}$ *is also finitary.*

Proof: Assume that $\mathcal{I}$ is a weakly family algebraizable π-institution, such that $\mathcal{Q}^{\mathsf{K}}$, $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, is finitary, and that Ω^{-1} is continuous. Let $\{T^i : i \in I\} \subseteq \mathrm{ThFam}(\mathcal{I})$ be a directed collection of theory families. Then, since, by Theorem 296, Ω is an order isomorphism, $\{\Omega(T^i) : i \in I\}$ is a directed family of congruence systems. Since $\mathcal{Q}^{\mathsf{K}}$ is finitary, by Proposition 112, $\bigvee_{i\in I}\Omega(T^i) = \bigcup_{i\in I}\Omega(T^i)$. Now we have

$$\begin{array}{lll}\bigvee_{i\in I} T^i & = & \Omega^{-1}(\Omega(\bigvee_{i\in I} T^i)) \quad (\Omega \text{ isomorphism})\\ & = & \Omega^{-1}(\bigvee_{i\in I}\Omega(T^i)) \quad (\Omega \text{ order isomorphism})\\ & = & \Omega^{-1}(\bigcup_{i\in I}\Omega(T^i)) \quad (\mathcal{Q}^{\mathsf{K}} \text{ finitary})\\ & = & \bigcup_{i\in I}\Omega^{-1}(\Omega(T^i)) \quad (\Omega^{-1} \text{ continuous})\\ & = & \bigcup_{i\in I} T^i. \quad (\Omega \text{ isomorphism})\end{array}$$

Thus, $\mathrm{ThFam}(\mathcal{I})$ is closed under directed unions and, hence, by Proposition 112, $\mathcal{I}$ is finitary. ∎

Gathering together all conclusions drawn during the studies undertaken in this section, we get the following

Corollary 668 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a weakly family algebraizable* π*-institution based on* $\mathbf{F}$ *and set* $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$*.*

(a) *If both* Ω *and* Ω^{-1} *are continuous, then* $\mathcal{I}$ *is finitary if and only if* $\mathcal{Q}^{\mathsf{K}}$ *is finitary.*

(b) *If $\mathcal{I}$ is finitary, then $\mathcal{Q}^{\mathsf{K}}$ is finitary if and only if* $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is continuous.*

(c) *If $\mathcal{Q}^{\mathsf{K}}$ is finitary, then $\mathcal{I}$ is finitary if and only if* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *is continuous.*

In each of (a)-(c), if the two equivalent conditions hold, then all four finitarity conditions hold.

Proof:

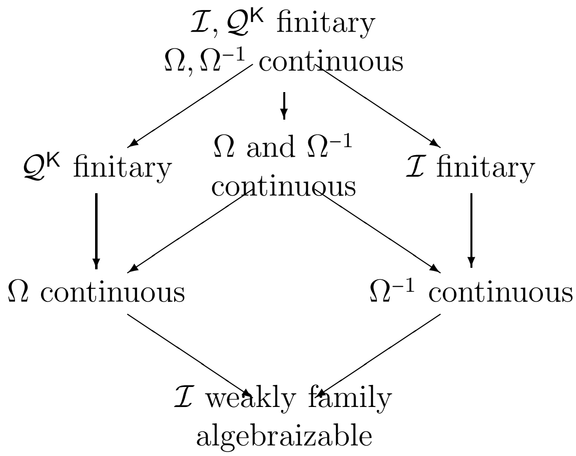
(a) Suppose Ω and Ω^{-1} are continuous. Then, if $\mathcal{I}$ is finitary, $\mathcal{Q}^{\mathsf{K}}$ is finitary, by Proposition 666, and if $\mathcal{Q}^{\mathsf{K}}$ is finitary, then $\mathcal{I}$ is finitary, by Proposition 667.

(b) Suppose that $\mathcal{I}$ is finitary. Then, by Proposition 664, Ω^{-1} is continuous. If $\mathcal{Q}^{\mathsf{K}}$ is finitary, then Ω is continuous, by Proposition 665. On the other hand, if Ω is continuous, then $\mathcal{Q}^{\mathsf{K}}$ is finitary, by Proposition 666.

(c) Suppose that $\mathcal{Q}^{\mathsf{K}}$ is finitary. Then, by Proposition 665, Ω is continuous. If $\mathcal{I}$ is finitary, then Ω^{-1} is continuous, by Proposition 664. On the other hand, if Ω^{-1} is continuous, then $\mathcal{I}$ is finitary, by Proposition 667.

We turn to the last statement. For Part (a), assume that $\mathcal{I}$ and $\mathcal{Q}^{\mathsf{K}}$ are finitary. Then, we get, by Propositions 664 and 665, that Ω and Ω^{-1} are continuous. For Part (b), if $\mathcal{I}$ is finitary, $\mathcal{Q}^{\mathsf{K}}$ is finitary and $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is continuous, then, by Proposition 664, Ω^{-1} is continuous. A similar reasoning applies to Part (c). ■

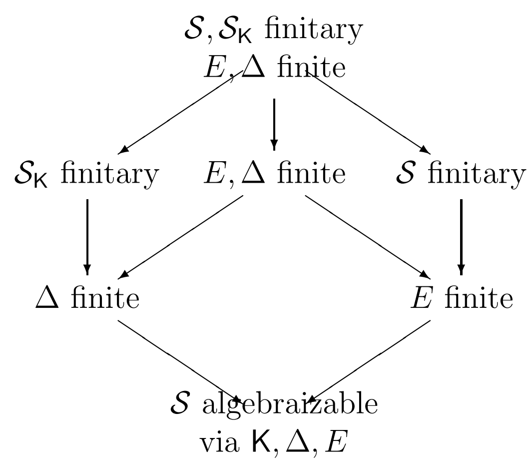
We summarize our conclusions in the accompanying diagram. At the bottom is situated the underlying assumption (holding at all levels) that $\mathcal{I}$ is weakly family algebraizable. The top consists of the situation in which all four finitarity conditions hold, i.e., both $\mathcal{I}$ and $\mathcal{Q}^{\mathsf{K}}$, for $\mathsf{K} = \mathrm{AlgSys}(\mathcal{I})$, are finitary and both Ω and Ω^{-1} are continuous. The intermediate classes constitute the various different intermediate possibilities that were detailed previously.



This diagram is a modified version of the one shown in Figure 3 of Section 3.4 of [86]. Instead of dealing with sentential logics, it concerns the more general case of π-institutions and, instead of being expressed in terms of syntactic constructs (which in the case of sentential logics turn out to be equivalent), it relies entirely on corresponding properties of the Leibniz operator and its inverse. These analogies and similarities will be exploited in the remainder of the chapter to obtain examples that separate the various classes involved in this hierarchy by adapting appropriate examples that serve an analogous purpose in the framework of sentential logics.

9.5 The Case of Sentential Logics

In the Introduction and, briefly, in concluding Section 9.4, we pointed out that the semantic finitarity hierarchy of π-institutions reflects the finitarity hierarchy presented in Section 3.4 of [86], which is duplicated below.



In [86], Font presents examples of sentential logics to separate the classes in this hierarchy. In this section, we revisit some of them in detail and, then, rely on them in Section 9.6 to separate the classes of π-institutions shown in the hierarchy of Section 9.4. We provide, now, a brief overview of the examples chosen and what each accomplishes, before describing them in full detail.

The first example we present is Łukasiewicz's infinite valued logic $Ł_\infty$. This logic is introduced in Example 1.12 of Section 1.2 of [86]. In Example 1.15, in the same section, in conjunction with Exercise 1.26 of [86], it is shown that it is not finitary. On the other hand, in Example 3.41 of Section 3.4 of [86], it is shown that it is finitely algebraizable, with defining equations $E(x) = \{x \approx \top\}$ and equivalence formulas $\Delta(x,y) = \{x \to y, y \to x\}$, both finite. Thus, $Ł_\infty$ serves in showing that the three vertical arrows in the preceding diagram represent proper inclusions. As Font points out in [86], more information about Ł$_\infty$ and similar logics may be found in specialized references, such as [61, 65, 56] and Chapters 1, 2 and 6 of [83].

The second example that Font presents in Section 3.4 of [86] is Herrmann's Last Judgement Logic $\mathcal{L}J$ [53]. This is a finitary logic which is syntactically defined and which is algebraizable with a single defining equation $E(x) = \{\neg x \approx \neg(x \to x)\}$ and an infinite set of equivalence formulas $\Delta(x,y) = \{\Box^n(x \to y) \approx \Box^n(y \to x) : n \geq 0\}$. So this logic serves to separate all classes related by southeast arrows in the diagram. The same separations may be attained by a logic introduced by Dellunde in [48]. Dellunde's logic is actually the logic we opt to present as our second example. Here, we shall name it Dellunde's Logic $\mathcal{D}$.

The last example, presented in Section 3.4 of [86] is a logic introduced by Raftery in [82]. This is a semantically defined logic which is not finitary but is algebraizable via a finitary equational consequence, with an infinite set of defining equations and a single equivalence formula. So this logic, which we shall refer to as Raftery's Logic $\mathcal{R}$, shows that all southwest arrows in the diagram represent proper inclusions. This will be the third, and last example, presented in detail in this section.

9.5.1 Łukasiewicz's Infinite Valued Logic

We begin with Łukasiewicz's infinite valued logic Ł$_\infty$. Define an algebra $\mathbf{A} = \langle A, \wedge, \vee, \to, \neg\rangle$ as follows:

- The universe A is the unit interval $A = [0,1]$.
- The operations are defined, for all $a, b \in A$, by:
  - $a \wedge b = \min\{a, b\}$;
  - $a \vee b = \max\{a, b\}$;
  - $a \to b = \min\{1, 1 - a + b\} = \begin{cases} 1, & \text{if } a \leq b \\ 1 - a + b, & \text{if } a > b \end{cases}$;
  - $\neg a = 1 - a$.

Łukasiewicz's infinite valued logic Ł$_\infty = \langle \mathcal{L}, \vdash_\infty\rangle$ is the sentential logic over the language $\mathcal{L} = \{\wedge, \vee, \to, \neg\}$ defined, for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$, by

$$\Gamma \vdash_\infty \varphi \quad \text{iff} \quad \begin{array}{l} \text{for every homomorphism } h : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{A}, \\ h(\Gamma) \subseteq \{1\} \quad \text{implies} \quad h(\varphi) = 1. \end{array}$$

Over the same language $\mathcal{L}$, we define the derived binary connective $\oplus$ by setting

$$x \oplus y := \neg x \to y.$$

This operation satisfies some key properties.

Lemma 669 *For all $a, b \in A$,*

$$a \oplus b = \begin{cases} 1, & \textit{if } a + b \geq 1, \\ a + b, & \textit{if } a + b < 1 \end{cases}.$$

Proof: Let $a, b \in A$. We perform a straightforward calculation using the definitions of the operations in $\mathbf{A}$.

$$\begin{array}{rcl} a \oplus b & = & \neg a \to b = (1 - a) \to b \\ & = & \left\{ \begin{array}{ll} 1, & \text{if } 1 - a \leq b \\ 1 - (1 - a) + b, & \text{if } 1 - a > b \end{array} \right\} = \left\{ \begin{array}{ll} 1, & \text{if } a + b \geq 1 \\ a + b, & \text{if } a + b < 1 \end{array} \right. . \end{array}$$

■

Lemma 669 helps us establish the following

Lemma 670 *For all $a \in A$ and all $n \geq 2$,*

$$\underbrace{a \oplus \cdots \oplus a}_{n} = \begin{cases} 1, & \textit{if } a \geq \frac{1}{n} \\ na, & \textit{if } a < \frac{1}{n} \end{cases}.$$

Proof: We use induction on n. Lemma 669 guarantees that the formula holds for $n = 2$. Assume that the formula holds for some $n \geq 2$. Then, we get

$$\begin{array}{rcl} \underbrace{a \oplus \cdots \oplus a}_{n+1} & = & \underbrace{(a \oplus \cdots \oplus a)}_{n} \oplus a = \left\{ \begin{array}{ll} 1 \oplus a, & \text{if } a \geq \frac{1}{n} \\ (na) \oplus a, & \text{if } a < \frac{1}{n} \end{array} \right. \\ & = & \left\{ \begin{array}{ll} 1, & \text{if } a \geq \frac{1}{n} \\ 1, & \text{if } (n+1)a \geq 1 \\ (n+1)a, & \text{if } (n+1)a < 1 \end{array} \right\} = \left\{ \begin{array}{ll} 1, & \text{if } a \geq \frac{1}{n+1} \\ (n+1)a, & \text{if } a < \frac{1}{n+1} \end{array} \right. . \end{array}$$

■

We now show that $Ł_\infty$ is not finitary.

Theorem 671 *Łukasiewicz's infinite valued logic $Ł_\infty$ is not finitary.*

Proof: We set

$$\Phi = \{\underbrace{(x \oplus \cdots \oplus x)}_{n} \to y : n \geq 2\} \cup \{\neg x \to y\}.$$

We show that $\Phi \vdash_\infty y$, but $\Phi_0 \nvdash_\infty y$, for any finite $\Phi_0 \subseteq \Phi$.

Suppose $h : \mathbf{Fm}_\mathcal{L}(V) \to \mathbf{A}$ is such that

$$h(\neg y \to x) = 1 \quad \text{and} \quad h(\underbrace{(x \oplus \cdots \oplus x)}_{n} \to y) = 1, \text{ for all } n \geq 2.$$

By definition, these imply that $h(x) + h(y) \geq 1$ and $h(\underbrace{x \oplus \cdots \oplus x}_{n}) \leq h(y)$, for all $n \geq 2$.

- If $h(x) = 0$, then, by the first inequality, $h(y) = 1$.
- If $h(x) \neq 0$, then $h(x) \geq \frac{1}{n}$, for some $n > 0$. In this case, $h(\underbrace{x \oplus \cdots \oplus x}_{n}) = 1$, whence, by the second inequality, $h(y) = 1$.

Since, in either case, $h(y) = 1$, we get that $\Phi \vdash_\infty y$.

To refute finitarity, assume, towards obtaining a contradiction, that, for some finite $\Phi_0 \subseteq \Phi$, $\Phi_0 \vdash_\infty y$. Then, there exists $k \geq 2$, such that

$$\{(\underbrace{x \oplus \cdots \oplus x}_{n}) \to y : 2 \leq n \leq k\} \cup \{\neg x \to y\} \vdash_\infty y.$$

Consider a homomorphism $h : \mathbf{Fm}_\mathcal{L}(V) \to \mathbf{A}$, such that

$$h(x) = \frac{1}{k+1} \quad \text{and} \quad h(y) = \frac{k}{k+1}.$$

Then, we have

$$\begin{array}{l} h(\neg x \to y) = (1 - h(x)) \to y = \frac{k}{k+1} \to \frac{k}{k+1} = 1; \\ h((\underbrace{x \oplus \cdots \oplus x}_{n}) \to y) = h((\underbrace{x \oplus \cdots \oplus x}_{n})) \to h(y) \stackrel{n<k+1}{=} \frac{n}{k+1} \to \frac{k}{k+1} \stackrel{n\leq k}{=} 1. \end{array}$$

On the other hand, $h(y) = \frac{k}{k+1} \neq 1$. Therefore, $\Phi_0 \nvdash_\infty y$, contrary to hypothesis. We conclude that Ł$_\infty$ is not a finitary sentential logic. ■

Our final result pertaining to this logic is that it is algebraizable, via the class $\{\mathbf{A}\}$, with defining equation $E(x) = \{x \approx \top\}$, where $\top := x \to x$ (interpreted as 1), and equivalence formulas $\Delta(x, y) = \{x \to y, y \to x\}$. In the proof, we will rely on the general theory of algebraizable logics (see, e.g., Sections 3.2 and 6.5 of [86] or Section 4.5 of [64]).

Theorem 672 *Lukasiewicz's infinite value logic Ł$_\infty$ is algebraizable via the class $\{\mathbf{A}\}$, with defining equations $E(x) = \{x \approx \top\}$ and equivalence formulas $\Delta(x, y) = \{x \to y, y \to x\}$.*

Proof: According to the general theory of algebraizability, it suffices to show that, for all $\Gamma \cup \{\varphi, \psi\} \subseteq \mathrm{Fm}_\mathcal{L}(V)$,

$$\begin{array}{c} \Gamma \vdash_\infty \varphi \quad \text{iff} \quad \{\gamma \approx \top : \gamma \in \Gamma\} \vDash_\mathcal{A} \varphi \approx \top, \\ \varphi \approx \psi \dashv\vDash_\mathbf{A} \{\varphi \to \psi \approx \top, \psi \to \varphi \approx \top\}. \end{array}$$

For the first, note that

$$\begin{array}{lll} \Gamma \vdash_\infty \varphi & \text{iff} & (\forall h : \mathbf{Fm}_\mathcal{L}(V) \to \mathbf{A})(h(\Gamma) \subseteq \{1\} \text{ implies } h(\varphi) = 1) \\ & \text{iff} & (\forall h : \mathbf{Fm}_\mathcal{L}(V) \to \mathbf{A})((\forall \gamma \in \Gamma)(h(\gamma) = 1) \text{ implies } h(\varphi) = 1) \\ & \text{iff} & \{\gamma \approx \top : \gamma \in \Gamma\} \vDash_\mathbf{A} \varphi \approx \top. \end{array}$$

Finally, noting that, for all $h : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{A}$, we have $h(\varphi \to \psi) = 1$ iff $h(\varphi) \leq h(\psi)$, we get

$$h(\varphi) = h(\psi) \quad \text{iff} \quad h(\varphi \to \psi) = h(\psi \to \varphi) = 1,$$

whence $\varphi \approx \psi \mathrel{=\!|\!\models_{\mathbf{A}}} \{\varphi \to \psi \approx \top, \psi \to \varphi \approx \top\}$. The conclusion now follows. ■

9.5.2 Dellunde's Logic

We switch to the second example of the section, a logic due to Dellunde [48].

Let $\mathcal{L} = \{\leftrightarrow, \Box\}$ be the algebraic language consisting of a binary operation $\leftrightarrow$ and a unary operation $\Box$. **Dellunde's logic** $\mathcal{D} = \langle \mathcal{L}, \vdash_D \rangle$ is the logic over the language $\mathcal{L}$ defined by the following Hilbert style calculus, where x, y and x_1, y_1, x_2, y_2 denote distinct variables:

(1) $\vdash_D x \leftrightarrow x$;

(2) $x, x \leftrightarrow y \vdash_D y$;

(3) $x, y \vdash_D \Box^n x \leftrightarrow \Box^n y$, for all $n \in \omega$;

(4) $x_1 \leftrightarrow y_1, x_2 \leftrightarrow y_2 \vdash_D \Box^n(x_1 \leftrightarrow x_2) \leftrightarrow \Box^n(y_1 \leftrightarrow y_2)$, for all $n \in \omega$.

Since $\mathcal{D}$ is defined via a Hilbert calculus, it is finitary. We further define

$$\Delta(x, y) = \{\Box^n x \leftrightarrow \Box^n y : n \in \omega\}.$$

Dellunde shows that $\mathcal{D}$ is 1-equivalential, which implies that it is regularly algebraizable [53].

Theorem 673 *Dellunde's logic $\mathcal{D} = \langle \mathcal{L}, \vdash_D \rangle$ is regularly algebraizable.*

Proof: It suffices to show that, for distinct variables x, y, x_1, y_1, x_2, y_2, the following hold:

(R) $\vdash_D \Delta(x, x)$;

(MP) $x, \Delta(x, y) \vdash_D y$;

(RP) $\Delta(x, y) \vdash_D \Delta(\Box x, \Box y)$ and

$\Delta(x_1, y_1), \Delta(x_2, y_2) \vdash_D \Delta(x_1 \leftrightarrow x_2, y_1 \leftrightarrow y_2)$;

(RG) $x, y \vdash_D \Delta(x, y)$.

By (1), we have $\vdash_D x \leftrightarrow x$. By structurality, $\vdash_D \Box^n x \leftrightarrow \Box^n x$, for all $n \in \omega$. That is, $\vdash_D \Delta(x,x)$. So (R) holds.

Rule (2) assures that $x, x \leftrightarrow y \vdash_D y$. Now, note that $x \leftrightarrow y \in \Delta(x,y)$ and apply monotonicity of entailment to get $x, \Delta(x,y) \vdash_D y$. That is, (MP) holds.

The first rule in (RP) is a consequence of monotonicity, since

$$\begin{array}{rcl}\Delta(\Box x, \Box y) & = & \{\Box^n \Box x \leftrightarrow \Box^n \Box y : n \in \omega\}\\ & = & \{\Box^n x \leftrightarrow \Box^n y : n \geq 1\}\\ & \subseteq & \{\Box^n x \leftrightarrow \Box^n y : n \in \omega\}\\ & = & \Delta(x,y).\end{array}$$

For the second rule in (RP), note that (4) gives $x_1 \leftrightarrow y_1, x_2 \leftrightarrow y_2 \vdash_D \Delta(x_1 \leftrightarrow x_2, y_1 \leftrightarrow y_2)$. On the other hand, $x_1 \leftrightarrow y_1 \in \Delta(x_1,y_1)$ and $x_2 \leftrightarrow y_2 \in \Delta(x_2,y_2)$. Therefore, we conclude that $\Delta(x_1,y_1), \Delta(x_2,y_2) \vdash_D \Delta(x_1 \leftrightarrow x_2, y_1 \leftrightarrow y_2)$, whence (RP) holds.

Finally, note that, by (3), (RG) holds.

We conclude that $\mathcal{D}$ is regularly algebraizable, with a singleton set of defining equations $E(x) = \{x \approx \top\}$, where $\top := x \leftrightarrow x$ is a unary term interpreted as the unique element of the $\mathcal{D}$-filter of any reduced $\mathcal{D}$-matrix, and set of equivalence formulas $\Delta(x,y)$. ■

Finally, Dellunde shows that $\mathcal{D}$ is not finitely equivalential, i.e., that there does not exist a finite subset $\Delta_0 \subseteq \Delta$ that can also serve as a set of equivalence formulas. In relation to this, see Lemma 3.36 in Section 3.4 of [86].

Theorem 674 *Dellunde's logic $\mathcal{D} = \langle \mathcal{L}, \vdash_D \rangle$ is not finitely equivalential, i.e., there exists no finite $\Delta_0 \subseteq \Delta$ which is also a set of equivalence formulas for $\mathcal{D}$.*

Proof: Assume, towards a contradiction, that there exists finite $\Delta_0 \subseteq \Delta$, which serves as a set of equivalence formulas for $\mathcal{D}$. Then, there exists a maximum $m \in \omega$, such that $\Box^m x \leftrightarrow \Box^m y \in \Delta_0$. To obtain a contradiction, we construct a $\mathcal{D}$-matrix $\mathfrak{A} = \langle \mathbf{A}, F \rangle$ and choose elements $c, d \in A$, such that

$$\Delta_0^{\mathbf{A}}(c,d) \subseteq F \quad \text{but} \quad \langle c,d \rangle \notin \Omega_{\mathbf{A}}(F).$$

As a preparatory step in defining the $\mathcal{L}$-algebra $\mathbf{A}$, we define on $\omega \times \omega$ the following equivalence relation:

$$R = \mathrm{Id}_{\omega\times\omega} \cup \{\langle \langle i,j \rangle, \langle k,\ell \rangle \rangle : i = k, i < j, k < \ell\}.$$

The algebra $\mathbf{A} = \langle A, \leftrightarrow^{\mathbf{A}}, \Box^{\mathbf{A}} \rangle$ is defined as follows:

- $A = \omega \times \omega$;
- The operations are defined, for all $i, j \in \omega$ and all $a, b \in \omega \times \omega$,

– $\Box^{\mathbf{A}}(\langle i,j\rangle) = \langle i+1,j\rangle$;

– $\leftrightarrow^{\mathbf{A}} (a,b) = \begin{cases} \langle 1,0\rangle, & \text{if } \langle a,b\rangle \in R \\ \langle 0,0\rangle, & \text{if } \langle a,b\rangle \notin R \end{cases}$.

The filter $F = \{\langle 1,0\rangle\}$ and the elements $c,d \in A$ are chosen as $c = \langle 0,m+1\rangle$ and $d = \langle 0,m+2\rangle$, where, recall that, $m = \max\{k : \Box^k x \leftrightarrow \Box^k y \in \Delta_0\}$. It suffices, now, to show the following:

(a) $\mathfrak{A} = \langle \mathbf{A}, F\rangle$ is a $\mathcal{D}$-matrix, i.e., F is closed under all $\mathcal{D}$-rules;

(b) $\Delta_0^{\mathbf{A}}(c,d) \subseteq F$;

(c) $\langle c,d\rangle \notin \Omega_{\mathbf{A}}(F)$.

For (a), let $h : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{A}$ be arbitrary. Then:

- For all $n \in \omega$, $h(\Box^n x \leftrightarrow \Box^n x) = h(\Box^n x) \leftrightarrow^{\mathbf{A}} h(\Box^n x) = \langle 1,0\rangle \in F$.
- Suppose $h(x) = \langle 1,0\rangle$ and $h(x \leftrightarrow y) = \langle 1,0\rangle$. So $h(x) = \langle 1,0\rangle$ and $h(x) \leftrightarrow^{\mathbf{A}} h(y) = \langle 1,0\rangle$. Since $h(x) = \langle 1,0\rangle$ and $1 \nleq 0$, we get $h(x) = h(y)$. So, $h(y) = \langle 1,0\rangle \in F$.
- If $h(x) = h(y) = \langle 1,0\rangle$, then $h(\Box^n x) = \Box^{\mathbf{A}^n} h(x) = \Box^{\mathbf{A}^n} h(y) = h(\Box^n y)$, whence, $h(\Box^n x \leftrightarrow \Box^n y) = h(\Box^n x) \leftrightarrow^{\mathbf{A}} h(\Box^n y) = \langle 1,0\rangle \in F$.
- If $h(x_1 \leftrightarrow y_1) = h(x_2 \leftrightarrow y_2) = \langle 1,0\rangle$, then, since R is an equivalence relation, it follows from

$$\begin{array}{ccc} h(x_1) & \text{—}R\text{—} & h(y_1) \\ \vdots & & \vdots \\ R & & R \\ \vdots & & \vdots \\ h(x_2) & \text{—}R\text{—} & h(y_2) \end{array}$$

that $\langle h(x_1),h(x_2)\rangle \in R$ iff $\langle h(y_1),h(y_2)\rangle \in R$, i.e., that

$$h(x_1 \leftrightarrow x_2) = h(y_1 \leftrightarrow y_2) = \begin{cases} \langle 1,0\rangle, & \text{if } \langle h(x_1),h(x_2)\rangle \in R \\ \langle 0,0\rangle, & \text{if } \langle h(x_1),h(x_2)\rangle \notin R \end{cases}.$$

Then, we obtain, for all $n \in \omega$, $h(\Box^n(x_1 \leftrightarrow x_2)) = h(\Box^n(y_1 \leftrightarrow y_2))$, which yields that $h(\Box^n(x_1 \leftrightarrow x_2) \leftrightarrow \Box^n(y_1 \leftrightarrow y_2)) = \langle 1,0\rangle$.

Thus, $\mathfrak{A}$ is indeed a $\mathcal{D}$-matrix.

For (b), suppose $\Box^k x \leftrightarrow \Box^k y \in \Delta_0$, i.e., $k \leq m$. Then, we have

$$\begin{aligned} \Box^{\mathbf{A}^k} c \leftrightarrow^{\mathbf{A}} \Box^{\mathbf{A}^k} d &= \Box^{\mathbf{A}^k}\langle 0,m+1\rangle \leftrightarrow^{\mathbf{A}} \Box^{\mathbf{A}^k}\langle 0,m+2\rangle \\ &= \langle k,m+1\rangle \leftrightarrow^{\mathbf{A}} \langle k,m+2\rangle \\ &= \langle 1,0\rangle. \end{aligned}$$

So, $\Delta_0^{\mathbf{A}}(c,d) \subseteq F$.

Finally, for (c), observe that

$$\begin{array}{rcl} \Box^{\mathbf{A}^{m+1}} c \leftrightarrow^{\mathbf{A}} \Box^{\mathbf{A}^{m+1}} d & = & \Box^{\mathbf{A}^{m+1}} \langle 0, m+1\rangle \leftrightarrow^{\mathbf{A}} \Box^{\mathbf{A}^{m+1}} \langle 0, m+2\rangle \\ & = & \langle m+1, m+1\rangle \leftrightarrow^{\mathbf{A}} \langle m+1, m+2\rangle \\ & = & \langle 0,0\rangle \notin F. \end{array}$$

Therefore, by Theorem 673 and the general theory of algebraizability, $\langle c,d\rangle \notin \Omega_{\mathbf{A}}(F)$.

The conjunction of assertions (a), (b) and (c) shows that Δ_0 is not a set of equivalence formulas for $\mathcal{D}$ and, consequently, taking into account the finitarity of $\mathcal{D}$ and Lemma 3.36 of Section 3.4 of [86], $\mathcal{D}$ does not possess a finite set of equivalence formulas. ■

9.5.3 Raftery's Logic

Finally, we turn to a detailed description of Raftery's logic [82].

The construction unfolds in several stages. It starts with the set

$$B = \{0,1\} \cup (\{0,1\} \times \{0,1\})^\omega$$

consisting of the bits 0 and 1 and of infinite sequences of pairs of bits. On this set B, three unary operations π_1, π_2 and $\Diamond$ are defined by setting, for all $b \in \{0,1\}$ and all $\langle\langle b_0, b_0'\rangle, \langle b_1, b_1'\rangle, \ldots\rangle \in (\{0,1\} \times \{0,1\})^\omega$,

$$\begin{array}{rl} \pi_1(b) = b, & \pi_1(\langle\langle b_0, b_0'\rangle, \langle b_1, b_1'\rangle, \ldots\rangle) = b_0; \\ \pi_2(b) = b, & \pi_2(\langle\langle b_0, b_0'\rangle, \langle b_1, b_1'\rangle, \ldots\rangle) = b_0'; \\ \Diamond b = b, & \Diamond(\langle\langle b_0, b_0'\rangle, \langle b_1, b_1'\rangle, \ldots\rangle) = \langle\langle b_1, b_1'\rangle, \langle b_2, b_2'\rangle, \ldots\rangle. \end{array}$$

In the next stage, Raftery constructs the universe A of the algebra $\mathbf{A}$ that forms the algebraic reduct of the logical matrix used to define Raftery's logic. This is accomplished by closing under the formation of ordered pairs.

$$\begin{array}{rcl} B^{[1]} & = & B; \\ B^{[n]} & = & (\bigcup_{0<m<n} B^{[m]}) \times (\bigcup_{0<m<n} B^{[m]}), \quad n > 1; \end{array}$$

and, finally,

$$A = \bigcup_{0<n\in\omega} B^{[n]}.$$

First, observe that no element of B is an ordered pair and that every element of $A - B$ is an ordered pair.

To define the algebra $\mathbf{A}$, the operations introduced previously on B are extended on A. We set, for all $\langle a, a'\rangle \in A - B$,

$$\pi_1(\langle a, a'\rangle) = a, \qquad \pi_2(\langle a, a'\rangle) = a', \qquad \Diamond\langle a, a'\rangle = \langle a, a'\rangle.$$

To complete the specification of $\mathbf{A}$, we add a "pair forming" binary operation $\leftrightarrow$, defined, for all $a, a' \in A$, by

$$a \leftrightarrow a' = \langle a, a' \rangle.$$

So the algebra used to specify Raftery's logic is $\mathbf{A} = \langle A, \leftrightarrow, \pi_1, \pi_2, \lozenge \rangle$. It is easy to check that $\mathbf{A}$ satisfies the equations

$$\begin{array}{rcl} \pi_1(x \leftrightarrow y) & \approx & x, \\ \pi_2(x \leftrightarrow y) & \approx & y, \\ \lozenge(x \leftrightarrow y) & \approx & x \leftrightarrow y. \end{array}$$

We now define two logical systems semantically. The first is defined via a logical matrix with underlying algebra $\mathbf{A}$. We define the matrix $\mathfrak{A} = \langle \mathbf{A}, D \rangle$, where D is the set of so-called "diagonal elements" of A, i.e., the elements

- 0 and 1;
- $\langle \langle b_0, b_0 \rangle, \langle b_1, b_1 \rangle, \dots \rangle$, for $b_0, b_1, \dots \in \{0, 1\}$;
- $\langle a, a \rangle$, for $a \in A$.

This matrix $\mathfrak{A}$ specifies the logic $\mathcal{S}_{\mathfrak{A}} = \langle \mathcal{L}, \vdash_{\mathfrak{A}} \rangle$ in the standard way, i.e., for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\begin{array}{lll} \Gamma \vdash_{\mathfrak{A}} \varphi & \text{iff} & \text{for every } h : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{A}, \\ & & h(\Gamma) \subseteq D \quad \text{implies} \quad h(\varphi) \in D. \end{array}$$

The second logical system is defined using a variety V of $\mathcal{L}$-algebras, for $\mathcal{L} = \{\leftrightarrow, \pi_1, \pi_2, \lozenge\}$, namely the variety axiomatized by the three equations

$$\begin{array}{rcl} \pi_1(x \leftrightarrow y) & \approx & x, \\ \pi_2(x \leftrightarrow y) & \approx & y, \\ \lozenge(x \leftrightarrow y) & \approx & x \leftrightarrow y. \end{array}$$

We set $\delta_i(x) = \pi_1(\lozenge^i x)$ and $\varepsilon_i(x) = \pi_2(\lozenge^i x)$ and define **Raftery's logic** $\mathcal{R} = \langle \mathcal{L}, \vdash_R \rangle$ by setting, for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\Gamma \vdash_{\mathcal{R}} \varphi \quad \text{iff} \quad (\delta \approx \varepsilon)(\Gamma) \vDash_V (\delta \approx \varepsilon)(\phi),$$

i.e., $\Gamma \vdash_{\mathcal{R}} \varphi$ iff, for every $\mathbf{A} \in V$, all $h : \mathbf{Fm}_{\mathcal{L}}(V) \to \mathbf{A}$ and all $j \in \omega$,

$$\begin{array}{ll} \delta_i^{\mathbf{A}}(h(\gamma)) = \varepsilon_i^{\mathbf{A}}(h(\gamma)), & \text{for all } i \in \omega,\ \gamma \in \Gamma, \\ & \text{implies} \quad \delta_j^{\mathbf{A}}(h(\varphi)) = \varepsilon_j^{\mathbf{A}}(h(\varphi)). \end{array}$$

The first result relating the logics $\mathcal{S}_{\mathfrak{A}}$ and $\mathcal{R}$ asserts that the latter is a weakening of the former.

Lemma 675 *Raftery's logic* $\mathcal{R} = \langle \mathcal{L}, \vdash_R \rangle$ *is a weakening of* $\mathcal{S}_{\mathfrak{A}} = \langle \mathcal{L}, \vdash_{\mathfrak{A}} \rangle$.

Proof: Since, as remarked previously, $\mathbf{A}$ satisfies the three equations axiomatizing the variety V, we get that $\mathbf{A} \in V$. Consequently, it suffices to show that for all $a \in A$,

$$a \in D \quad \text{iff} \quad \delta_i^{\mathbf{A}}(a) = \epsilon_i^{\mathbf{A}}(a), \text{ for all } i \in \omega.$$

Suppose, first, that $a \in D$.

- If $a \in \{0,1\}$, then $\delta_i^{\mathbf{A}}(a) = \pi_1^{\mathbf{A}}(a)(\Diamond^{\mathbf{A}^i} a) = \pi_1^{\mathbf{A}}(a) = a = \pi_2^{\mathbf{A}}(a) = \pi_2^{\mathbf{A}}(a)(\Diamond^{\mathbf{A}^i} a) = \varepsilon_i^{\mathbf{A}}(a)$.
- If $a = \langle\langle b_0, b_0\rangle, \langle b_1, b_1\rangle, \dots\rangle$, then
$$\begin{aligned} &\delta_i^{\mathbf{A}}(a) = \pi_1^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a) = \pi_1^{\mathbf{A}}(\langle\langle b_i, b_i\rangle, \langle b_{i+1}, b_{i+1}\rangle, \dots\rangle) = b_i \\ &= \pi_2^{\mathbf{A}}(\langle\langle b_i, b_i\rangle, \langle b_{i+1}, b_{i+1}\rangle, \dots\rangle) = \pi_2^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a) = \varepsilon_i^{\mathbf{A}}(a).\end{aligned}$$
- If $a = \langle a', a'\rangle$, with $a' \in A$, then
$$\begin{aligned} &\delta_i^{\mathbf{A}}(\langle a', a'\rangle) = \pi_1^{\mathbf{A}}(\Diamond^{\mathbf{A}^i}\langle a', a'\rangle) = \pi_1^{\mathbf{A}}(\langle a', a'\rangle) = a' \\ &= \pi_2^{\mathbf{A}}(\langle a', a'\rangle) = \pi_2^{\mathbf{A}}(\Diamond^{\mathbf{A}^i}\langle a', a'\rangle) = \varepsilon_i^{\mathbf{A}}(\langle a', a'\rangle).\end{aligned}$$

Assume, conversely, that $\delta_i^{\mathbf{A}}(a) = \varepsilon_i^{\mathbf{A}}(a)$, for all $i \in \omega$. This means $\pi_1^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a) = \pi_2^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a)$, for all $i \in \omega$. if $a = 0$ or $a = 1$, there is nothing to prove. If $a = \langle\langle b_0, b_0'\rangle, \langle b_1, b_1'\rangle, \dots\rangle$, then the i-th equation gives $b_i = b_i'$. So we conclude that $a \in D$. Finally, if $a = \langle a', a''\rangle$, for some $a', a'' \in A$, then the equations ensure that $a' = a''$ and, therefore, $a = \langle a', a''\rangle \in D$. ■

To verify that Raftery's logic accomplishes its mission, one has to establish that it is not finitary, but that it is algebraizable with the variety V as its equivalent algebraic semantics. Then, by Theorem 3.37 and Corollary 3.38 of Section 3.4 of [86], it becomes clear that the algebraization of $\mathcal{R}$ is carried out by a necessarily infinite set of defining equations and a set of equivalence formulas that may be taken to be finite. We formalize the second statement first.

Theorem 676 (Fact 9 of [82]) *Raftery's logic $\mathcal{R} = \langle \mathcal{L}, \vdash_R\rangle$ is algebraizable with equivalent algebraic semantics V via the set of defining equations $\delta(x) \approx \varepsilon(x) = \{\delta_i(x) \approx \varepsilon_i(x) : i \in \omega\}$ and the equivalence formula $\Delta(x,y) = \{x \leftrightarrow y\}$.*

Proof: By the definition of $\vdash_R$, for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\Gamma \vdash_R \varphi \quad \text{iff} \quad (\delta \approx \varepsilon)(\Gamma) \vDash_V (\delta \approx \varepsilon)(\varphi).$$

Moreover, for all $\varphi, \psi \in \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\begin{aligned} (\delta \approx \varepsilon)(\varphi \leftrightarrow \psi) &= \pi_1(\Diamond^i(\varphi \leftrightarrow \psi)) \approx \pi_2(\Diamond^i(\varphi \leftrightarrow \psi)), i \in I \\ &\dashv\vDash_V \pi_1(\varphi \leftrightarrow \psi) \approx \pi_2(\varphi \leftrightarrow \psi) \\ &\qquad (\text{since } V \vDash \Diamond(x \leftrightarrow y) \approx x \leftrightarrow y) \\ &\dashv\vDash_V \varphi \approx \psi \\ &\qquad (\text{since } V \vDash \pi_1(x \leftrightarrow y) \approx x \\ &\qquad \text{and } V \vDash \pi_2(x \leftrightarrow y) \approx y). \end{aligned}$$

By the general theory of algebraizable logics, these two conditions suffice to guarantee the conclusion. ■

And, finally, we show that $\mathcal{R}$ is not finitary.

Theorem 677 (Fact 10 of [82]) *The logics* $\mathcal{S}_{\mathfrak{A}} = \langle \mathcal{L}, \vdash_{\mathfrak{A}} \rangle$ *and* $\mathcal{R} = \langle \mathcal{L}, \vdash_R \rangle$ *are not finitary.*

Proof: Note that the two conditions established in the proof of Theorem 676, which suffice to establish algebraizability, imply, by the general theory of algebraizability (see, e.g., Exercise 39 of Section 3.2 of [86]), that

$$\{\delta_i(x) \leftrightarrow \varepsilon_i(x) : i \in \omega\} \vdash_R x$$

also holds. In addition, since, by Lemma 675, $\mathcal{R} \leq \mathcal{S}_{\mathfrak{A}}$,

$$\{\delta_i(x) \leftrightarrow \varepsilon_i(x) : i \in \omega\} \vdash_{\mathfrak{A}} x.$$

So to prove that $\mathcal{S}_{\mathfrak{A}}$ and $\mathcal{R}$ are not finitary, it suffices to show that, for no finite $K \subseteq \omega$ is it the case that $\{\delta_k(x) \leftrightarrow \varepsilon_k(x) : k \in K\} \vdash_{\mathfrak{A}} x$.

Let $j \in \omega - K$ and consider $a = \langle \langle b_0, b'_0 \rangle, \langle b_1, b'_1 \rangle, \dots \rangle \in B - \{0, 1\}$, such that $b_k = b'_k$, for all $k \in K$, but $b_j \neq b'_j$. Now, we compute

$$\delta_i^{\mathbf{A}}(a) \leftrightarrow^{\mathbf{A}} \varepsilon_i^{\mathbf{A}}(a) = \pi_1^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a) \leftrightarrow^{\mathbf{A}} \pi_2^{\mathbf{A}}(\Diamond^{\mathbf{A}^i} a) = b_i \leftrightarrow^{\mathbf{A}} b'_i,$$

whence, $(\delta_k \leftrightarrow \varepsilon_k)^{\mathbf{A}}(a) \in D$, for all $k \in K$, whereas, since $(\delta_j \leftrightarrow \varepsilon_j)^{\mathbf{A}}(a) \notin D$, by what was proven in Lemma 675, $a \notin D$. This shows that $\{\delta_k(x) \leftrightarrow \varepsilon_k(x) : k \in K\} \nvdash_{\mathfrak{A}} x$. Hence $\mathcal{S}_{\mathfrak{A}}$ and, a fortiori, $\mathcal{R}$ are not finitary. ■

So, the logic $\mathcal{R}$ does indeed attain the goal of discovering a non-finitary logic that is elementarily algebraizable (i.e., has a finitary equivalent algebraic semantics).

9.6 Separating Classes of π-Institutions

Using the framework detailed in Section 1.1, we recast the three sentential logics introduced in Section 9.5 as π-institutions and show that they provide examples that serve to separate the classes of π-institutions appearing in the steps of the finitarity hierarchy studied in Section 9.4.

In the first example, we recast Łukasiewicz's infinite valued logic as a π-institution.

Example 678 *Consider the algebraic system* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by* $\mathrm{SEN}^\flat(\Sigma) = \mathrm{Fm}_{\mathcal{L}}(V)$, *where* $\mathcal{L} = \{\wedge, \vee, \to, \neg\}$ *is the language of Łukasiewicz's infinite valued logic;*

- $N^\flat$ *is the category of natural transformations generated by the binary operations* $\wedge, \vee, \to : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *and the unary operation* $\neg : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$, *defined as usual on the absolutely free algebra of formulas.*

Now define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C\rangle$, *where, for all* $\Gamma \cup \{\varphi\} \subseteq \mathrm{SEN}^\flat(\Sigma)$,

$$\varphi \in C_\Sigma(\Gamma) \quad \text{iff} \quad \Gamma \vdash_\infty \varphi.$$

By Theorem 671, $\mathcal{I}$ *is not finitary. By Theorem 672 and the general theory of algebraizable logics, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and* $\theta = \mathrm{ConSys}^*(\mathcal{I})$,

$$\begin{array}{rcl}\Omega_\Sigma(T) & = & \{\langle\varphi,\psi\rangle \in \mathrm{Fm}^2_{\mathcal{L}}(V) : \varphi \to \psi, \psi \to \varphi \in T_\Sigma\};\\ \Omega^{-1}_\Sigma(\theta) & = & \{\varphi \in \mathrm{Fm}_{\mathcal{L}}(V) : \langle \varphi, \top\rangle \in \theta_\Sigma\}.\end{array}$$

We show that the Leibniz operator $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *and its inverse* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *are continuous. Suppose* $\{T^i\}_{i\in I} \subseteq \mathrm{ThFam}(\mathcal{I})$ *is directed and that* $\bigcup_{i\in I} T^i \in \mathrm{ThFam}(\mathcal{I})$. *Then we get, for all* $\varphi, \psi \in \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\begin{array}{rll}\langle\varphi,\psi\rangle \in \Omega_\Sigma(\bigcup_{i\in I} T^i) & \text{iff} & \varphi \to \psi, \psi \to \varphi \in \bigcup_{i\in I} T^i_\Sigma\\ & \text{iff} & \varphi \to \psi \in T^i_\Sigma, \psi \to \varphi \in T^j_\Sigma, \text{ for some } i, j \in I,\\ & \text{iff} & \varphi \to \psi, \psi \to \varphi \in T^k_\Sigma, \text{ for some } k \in I,\\ & \text{iff} & \langle\varphi,\psi\rangle \in \Omega_\Sigma(T^k), \text{ for some } k \in I,\\ & \text{iff} & \langle\varphi,\psi\rangle \in \bigcup_{i\in I} \Omega_\Sigma(T^i).\end{array}$$

The proof for Ω^{-1} *is similar.*

This π*-institution serves to separate the classes connected by the three vertical arrows in the diagram concluding Section 9.4.*

The second example revisits Dellunde's logic in a similar way.

Example 679 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is defined by setting* $\mathrm{SEN}^\flat(\Sigma) = \mathrm{Fm}_{\mathcal{L}}(V)$, *where* $\mathcal{L} = \{\leftrightarrow, \Box\}$ *is the language of Dellunde's logic;*

- $N^\flat$ *is the category of natural transformations generated by the binary operation* $\leftrightarrow : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *and the unary operation* $\Box : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined as usual on the absolutely free algebra of formulas.*

Define the π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, by setting, for all $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\varphi \in C_\Sigma(\Gamma) \quad \text{iff} \quad \Gamma \vdash_D \varphi.$$

Since, as remarked in Section 9.5, Dellunde's logic $\mathcal{D}$ is finitary, so is the π-institution $\mathcal{I}$. Moreover, by Theorem 673 and the general theory of algebraizable logics, for all $T \in \mathrm{ThFam}(\mathcal{I})$ and all $\theta \in \mathrm{ConSys}^*(\mathcal{I})$, we have

$$\begin{array}{lll}\Omega_\Sigma(T) & = & \{\langle \varphi, \psi \rangle \in \mathrm{Fm}^2_{\mathcal{L}}(V) : \Box^n \varphi \leftrightarrow \Box^n \psi \in T_\Sigma, \text{ for all } n \in \omega\};\\ \Omega^{-1}_\Sigma(\theta) & = & \{\varphi \in \mathrm{Fm}_{\mathcal{L}}(V) : \langle \varphi, \top \rangle \in \theta_\Sigma\}.\end{array}$$

We show that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ is not continuous. Assume to the contrary, and define, for all $i \in \omega$, $T^i = \{T^i_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|}$ by setting

$$T^i_\Sigma = C_\Sigma(\{\Box^k x \leftrightarrow \Box^k y : k \leq i\}).$$

Note the following:

(1) $\{T^i\}_{i=0}^\infty$ is directed;

(2) $\bigcup_{i=0}^\infty T^i \in \mathrm{ThFam}(\mathcal{I})$, since $\mathcal{I}$ is finitary;

(3) $\langle x, y \rangle \in \Omega_\Sigma(\bigcup_{i=0}^\infty T^i)$, since $\Box^n x \leftrightarrow \Box^n y \in \bigcup_{i=0}^\infty T^i_\Sigma$, for all $n \in \omega$.

By the hypothesized continuity of Ω, since $\langle x, y \rangle \in \bigcup_{i=0}^\infty \Omega_\Sigma(T^i)$, there exists $m \in \omega$, such that $\langle x, y \rangle \in \Omega_\Sigma(T^m)$. But this implies that, for all $n > m$,

$$\Box^n x \leftrightarrow \Box^n y \in C_\Sigma(\{\Box^k x \leftrightarrow \Box^k y : k \leq m\}),$$

which contradicts what was shown in Theorem 674.

The π-institution $\mathcal{I}$, constructed here, serves to separate the classes connected by the southeast arrows in the finitarity hierarchy of π-institutions, shown at the end of Section 9.4.

Finally, we formulate an example that employs Raftery's logic $\mathcal{R}$.

Example 680 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object Σ;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is the functor specified by $\mathrm{SEN}^\flat(\Sigma) = \mathrm{Fm}_{\mathcal{L}}(V)$, where $\mathcal{L} = \{\leftrightarrow, \pi_1, \pi_2, \Diamond\}$ is the language of Raftery's logic;*
- $N^\flat$ *is the category of natural transformations generated by the binary operation $\leftrightarrow : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ and the unary operations $\pi_1, \pi_2, \Diamond : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ defined as usual on the absolutely free algebra of formulas.*

Define the π*-institution* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *by setting, for all* $\Gamma \cup \{\varphi\} \subseteq \mathrm{Fm}_{\mathcal{L}}(V)$,

$$\varphi \in C_\Sigma(\Gamma) \quad \textit{iff} \quad \Gamma \vdash_R \varphi.$$

By Theorem 677, $\mathcal{I}$ *is not finitary. By Theorem 676 and the general theory of algberaizable logics, for all* $T \in \mathrm{ThFam}(\mathcal{I})$ *and all* $\theta \in \mathrm{ConSys}^*(\mathcal{I})$,

$$\begin{array}{lll}\Omega_\Sigma(T) & = & \{\langle \varphi, \psi \rangle \in \mathrm{Fm}^2_{\mathcal{L}}(V) : \varphi \leftrightarrow \psi \in T_\Sigma\};\\ \Omega^{-1}_\Sigma(\theta) & = & \{\varphi \in \mathrm{Fm}_{\mathcal{L}}(V) : \langle \pi_1(\Box^i\varphi), \pi_2(\Box^i\varphi)\rangle \in \theta_\Sigma, \ \textit{for all } i \in \omega\}.\end{array}$$

We may now show that $\Omega : \mathrm{ThFam}(\mathcal{I}) \to \mathrm{ConSys}^*(\mathcal{I})$ *is continuous, but* $\Omega^{-1} : \mathrm{ConSys}^*(\mathcal{I}) \to \mathrm{ThFam}(\mathcal{I})$ *is not continuous.*

To show continuity of Ω*, assume* $\{T^i\}_{i \in I} \subseteq \mathrm{ThFam}(\mathcal{I})$ *is directed, such that* $\bigcup_{i \in I} T^i \in \mathrm{ThFam}(\mathcal{I})$*. Let* $\langle \varphi, \psi \rangle \in \Omega_\Sigma(\bigcup_{i \in I} T^i)$*. This holds iff* $\varphi \leftrightarrow \psi \in \bigcup_{i \in I} T^i_\Sigma$*, i.e., iff, for some* $i \in I$*,* $\varphi \leftrightarrow \psi \in T^i$*. This is equivalent to* $\langle \varphi, \psi \rangle \in \Omega_\Sigma(T^i)$*, for some* $i \in I$*, showing that* $\Omega(\bigcup_{i \in I} T^i) = \bigcup_{i \in I} \Omega(T^i)$.

To show that Ω^{-1} *is not continuous, let, for all* $i \in \omega$*,* $\theta^i = \{\theta^i_\Sigma\}_{\Sigma \in |\mathbf{Sign}^\flat|} \in \mathrm{ConSys}^*(\mathcal{I})$ *be defined by*

$$\theta^i_\Sigma = \{\langle \varphi, \psi \rangle \in \mathrm{Fm}^2_{\mathcal{L}}(V) : \{\delta_k(x) \approx \varepsilon_k(x) : k \leq i\} \vDash_V \varphi \approx \psi\},$$

where, as before, for all $i \in \omega$,

$$\delta_i(x) = \pi_1(\Diamond^i x) \quad \textit{and} \quad \varepsilon_i(x) = \pi_2(\Diamond^i x).$$

Note that

(1) $\{\theta^i\}^\infty_{i=0}$ *is directed;*

(2) $\bigcup^\infty_{i=0} \theta^i \in \mathrm{ConSys}^*(\mathcal{I})$*, since* $\vDash_V$ *is finitary;*

(3) $x \in \Omega^{-1}_\Sigma(\bigcup^\infty_{i=0} \theta^i)$*, since* $\delta(x) \approx \varepsilon(x) \subseteq \bigcup^\infty_{i=0} \theta^i_\Sigma$.

If Ω^{-1} *were continuous, there would exist* $m \in \omega$*, such that* $x \in \Omega^{-1}_\Sigma(\theta^m)$*. But, this would imply that*

$$\{\delta_k(x) \approx \varepsilon_k(x) : k \leq m\} \vDash_V \delta(x) \approx \varepsilon(x),$$

which yields $\{\delta_k(x) \leftrightarrow \varepsilon_k(x) : k \leq m\} \vdash_R x$*, contradicting Theorem 677.*

The π*-institution* $\mathcal{I}$*, constructed in this example, separates the classes of* π*-institutions related by the southwest arrows in the finitarity hierarchy shown at the end of Section 9.4.*

Chapter 10

Elements of Syntax

10.1 Natural Transformations and Parameters

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system. Consider a set

$$I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$$

of natural transformations in $N^\flat$. Of course, by definition, each $\sigma^\flat \in I^\flat \subseteq N^\flat$ is finitary, but the arities in the collection may be unbounded, whence the notation becomes handy.

Recall that, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} \in \mathrm{SEN}^\flat(\Sigma)^\omega$,

$$I^\flat_\Sigma(\vec{\phi}) = \{\sigma^\flat_\Sigma(\phi_0, \ldots, \phi_{k-1}) : \sigma^\flat : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat \in I^\flat\}.$$

Moreover, we may view the first n of the arguments in the input sequence as **distinguished** and the remaining as **parameters** or **parametric arguments**. In that case, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\vec{\phi} = \langle \phi_0, \ldots, \phi_{n-1} \rangle \in \mathrm{SEN}^\flat(\Sigma)$, we define

$$I^\flat_\Sigma[\vec{\phi}] = \{I^\flat_{\Sigma,\Sigma'}[\vec{\phi}]\}_{\Sigma' \in |\mathbf{Sign}^\flat|},$$

where, for all $\Sigma' \in |\mathbf{Sign}^\flat|$,

$$I^\flat_{\Sigma,\Sigma'}[\vec{\phi}] = \bigcup\{I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi}) : f \in \mathbf{Sign}^\flat(\Sigma, \Sigma'), \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')\}.$$

The following diagram illustrates where the various sentences and components sit as we move from inputs to outputs in this construct.

$$\begin{array}{ccc}
\mathrm{SEN}^\flat(\Sigma) & \xrightarrow{\mathrm{SEN}^\flat(f)} & \mathrm{SEN}^\flat(\Sigma') \\
\vec{\phi} & \longmapsto & \mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi} \\
 & & \big\downarrow \\
 & & I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\vec{\phi}), \vec{\chi})
\end{array}$$

Suppose that in $I^\flat$ we take $n = 2$, i.e., we consider only the first two arguments as distinguished and the remaining as parameters. Then, we define for $\sigma : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat \in N^\flat$, the natural transformation $\overline{\sigma} : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$\overline{\sigma}_\Sigma(\phi, \psi, \vec{\chi}) = \sigma_\Sigma(\psi, \phi, \vec{\chi}).$$

Further, we set

$$\overline{I^\flat} = \{\overline{\sigma} : \sigma \in I^\flat\}$$

and

$$\overleftrightarrow{I^\flat} = I^\flat \cup \overline{I^\flat}.$$

It is not difficult to see that, given $I^\flat \subseteq N^\flat$, the collections $\overline{I^\flat}$ and $\overleftrightarrow{I^\flat}$ both consist of natural transformations in $N^\flat$.

Lemma 681 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system and let* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *be a collection of natural transformations in* $N^\flat$. *Then* $\overline{I^\flat}, \overleftrightarrow{I^\flat} \subseteq N^\flat$.

Proof: The inclusion $\overline{I^\flat} \subseteq N^\flat$ follows from Proposition 11. Then the second inclusion follows directly from the definition of $\overleftrightarrow{I^\flat}$. ∎

Finally, recall that, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$, a collection $I^\flat \subseteq N^\flat$, with two distinguished arguments, and $T \in \mathrm{SenFam}(\mathbf{F})$, we define $I^\flat(T) = \{I^\flat_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}^\flat|}$, by setting, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\langle \phi, \psi \rangle \in I^\flat_\Sigma(T) \quad \text{iff} \quad I^\flat_\Sigma[\phi, \psi] \leq T.$$

It was shown in Lemma 93 that $I^\flat(T)$ is a relation system on $\mathbf{F}$, i.e., invariant under signature morphisms.

In what follows we explore some properties that collections of natural transformations may or may not satisfy in π-institutions based on the algebraic systems on which they are defined.

10.2 Reflexivity

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. Taking into account Proposition 103, we say that $I^\flat$ is **reflexive in** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$I^\flat_\Sigma(\phi, \phi, \vec{\chi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I}) \coloneqq C_\Sigma(\varnothing).$$

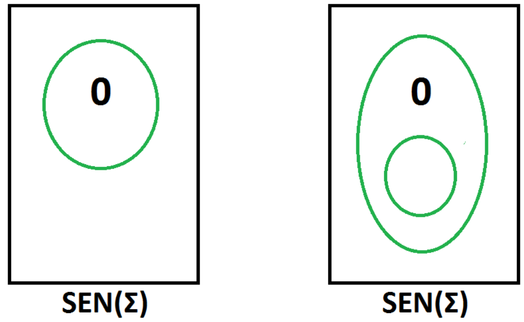
Example 682 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with object* Σ*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0\}$*;*
- $N^\flat$ *is the trivial category of natural transformations consisting only of the projections.*

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{0\}\}$ *and* $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ *be the* π*-institution determined by* $\mathcal{C}'_\Sigma = \{\varnothing, \{0\}\}$.

Consider the set $I^\flat = \{p^{2,0}\}$, *with* $p^{2,0} : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *be the 2-argument projection function projecting onto the first argument.*

In this case, it is easy to verify that $I^\flat$ *is reflexive in* $\mathcal{I}$ *but* $I^\flat$ *is not reflexive in* $\mathcal{I}'$.



As was the case with the various properties of the Leibniz operator that gave rise to the various classes of the semantic hierarchy of π-institutions, the surjectivity of the morphism components in interpreted algebraic systems affords transferring the properties that give rise to the syntactic hierarchy studied in the present chapter from the theory families of a π-institution to the filter families over arbitrary algebraic systems. The key in proving these tranfer properties is Lemma 95, which will be used repeatedly in the proofs throughout the chapter.

The first of this type of transfer properties is the transfer property for reflexivity. In formulating the property it is convenient to adopt the following terminology. We consider, as is usual in this context, a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ and a set $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ of natural transformations in $N^\flat$. Given a π-institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on $\mathbf{F}$, and an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, we say that I is **reflexive in** $\mathcal{A}$ if the collection $I : \mathrm{SEN}^\omega \to \mathrm{SEN}$ of natural transformations in N, that are images of those in $I^\flat$, is reflexive in the π-institution $\langle \mathbf{A}, C^{\mathcal{I},\mathcal{A}} \rangle$, $C^{\mathcal{I},\mathcal{A}}$ being the closure (operator) system whose closed set families are the $\mathcal{I}$-filter families on $\mathcal{A}$.

We use similar terminology for all other properties that we study in this chapter, pertaining to subsets $I^\flat$ of $N^\flat$. In particular, such terminology will be used in all transfer results for these properties.

Proposition 683 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $I^\flat \subseteq N^\flat$ a collection of natural transformations $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $I^\flat$ is reflexive in $\mathcal{I}$ if and only if, for every algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, I is reflexive in $\mathcal{A}$.*

Proof: First, note that if reflexivity of I in $\mathcal{A}$ is assumed, for all $\mathcal{A}$, then it holds, in particular, for $\mathcal{A} = \mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Moreover $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}} \rangle = \mathcal{I}$. Thus, we conclude that $I^\flat$ is reflexive in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ is reflexive in $\mathcal{I}$. By the surjectivity of $\langle F, \alpha \rangle$, it suffices to show that, for all $\sigma : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat \in I^\flat$, all $\Sigma \in |\mathbf{Sign}^\flat|$, all $\phi \in \mathrm{SEN}^\flat(\Sigma)$ and all $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\sigma_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)), \mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma')}(\varnothing).$$

To this end, let $\sigma : (\mathrm{SEN}^\flat)^k \to \mathrm{SEN}^\flat \in I^\flat$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi \in \mathrm{SEN}^\flat(\Sigma)$ and $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$. Since $C^{\mathcal{I},\mathcal{A}}(\varnothing)$ is, by definition, an $\mathcal{I}$-filter family on $\mathcal{A}$, by Lemma 51, $\alpha^{-1}(C^{\mathcal{I},\mathcal{A}}(\varnothing)) \in \mathrm{ThFam}(\mathcal{I})$. Hence, since $I^\flat$ is reflexive in $\mathcal{I}$, we get

$$\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\phi), \vec{\chi}) \in \alpha^{-1}_{\Sigma'}(C^{\mathcal{I},\mathcal{A}}_{F(\Sigma')}(\varnothing)).$$

This is equivalent to

$$\alpha_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\phi), \vec{\chi})) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma')}(\varnothing),$$

which is, in turn, equivalent to

$$\sigma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)), \alpha_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in C^{\mathcal{I},\mathcal{A}}_{F(\Sigma')}(\varnothing).$$

Finally, by the naturality of α, we get the conclusion. Therefore, I is indeed reflexive in $\mathcal{A}$. ■

10.3 Symmetry

We look now at various versions of the symmetry property, taking into account both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local family symmetry in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, implies that $I^\flat_\Sigma(\psi, \phi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$;
- $I^\flat$ has the **local system symmetry in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, implies that $I^\flat_\Sigma(\psi, \phi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$;
- $I^\flat$ has the **global family symmetry in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \psi] \leq T$ implies $I^\flat_\Sigma[\psi, \phi] \leq T$;
- $I^\flat$ has the **global system symmetry in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \psi] \leq T$ implies $I^\flat_\Sigma[\psi, \phi] \leq T$.

The following proposition establishes a hierarchy of symmetry properties.

Proposition 684 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments.*

(a) *If $I^\flat$ has the local family symmetry, then it has the local system symmetry in $\mathcal{I}$;*

(b) *If $I^\flat$ has the local system symmetry, then it has the global family symmetry in $\mathcal{I}$;*

(c) *$I^\flat$ has the global family symmetry if and only if it has the global system symmetry in $\mathcal{I}$.*

Proof: Parts (a) and one of the implications in Part (c) follow directly from the fact that every theory system of $\mathcal{I}$ is also a theory family of $\mathcal{I}$.

For Part (b), suppose that $I^\flat$ has the local system symmetry in $\mathcal{I}$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi,\psi] \leq T$. Then by Lemma 93, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$,

$$I^\flat_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)] \leq T.$$

This implies, by Lemma 99, that, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}.$$

Since $I^\flat$ has the local system symmetry and, by Proposition 42, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get that $I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \mathrm{SEN}^\flat(f)(\phi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'} \subseteq T_{\Sigma'}$. Since this holds for all $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$, we conclude that $I^\flat_\Sigma[\psi,\phi] \leq T$. Therefore $I^\flat$ has the global family symmetry in $\mathcal{I}$.

Suppose, finally, that $I^\flat$ has the global system symmetry in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi,\psi] \leq T$. By Lemma 99, we get that $I^\flat_\Sigma[\phi,\psi] \leq \overleftarrow{T}$. Since $I^\flat$ has the global system symmetry and, by Proposition 42, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get that $I^\flat_\Sigma[\psi,\phi] \leq \overleftarrow{T}$. Using again Lemma 99, we conclude that $I^\flat_\Sigma[\psi,\phi] \leq T$. Therefore, $I^\flat$ has the global family symmetry in $\mathcal{I}$. ■

Proposition 684 has established the following hierarchy of symmetry properties:

Local Family Symmetry

↓

Local System Symmetry

↓

Global Symmetry

We look, next, at some natural sufficient conditions under which some of these three symmetry properties coincide.

Proposition 685 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the local family and the local system symmetry coincide;*

(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the local system symmetry and the global symmetry coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and, hence, the local family and local system symmetries coincide.

Suppose, next that $I^\flat$ is parameter free and has the global system symmetry in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma(\phi, \psi) \subseteq T_\Sigma$. Then, by Proposition 99, $I^\flat[\phi, \psi] \leq T$. Thus, by the global system property, $I^\flat_\Sigma[\psi, \phi] \leq T$, which implies that $I^\flat_\Sigma(\psi, \phi) \subseteq T_\Sigma$. Therefore, $I^\flat$ has the local system symmetry in $\mathcal{I}$. ■

So in the case of a systemic π-institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter-free set of natural transformations we have the hierarchy on the right.

Local Symmetry	Local Family Symmetry
↓	↓
Global Symmetry	Local System/Global Symmetry

Finally, for a systemic π-institution with a parameter-free set of natural transformations all four symmetry properties collapse to a single one.

We provide some examples to show that the implications of Proposition 684 are not equivalences in general, i.e., in the 3-class hierarchy all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding symmetry properties are proper inclusions.

We first present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that have the local system symmetry but not the local family symmetry in $\mathcal{I}$.

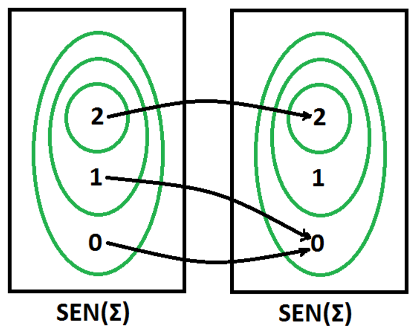
Example 686 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single objects* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0, 1, 2\} \to \{0, 1, 2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*

- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 1, & \textit{if } (x,y) = (0,1) \\ 0, & \textit{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system symmetry in* $\mathcal{I}$*, but it does not have the local family symmetry in* $\mathcal{I}$*.*

For the local system symmetry note that, if $T = \mathrm{SEN}^\flat$*, then the defining implication is trivially true, whereas, if* $T = \mathrm{Thm}(\mathcal{I})$*, then, since, for all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\psi) \neq 2$*, the defining implication is vacuously true. So* $I^\flat$ *has the local system symmetry in* $\mathcal{I}$*.*

On the other hand, for $T = \{\{1,2\}\} \in \mathrm{ThFam}(\mathcal{I})$*, we have* $\sigma^\flat_\Sigma(0,1) = 1 \in T_\Sigma$*, but* $\sigma^\flat_\Sigma(1,0) = 0 \notin T_\Sigma$*. Therefore, the implication defining local family symmetry fails for* $T = \{\{1,2\}\}$*. So* $I^\flat$ *is not locally family symmetric in* $\mathcal{I}$*.*

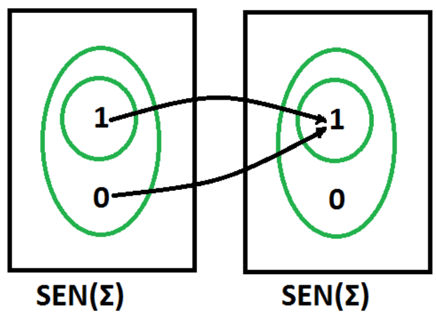
Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that have the global family symmetry but not the local system symmetry in $\mathcal{I}$.

Example 687 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single objects* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*

- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1\} \to \{0,1\}$ *given by* $0 \mapsto 1$ *and* $1 \mapsto 1$;
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^3 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 0, & \textit{if } (x,z) = (1,0) \\ 1, & \textit{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$. *Note that both theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$, *are also theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global family symmetry in* $\mathcal{I}$, *but it does not have the local system symmetry in* $\mathcal{I}$.

For the global family symmetry note that, if $T = \mathrm{SEN}^\flat$, *then the defining implication is trivially true, whereas, if* $T = \mathrm{Thm}(\mathcal{I})$, *then, since, for all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), 0) = \sigma^\flat_\Sigma(1,1,0) = 0,$$

the defining implication is vacuously true. So $I^\flat$ *has the global family symmetry in* $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(0,1,\xi) = 1$, *for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$, *but* $\sigma^\flat_\Sigma(1,0,0) = 0 \notin \{1\}$. *Therefore, the implication defining local system symmetry fails for* $\mathrm{Thm}(\mathcal{I})$. *So* $I^\flat$ *is not locally system symmetric in* $\mathcal{I}$.

To close the study of symmetry properties, we prove that all three symmetry properties transfer from π-institutions to their models.

Proposition 688 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $I^\flat$ *has a symmetry property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, I *has the corresponding symmetry property in* $\mathcal{A}$.

Proof: If I has a symmetry property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same symmetry in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}} \rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding symmetry in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has a symmetry in $\mathcal{I}$. We look at each of the three properties in turn.

(a) Suppose $I^\flat$ has the local family symmetry in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. Since this is equivalent to $\alpha_\Sigma(I^\flat_\Sigma(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, we get that $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. But, by hypothesis, $I^\flat$ has the local family symmetry in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Therefore, we get that $I^\flat_\Sigma(\psi, \phi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. This now gives $\alpha_\Sigma(I^\flat_\Sigma(\psi, \phi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\psi), \alpha_\Sigma(\phi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}.$$

We conclude that I has the local family symmetry in $\mathcal{A}$.

(b) The case of the local system symmetry can be proven similarly, taking into account that, if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

(c) Suppose that $I^\flat$ has the global (family) symmetry in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \le T.$$

Then, we have, by Lemma 95, $I^\flat_\Sigma[\phi, \psi] \le \alpha^{-1}(T)$. Now, since, by hypothesis, $I^\flat$ has the global family symmetry in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that $I^\flat_\Sigma[\psi, \phi] \le \alpha^{-1}(T)$, or, equivalently, by Lemma 95, $I_{F(\Sigma)}[\alpha_\Sigma(\psi), \alpha_\Sigma(\phi)] \le T$. Thus, I has the global family symmetry in $\mathcal{A}$.

■

10.4 Transitivity

We study next various versions of the transitivity property, taking into account, again, both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local family transitivity in** $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \text{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$ and $I^\flat_\Sigma(\psi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^\flat(\Sigma)$, imply that $I^\flat_\Sigma(\phi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^\flat(\Sigma)$;
- $I^\flat$ has the **local system transitivity in** $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \text{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$ and $I^\flat_\Sigma(\psi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^\flat(\Sigma)$, imply that $I^\flat_\Sigma(\phi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^\flat(\Sigma)$;
- $I^\flat$ has the **global family transitivity in** $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \text{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \psi] \leq T$ and $I^\flat_\Sigma[\psi, \chi] \leq T$ imply $I^\flat_\Sigma[\phi, \chi] \leq T$;
- $I^\flat$ has the **global system transitivity in** $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi, \chi \in \text{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \psi] \leq T$ and $I^\flat_\Sigma[\psi, \chi] \leq T$ imply $I^\flat_\Sigma[\phi, \chi] \leq T$.

The following proposition establishes the hierarchy of transitivity properties.

Proposition 689 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\text{SEN}^\flat)^\omega \to \text{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $I^\flat$ *has the local family transitivity, then it has the local system transitivity in* $\mathcal{I}$*;*

(b) If $I^\flat$ *has the local system transitivity, then it has the global family transitivity in* $\mathcal{I}$*;*

(c) $I^\flat$ *has the global family transitivity if and only if it has the global system transitivity in* $\mathcal{I}$*.*

Proof: The statement in Part (a) as well as one of the two implications of Part (c) follow from the fact that every theory system is also a theory family of $\mathcal{I}$.

For Part (b), suppose that $I^\flat$ has the local system transitivity and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \text{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi, \psi] \leq T$ and $I^\flat_\Sigma[\psi, \chi] \leq T$. By Lemma 93, we get that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$I^\flat_{\Sigma'}[\text{SEN}^\flat(f)(\phi), \text{SEN}^\flat(f)(\psi)] \leq T, \;\; I^\flat_{\Sigma'}[\text{SEN}^\flat(f)(\psi), \text{SEN}^\flat(f)(\chi)] \leq T.$$

So, by Proposition 99, we get, for all $\vec{\xi} \in \text{SEN}^\flat(\Sigma')$,

$$\begin{aligned} &I^\flat_{\Sigma'}(\text{SEN}^\flat(f)(\phi), \text{SEN}^\flat(f)(\psi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}, \\ &I^\flat_{\Sigma'}(\text{SEN}^\flat(f)(\psi), \text{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}. \end{aligned}$$

By local system transitivity, we obtain $I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\chi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}$, Since this holds for all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$, we conclude that $I^\flat_{\Sigma'}[\phi, \chi] \leq T$, Therefore, $I^\flat$ has the global family transitivity in $\mathcal{I}$.

Finally, suppose that $I^\flat$ has the global system transitivity in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi, \psi] \leq T$ and $I^\flat_\Sigma[\psi, \chi] \leq T$. By Proposition 99, we get $I^\flat_\Sigma[\phi, \psi] \leq \overleftarrow{T}$ and $I^\flat_\Sigma[\psi, \chi] \leq \overleftarrow{T}$. Hence, by global system transitivity, $I^\flat_\Sigma[\phi, \chi] \leq \overleftarrow{T}$. Now, using Proposition 99 again, we conclude that $I^\flat_\Sigma[\phi, \chi] \leq T$. Therefore, $I^\flat$ has the global family transitivity in $\mathcal{I}$. ■

Proposition 689 has established the following hierarchy of transitivity properties:

Local Family Transitivity

$\downarrow$

Local System Transitivity

$\downarrow$

Global Transitivity

We also have the following result regarding natural sufficient conditions under which some of these three transitivity properties coincide.

Proposition 690 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the local family and the local system transitivity coincide;*

(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the local system transitivity and the global transitivity properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and the local family and local system transitivity properties collapse.

Suppose that $I^\flat$ is parameter-free and that $I^\flat$ has the global (family) transitivity in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma(\phi, \psi) \subseteq T_\Sigma$ and $I^\flat_\Sigma(\psi, \chi) \subseteq T_\Sigma$. By Proposition 99, $I^\flat_\Sigma[\phi, \psi] \leq T$ and $I^\flat_\Sigma[\psi, \chi] \leq T$. Thus, by the global family transitivity property, $I^\flat_\Sigma[\phi, \chi] \leq T$, which implies that $I^\flat_\Sigma(\phi, \chi) \subseteq T_\Sigma$. We conclude that $I^\flat$ has the local system transitivity in $\mathcal{I}$. ■

So in the case of a systemic π-institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter-free set of natural transformations we have the hierarchy on the right.

Local Transitivity	Local Family Transitivity
$\downarrow$	$\downarrow$
Global Transitivity	Local System/Global Transitivity

Finally, for a systemic π-institution with a parameter-free set of natural transformations all four transitivity properties collapse to a single one.

We provide some examples to show that the implications of Proposition 689 are not equivalences in general, i.e., in the 3-class transitivity hierarchy all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding transitivity properties are proper inclusions.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the local system transitivity but not the local family transitivity in $\mathcal{I}$.

Example 691 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single objects* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 1, & \textit{if } (x,y) = (0,1) \textit{ or } (1,2) \\ 0, & \textit{otherwise} \end{cases}$$

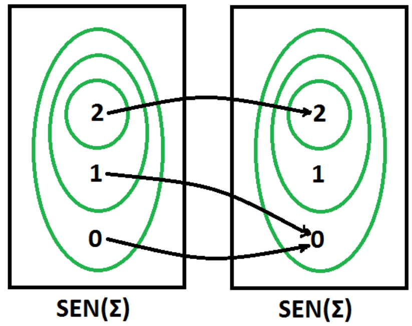
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system transitivity in* $\mathcal{I}$*, but it does not have the local family transitivity in* $\mathcal{I}$*.*

For the local system transitivity note that, if $T = \mathrm{SEN}^\flat$*, then the defining implication is trivially true, whereas, if* $T = \mathrm{Thm}(\mathcal{I})$*, then, since, for all*



$\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(\phi, \psi) \neq 2$, the defining implication is vacuously true. So $I^\flat$ has the local system transitivity in $\mathcal{I}$.

On the other hand, for $T = \{\{1,2\}\} \in \mathrm{ThFam}(\mathcal{I})$, we have $\sigma^\flat_\Sigma(0,1) = \sigma^\flat_\Sigma(1,2) = 1 \in T_\Sigma$, but $\sigma^\flat_\Sigma(0,2) = 0 \notin T_\Sigma$. Therefore, the implication defining local family transitivity fails for $T = \{\{1,2\}\}$. So $I^\flat$ is not locally family transitive in $\mathcal{I}$.

We now present an example to show that there is π-institution $\mathcal{I}$, with a set of natural transformations that has the global family transitivity but not the local system transitivity in $\mathcal{I}$.

Example 692 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

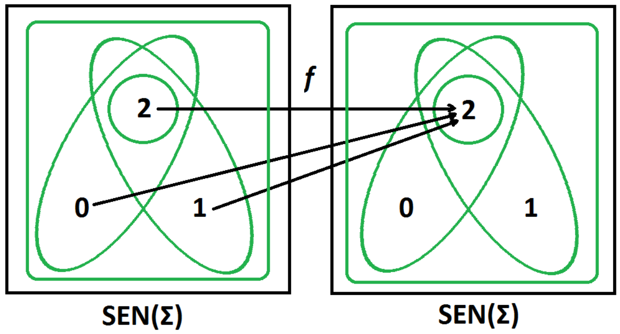
- *$\mathbf{Sign}^\flat$ is the category with a single objects Σ and a single (non-identity) morphism $f : \Sigma \to \Sigma$, such that $f \circ f = f$;*
- *$\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ is specified by $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ and $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ given by $0 \mapsto 2$, $1 \mapsto 2$ and $2 \mapsto 2$;*
- *$N^\flat$ is the category of natural transformations generated by the single ternary natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ defined by letting $\sigma^\flat_\Sigma : \{0,1,2\}^3 \to \{0,1,2\}$ be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 0, & \text{if } x = y = 0 \text{ or } x = y = 1 \\ 2, & \text{if } \{x,y\} = \{0,1\} \text{ or } x = y = z = 2 \\ z, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

Note that all four theory families, $\mathrm{Thm}(\mathcal{I})$, $T = \{\{0,2\}\}$, $T' = \{\{1,2\}\}$ and $\mathrm{SEN}^\flat$, are also theory systems.



Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global family transitivity in* $\mathcal{I}$, *but it does not have the local system transitivity in* $\mathcal{I}$.

For the global family transitivity note that, because, for all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), 0) = 0$ *and* $\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), 1) = 1$, *the implication of the defining condition is vacuously true for* $\mathrm{Thm}(\mathcal{I})$, T *and* T' *and trivially true for* $\mathrm{SEN}^\flat$. *Therefore, we get that* $I^\flat$ *has the global family transitivity in* $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(0,1,\xi) = \sigma^\flat_\Sigma(1,0,\xi) = 2$, *for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$, *but* $\sigma^\flat_\Sigma(0,0,0) = 0 \notin \{2\}$. *Therefore, the implication defining local system transitivity fails for* $\mathrm{Thm}(\mathcal{I})$. *So* $I^\flat$ *does not have the local system transitivity in* $\mathcal{I}$.

We close the study of transitivity by providing, again, a transfer property for transitivity.

Proposition 693 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$, *with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$. $I^\flat$ *has a transitivity property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, I *has the corresponding transitivity property in* $\mathcal{A}$.

Proof: If I has a transitivity property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same transitivity in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}} \rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding transitivity in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has a transitivity property in $\mathcal{I}$. We look at each of the three properties in turn.

(a) Suppose $I^\flat$ has the local family transitivity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi, \chi \in \mathrm{SEN}^\flat(\Sigma)$, such that, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$,

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)},$$
$$I_{F(\Sigma)}(\alpha_\Sigma(\psi), \alpha_\Sigma(\chi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}.$$

These are equivalent, respectively, to

$$\alpha_\Sigma(I^\flat_\Sigma(\phi,\psi,\vec{\xi})) \subseteq T_{F(\Sigma)},\ \alpha_\Sigma(I^\flat_\Sigma(\psi,\chi,\vec{\xi})) \subseteq T_{F(\Sigma)},$$

i.e., to $I^\flat_\Sigma(\phi,\psi,\vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and $I^\flat_\Sigma(\psi,\chi,\vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$. But, by hypothesis, $I^\flat$ has the local family transitivity in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Therefore, we get that $I^\flat_\Sigma(\phi,\chi,\vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $\alpha_\Sigma(I^\flat_\Sigma(\phi,\chi,\vec{\xi})) \subseteq T_{F(\Sigma)}$ and, hence, $I_{F(\Sigma)}(\alpha_\Sigma(\phi),\alpha_\Sigma(\chi),\alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}$. This, combined with the surjectivity of $\langle F,\alpha\rangle$, proves that I has the local family transitivity in $\mathcal{A}$.

(b) The case of the local system transitivity may be proven similarly, taking into account that, if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

(c) Suppose that $I^\flat$ has the global (family) transitivity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A},\langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign},\mathrm{SEN},N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi,\chi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$I_{F(\Sigma)}[\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)] \leq T \quad \text{and} \quad I_{F(\Sigma)}[\alpha_\Sigma(\psi),\alpha_\Sigma(\chi)] \leq T.$$

Then, we have, by Lemma 95, $I^\flat_\Sigma[\phi,\psi] \leq \alpha^{-1}(T)$ and $I^\flat_\Sigma[\psi,\chi] \leq \alpha^{-1}(T)$. Since, by hypothesis, $I^\flat$ has the global family transitivity in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that $I^\flat_\Sigma[\phi,\chi] \leq \alpha^{-1}(T)$, or, equivalently, using again Lemma 95, $I_{F(\Sigma)}[\alpha_\Sigma(\phi),\alpha_\Sigma(\chi)] \leq T$. Thus, I has the global family transitivity in $\mathcal{A}$.

■

10.5 Equivalence

We look now at sets of natural transformations $I^\flat$, with two distinguished arguments, that define (modulo theory families) equivalence relation families on the underlying algebraic system of a π-institution $\mathcal{I}$. We assume that $I^\flat$ has the reflexivity property and study combinations of possible symmetry and transitivity properties that the set of connectives may or may not possess.

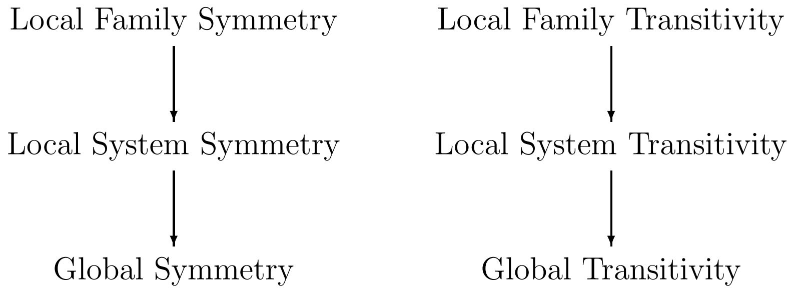
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat,\mathrm{SEN}^\flat,N^\flat\rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F},C\rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. Let $X,Y \in \{\mathrm{LF},\mathrm{LS},\mathrm{GB}\}$, where LF stands for "Local Family", LS stands for "Local System" and GB stands for "GloBal". We say that $I^\flat$ has the XY**-equivalence property in** $\mathcal{I}$ if it has

(a) reflexivity in $\mathcal{I}$;

(b) X symmetry in $\mathcal{I}$ and

(c) Y transitivity in $\mathcal{I}$.

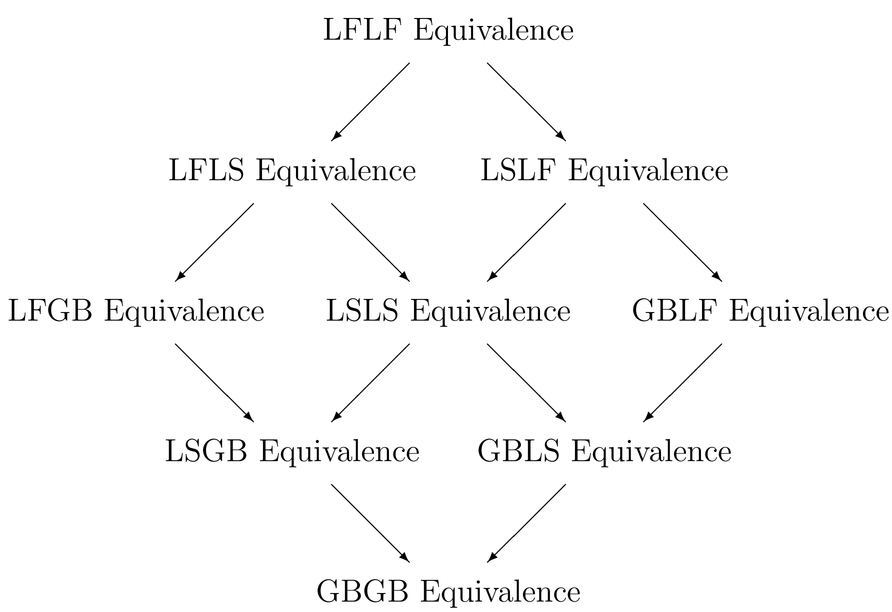
Recall the following hierarchies of symmetry and transitivity properties that we established previously:



From these, we can infer the following hierarchy of equivalence properties:

Corollary 694 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. The nine equivalence properties constitute the hierarchy depicted in the accompanying diagram.*

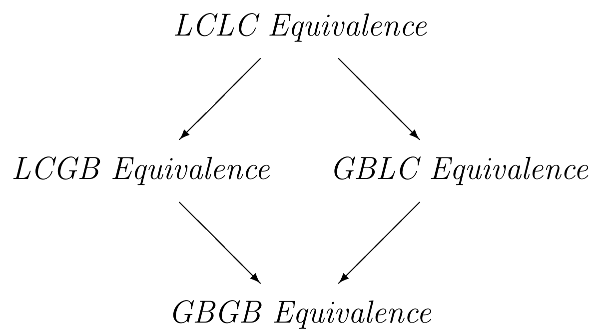
Proof: The statement is a direct consequence of Propositions 684 and 689.
■



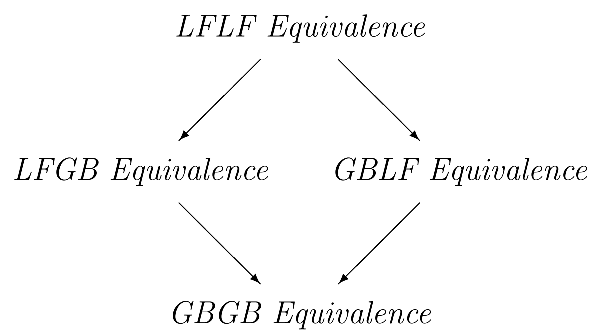
Based on the analysis performed on symmetry and transitivity, we have the following result regarding natural sufficient conditions under which some of the nine equivalence properties above coincide. We let LC stand for "LoCal" to summarize the case when the local family and the local system version of a property coincide.

Corollary 695 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the equivalence hierarchy collapses to the one depicted below;*



(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the equivalence hierarchy collapses to the one depicted below, where the local system versions coincide with (and, hence, are incorporated into) the global versions.*



Proof: The statement follows directly from Propositions 685 and 690. ■

For a systemic π-institution with a parameter-free set of natural transformations, there is only one equivalence property, since all versions of symmetry and all versions of transitivity collapse to a single property.

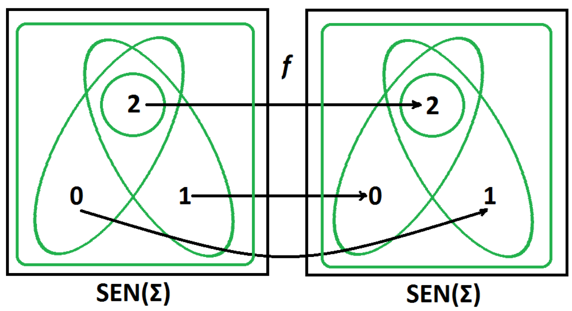
We provide some examples to show that the implications of Proposition 694 are not equivalences in general, i.e., that the nine classes of the equivalence hierarchy are all distinct.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the LSLF equivalence, but not the LFGB equivalence in $\mathcal{I}$.

Example 696 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = i_\Sigma$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$\sigma^\flat_\Sigma$	0	1	2
0	2	1	1
1	0	2	0
2	0	1	2



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

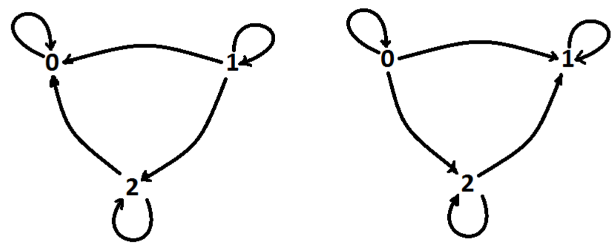
$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are four theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the LSLF equivalence in* $\mathcal{I}$*, but it does not have the LFGB equivalence in* $\mathcal{I}$*.*

Note, first, that reflexivity is obvious, since, by definition $\sigma^\flat_\Sigma(x,x) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $x \in \mathrm{SEN}^\flat(\Sigma)$*. Local system symmetry is also obvious, since the only theory systems in* $\mathcal{I}$ *are* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*. Local family transitivity is a little more challenging to verify, but it suffices to observe that the pairs that are related modulo* $T = \{\{0,2\}\}$ *are as shown on the left below and the pairs that are related modulo* $T' = \{\{1,2\}\}$ *are as on the right below. We conclude that* $I^\flat$ *has the LSLF equivalence in* $\mathcal{I}$*.*

On the other hand, for $T = \{\{0,2\}\} \in \mathrm{ThFam}(\mathcal{I})$*, we have* $\sigma^\flat_\Sigma(1,0) = 0 \in T_\Sigma$*, but* $\sigma^\flat_\Sigma(0,1) = 1 \notin T_\Sigma$*. Therefore, the implication defining local family symmetry fails for* $T = \{\{0,2\}\}$*. So* $I^\flat$ *is not locally family symmetric, and, hence, a fortiori, does not have the LFGB equivalence property in* $\mathcal{I}$*.*

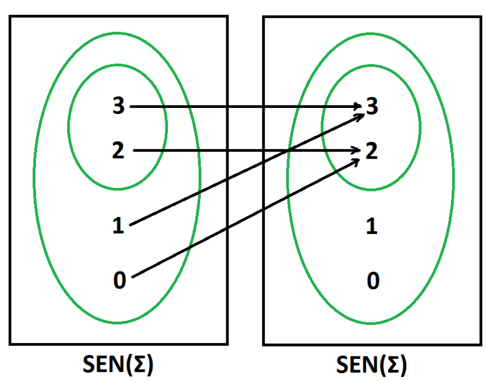


We now present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the GBLF equivalence but not the LSGB equivalence in $\mathcal{I}$.

Example 697 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, with* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3\} \to \{0,1,2,3\}$ *given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1,2,3\}^3 \to \{0,1,2,3\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x,y) = (0,1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2,3\}, \{0,1,2,3\}\}.$$

$\mathcal{I}$ *has two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, both of which are also theory systems. So it is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the GBLF equivalence in* $\mathcal{I}$, *but it does not have the LSGB equivalence in* $\mathcal{I}$.

First, note that $\sigma^\flat_\Sigma(\phi,\phi,\psi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. *Thus,* $I^\flat$ *is reflexive in* $\mathcal{I}$. *For global symmetry, the case of* $T = \mathrm{SEN}^\flat$ *is trivial, whereas, for* $T = \mathrm{Thm}(\mathcal{I})$, *observe that, for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, *with* $\phi \neq \psi$, *is it the case that* $\sigma^\flat_\Sigma[\phi,\psi] \leq T$. *Thus, the defining condition holds trivially for* $\mathrm{Thm}(\mathcal{I})$. *So* $I^\flat$ *has the global symmetry in* $\mathcal{I}$. *For local family transitivity, the case of* $T = \mathrm{SEN}^\flat$ *is also trivial and for* $T = \mathrm{Thm}(\mathcal{I})$, *the only pair* $\langle\phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma)$, *with* $\phi \neq \psi$, *for which* $\sigma^\flat_\Sigma(\phi,\psi,\xi) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$, *is the pair* $(\phi,\psi) = (0,1)$. *So the defining condition holds for* $\mathrm{Thm}(\mathcal{I})$ *also. Thus* $I^\flat$ *has the local family transitivity. We conclude that* $I^\flat$ *has the GBLF equivalence in* $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(0,1,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$, *but* $\sigma^\flat_\Sigma(1,0,0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$. *So the implication defining local system symmetry fails for* $\mathrm{Thm}(\mathcal{I})$. *Therefore,* $I^\flat$ *does not have the local system symmetry in* $\mathcal{I}$.

Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the LFLS equivalence but not the GBLF equivalence in $\mathcal{I}$.

Example 698 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

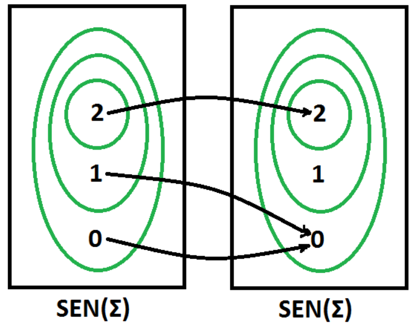
- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by the following table:*

$\sigma^\flat_\Sigma$	0	1	2
0	2	2	0
1	2	2	1
2	0	1	2

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that $\mathcal{I}$ *has three theory families, but only* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. So* $\mathcal{I}$ *is not systemic.*



Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the LFLS equivalence in* $\mathcal{I}$, *but it does not have the GBLF equivalence in* $\mathcal{I}$.

First, since $\sigma^\flat_\Sigma(\phi,\phi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat$ *is reflexive in* $\mathcal{I}$. *Next, observe from the table that, for all* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(\phi,\psi) = \sigma^\flat_\Sigma(\psi,\phi)$. *Therefore, a fortiori, for all* $T \in \mathrm{ThFam}(\mathcal{I})$, *and all* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, *if* $\sigma^\flat_\Sigma(\phi,\psi) \in T_\Sigma$, *then* $\sigma^\flat_\Sigma(\psi,\phi) \in T_\Sigma$, *showing that* $I^\flat$ *has the local family symmetry in* $\mathcal{I}$. *For the local system transitivity, the defining implication is trivial in the case of* $\mathrm{SEN}^\flat$, *whereas in the case of* $\mathrm{Thm}(\mathcal{I})$, *it is straightforward to check based on the table defining* $\sigma^\flat_\Sigma$. *Thus,* $I^\flat$ *has indeed the LFLS equivalence in* $\mathcal{I}$.

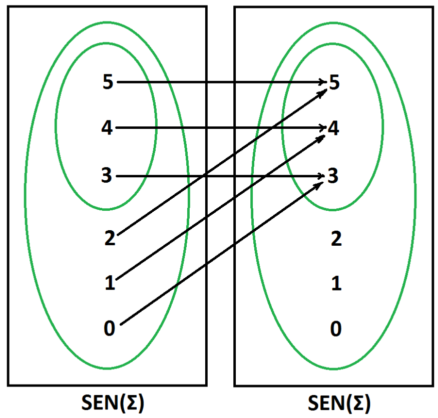
On the other hand, consider the theory family $T = \{\{1,2\}\}$. *We have* $\sigma^\flat_\Sigma(0,1) = 2$ *and* $\sigma^\flat_\Sigma(1,2) = 1$, *i.e.,* $\sigma^\flat_\Sigma(0,1), \sigma^\flat_\Sigma(1,2) \in T_\Sigma$, *whereas* $\sigma^\flat_\Sigma(0,2) = 0 \notin T_\Sigma$. *Therefore,* $I^\flat$ *does not have the local family transitivity and, hence, a fortiori, does not satisfy the GBLF equivalence property in* $\mathcal{I}$.

Finally, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the LFGB equivalence but not the GBLS equivalence in $\mathcal{I}$.

Example 699 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *with* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4,5\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3,4,5\} \to \{0,1,2,3,4,5\}$ *given by* $0 \mapsto 3$, $1 \mapsto 4$, $2 \mapsto 5$, $3 \mapsto 3$, $4 \mapsto 4$ *and* $5 \mapsto 5$;
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1,2,3,4,5\}^3 \to \{0,1,2,3,4,5\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 3, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \text{ or } \{x,y\} = \{1,2\} \\ & \quad \text{or } z = 3 \text{ or } z = 4 \text{ or } z = 5 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{3,4,5\},\{0,1,2,3,4,5\}\}.$$

$\mathcal{I}$ has two theory families, $\mathrm{Thm}(\mathcal{I})$ and $\mathrm{SEN}^\flat$, both of which are also theory systems. So it is a systemic π-institution.

Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ having two distinguished arguments. We show that $I^\flat$ has the LFGB equivalence in $\mathcal{I}$, but it does not have the GBLS equivalence in $\mathcal{I}$.

First, note that $\sigma^\flat_\Sigma(\phi,\phi,\psi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $I^\flat$ is reflexive in $\mathcal{I}$. For local family symmetry, the case of $T = \mathrm{SEN}^\flat$ is trivial, whereas, for $T = \mathrm{Thm}(\mathcal{I})$, observe that, if $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, with $\phi \neq \psi$, are such that $\sigma^\flat_\Sigma(\phi,\psi,\xi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$, then $\{x,y\} = \{0,1\}$ or $\{x,y\} = \{1,2\}$. Thus, $I^\flat$ is local family symmetric. For global transitivity, the case of $T = \mathrm{SEN}^\flat$ is also trivial and for $T = \mathrm{Thm}(\mathcal{I})$, there is no pair $\langle\phi,\psi\rangle \in \mathrm{SEN}^\flat(\Sigma)$, with $\phi \neq \psi$, for which $\sigma^\flat_\Sigma[\phi,\psi] \subseteq \mathrm{Thm}(\mathcal{I})$. So the defining condition holds trivially for $\mathrm{Thm}(\mathcal{I})$ also. Thus $I^\flat$ has the global transitivity. We conclude that $I^\flat$ has the LFGB equivalence in $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(0,1,\xi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ and $\sigma^\flat_\Sigma(1,2,\xi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$, but $\sigma^\flat_\Sigma(0,2,0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$. So the implication defining local system transitivity fails for $\mathrm{Thm}(\mathcal{I})$. Therefore, $I^\flat$ does not have the local system transitivity in $\mathcal{I}$.

We close the study of equivalence by providing, again, a transfer property.

Corollary 700 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $I^\flat$ a collection of natural transformations $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ in $N^\flat$, with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π-institution based on $\mathbf{F}$. $I^\flat$ has a transitivity property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, I has the corresponding transitivity property in $\mathcal{A}$.*

Proof: This follows directly from Propositions 688 and 693. ■

10.6 Antisymmetry

We look next at the antisymmetry property.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local antisymmetry in** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$ and $I^\flat_\Sigma(\psi, \phi, \vec{\xi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, imply $\phi = \psi$;

- $I^\flat$ has the **global antisymmetry in** $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma[\phi, \psi] \leq \mathrm{Thm}(\mathcal{I})$ and $I^\flat_\Sigma[\psi, \phi] \leq \mathrm{Thm}(\mathcal{I})$ imply $\phi = \psi$.

The antisymmetry properties stratify in the following hierarchy.

Proposition 701 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. If* $I^\flat$ *has the local antisymmetry in* $\mathcal{I}$*, then it has the global antisymmetry in* $\mathcal{I}$*.*

Proof: Suppose that $I^\flat$ has the local antisymmetry and let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma[\phi, \psi] \leq \mathrm{Thm}(\mathcal{I})$ and $I^\flat_\Sigma[\psi, \phi] \leq \mathrm{Thm}(\mathcal{I})$. Then we get, in particular, that, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\xi}) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$ and $I^\flat_\Sigma(\psi, \phi, \xi) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$. Thus, by local antisymmetry, we obtain $\phi = \psi$. We conclude that $I^\flat$ has the global antisymmetry in $\mathcal{I}$. ■

Proposition 701 has established the following hierarchy of antisymmetry properties:

Local Antisymmetry

↓

Global Antisymmetry

We look, next, at a natural sufficient condition under which the antisymmetry properties coincide.

Proposition 702 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. If* $I^\flat$ *has only two arguments (i.e., is parameter free), then the local antisymmetry and the global antisymmetry properties coincide.*

Proof: Suppose that $I^\flat$ is parameter free and has the global antisymmetry in $\mathcal{I}$. Let $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma(\phi, \psi) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$ and $I^\flat_\Sigma(\psi, \phi) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I})$. Then, by Proposition 99, $I^\flat_\Sigma[\phi, \psi] \leq \mathrm{Thm}(\mathcal{I})$ and $I^\flat_\Sigma[\psi, \phi] \leq \mathrm{Thm}(\mathcal{I})$. Thus, by global antisymmetry, $\phi = \psi$. Therefore, $I^\flat$ has the local antisymmetry in $\mathcal{I}$. ■

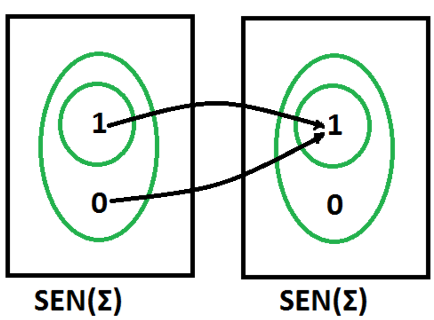
So in the case of a parameter-free set of natural transformations we have a single antisymmetry property.

We provide an example to show that the implication of Proposition 701 is not an equivalence in general. That is, we provide an example of a π-institution $\mathcal{I}$ with a set $I^\flat$ of natural transformations, with two distinguished arguments, that has the global antisymmetry but not the local antisymmetry in $\mathcal{I}$.

Example 703 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single objects* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1\}$ *and* $\mathrm{SEN}^\flat(f) : \{0, 1\} \to \{0, 1\}$ *given by* $0 \mapsto 1$ *and* $1 \mapsto 1$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0, 1\}^3 \to \{0, 1\}$ *be given by*

$$\sigma^\flat_\Sigma(x, y, z) = \begin{cases} 0, & \textit{if } (x, y, z) = (1, 1, 0) \\ 1, & \textit{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$*. Note that there are two theory families,* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, both of which are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global antisymmetry in* $\mathcal{I}$, *but it does not have the local antisymmetry in* $\mathcal{I}$.

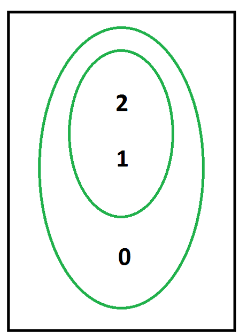
To see that $I^\flat$ *has the global antisymmetry in* $\mathcal{I}$, *it suffices to notice that, for no* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$ *is it the case that* $I^\flat_\Sigma[\phi,\psi] \le \mathrm{Thm}(\Sigma)$. *Therefore, the defining condition holds vacuously, for all* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$.

On the other hand, for $0 \ne 1$, *we have* $\sigma^\flat_\Sigma(0,1,\xi) = \sigma^\flat_\Sigma(1,0,\xi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\xi \in \{0,1\}$. *So* $I^\flat$ *is not locally antisymmetric in* $\mathcal{I}$.

To close the study of antisymmetry properties, we show that they do not transfer from π-institutions to their models. This is to be expected, since the inverse image $\alpha^{-1}(T)$ of the minimum $\mathcal{I}$ filter family of a π-institution $\mathcal{I}$ on an algebraic system $\mathcal{A}$ may not coincide with the theorem system of $\mathcal{I}$.

Example 704 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the trivial category with a single object* Σ;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by* $\sigma^\flat_\Sigma(x,y) = 0$, *for all* $x, y \in \mathrm{SEN}^\flat(\Sigma)$.



SEN(Σ)

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{1,2\},\{0,1,2\}\}.$$

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local antisymmetry in* $\mathcal{I}$, *but that there exists an* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, *such that* I *does not have the local antisymmetry in* $\mathcal{A}$.

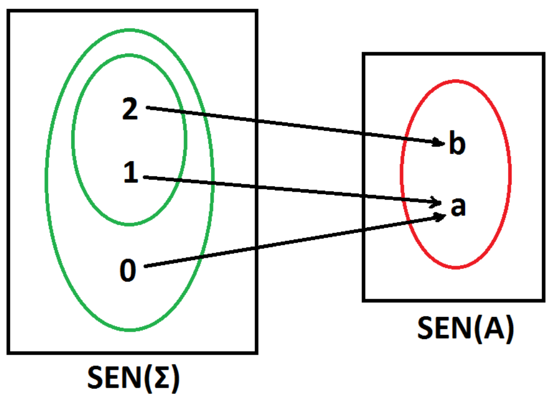
Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$ *be the algebraic system determined as follows:*

- **Sign** *is the trivial category with a single object* A*;*
- $\mathrm{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}(A) = \{a, b\}$*;*
- N *is the category of natural transformations generated by the single binary natural transformation* $\sigma : \mathrm{SEN}^2 \to \mathrm{SEN}$ *defined by letting:* $\sigma_A : \{a, b\}^2 \to \{a, b\}$ *be given by* $\sigma_A(x, y) = a$*, for all* $x, y \in \mathrm{SEN}(A)$*.*

$\mathbf{A}$ *is an* $N^\flat$*-algebraic system, as can be seen by sending* $\sigma^\flat \mapsto \sigma$ *and extending to categories by composition.*

Now let $\langle F, \alpha\rangle : \mathbf{F} \to \mathbf{A}$ *be the morphism defined as follows:*

- $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ *is the obvious functor between trivial categories;*
- $\alpha : \mathrm{SEN}^\flat \to \mathrm{SEN} \circ F$ *is defined by setting* $\alpha_\Sigma(0) = a$*,* $\alpha_\Sigma(1) = a$ *and* $\alpha_\Sigma(2) = b$*.*



Our goal is to show that $I^\flat$ *has the local antisymmetry in* $\mathcal{I}$ *but that* I *does not have the local antisymmetry in* $\mathcal{A}$*. We have, for all* $\phi, \psi \in \mathrm{SEN}(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi, \psi) \notin \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $\sigma^\flat_\Sigma(\psi, \phi) \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*, whence the defining condition of local antisymmetry for* $I^\flat$ *is vacuously true. So* $I^\flat$ *is locally antisymmetric in* $\mathcal{I}$*.*

On the other hand, note that the least $\mathcal{I}$*-filter system on* $\mathcal{A}$ *is* SEN*. Moreover, we have* $\sigma_A(a, b) = \sigma_A(b, a) = a \in \mathrm{SEN}(A)$*, with* $a \neq b$*. Thus* $I = \{\sigma\}$ *does not have local antisymmetry in* $\mathcal{A}$*.*

10.7 Order

We look next at sets of natural transformations $I^\flat$, with two distinguished arguments, that define (modulo theory families) partial order families on the underlying algebraic system of a π-institution $\mathcal{I}$. We assume that $I^\flat$ has the reflexivity property and study combinations of possible antisymmetry and transitivity properties that the set of connectives may or may not possess.

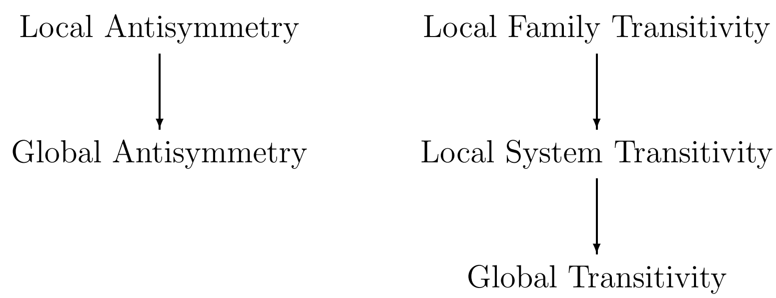
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. Let $X \in \{LC, GB\}$, where LC and GB stand for "LoCal" and "GloBal", respectively, and let $Y \in \{LF, LS, GB\}$, where LF stands for "Local Family" and LS for "Local System". We say that $I^\flat$ has the XY **poset property in** $\mathcal{I}$ if it has

(a) reflexivity in $\mathcal{I}$;

(b) X antisymmetry in $\mathcal{I}$ and

(c) Y transitivity in $\mathcal{I}$.

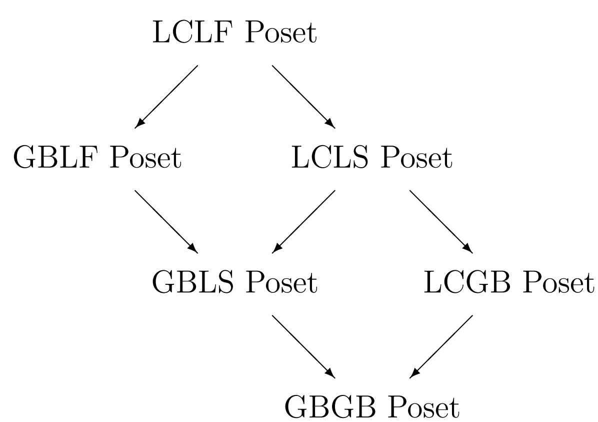
Recall, again, the following hierarchies of antisymmetry and of transitivity properties:



From these, we can infer the following hierarchy of equivalence properties:

Corollary 705 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. The six poset properties of* $I^\flat$ *satisfy the hierarchy depicted in the accompanying diagram.*

Proof: The statement is a direct consequence of Propositions 701 and 689. ■



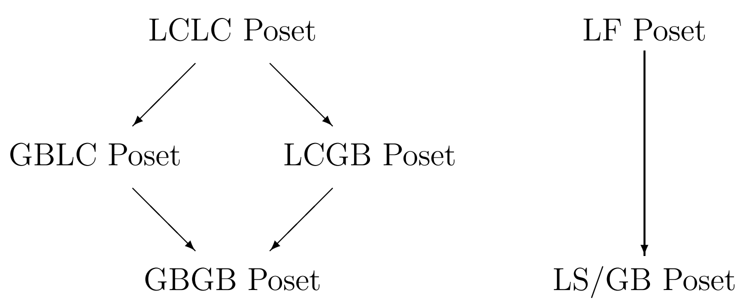
Based on the analyses performed on antisymmetry and transitivity, we have the following result regarding natural sufficient conditions under which some of these poset properties coincide.

Corollary 706 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the equivalence hierarchy collapses to the one depicted on the left of the accompanying diagram;*

(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the equivalence hierarchy collapses to the one depicted on the right of the diagram, where, since there is only one antisymmetry property, the qualifications refer to the type of transitivity that holds.*

Proof: The statement follows directly from Propositions 690 and 702. ∎



For a systemic π-institution with a parameter-free set of natural transformations, there is only one poset property, since the two versions of antisymmetry and all three versions of transitivity collapse, respectively, to a single property.

We provide some examples to show that the implications of Corollary 705 are not equivalences, i.e., the six classes of the poset hierarchy are all distinct in general.

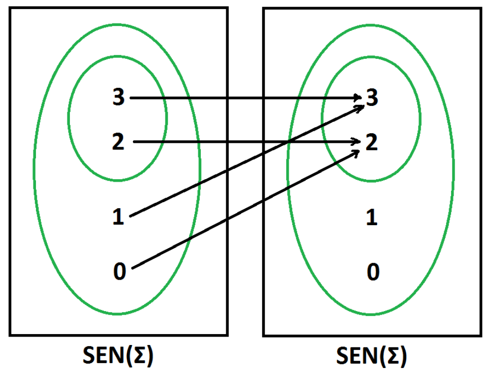
First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the GBLF poset property, but not the LCGB poset property in $\mathcal{I}$.

Example 707 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0, 1, 2, 3\}$ *and* $\mathrm{SEN}^\flat(f) : \{0, 1, 2, 3\} \to \{0, 1, 2, 3\}$ *given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting*

$\sigma^\flat_\Sigma : \{0,1,2,3\}^3 \to \{0,1,2,3\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x,y) = (0,1) \text{ or } (x,y) = (1,0) \\ & \quad \text{or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{0,1,2,3\}\}.$$

Note that both theory families, $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems. So* $\mathcal{I}$ *is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the GBLF poset property in* $\mathcal{I}$*, but it does not have the LCGB poset property in* $\mathcal{I}$*.*

Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*. For global antisymmetry, note that if, for some* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$ *and* $\sigma^\flat_\Sigma[\psi,\phi] \leq \mathrm{Thm}(\mathcal{I})$*, then we must have* $\phi = \psi$*. Finally, for local family transitivity, the defining equation holds trivially for* $T = \mathrm{SEN}^\flat$*, whereas, if for some* $\phi,\psi,\chi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \neq \chi$*,* $\sigma^\flat_\Sigma(\phi,\psi,\xi) \in \{2,3\}$ *and* $\sigma^\flat_\Sigma(\psi,\chi,\xi) \in \{2,3\}$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*, we must have* $\phi = \psi$ *or* $\psi = \chi$*, whence the condition is satisfied in this case as well. Thus,* $I^\flat$ *is also locally family transitive in* $\mathcal{I}$ *and, therefore, has the GBLF poset property in* $\mathcal{I}$*.*

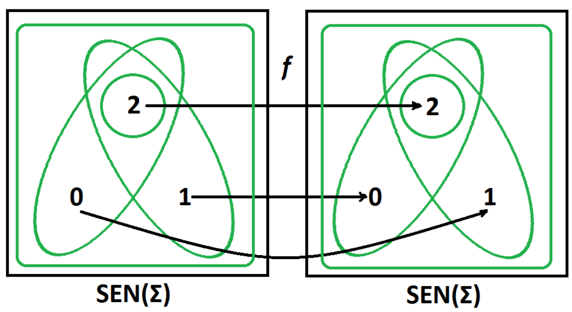
On the other hand, since $\sigma^\flat_\Sigma(0,1,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $\sigma^\flat_\Sigma(1,0,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*,* $I^\flat$ *does not have the local antisymmetry property. A fortiori,* $I^\flat$ *does not have the LCGB poset property in* $\mathcal{I}$*.*

Next, we present an example to show that there is a π-institution $\mathcal{I}$ with a set of natural transformations that has the LCLS poset property but not the GBLF poset property in $\mathcal{I}$.

Example 708 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *with* $f \circ f = i_\Sigma$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 0, & \text{if } (x,y) = (0,1) \text{ or } (x,y) = (1,2) \\ 1, & \text{if } (x,y) = (1,0) \text{ or } (x,y) = (0,2) \\ 2, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

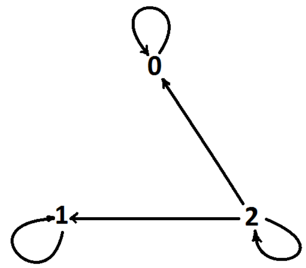
$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families, but only* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. So* $\mathcal{I}$ *is not systemic.*

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the LCLS poset property but it does not have the GBLF poset property in* $\mathcal{I}$.

First, note that $\sigma^\flat_\Sigma(\phi,\phi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *for all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$. *Thus,* $I^\flat$ *is reflexive in* $\mathcal{I}$. *For the local antisymmetry, note that for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, *with* $\phi \neq \psi$ *is it the case that both* $\sigma^\flat_\Sigma(\phi,\psi) = \sigma^\flat_\Sigma(\psi,\phi) = 2$. *Finally, for the local system transitivity, the defining condition is trivially satisfied for* $\mathrm{SEN}^\flat$, *whereas the pairs related modulo* $\mathrm{Thm}(\mathcal{I})$ *are as in the following diagram, an examination of which verifies transitivity. Therefore* $I^\flat$ *is also locally system transitive in* $\mathcal{I}$ *and, hence has the LCLS poset property in* $\mathcal{I}$.

On the other hand, for $T = \{\{0,2\}\} \in \mathrm{ThFam}(\mathcal{I})$, *we have* $\sigma^\flat_\Sigma(0,1) = \sigma^\flat_\Sigma(1,2) = 0 \in T_\Sigma$, *whereas* $\sigma^\flat_\Sigma(0,2) = 1 \notin T_\Sigma$. *So the implication defining local family transitivity fails for* T. *Therefore,* $I^\flat$ *does not have the local family transitivity and, a fortiori, does not have the GBLF poset property in* $\mathcal{I}$.

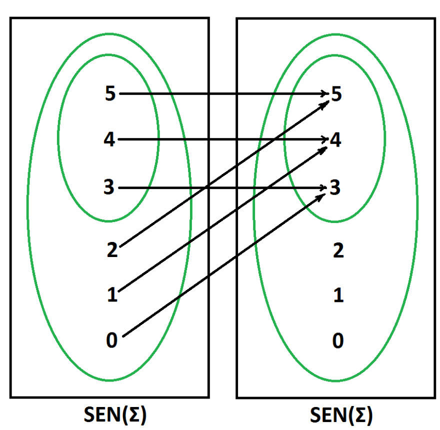


Finally, we look at an example that shows that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the LCGB poset property but not the GBLS poset property in $\mathcal{I}$.

Example 709 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, with* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3,4,5\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3,4,5\} \to \{0,1,2,3,4,5\}$ *given by* $0 \mapsto 3$*,* $1 \mapsto 4$*,* $2 \mapsto 5$*,* $3 \mapsto 3$*,* $4 \mapsto 4$ *and* $5 \mapsto 5$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting:* $\sigma^\flat_\Sigma : \{0,1,2,3,4,5\}^3 \to \{0,1,2,3,4,5\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 3, & \text{if } x = y \text{ or } (x,y) = (0,1) \text{ or } (x,y) = (1,2) \\ & \quad \text{or } z = 3 \text{ or } z = 4 \text{ or } z = 5 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{3,4,5\},\{0,1,2,3,4,5\}\}.$$

$\mathcal{I}$ has two theory families, $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, both of which are also theory systems. So it is a systemic π-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ having two distinguished arguments. We show that $I^\flat$ has the LCGB poset property in $\mathcal{I}$, but not the GBLS poset property in $\mathcal{I}$.

First, note that, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, $\sigma^\flat_\Sigma(\phi,\phi,\xi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$. Thus, $I^\flat$ is reflexive in $\mathcal{I}$. For local antisymmetry, it suffices to observe that, for no $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma^\flat_\Sigma(\phi,\psi,\xi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$ and $\sigma^\flat_\Sigma(\psi,\phi,\xi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$. For global transitivity, the defining condition holds trivially for $T = \mathrm{SEN}^\flat$, whereas for $T = \mathrm{Thm}(\mathcal{I})$, it suffices to note that, for no $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$. We conclude that $I^\flat$ has the LCGB poset property in $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(0,1,\xi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ and $\sigma^\flat_\Sigma(1,2,\xi) = 3 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$, but $\sigma^\flat_\Sigma(0,2,0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$. So the implication defining local system transitivity fails for $\mathrm{Thm}(\mathcal{I})$*. Therefore, $I^\flat$ does not have the local system transitivity in $\mathcal{I}$ and, hence, a fortiori, it does not have the GBLS poset property in $\mathcal{I}$.*

Because of the non-transference of antisymmetry, which was shown in Example 704, it is to be expected that none of the poset properties transfers from a π-institution to its models. We provide an example that showcases a π-institution $\mathcal{I}$, with a set $I^\flat$ of natural transformations having two distinguished arguments, that has the LCLF poset property, but one of whose models does not have the GBGB poset property.

Example 710 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ be the algebraic system determined as follows:*

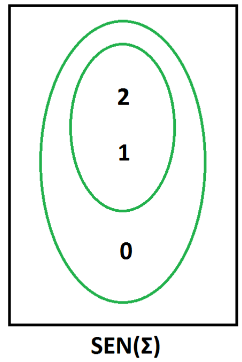
- $\mathbf{Sign}^\flat$ *is the trivial category with a single object Σ;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$*;*
- *$N^\flat$ is the category of natural transformations generated by the single binary natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ defined by letting: $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ be given, for all $x,y \in \mathrm{SEN}^\flat(\Sigma)$, by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be the π-institution determined by $\mathcal{C}_\Sigma = \{\{1,2\},\{0,1,2\}\}$.

Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ having two distinguished arguments. We show that $I^\flat$ has the LCLF poset property in $\mathcal{I}$, but that there exists an $\mathbf{F}$-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, such that I does not have the GBGB poset property in $\mathcal{A}$.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$ be the algebraic system determined as follows:



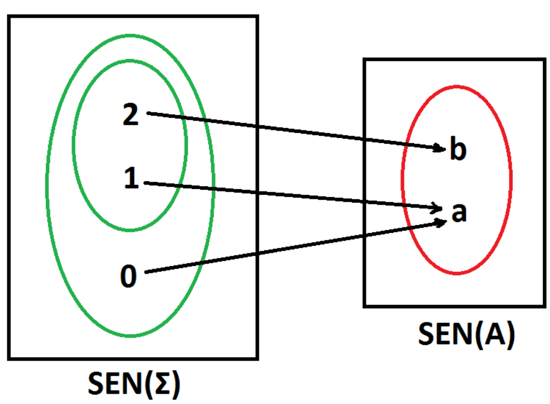
- **Sign** *is the trivial category with a single object* A*;*
- $\text{SEN} : \mathbf{Sign} \to \mathbf{Set}$ *is specified by* $\text{SEN}(A) = \{a, b\}$*;*
- N *is the category of natural transformations generated by the single binary natural transformation* $\sigma : \text{SEN}^2 \to \text{SEN}$ *defined by letting:* $\sigma_A : \{a, b\}^2 \to \{a, b\}$ *be given, for all* $x, y \in \text{SEN}(A)$*, by*

$$\sigma_A(x, y) = a.$$

$\mathbf{A}$ *is an* $N^\flat$*-algebraic system, as can be seen by sending* $\sigma^\flat \mapsto \sigma$ *and extending to categories by composition.*

Now let $\langle F, \alpha \rangle : \mathbf{F} \to \mathbf{A}$ *be the morphism defined as follows:*

- $F : \mathbf{Sign}^\flat \to \mathbf{Sign}$ *is the obvious functor between trivial categories;*
- $\alpha : \text{SEN}^\flat \to \text{SEN} \circ F$ *is defined by setting* $\alpha_\Sigma(0) = a$*,* $\alpha_\Sigma(1) = a$ *and* $\alpha_\Sigma(2) = b$*.*



We show that $I^\flat$ *has the LCLF poset property in* $\mathcal{I}$ *but that* I *does not have the GBGB poset property in* $\mathcal{A}$*.*

First, since $\sigma^\flat_\Sigma(\phi,\phi) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, we have that* $I^\flat$ *is reflexive in* $\mathcal{I}$*. Second, if* $\sigma^\flat_\Sigma(\phi,\psi) = 1 = \sigma^\flat_\Sigma(\psi,\phi)$*, then* $\phi = \psi$*. So* $I^\flat$ *has the local antisymmetry in* $\mathcal{I}$*. Finally, local family transitivity is obvious, since for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \neq \psi$ *is it the case that* $\sigma^\flat_\Sigma(\phi,\psi) = 1$*. We conclude that* $I^\flat$ *has the LCLF poset property in* $\mathcal{I}$*.*

On the other hand, note that the least $\mathcal{I}$*-filter system on* $\mathcal{A}$ *is* SEN *and since* $\sigma_A(a,b) = \sigma_A(b,a) = a \in \mathrm{SEN}(A)$*, with* $a \neq b$*,* $I = \{\sigma\}$ *does not have the global antisymmetry in* $\mathcal{A}$*. So, a fortiori, it does not have the GBGB poset property in* $\mathcal{A}$*.*

10.8 Compatibility

We look next at various versions of the compatibility property, taking again into account both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local family compatibility in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\overleftrightarrow{I^\flat}_\Sigma(\phi,\psi,\vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, implies
$$I^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}),\vec{\xi}) \subseteq T_{\Sigma'},$$
for all $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$;
- $I^\flat$ has the **local system compatibility in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\overleftrightarrow{I^\flat}_\Sigma(\phi,\psi,\vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$, implies
$$I^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi}),\vec{\xi}) \subseteq T_{\Sigma'},$$
for all $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi},\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$;
- $I^\flat$ has the **global family compatibility in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, $\overleftrightarrow{I^\flat}_\Sigma[\phi,\psi] \leq T$ implies
$$I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq T,$$
for all $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$;

- $I^\flat$ has the **global system compatibility in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \le T$ implies

$$I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})] \le T,$$

for all $\sigma^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$.

The following proposition establishes a hierarchy of compatibility properties.

Proposition 711 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $I^\flat$ *has the local family compatibility, then it has the local system compatibility in* $\mathcal{I}$*;*

(b) If $I^\flat$ *has the local system compatibility, then it has the global family compatibility in* $\mathcal{I}$*;*

(c) $I^\flat$ *has the global family compatibility in* $\mathcal{I}$ *if and only if it has the global system compatibility in* $\mathcal{I}$*.*

Proof: Part (a) and one of the implications in Part (c) follow directly from the fact that every theory system of $\mathcal{I}$ is also a theory family of $\mathcal{I}$.

For Part (b), suppose that $I^\flat$ has the local system compatibility in $\mathcal{I}$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \le T$. Then by Lemma 93, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$\overleftrightarrow{I^\flat}_{\Sigma'}[\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)] \le T.$$

This implies, by Lemma 99, that, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$\overleftrightarrow{I^\flat}_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}.$$

Since $I^\flat$ has the local system compatibility and, by Proposition 42, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get that, for all $\sigma^\flat \in N^\flat$, all $\Sigma'' \in |\mathbf{Sign}^\flat|$, all $g \in \mathbf{Sign}^\flat(\Sigma', \Sigma'')$

$$\Sigma \xrightarrow{\ f\ } \Sigma' \xrightarrow{\ g\ } \Sigma''$$

and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$ and $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma'')$,

$$\begin{aligned} I^\flat_{\Sigma''}(&\sigma^\flat_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\phi), \mathrm{SEN}^\flat(g)(\vec{\chi})),\\ &\sigma^\flat_{\Sigma''}(\mathrm{SEN}^\flat(gf)(\psi), \mathrm{SEN}^\flat(g)(\vec{\chi})), \vec{\xi}) \subseteq T_{\Sigma''},\end{aligned}$$

or, equivalently,

$$\begin{aligned}I^\flat_{\Sigma''}(&\mathrm{SEN}^\flat(g)(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi})),\\ &\qquad\mathrm{SEN}^\flat(g)(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})),\vec{\xi}) \subseteq T_{\Sigma''}.\end{aligned}$$

Since this holds for all $\Sigma'' \in |\mathbf{Sign}^\flat|$, $g \in \mathbf{Sign}^\flat(\Sigma',\Sigma'')$ and $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma'')$, we conclude that $I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq T$. Therefore $I^\flat$ has the global family compatibility in $\mathcal{I}$.

Suppose, finally, that $I^\flat$ has the global system compatibility in $\mathcal{I}$ and let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\overleftrightarrow{I^\flat}_\Sigma[\phi,\psi] \leq T$. By Lemma 99, we get that $\overleftrightarrow{I^\flat}_\Sigma[\phi,\psi] \leq \overleftarrow{T}$. Since $I^\flat$ has the global system compatibility and, by Proposition 42, $\overleftarrow{T} \in \mathrm{ThSys}(\mathcal{I})$, we get that, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, $I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq \overleftarrow{T}$. Using again Lemma 99, we conclude that $I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq T$. Therefore, $I^\flat$ has the global family compatibility in $\mathcal{I}$. ■

Proposition 711 has established the following hierarchy of compatibility properties:

Local Family Compatibility

↓

Local System Compatibility

↓

Global Compatibility

We look, next, at some natural sufficient conditions under which some of these three compatibility properties coincide.

Proposition 712 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the local family and the local system compatibility coincide;*

(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the local system compatibility and the global compatibility coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and, hence, the local family and local system compatibility properties coincide.

Suppose, next that $I^\flat$ is parameter free and has the global system compatibility in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$, $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$\overleftrightarrow{I}^\flat{}_\Sigma(\phi,\psi) \subseteq T_\Sigma$. Then, by Proposition 99, $\overleftrightarrow{I}^\flat{}_\Sigma[\phi,\psi] \leq T$. Thus, by the global system compatibility, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, $I^\flat_{\Sigma'}[\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})] \leq T$, which implies that, for all $\sigma^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma,\Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$, $I^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi),\vec{\chi}),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi),\vec{\chi})) \subseteq T_{\Sigma'}$. Therefore, $I^\flat$ has the local system compatibility in $\mathcal{I}$. ■

So in the case of a systemic π-institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter-free set of natural transformations we have the hierarchy on the right.

$$\begin{array}{ccc} \text{Local Compatibility} & \qquad & \text{Local Family Compatibility} \\ \downarrow & & \downarrow \\ \text{Global Compatibility} & & \text{Local System/Global Compatibility} \end{array}$$

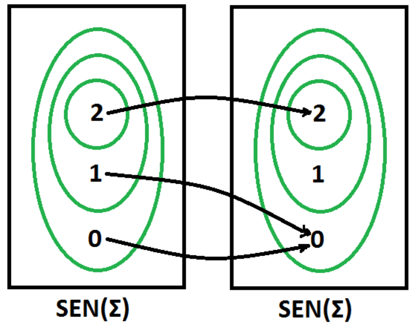
Of course, for a systemic π-institution with a parameter-free set of natural transformations all four compatibility properties coincide.

We provide some examples to show that the implications of Proposition 711 are not equivalences in general, i.e., in the 3-class hierarchy all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding compatibility properties are proper inclusions.

We first present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the local system compatibility but not the local family compatibility in $\mathcal{I}$.

Example 713 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single objects* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by two binary natural transformations:*
  - $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*
  $$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } \{x,y\} = \{0,1\} \\ 0, & \text{otherwise} \end{cases}$$
  - $\lambda^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\lambda^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*
  $$\lambda^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system compatibility in* $\mathcal{I}$*, but it does not have the local family compatibility in* $\mathcal{I}$*.*

For the local system compatibility note that, if $T = \mathrm{SEN}^\flat$*, then the defining implication is trivially true. If, on the other hand,* $T = \mathrm{Thm}(\mathcal{I})$*, then* $\sigma^\flat_\Sigma(\phi,\psi) = 2$ *if and only if* $\phi = 2$ *or* $\psi = 2$*. But then we get, for all* $\chi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\begin{array}{l}\sigma^\flat_\Sigma(\sigma^\flat_\Sigma(\phi,\chi),\sigma^\flat_\Sigma(\psi,\chi)) = 2,\\ \sigma^\flat_\Sigma(\lambda^\flat_\Sigma(\phi,\chi),\lambda^\flat_\Sigma(\psi,\chi)) = 2.\end{array}$$

So $I^\flat$ *has the local system compatibility in* $\mathcal{I}$*.*

To see that $I^\flat$ *does not have the local family compatibility in* $\mathcal{I}$*, consider the theory family* $T = \{\{1,2\}\}$*. We have* $\sigma^\flat_\Sigma(0,1) = \sigma^\flat_\Sigma(1,0) = 1 \in T_\Sigma$*, but*

$$\sigma^\flat_\Sigma(\lambda^\flat_\Sigma(1,0),\lambda^\flat_\Sigma(0,0)) = \sigma^\flat_\Sigma(0,0) = 0 \notin T_\Sigma.$$

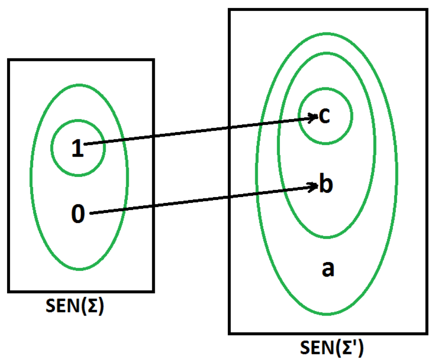
Therefore, the implication defining local family compatibility fails for $T = \{\{1,2\}\}$*. So* $I^\flat$ *does not have locally family compatibility in* $\mathcal{I}$*.*

Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the global (family) compatibility but not the local system compatibility in $\mathcal{I}$.

Example 714 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two objects* Σ, Σ' *and a single (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$*,* $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1\} \to \{a,b,c\}$ *given by* $0 \mapsto b$*,* $1 \mapsto c$*;*

- *$N^\flat$ is the category of natural transformations generated by one ternary natural transformation $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$, defined as follows:*
  - *$\sigma^\flat_\Sigma : \{0,1\}^3 \to \{0,1\}$ be given by*
  $$\sigma^\flat_\Sigma(x,y,z) = 0, \text{ for all } x,y,z \in \{0,1\};$$
  - *$\sigma^\flat_{\Sigma'} : \{a,b,c\}^3 \to \{a,b,c\}$ be given by*
  $$\sigma^\flat_{\Sigma'}(x,y,z) = \begin{cases} a, & \text{if } a \in \{x,y,z\} \\ b, & \text{otherise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ be the π-institution determined by

$$\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}, \quad \mathcal{C}_{\Sigma'} = \{\{c\},\{b,c\},\{a,b,c\}\}.$$

$\mathrm{Thm}(\mathcal{I})$ *has six theory families all of which, except $\{\{0,1\},\{c\}\}$, are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$, with $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ having two distinguished arguments. We show that $I^\flat$ has the global family compatibility in $\mathcal{I}$, but it does not have the local system compatibility in $\mathcal{I}$.

For the global compatibility note that, if, for some $x,y \in \mathrm{SEN}^\flat(\Sigma)$, we have $\sigma^\flat_\Sigma[x,y] \leq T$, then $T = \mathrm{SEN}^\flat$. Similarly, if, for some $x,y \in \mathrm{SEN}^\flat(\Sigma')$, $\sigma^\flat_{\Sigma'}[x,y] \leq T$, then $T_{\Sigma'} = \{a,b,c\}$. In both cases, the conclusion of the defining implication is trivially true. So $I^\flat$ has the global compatibility in $\mathcal{I}$.

On the other hand, consider the theory system $T = \{\{0,1\},\{b,c\}\}$. Let $\phi = 0$ and $\psi = 1$. Then, we have, for all $z \in \{0,1\}$,

$$\sigma^\flat_\Sigma(0,1,z) = \sigma^\flat_\Sigma(1,0,z) = 0 \in T_\Sigma.$$

On the contrary,

$$\sigma^\flat_{\Sigma'}(\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(0),c,c),\sigma^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(1),c,c),a) = a \notin T_{\Sigma'}.$$

Therefore, the implication defining local system compatibility fails for T. So $I^\flat$ does not have the local system compatibility in $\mathcal{I}$.

We close by proving that all three compatibility properties transfer from π-institutions to their models.

Proposition 715 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has a compatibility property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* I *has the corresponding compatibility property in* $\mathcal{A}$*.*

Proof: If I has a compatibility property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same compatibility property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}} \rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding compatibility in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has a compatibility property in $\mathcal{I}$. We look at each of the three properties in turn.

(a) Suppose $I^\flat$ has the local family compatibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, let $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\overleftrightarrow{I}_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. Since this is equivalent to $\alpha_\Sigma(\overleftrightarrow{I^\flat}_\Sigma(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, we get that $\overleftrightarrow{I^\flat}_\Sigma(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma)$. But, by hypothesis, $I^\flat$ has the local family compatibility in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Therefore, we get that, for all $\lambda^\flat \in N^\flat$, all $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$I^\flat_{\Sigma'}(\lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \vec{\xi}) \subseteq \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}).$$

This now gives

$$\alpha_{\Sigma'}(I^\flat_{\Sigma'}(\lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}), \vec{\xi})) \subseteq T_{F(\Sigma')},$$

or, equivalently,

$$\begin{aligned} &I_{F(\Sigma')}(\lambda_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})), \\ &\qquad \lambda_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi})), \alpha_{\Sigma'}(\vec{\xi})) \subseteq T_{F(\Sigma')}. \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that I has the local family compatibility in $\mathcal{A}$.

(b) The case of the local system compatibility can be proven similarly, taking into account that, if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

(c) Suppose that $I^\flat$ has the global (family) compatibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\overleftrightarrow{I}_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.$$

Then, we have, by Lemma 95, $\overleftrightarrow{I^\flat}_\Sigma[\phi, \psi] \leq \alpha^{-1}(T)$. Now, since, by hypothesis, $I^\flat$ has the global family compatibility in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that, for all $\lambda^\flat \in N^\flat$, $\Sigma' \in |\mathbf{Sign}^\flat|$, all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma')$,

$$I^\flat_{\Sigma'}[\lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi}), \lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi})] \leq \alpha^{-1}(T),$$

or, equivalently, by Lemma 95,

$$I_{F(\Sigma')}[\alpha_{\Sigma'}(\lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \vec{\chi})), \alpha_{\Sigma'}(\lambda^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\psi), \vec{\chi}))] \leq T.$$

But this amounts to

$$\begin{aligned} I_{F(\Sigma')}[&\lambda_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})), \\ &\lambda_{F(\Sigma')}(\mathrm{SEN}(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi}))] \leq T. \end{aligned}$$

Thus, I has the global family compatibility in $\mathcal{A}$.

■

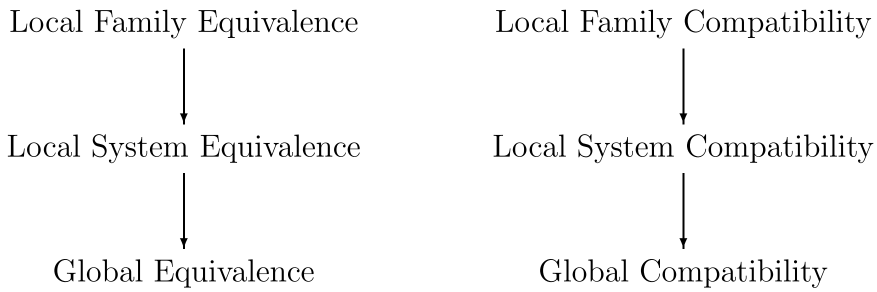
10.9 Congruence

In this section we focus on the three **uniform equivalence properties**, i.e., on LFLF equivalence, LSLS equivalence and GBGB equivalence, and we add to those versions of the compatibility property to obtain several versions of the congruence property.

To fix some terminology, we say that a set $I^\flat$ of natural transformations in a π-institution $\mathcal{I}$ has:

- the **local family equivalence in** $\mathcal{I}$ if it has the LFLF equivalence in $\mathcal{I}$;
- the **local system equivalence in** $\mathcal{I}$ if it has the LSLS equivalence in $\mathcal{I}$;
- the **global equivalence in** $\mathcal{I}$ if it has the GBGB equivalence in $\mathcal{I}$.

By previous work, we know that these three uniform equivalence properties are stratified in the linear hierarchy shown on the left below.



Moreover, by our study of the compatibility properties, we know that they also fall into a similar linear hierarchy, as shown on the right of the diagram.

By combining equivalence with compatibility properties, we obtain nine congruence properties as follows. Let $X, Y \in \{\text{LF}, \text{LS}, \text{GB}\}$, where, as before, LF stands for "Local Family", LS stands for "Local System" and GB stands for "GloBal".

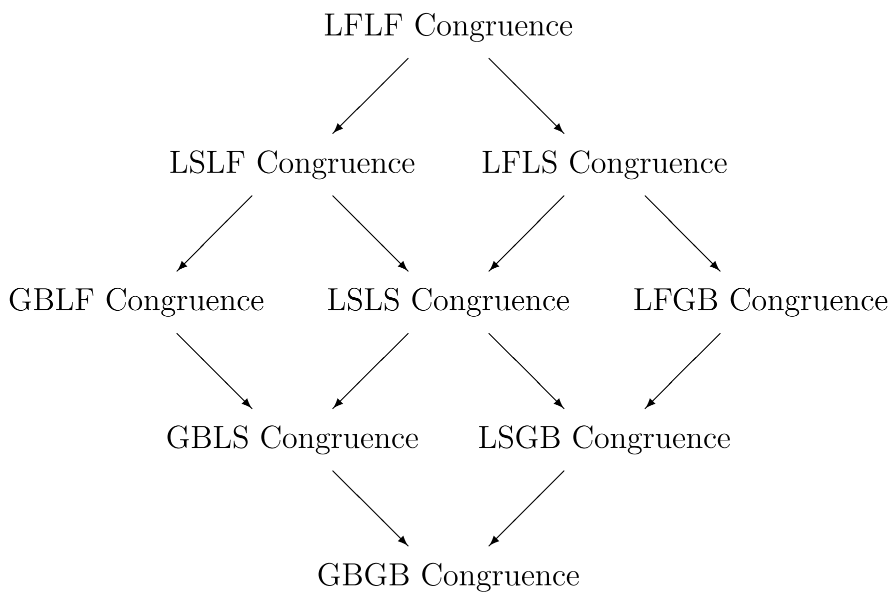
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\text{SEN}^\flat)^\omega \to \text{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that $I^\flat$ has the **XY-congruence in** $\mathcal{I}$ if it has

- the X (uniform) equivalence in $\mathcal{I}$;
- the Y compatibility in $\mathcal{I}$.

Based on the hierarchies of the equivalence and compatibility properties, we obtain the following hierarchical structure for the various flavors of the congruence property.

Corollary 716 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \text{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\text{SEN}^\flat)^\omega \to \text{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments. The nine congruence properties form the hierarchy shown on the accompanying diagram.*

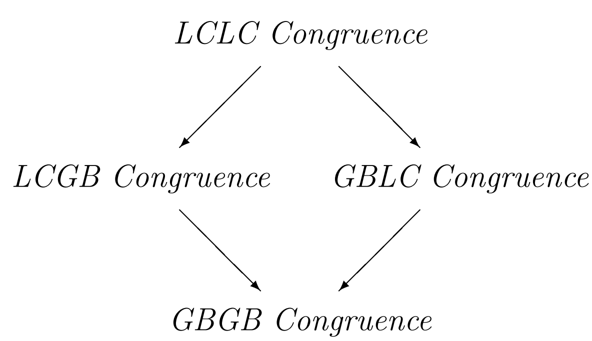
Proof: This follows directly from Corollary 694 and Proposition 711. ■



Based on the analysis performed on symmetry and transitivity, we have the following result regarding natural sufficient conditions under which some of the nine congruence properties above coincide.

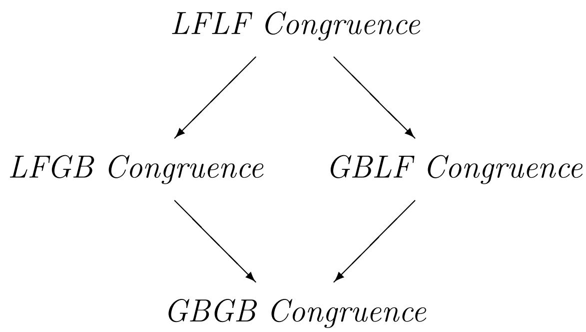
Corollary 717 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$*, with two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the congruence hierarchy collapses to the one depicted below, where LC (for LoCal) is used to incorporate the LF and LS properties, which coincide;*



(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the congruence hierarchy collapses to the one depicted below, where the Local System versions coincide with (and, thus, are incorporated into) the*

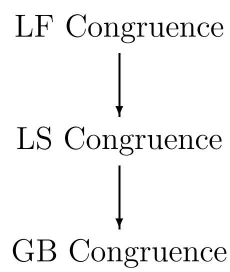
GloBal versions.



Proof: The statement follows from Corollary 695 and Proposition 712. ■

For a systemic π-institution with a parameter-free set of natural transformations, there is only one congruence property, since all versions of equivalence and all versions of compatibility collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, to the uniformly defined classes. So we define **LF congruence**, **LS congruence** and **GB congruence** to mean, respectively, LFLF congruence, LSLS congruence and GBGB congruence. These are the three diagonal classes in the original diagram that form, according to Corollary 716, the subhierarchy depicted below.



And, of course, according to Corollary 717, this reduces to the hierarchy depicted on the left below for a systemic π-institution and to the one depicted on the right below for a parameter free set of natural transformations.

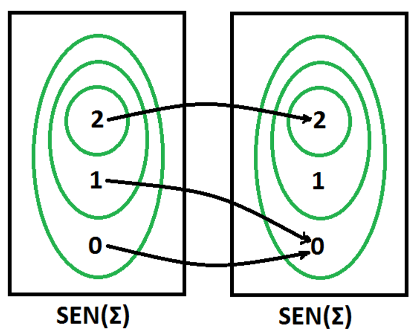
We provide examples to show that the three uniform classes of the congruence hierarchy are distinct in general.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the LS congruence, but not the LF congruence property in $\mathcal{I}$.

Example 718 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by a single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 1, & \text{if } (x,y) = (1,2) \\ 0, & \text{otherwise} \end{cases}$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system congruence in* $\mathcal{I}$*, but it does not have the local family congruence in* $\mathcal{I}$*.*

First note that $\sigma^\flat_\Sigma(\phi,\phi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\phi \in \{0,1,2\}$*, whence* $I^\flat$ *is reflexive in* $\mathcal{I}$*. Next note that the condition defining local system symmetry holds trivially for* $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, if* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for some* $\phi \neq \psi$*, then* $\{\phi,\psi\} = \{0,1\}$*, whence* $\sigma^\flat_\Sigma(\psi,\phi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. So* $I^\flat$ *is locally system symmetric in* $\mathcal{I}$*. For local system transitivity, the defining condition holds, again, trivially for* $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, it holds due to the fact that* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \neq \psi$*, other than* $(\phi,\psi) = (0,1)$ *or* $(1,0)$*. Thus,* $I^\flat$ *is also locally system transitive in*

$\mathcal{I}$. Finally, note that the condition defining local system compatibility is also trivial for $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, if* $\sigma^\flat_\Sigma(\phi,\psi) = 2$ *and* $\sigma^\flat_\Sigma(\psi,\phi) = 2$*, with* $\phi \neq \psi$*, then* $\{\phi,\psi\} = \{0,1\}$ *and, in that case,*

$$\sigma^\flat_\Sigma(\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(h)(\phi),\chi),\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(h)(\psi),\chi)) = 2$$

and

$$\sigma^\flat_\Sigma(\sigma^\flat_\Sigma(\chi,\mathrm{SEN}^\flat(h)(\phi)),\sigma^\flat_\Sigma(\chi,\mathrm{SEN}^\flat(h)(\psi))) = 2,$$

for all $h \in \mathbf{Sign}^\flat(\Sigma,\Sigma)$ *and all* $\chi \in \{0,1,2\}$*. Thus,* $I^\flat$ *has the local system compatibility in* $\mathcal{I}$ *and, therefore, has the local system congruence in* $\mathcal{I}$*.*

On the other hand, note that $\sigma^\flat_\Sigma(1,2) = 1 \in \{1,2\}$*, but* $\sigma^\flat_\Sigma(2,1) = 0 \notin \{1,2\}$*. Thus, the local family symmetry condition fails for* $T = \{\{1,2\}\} \in \mathrm{ThFam}(\mathcal{I})$*. Hence,* $I^\flat$ *is not locally family symmetric in* $\mathcal{I}$ *and, therefore, a fortiori, it fails to satisfy the local family congruence in* $\mathcal{I}$*.*

Finally, we present an example to show that there is a π-institution $\mathcal{I}$ with a set of natural transformations that has the GB congruence but not the LS congruence in $\mathcal{I}$.

Example 719 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3\} \to \{0,1,2,3\}$ *given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2,3\}^3 \to \{0,1,2,3\}$ *be given by*

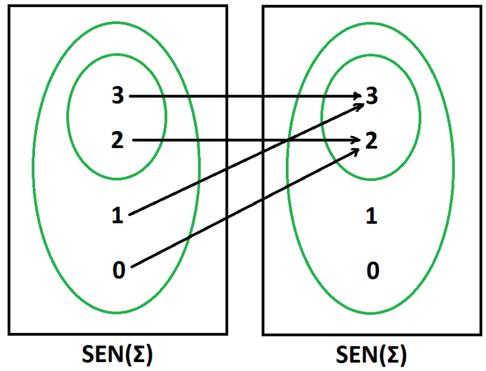
$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x,y) = (0,1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2,3\},\{0,1,2,3\}\}.$$

Note that both theory families, $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems. So* $\mathcal{I}$ *is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the GB congruence in* $\mathcal{I}$*, but it does not have the LS congruence in* $\mathcal{I}$*.*



Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi, \phi, \xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*. For global symmetry, note that if, for some* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma[\phi, \psi] \le \mathrm{Thm}(\mathcal{I})$*, then we must have* $\phi = \psi$*, whence* $\sigma^\flat_\Sigma[\psi, \phi] \le \mathrm{Thm}(\mathcal{I})$ *holds. For global transitivity, note again that for no* $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \ne \psi$*, is it the case that* $\sigma^\flat_\Sigma[\phi, \psi] \le \mathrm{Thm}(\mathcal{I})$*, whence the condition is satisfied in this case as well. Finally, the same observation leads to the conclusion that* $I^\flat$ *satisfies the global compatibility property in* $\mathcal{I}$*. We conclude that* $I^\flat$ *has the GB congruence in* $\mathcal{I}$*.*

On the other hand, since $\sigma^\flat_\Sigma(0, 1, \xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*, but* $\sigma^\flat_\Sigma(1, 0, 0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*,* $I^\flat$ *does not have the local system symmetry. A fortiori,* $I^\flat$ *does not have the LS congruence in* $\mathcal{I}$*.*

And here is a transfer property for the congruence properties that we have focused on in this section.

Corollary 720 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has a congruence property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* I *has the corresponding congrunece property in* $\mathcal{A}$*.*

Proof: This follows directly from Corollary 700 and Proposition 715. ■

10.10 Modus Ponens

We turn now to the study of various versions of the modus ponens property, taking again into account both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that:

- $I^\flat$ has the **local family modus ponens** (**local family MP**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \text{ and, for all } \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma),\ I^\flat_\Sigma(\phi, \psi, \vec{\chi}) \subseteq T_\Sigma \text{ imply } \psi \in T_\Sigma;$$
- $I^\flat$ has the **local system modus ponens** (**local system MP**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \text{ and, for all } \vec{\chi} \in \mathrm{SEN}^\flat(\Sigma),\ I^\flat_\Sigma(\phi, \psi, \vec{\chi}) \subseteq T_\Sigma \text{ imply } \psi \in T_\Sigma;$$
- $I^\flat$ has the **global family modus ponens** (**global family MP**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \text{ and } I^\flat_\Sigma[\phi, \psi] \leq T \text{ imply } \psi \in T_\Sigma;$$
- $I^\flat$ has the **global system modus ponens** (**global system MP**) **in** $\mathcal{I}$ if, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \text{ and } I^\flat_\Sigma[\phi, \psi] \leq T \text{ imply } \psi \in T_\Sigma.$$

The following proposition establishes the hierarchy of modus ponens rules.

Proposition 721 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments.*

(a) If $I^\flat$ has the local family MP, then it has both the global family MP in $\mathcal{I}$ and the local system MP in $\mathcal{I}$;

(b) If $I^\flat$ has the global family MP, then it has the global system MP in $\mathcal{I}$;

(c) If $I^\flat$ has the local system MP, then it has the global system MP in $\mathcal{I}$.

Proof:

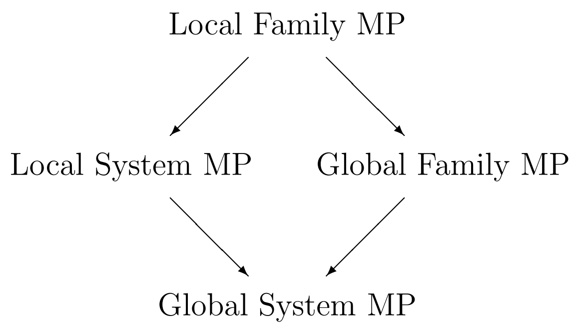
(a) Suppose that $I^\flat$ has the local family MP in $\mathcal{I}$. Let $T \in \mathrm{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\phi \in T_\Sigma$ and $I^\flat_\Sigma[\phi, \psi] \leq T$. Then, we have, in particular, that, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\chi}) \subseteq T_\Sigma$. But then, since $\phi \in T_\Sigma$ and, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$, $I^\flat_\Sigma(\phi, \psi, \vec{\chi}) \subseteq T_\Sigma$, we get by the local family MP that $\psi \in T_\Sigma$. We conclude that $I^\flat$ has the global family MP in $\mathcal{I}$.

If $I^\flat$ has the local family MP in $\mathcal{I}$, then it has a fortiori the local system MP in $\mathcal{I}$ due to the fact that every theory system of $\mathcal{I}$ is also a theory family.

(b) This follows, similarly to the second part of (a), from the fact that every theory system of $\mathcal{I}$ is also a theory family.

(c) We repeat the argument used in the proof of the first part of (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families. ■

Proposition 721 has established the following hierarchy of modus ponens properties, where the southwest arrows are based on the family-system duality whereas the southeast arrows on the local-global duality.



We also note the following regarding natural sufficient conditions under which some of these four classes coincide.

Proposition 722 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the local (global) family and the local (global) system MP coincide;*

(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the local system MP and the global system MP coincide;*

(c) If $\mathcal{I}$ *is systemic and* $I^\flat$ *is parameter-free, then the local family MP and the global family MP also coincide.*

Proof:

(a) If $\mathcal{I}$ is systemic, then all theory families are theory systems and the family and system properties collapse.

(b) Suppose that $I^\flat$ is parameter-free and that $I^\flat$ has the global system MP in $\mathcal{I}$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $I^\flat_\Sigma(\phi, \psi) \subseteq T_\Sigma$. Since T is a theory system, we have, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$,

$$I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)) = \mathrm{SEN}^\flat(f)(I^\flat_\Sigma(\phi, \psi)) \subseteq T_{\Sigma'}.$$

Equivalently, $I^\flat_\Sigma[\phi, \psi] \leq T$. Thus, by the global system MP, we get that $\psi \in T_\Sigma$. Thus, $I^\flat$ has the local system MP.

(c) This follows from Parts (a) and (b).

■

So in the case of a systemic π-institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter-free set of natural transformations we have the hierarchy on the right.

$$\begin{array}{ccc} \text{Local MP} & \quad & \text{Local Family MP} \\ \downarrow & & \downarrow \\ \text{Global MP} & & \text{Global Family MP} \\ & & \downarrow \\ & & \text{System MP} \end{array}$$

Finally, for a systemic π-institution with a parameter-free set of natural transformations all four MP properties collapse to a single one.

We provide some examples to show that the implications of Proposition 721 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding modus ponens properties are proper inclusions.

We first present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that have the global family MP but not the local system MP in $\mathcal{I}$.

Example 723 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

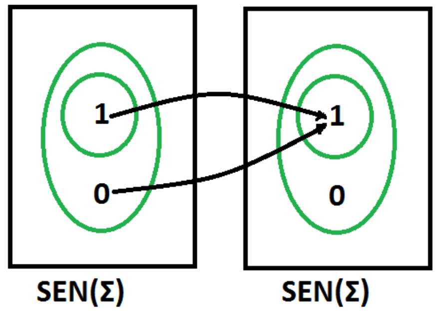
- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1\} \to \{0,1\}$ *given by* $0 \mapsto 1$ *and* $1 \mapsto 1$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1\}^3 \to \{0,1\}$ *be given by*

$$\sigma^\flat_\Sigma(a,b,c) = \begin{cases} 0, & \text{if } (a,b,c) = (1,1,0) \\ 1, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{1\},\{0,1\}\}$*.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments.*

Clearly, both $\mathrm{Thm}(\mathcal{I})$ *and* SEN*, which are the only theory families, are also theory systems. We show that* $I^\flat$ *has the global family MP in* $\mathcal{I}$*, but it does not have the local system MP in* $\mathcal{I}$*.*



For the global family MP notice that we only need to check the case with $T = \mathrm{Thm}(\mathcal{I})$, $\phi = 1$ *and* $\psi = 0$. *Since* $\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(1), \mathrm{SEN}^\flat(f)(0), 0) = \sigma^\flat_\Sigma(1,1,0) = 0$, *we have that* $I^\flat_\Sigma[\phi,\psi] \nsubseteq T$, *whence the condition is vacuously satisfied. Therefore, we get that* $I^\flat$ *has the global family MP in* $\mathcal{I}$.

On the other hand, we have $\sigma^\flat_\Sigma(1,0,0) = \sigma^\flat_\Sigma(1,0,1) = 1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $1 \in \mathrm{Thm}_\Sigma(\mathcal{I})$, *but* $0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$, *which shows that* $I^\flat$ *does not have the local system MP in* $\mathcal{I}$.

Next we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that have the local system MP but not the global family MP in $\mathcal{I}$.

Example 724 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

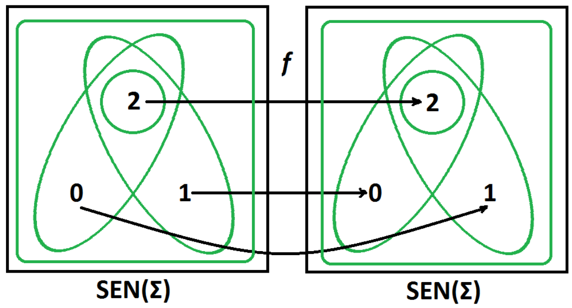
- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = i_\Sigma$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given, for all* $a, b \in \mathrm{SEN}^\flat(\Sigma)$, *by*

$$\sigma^\flat_\Sigma(a,b) = \begin{cases} 1, & \text{if } (a,b) = (2,0) \\ 0, & \text{if } (a,b) = (2,1) \\ 2, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\}, \{0,2\}, \{1,2\}, \{0,1,2\}\}.$$

Consider the set $I^\flat = \{\sigma^\flat\}$.



$\mathcal{I}$ has four theory families $\mathrm{Thm}(\mathcal{I})$, $T = \{\{0,2\}\}$, $T' = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$. *We show that $I^\flat$ has the local system MP in $\mathcal{I}$, but it does not have the global family MP in $\mathcal{I}$.*

For the local system MP notice that we only need to check the case for $\mathrm{Thm}(\mathcal{I})$, $\phi = 2$ *and* $\psi = 0$ *or* $\psi = 1$. *Since* $\sigma^\flat_\Sigma(2,0) = 1 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$ *and* $\sigma^\flat_\Sigma(2,1) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$, *we conclude that $I^\flat$ has the local system MP in $\mathcal{I}$.*

On the other hand, for the theory family T and for $\phi = 0$ and $\psi = 1$, we get that $\phi = 0 \in T_\Sigma$ and $\sigma^\flat_\Sigma(\phi,\psi) = \sigma^\flat_\Sigma(0,1) = 2$ *and*

$$\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(f)(\phi), \mathrm{SEN}^\flat(f)(\psi)) = \sigma^\flat_\Sigma(1,0) = 2,$$

whence $\sigma^\flat_\Sigma[0,1] \leq T$. *But clearly* $1 \notin T_\Sigma$. *Therefore $I^\flat$ does not have the global family MP in $\mathcal{I}$.*

We prove next a transfer property for modus ponens.

Proposition 725 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system, $I^\flat$ a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in $N^\flat$, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a π-institution based on $\mathbf{F}$. $I^\flat$ has a modus ponens property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, *with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, *$I$ has the corresponding modus ponens property in $\mathcal{A}$.*

Proof: If I has a modus ponens property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same modus ponens in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}} \rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding modus ponens in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has a modus ponens in $\mathcal{I}$. We look at each of the four properties in turn.

(a) Suppose $I^\flat$ has the local family MP in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathrm{SEN}^\flat(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$. Since the latter is equivalent to $\alpha_\Sigma(I^\flat_\Sigma(\phi,\psi,\vec{\chi})) \subseteq T_{F(\Sigma)}$, we get that $\phi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$ and $I^\flat_\Sigma(\phi,\psi,\vec{\chi}) \subseteq \alpha^{-1}_\Sigma(T_{F(\Sigma)})$, for all $\vec{\chi} \in \mathrm{SEN}^\flat(\Sigma)$. But, by hypothesis, $I^\flat$ has the local family MP in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$. Therefore, we get that $\psi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$, or, equivalently, $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. This proves that I has the local family MP in $\mathcal{A}$.

(b) The case of the local system MP can be proven similarly, taking into account that, if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

(c) Suppose that $I^\flat$ has the global family MP in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F,\alpha\rangle\rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$, such that

$$\alpha_\Sigma(\phi) \quad \text{and} \quad I_{F(\Sigma)}[\alpha_\Sigma(\phi),\alpha_\Sigma(\psi)] \leq T.$$

Then, we have $\phi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$ and, by Lemma 95, $I^\flat_\Sigma[\phi,\psi] \leq \alpha^{-1}(T)$. Now, since, by hypothesis, $I^\flat$ has the global family MP in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathrm{ThFam}(\mathcal{I})$, we get that $\psi \in \alpha^{-1}_\Sigma(T_{F(\Sigma)})$, or, equivalently, $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Thus, I has the global family MP in $\mathcal{A}$.

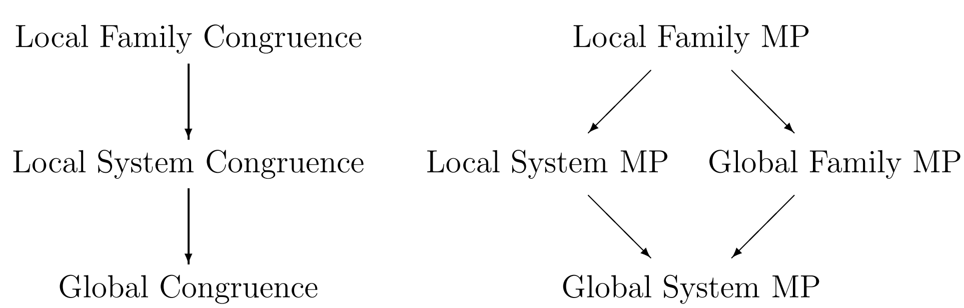
(d) Similar to (c).

■

10.11 Syntactic Protoalgebraicity

In this section we focus on the three **uniform congruence properties**, i.e., on LF congruence, LS congruence and GB congruence, and we add to those versions of the modus ponens property to obtain several versions of the syntactic protoalgebraicity property.

By previous work, we know that the three uniform congruence properties are stratified in the linear hierarchy shown on the left below.



Moreover, by our study of the modus ponens, we know that they fall into the hierarchy shown on the right of the diagram.

By combining equivalence with compatibility properties, we obtain twelve syntactic protoalgebraicity properties as follows. Let $X \in \{\mathrm{LF},\mathrm{LS},\mathrm{GB}\}$ and

$Y \in \{\mathrm{LF}, \mathrm{LS}, \mathrm{GF}, \mathrm{GS}\}$, where, as before, LF stands for "Local Family", LS stands for "Local System", GF stands for "Global Family", GS stands for "Global System" and GB stands for "GloBal".

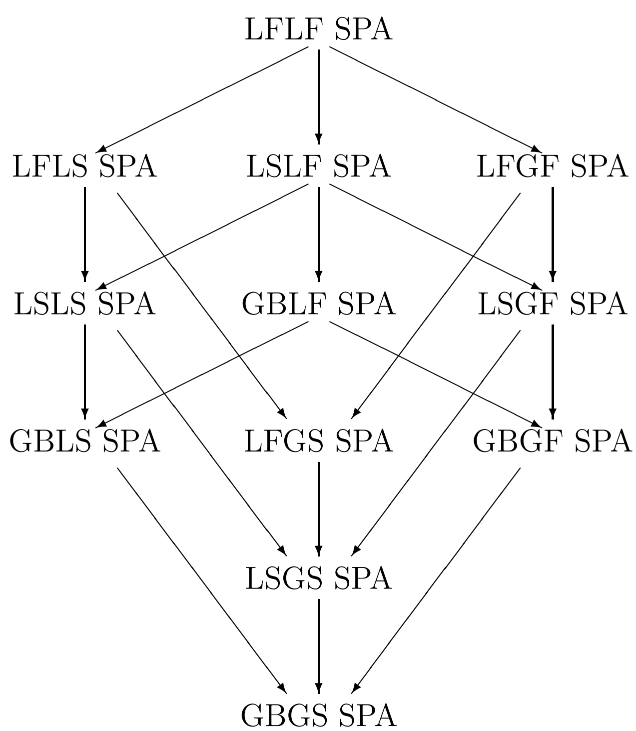
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that $I^\flat$ has the **XY syntactic protoalgebraicity in** $\mathcal{I}$ (**XY SPA in** $\mathcal{I}$) if it has

- the X congruence in $\mathcal{I}$;
- the Y modus ponens in $\mathcal{I}$.

Based on the hierarchies of the congruence and MP properties, we obtain the following hierarchical structure for the various flavors of the syntactic protoalgebraicity property.

Corollary 726 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. The twelve syntactic protoalgebraicity properties form the hierarchy shown on the accompanying diagram.*

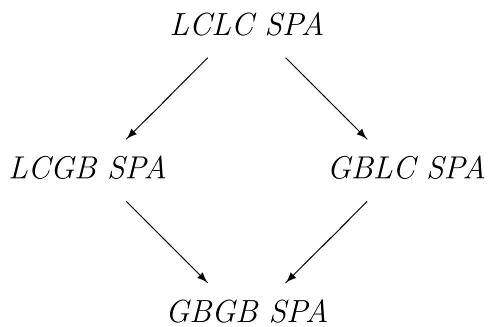
Proof: This follows directly from Corollary 716 and Proposition 721. ■



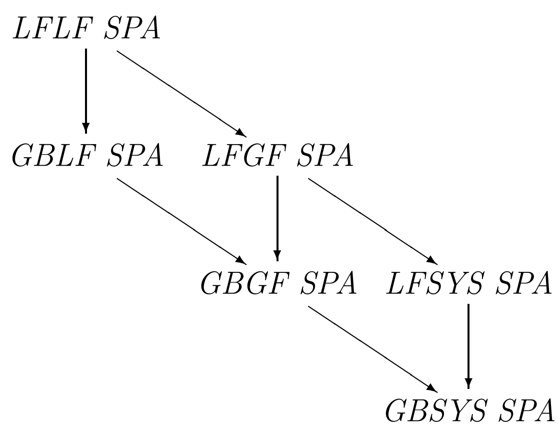
Based on the analysis performed on congruence and modus ponens, we have the following result regarding natural sufficient conditions under which some of the twelve syntactic protoalgebraicity properties above coincide.

Corollary 727 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the syntactic protoalgebraicity hierarchy collapses to the one depicted below;*



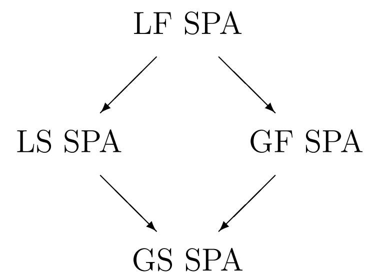
(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the syntactic protoalgebraicity hierarchy collapses to the one depicted below, where the Local System versions of congruence coincide with (and are incorporated into) the global versions and the Local and Global System versions of MP also coincide and are denoted by SYS.*



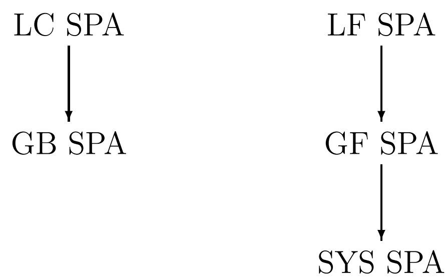
Proof: The statement follows from Corollary 717 and Proposition 722. ■

For a systemic π-institution with a parameter-free set of natural transformations, there is only one syntactic protoalgebraicity property, since all versions of congruence and all versions of modus ponens collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, on the uniformly defined classes. So we define **LF SPA**, **LS SPA**, **GF SPA** and **GS SPA** to mean, respectively, LFLF syntactic, LSLS syntactic, GFGF syntactic and GSGS syntactic protoalgebraicity. These classes form, according to the diagram above, based on Corollary 726, the sub hierarchy depicted below.



Moreover, according to Corollary 727, this reduces to the hierarchy depicted on the left below for a systemic π-institution and to the one depicted on the right below for a parameter free set of natural transformations.



We provide examples to show that the four uniform classes of the syntactic protoalgebraicity hierarchy are distinct in general.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic protoalgebraicity, but not the GF syntactic protoalgebraicity in $\mathcal{I}$.

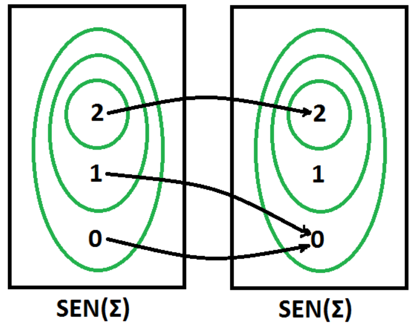
Example 728 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by a single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 1, & \text{if } \{x,y\} = \{1,2\} \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$



Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system syntactic protoalgebraicity in* $\mathcal{I}$*, but it does not have the global family syntactic protoalgebraicity in* $\mathcal{I}$*.*

First note that $\sigma^\flat_\Sigma(\phi,\phi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\phi \in \{0,1,2\}$*, whence* $I^\flat$ *is reflexive in* $\mathcal{I}$*.*

Next, note that the condition defining local system symmetry holds trivially for $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, if* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for some* $\phi \neq \psi$*, then* $\{\phi,\psi\} = \{0,1\}$*, whence* $\sigma^\flat_\Sigma(\psi,\phi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$*. So* $I^\flat$ *is local system symmetric in* $\mathcal{I}$*.*

For local system transitivity, the defining condition holds, again, trivially for $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, it holds due to the fact that* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \neq \psi$*, other than* $(\phi,\psi) = (0,1)$ *or* $(1,0)$*. Thus,* $I^\flat$ *is also local system transitive in* $\mathcal{I}$*.*

Next, note that the condition defining local system compatibility is also trivial for $\mathrm{SEN}^\flat$*, whereas for* $\mathrm{Thm}(\mathcal{I})$*, if* $\sigma^\flat_\Sigma(\phi,\psi) = 2$ *and* $\sigma^\flat_\Sigma(\psi,\phi) = 2$*, with* $\phi \neq \psi$*, then* $\{\phi,\psi\} = \{0,1\}$ *and, in that case,*

$$\sigma^\flat_\Sigma(\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(h)(\phi),\chi),\sigma^\flat_\Sigma(\mathrm{SEN}^\flat(h)(\psi),\chi)) = 2$$

and

$$\sigma^\flat_\Sigma(\sigma^\flat_\Sigma(\chi,\mathrm{SEN}^\flat(h)(\phi)),\sigma^\flat_\Sigma(\chi,\mathrm{SEN}^\flat(h)(\psi))) = 2,$$

for all $h \in \mathbf{Sign}^\flat(\Sigma,\Sigma)$ *and all* $\chi \in \{0,1,2\}$*. Thus,* $I^\flat$ *has the local system compatibility in* $\mathcal{I}$ *and, therefore, has the local system congruence in* $\mathcal{I}$*.*

To finish up, note that, since the only pairs (ϕ,ψ)*, with* $\phi \neq \psi$*, such that* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *are* $(0,1)$ *and* $(1,0)$ *and for neither of these is* $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I})$*,* $I^\flat$ *has the local system modus ponens in* $\mathcal{I}$ *and, therefore, it has the local system syntactic protoalgebraicity in* $\mathcal{I}$ *as well.*

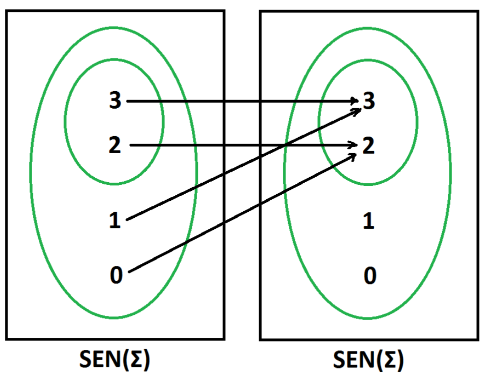
On the other hand, $1 \in \{1,2\}$ *and* $\sigma^\flat_\Sigma[1,0] \leq \{\{1,2\}\}$*, but* $0 \notin \{1,2\}$*. Therefore,* $I^\flat$ *does not have the global family modus ponens in* $\mathcal{I}$ *and, hence, a fortiori, it does not have the global family syntactic protoalgebraicity in* $\mathcal{I}$*.*

Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the GF syntactic protoalgebraicity but not the LS syntactic protoalgebraicity in $\mathcal{I}$.

Example 729 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2,3\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2,3\} \to \{0,1,2,3\}$ *given by* $0 \mapsto 2$*,* $1 \mapsto 3$*,* $2 \mapsto 2$ *and* $3 \mapsto 3$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2,3\}^3 \to \{0,1,2,3\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x,y) = (0,1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$C_\Sigma = \{\{2,3\},\{0,1,2,3\}\}.$$

Note that both theory families, $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$*, are also theory systems. So* $\mathcal{I}$ *is a systemic* π*-institution.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the global family syntactic protoalgebraicity in* $\mathcal{I}$*, but it does not have the local system syntactic protoalgebraicity in* $\mathcal{I}$*.*

Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma(\phi,\phi,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*. For global symmetry, note that if, for some* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*,* $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$*, then we* *must have* $\phi = \psi$*, whence* $\sigma^\flat_\Sigma[\psi,\phi] \leq \mathrm{Thm}(\mathcal{I})$ *holds. For global transitivity, note again that for no* $\phi,\psi \in \mathrm{SEN}^\flat(\Sigma)$*, with* $\phi \neq \psi$*, is it the case that* $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$*, whence the condition is satisfied in this case as well. Finally, the same observation leads to the conclusion that* $I^\flat$ *satisfies both the global compatibility property in* $\mathcal{I}$ *and the global modus ponens. We conclude that* $I^\flat$ *has the global family syntactic protoalgebtaicity in* $\mathcal{I}$*.*

On the other hand, since $\sigma^\flat_\Sigma(0,1,\xi) = 2 \in \mathrm{Thm}_\Sigma(\mathcal{I})$*, for all* $\xi \in \mathrm{SEN}^\flat(\Sigma)$*, but* $\sigma^\flat_\Sigma(1,0,0) = 0 \notin \mathrm{Thm}_\Sigma(\mathcal{I})$*,* $I^\flat$ *does not have the local system symmetry. A fortiori,* $I^\flat$ *does not have the local system congruence and, hence, does not have the local system syntactic protoalgebraicity in* $\mathcal{I}$ *either.*

And here is a transfer property for the syntactic protoalgebraicity properties that we have focused on in this section.

Corollary 730 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has a (uniform) syntactic protoalgebraicity property in* $\mathcal{I}$ *if and only if, for every algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$*,* I *has the corresponding syntactic protoalgebraicity property in* $\mathcal{A}$*.*

Proof: This follows directly from Corollary 720 and Proposition 1440. ∎

10.12 Invertibility

We study, next, various versions of the invertibility property, once again based on the local versus global and the theory family versus theory system dualities.

Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments. We say that:

- $I^\flat$ has the **local family invertibility in** $\mathcal{I}$ if there exists a set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \text{ iff } \overleftrightarrow{I^\flat}_\Sigma(\tau_\Sigma(\phi), \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$

- $I^\flat$ has the **local system invertibility in** $\mathcal{I}$ if there exists a set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, such that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi \in T_\Sigma \text{ iff } \overleftrightarrow{I^\flat}_\Sigma(\tau_\Sigma(\phi), \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma);$$

- $I^\flat$ has the **global family invertibility in** $\mathcal{I}$ if there exists a set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, such that, for all $T \in \mathrm{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{iff} \quad \overleftrightarrow{I^\flat}_\Sigma[\tau_\Sigma(\phi)] \leq T;$$
- $I^\flat$ has the **global system invertibility in** $\mathcal{I}$ if there exists a set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ of natural transformations in $N^\flat$, such that, for all $T \in \mathrm{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^\flat|$ and all $\phi \in \mathrm{SEN}^\flat(\Sigma)$,
$$\phi \in T_\Sigma \quad \text{iff} \quad \overleftrightarrow{I^\flat}_\Sigma[\tau_\Sigma(\phi)] \leq T.$$

We look at the hierarchy of invertibility properties.

Proposition 731 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $I^\flat$ *has the local (global) family invertibility, then it has the local (global) system invertibility in* $\mathcal{I}$.

(b) If $I^\flat$ *has the local system invertibility, then it has the global system invertibility in* $\mathcal{I}$.

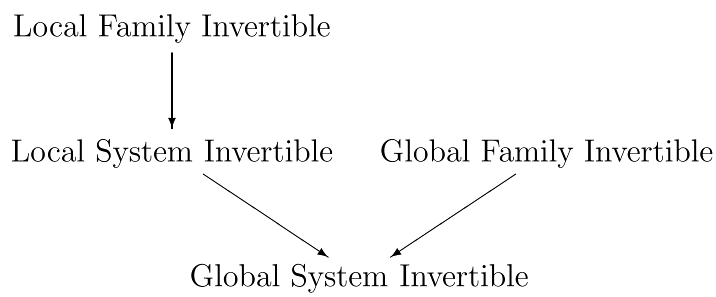
Proof: Since every theory system of $\mathcal{I}$ is a theory family, if $I^\flat$ has the local (global) family invertibility in $\mathcal{I}$, then it has, a fortiori, the local (global) system invertibility in $\mathcal{I}$, with the same witnessing set τ of natural transformations in $N^\flat$.

Suppose, next, that $I^\flat$ has the local system invertibility in $\mathcal{I}$, with witnessing set of natural transformations τ, and let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$.

- If $\phi \in T_\Sigma$, then, since $T \in \mathrm{ThSys}(\mathcal{I})$, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $\mathrm{SEN}^\flat(f)(\phi) \in T_{\Sigma'}$. Thus, by the local family invertibility,
$$I^\flat_{\Sigma'}(\tau_{\Sigma'}(\mathrm{SEN}^\flat(f)(\phi)), \vec{\xi}) \subseteq T_{\Sigma'}, \text{ for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma').$$
This is equivalent to $I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\tau_\Sigma(\phi)), \vec{\xi}) \subseteq T_{\Sigma'}$. Since $\Sigma' \in |\mathbf{Sign}^\flat|$, $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$ and $\vec{\xi} \in \mathrm{SEN}^\flat(\Sigma')$ were arbitrary, we conclude that $I^\flat_\Sigma[\tau_\Sigma(\phi)] \leq T$.
- Suppose, conversely, that $I^\flat_\Sigma[\tau_\Sigma(\phi)] \leq T$. This implies $I^\flat_\Sigma(\tau_\Sigma(\phi), \vec{\xi}) \subseteq T_\Sigma$, for all $\xi \in \mathrm{SEN}^\flat(\Sigma)$. Thus, by the local family invertibility, $\phi \in T_\Sigma$.

We conclude that $\phi \in T_\Sigma$ if and only if $I^\flat_\Sigma[\tau_\Sigma(\phi)] \leq T$, whence $I^\flat$ has the global system invertibility in $\mathcal{I}$. ■

Proposition 731 has established the following hierarchy of invertibility properties:



The following holds regarding natural sufficient conditions under which some of these properties coincide.

Proposition 732 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the local (global) family invertibility and the local (global) system invertibility properties coincide;*

(b) If $I^\flat$ *is parameter-free, then the local system invertibility and the global system invertibility properties coincide.*

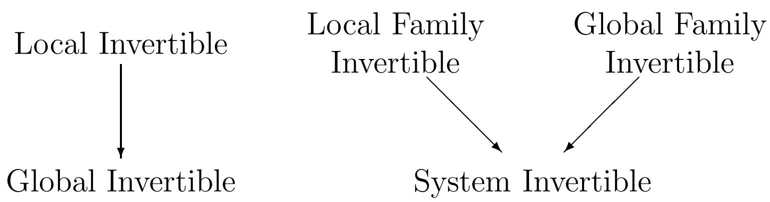
Proof: If $\mathcal{I}$ is systemic, then the local (global) system invertibility property coincides with the local (global) family invertibility property because of the fact that every theory family in $\mathcal{I}$ is also a theory system.

Suppose, next, that $I^\flat$ is parameter-free and that $I^\flat$ has the global system invertibility with witnessing set of natural transformations $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$. Let $T \in \mathrm{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$.

- If $\phi \in T_\Sigma$, then, by the global system invertibility, $I^\flat_\Sigma[\tau_\Sigma(\phi)] \leq T$. In particular, $I^\flat_\Sigma(\tau_\Sigma(\phi)) \subseteq T_\Sigma$.
- If, conversely, $I^\flat_\Sigma(\tau_\Sigma(\phi)) \subseteq T_\Sigma$, then, since $T \in \mathrm{ThSys}(\mathcal{I})$, we get that, for all $\Sigma' \in |\mathbf{Sign}^\flat|$ and all $f \in \mathbf{Sign}^\flat(\Sigma, \Sigma')$, $I^\flat_{\Sigma'}(\mathrm{SEN}^\flat(f)(\tau_\Sigma(\phi))) \subseteq T_{\Sigma'}$. Hence, $I^\flat_\Sigma[\tau_\Sigma(\phi)] \leq T$. Using the global system invertibility, we now conclude that $\phi \in T_\Sigma$.

Thus, the global system invertibility implies the local system invertibility property and, therefore that, provided $I^\flat$ is parameter-free, the local and global system invertibility properties coincide. ■

So, in the case of a systemic π-institution $\mathcal{I}$, the hierarchy of invertibility properties reduces to the one depicted on the left below, whereas in the case of a parameter-free set of natural transformations $I^\flat$, we get the hierarchy depicted on the right.



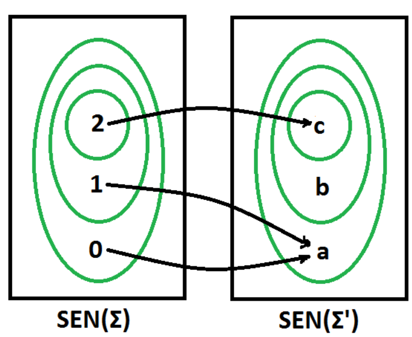
Finally, for a systemic π-institution and a parameter-free set of natural transformations, all four invertibility properties coincide.

We provide some examples to show that the implications of Proposition 731 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π-institutions with a set of natural transformations satisfying the corresponding invertibility properties are proper inclusions.

We first present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the local family invertibility but not the global family invertibility in $\mathcal{I}$.

Example 733 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with two objects* Σ *and* Σ' *and a single (non-identity) morphism* $f : \Sigma \to \Sigma'$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$, $\mathrm{SEN}^\flat(\Sigma') = \{a,b,c\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{a,b,c\}$ *given by* $0 \mapsto a$, $1 \mapsto a$ *and* $2 \mapsto c$*;*
- $N^\flat$ *is the trivial category of natural transformations consisting of the projections only.*



Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\} \quad \textit{and} \quad \mathcal{C}_{\Sigma'} = \{\{c\},\{b,c\},\{a,b,c\}\}.$$

Consider the set $I^\flat = \{p^{2,0}\}$*, with* $p^{2,0} : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *being the projection binary natural transformation (onto the first coordinate), viewed as having two distinguished arguments.*

$\mathcal{I}$ *has nine theory families, but only five of those are theory systems. So it is not a systemic* π*-institution. We show that* $I^\flat$ *has the local family invertibility in* $\mathcal{I}$*, but it does not have the global family invertibility in* $\mathcal{I}$*.*

For the local family invertibility, let $\tau \equiv \{\iota \approx \iota\}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity (or unary first coordinate projection) natural transformation. Then, for all* $T \in \mathrm{ThFam}(\mathcal{I})$*, all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and all* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\overleftrightarrow{I^\flat}_\Sigma(\iota_\Sigma(\phi), \iota_\Sigma(\phi)) \in T_\Sigma \quad \text{iff} \quad \phi \in T_\Sigma.$$

Thus, $I^\flat$ *has the local family invertibility in* $\mathcal{I}$*.*

On the other hand, for $T = \{\{1,2\},\{b,c\}\} \in \mathrm{ThFam}(\mathcal{I})$*, we have* $1 \in T_\Sigma$*, but*

$$p^{2,0}_{\Sigma'}(\mathrm{SEN}^\flat(f)(1), \mathrm{SEN}^\flat(f)(1)) = p^{2,0}_{\Sigma'}(a,a) = a \notin T_{\Sigma'}.$$

Therefore $I^\flat$ *does not have the global family invertibility in* $\mathcal{I}$*.*

Next we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the global family invertibility but not the local system invertibility in $\mathcal{I}$.

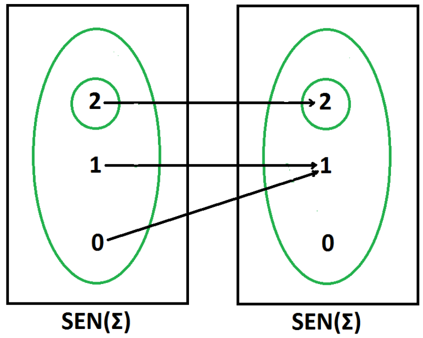
Example 734 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$*,* $1 \mapsto 1$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by the single ternary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^3 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^3 \to \{0,1,2\}$ *be given, for all* $x,y,z \in \mathrm{SEN}^\flat(\Sigma)$*, by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 1, & \text{if } (x,y,z) = (1,1,2) \\ 2, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by* $\mathcal{C}_\Sigma = \{\{2\},\{0,1,2\}\}$*. Consider the set* $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat$ *having two distinguished arguments.*

$\mathcal{I}$ *has two theory families* $\mathrm{Thm}(\mathcal{I})$*,* $\mathrm{SEN}^\flat$ *both of which are also theory systems. So* $\mathcal{I}$ *is systemic. We show that* $I^\flat$ *has the global family invertibility in* $\mathcal{I}$*, but it does not have the local system invertibility in* $\mathcal{I}$*.*



For the global family invertibility, consider $\tau = \{\iota \approx \iota\}$, *where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity natural transformation. The case of* $\mathrm{SEN}^\flat$ *is trivial, whereas for* $\mathrm{Thm}(\mathcal{I})$, *we have, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and* $\phi \in \mathrm{SEN}^\flat(\Sigma)$,

$$\phi = 2 \quad \textit{iff} \quad \overleftrightarrow{I^\flat}_\Sigma[\phi,\phi] \le \{\{2\}\},$$

which holds, for all $\phi \in \{0,1,2\}$, *as can be checked on a case-by-case basis.*

On the other hand, for the local system invertibility, note that $0 \notin \{2\}$, *but* $\sigma^\flat_\Sigma(\tau_\Sigma(0),\psi) = 2 \in \{2\}$, *for every set of unary natural transformations* $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$. *We conclude that* $I^\flat$ *does not have the local system invertibility in* $\mathcal{I}$.

Finally, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the local system invertibility but not the local family invertibility in $\mathcal{I}$.

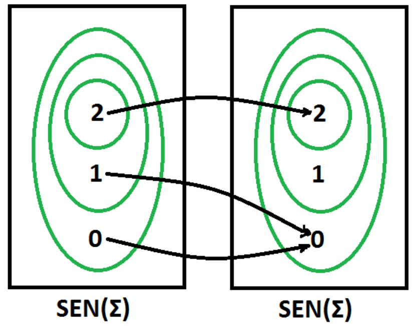
Example 735 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$, *such that* $f \circ f = f$;
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$, $1 \mapsto 0$ *and* $2 \mapsto 2$;
- $N^\flat$ *is the category of natural transformations generated by the single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given, for all* $x,y \in \mathrm{SEN}^\flat(\Sigma)$, *by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \textit{if } (x,y) = (2,2) \\ 0, & \textit{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$



Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat$ *having two distinguished arguments.*

$\mathcal{I}$ *has three theory families, but only* $\mathrm{Thm}(\mathcal{I})$, $\mathrm{SEN}^\flat$ *are theory systems. So* $\mathcal{I}$ *is not systemic. We show that* $I^\flat$ *has the local system invertibility in* $\mathcal{I}$*, but it does not have the local family invertibility in* $\mathcal{I}$*.*

For the local system invertibility, consider $\tau = \{\iota \approx \iota\}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity natural transformation. The case of* $\mathrm{SEN}^\flat$ *is trivial, whereas for* $\mathrm{Thm}(\mathcal{I})$*, we have to verify that, for all* $\Sigma \in |\mathbf{Sign}^\flat|$ *and* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*,*

$$\phi = 2 \quad \textit{iff} \quad \overleftrightarrow{I^\flat}_\Sigma(\phi,\phi) \subseteq \{\{2\}\}.$$

But this obviously holds, by the definition of $I^\flat$*.*

On the other hand, for the local family invertibility, note that $1 \in \{1,2\}$*, but*

$$\sigma^\flat_\Sigma(\tau_\Sigma(1)) = 0 \notin \{1,2\},$$

for every set of unary natural transformations $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *in* $N^\flat$*. We conclude that* $I^\flat$ *does not have the local family invertibility in* $\mathcal{I}$*.*

We now prove a transfer property for invertibility.

Proposition 736 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be an algebraic system,* $I^\flat$ *a collection of natural transformations* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *in* $N^\flat$*, with two distinguished arguments, and* $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *a* π*-institution based on* $\mathbf{F}$*.* $I^\flat$ *has an invertibility property in* $\mathcal{I}$ *if and only if, for every* $\mathbf{F}$*-algebraic system* $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha\rangle\rangle$*, with* $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N\rangle$*,* I *has the corresponding invertibility property in* $\mathcal{A}$*.*

Proof: If I has an invertibility property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same invertibility property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota\rangle\rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I},\mathcal{F}}\rangle = \mathcal{I}$, we conclude that $I^\flat$ has the corresponding invertibility property in $\mathcal{I}$.

Suppose, conversely, that $I^\flat$ has an invertibility property in $\mathcal{I}$, with witnessing set of natural transformations $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ in $N^\flat$. We look at each of the four properties in turn.

(a) Suppose $I^\flat$ has the global family invertibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. We then have

$$\begin{array}{lll}\alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \text{iff} & \overleftrightarrow{I^\flat}_\Sigma[\tau_\Sigma(\phi)] \le \alpha^{-1}(T) \\ & \text{iff} & \overleftrightarrow{I}_{F(\Sigma)}[\alpha_\Sigma(\tau_\Sigma(\phi))] \le T \\ & \text{iff} & \overleftrightarrow{I}_{F(\Sigma)}[\tau_{F(\Sigma)}(\alpha_\Sigma(\phi))] \le T.\end{array}$$

Taking into account the surjetivity of $\langle F, \alpha \rangle$, we conclude that I has the global family invertibility in $\mathcal{A}$.

(b) The global system invertibility follows analogously, taking into account the fact that if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

(c) Suppose $I^\flat$ has the local family invertibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathrm{SEN}, N \rangle$, be an $\mathbf{F}$-algebraic system, $T \in \mathrm{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi \in \mathrm{SEN}^\flat(\Sigma)$. Then we have

$$\begin{array}{lll}\alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \text{iff} & \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \text{iff} & \overleftrightarrow{I^\flat}_\Sigma(\tau_\Sigma(\phi), \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}), \\ & & \qquad \text{for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma), \\ & \text{iff} & \alpha_\Sigma(\overleftrightarrow{I^\flat}_\Sigma(\tau_\Sigma(\phi), \vec{\xi})) \subseteq T_{F(\Sigma)}, \\ & & \qquad \text{for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma), \\ & \text{iff} & \overleftrightarrow{I}_{F(\Sigma)}(\tau_{F(\Sigma)}(\alpha_\Sigma(\phi)), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}, \\ & & \qquad \text{for all } \vec{\xi} \in \mathrm{SEN}^\flat(\Sigma),\end{array}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that I has the local family invertibility in $\mathcal{A}$.

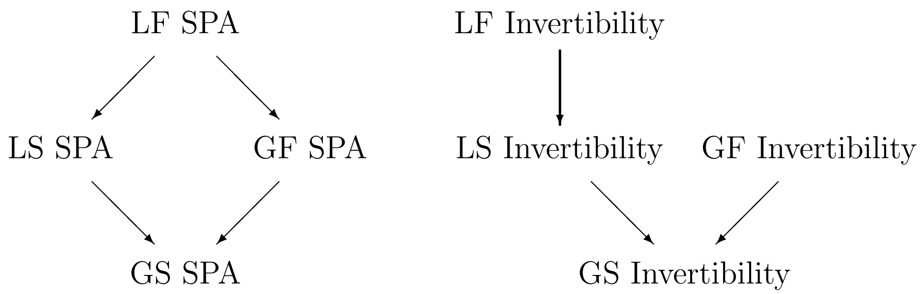
(d) The local system invertibility follows along the same lines, taking again into account the fact that if $T \in \mathrm{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \mathrm{ThSys}(\mathcal{I})$.

■

10.13 Syntactic Algebraizability

In this section we focus on the four **uniform syntactic protoalgebraicity properties**, i.e., on LF SPA, LS SPA and GF SPA and GS SPA, and we add to those versions of the invertibility property to obtain several versions of the syntactic algebraizability property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown on the left below.



Moreover, by our study of invertibility, we know that the various versions of invertibility fall into the hierarchy shown on the right of the diagram.

By combining syntactic protoalgebraicity with invertibility properties, we obtain sixteen syntactic algebraizability properties as follows. Let $X, Y \in \{\mathrm{LF}, \mathrm{LS}, \mathrm{GF}, \mathrm{GS}\}$, where LF stands for "Local Family", LS stands for "Local System", GF stands for "Global Family" and GS stands for "Global System".

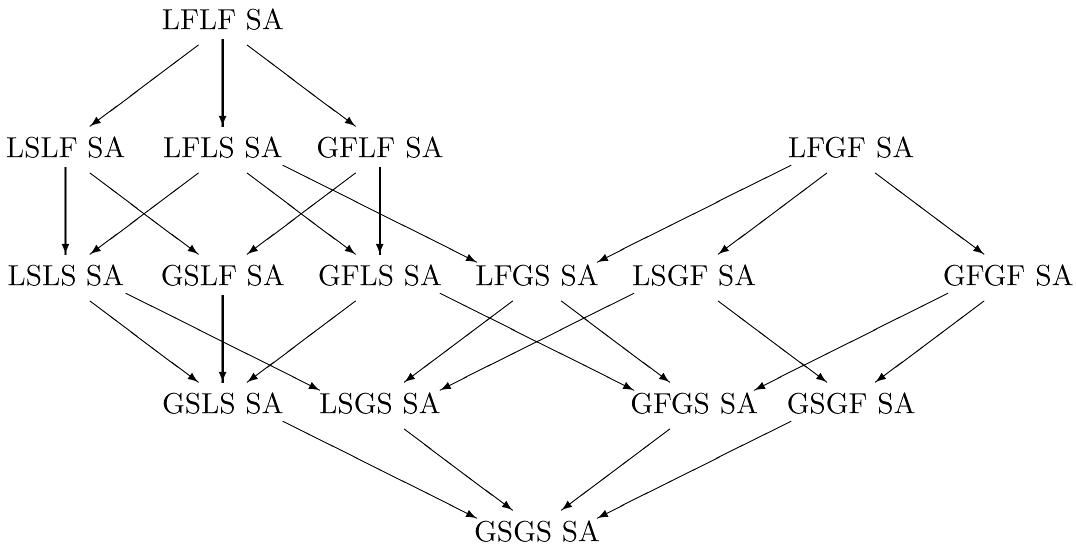
Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π-institution based on $\mathbf{F}$ and $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ a set of natural transformations in $N^\flat$, with two distinguished arguments. We say that $I^\flat$ has the **XY syntactic algebraizability in** $\mathcal{I}$ (**XY SA in** $\mathcal{I}$) if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y invertibility in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and invertibility properties, we obtain the following hierarchical structure for the various flavors of the syntactic algebraizability property.

Corollary 737 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments. The sixteen syntactic algebraizability properties form the hierarchy shown on the accompanying diagram.*

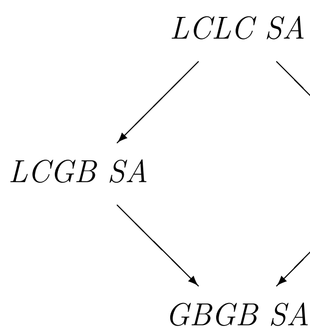
Proof: This follows directly from Corollary 726 and Proposition 731. ∎



Based on the analysis performed on SPA and Invertibility, we have the following result regarding sufficient conditions under which some of the sixteen syntactic algebraizability properties coincide.

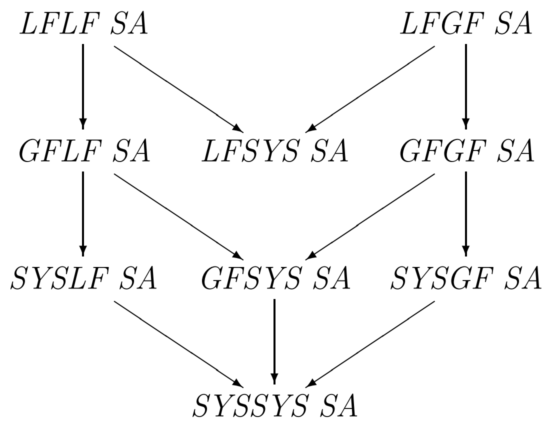
Corollary 738 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be an algebraic system,* $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be a* π*-institution based on* $\mathbf{F}$ *and* $I^\flat : (\mathrm{SEN}^\flat)^\omega \to \mathrm{SEN}^\flat$ *a set of natural transformations in* $N^\flat$ *having two distinguished arguments.*

(a) If $\mathcal{I}$ *is systemic, then the syntactic algebraizability hierarchy collapses to the one depicted below;*



(b) If $I^\flat$ *has only two arguments (i.e., is parameter free), then the syntactic algebraizability hierarchy collapses to the one depicted below, where the system versions of both the SPA and the invertibility properties are*

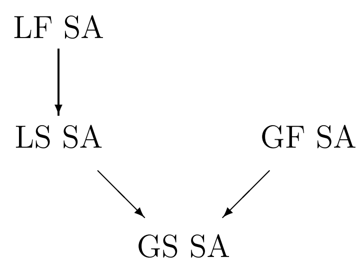
grouped together under the label SYS.



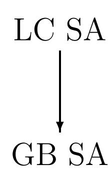
Proof: The statement follows from Corollary 727 and Proposition 732. ■

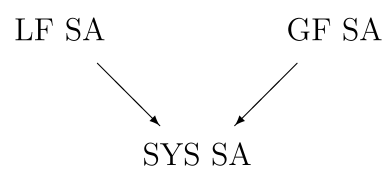
For a systemic π-institution with a parameter-free set of natural transformations, there is only one syntactic protoalgebraicity property, since all versions of syntactic protoalgebraicity and all versions of invertibility collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, on the uniformly defined classes. So we define **LF SA**, **LS SA**, **GF SA** and **GS SA** to mean, respectively, LFLF syntactic, LSLS syntactic, GFGF syntactic and GSGS syntactic algebraizability. These classes form the subhierarchy depicted below.



Moreover, according to Corollary 738, this reduces to the hierarchy depicted on the left below for a systemic π-institution and to the one depicted on the right below for a parameter free set of natural transformations.





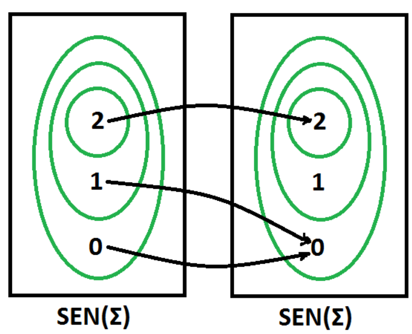
We provide examples to show that the inclusions between the four uniform classes of the syntactic algebraizability hierarchy are proper in general.

First, we present an example to show that there exists a π-institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic algebraizability, but not the LF syntactic algebraizability in $\mathcal{I}$.

Example 739 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat \rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with a single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = f$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 0$*,* $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by*
  - *a unary natural transformation* $\lambda^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\lambda^\flat_\Sigma : \{0,1,2\} \to \{0,1,2\}$ *be given by* $\lambda^\flat_\Sigma(x) = 2$*, for all* $x \in \{0,1,2\}$*;*
  - *a binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 1, & \text{if } \{x,y\} = \{1,2\} \\ 0, & \text{otherwise} \end{cases}$$



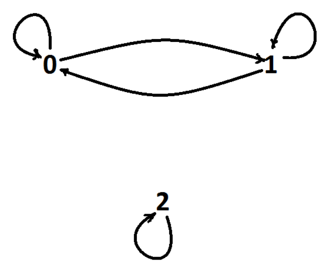
Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{1,2\},\{0,1,2\}\}.$$

Note that there are three theory families, but only $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$ *are theory systems. So* $\mathcal{I}$ *is not systemic.*

Consider the set $I^\flat = \{\sigma^\flat\}$*, with* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *having two distinguished arguments. We show that* $I^\flat$ *has the local system syntactic algebraizability in* $\mathcal{I}$*, but it does not have the local family syntactic algebraizability in* $\mathcal{I}$*.*

First, we look at local system equivalence. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$*. For the theory system* $\mathrm{Thm}(\mathcal{I})$*, it suffices to observe that the elements*



of $\mathrm{SEN}^\flat(\Sigma)$ *are related in local system equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *as shown in the diagram. Therefore,* $I^\flat$ *has the local system equivalence in* $\mathcal{I}$.

Next, observe that, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$*, the pairs* $(\sigma^\flat_\Sigma(\phi,0),\sigma^\flat_\Sigma(\phi,1))$, $(\sigma^\flat_\Sigma(0,\phi),\sigma^\flat_\Sigma(1,\phi))$ *and* $(\lambda^\flat_\Sigma(0),\lambda^\flat_\Sigma(1))$ *are related via* $I^\flat$ *modulo* $\mathrm{Thm}(\mathcal{I})$. *Thus,* $I^\flat$ *has the local system congruence in* $\mathcal{I}$.

Next, note that, since the only pairs (ϕ,ψ)*, with* $\phi \neq \psi$*, such that* $\sigma^\flat_\Sigma(\phi,\psi) \in \mathrm{Thm}_\Sigma(\mathcal{I})$ *are* $(0,1)$ *and* $(1,0)$ *and for neither of these is* $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I})$, $I^\flat$ *has the local system modus ponens in* $\mathcal{I}$.

Finally, consider the set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of natural transformations in* $N^\flat$*, given by* $\tau = \{\iota \approx \lambda^\flat\}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity natural transformation. Since, for every* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*, we have*

$$\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad \overleftrightarrow{I}_\Sigma(\phi,\lambda^\flat_\Sigma(\phi)) \subseteq \mathrm{Thm}_\Sigma(\mathcal{I}),$$

we also get that $I^\flat$ *has the local system invertibility in* $\mathcal{I}$ *and, therefore, we conclude that* $I^\flat$ *has the local system algebraizability in* $\mathcal{I}$.

On the other hand, $1 \in \{1,2\}$ *and* $\sigma^\flat_\Sigma(1,0) = 2 \in \{1,2\}$*, but* $0 \notin \{1,2\}$. *Therefore,* $I^\flat$ *does not have the local family modus ponens in* $\mathcal{I}$ *and, hence, a fortiori, it does not have the local family syntactic algebraizability in* $\mathcal{I}$.

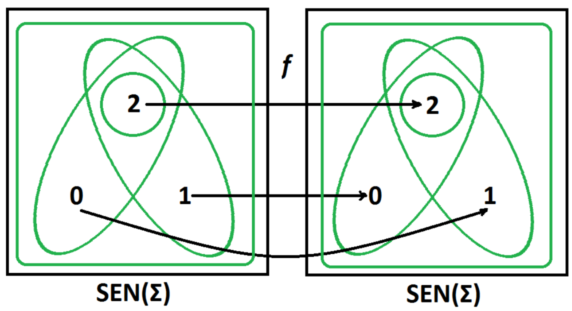
Next, we present an example to show that there is π-institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic algebraizability but not the GF syntactic algebraizability in $\mathcal{I}$.

Example 740 *Let* $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathrm{SEN}^\flat, N^\flat\rangle$ *be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ *is the category with single object* Σ *and a single (non-identity) morphism* $f : \Sigma \to \Sigma$*, such that* $f \circ f = i_\Sigma$*;*
- $\mathrm{SEN}^\flat : \mathbf{Sign}^\flat \to \mathbf{Set}$ *is specified by* $\mathrm{SEN}^\flat(\Sigma) = \{0,1,2\}$ *and* $\mathrm{SEN}^\flat(f) : \{0,1,2\} \to \{0,1,2\}$ *given by* $0 \mapsto 1$, $1 \mapsto 0$ *and* $2 \mapsto 2$*;*
- $N^\flat$ *is the category of natural transformations generated by*
  - *a unary natural transformation* $\lambda^\flat : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *defined by letting* $\lambda^\flat_\Sigma : \{0,1,2\} \to \{0,1,2\}$ *be given by* $\lambda^\flat_\Sigma(x) = 2$*, for all* $x \in \{0,1,2\}$*;*

– *a single binary natural transformation* $\sigma^\flat : (\mathrm{SEN}^\flat)^2 \to \mathrm{SEN}^\flat$ *defined by letting* $\sigma^\flat_\Sigma : \{0,1,2\}^2 \to \{0,1,2\}$ *be given by*

$$\sigma^\flat_\Sigma(x,y,z) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x,y\} = \{0,1\} \\ 1, & \text{if } (x,y) = (0,2) \text{ or } (x,y) = (2,0) \\ 0, & \text{if } (x,y) = (1,2) \text{ or } (x,y) = (2,1) \end{cases}.$$



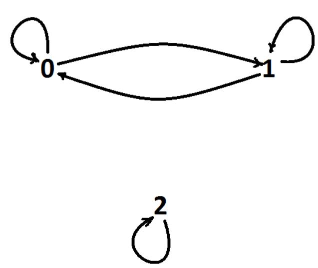
Let $\mathcal{I} = \langle \mathbf{F}, C\rangle$ *be the* π*-institution determined by*

$$\mathcal{C}_\Sigma = \{\{2\},\{0,2\},\{1,2\},\{0,1,2\}\}.$$

$\mathcal{I}$ *has four theory families* $\mathrm{Thm}(\mathcal{I})$, $T = \{\{0,2\}\}$, $T' = \{\{1,2\}\}$ *and* $\mathrm{SEN}^\flat$, *but only two theory systems* $\mathrm{Thm}(\mathcal{I})$ *and* $\mathrm{SEN}^\flat$. *In particular,* $\mathcal{I}$ *is not systemic.*

Consider the set $I^\flat = \{\sigma^\flat\}$, *with* $\sigma^\flat$ *having both arguments distinguished. We show that* $I^\flat$ *has the global system syntactic algebraizability in* $\mathcal{I}$, *but it does not have the global family syntactic algebraizability in* $\mathcal{I}$.

First, we look at global system equivalence. The defining conditions for reflexivity, symmetry and transitivity of $I^\flat$ *in* $\mathcal{I}$ *are all trivially satisfied for* $\mathrm{SEN}^\flat$. *For the theory system* $\mathrm{Thm}(\mathcal{I})$, *it suffices to observe that the elements of* $\mathrm{SEN}^\flat(\Sigma)$ *are related in global system equivalence modulo* $\mathrm{Thm}(\mathcal{I})$ *as shown in the diagram. Therefore,* $I^\flat$ *has the global system equivalence in* $\mathcal{I}$.



Next, observe that, for all $\phi \in \mathrm{SEN}^\flat(\Sigma)$, *the pairs* $(\sigma^\flat_\Sigma(\phi,0), \sigma^\flat_\Sigma(\phi,1))$, $(\sigma^\flat_\Sigma(0,\phi), \sigma^\flat_\Sigma(1,\phi))$ *and* $(\lambda^\flat_\Sigma(0), \lambda^\flat_\Sigma(1))$ *are related via* $I^\flat$ *modulo* $\mathrm{Thm}(\mathcal{I})$. *Thus,* $I^\flat$ *has the global system congruence in* $\mathcal{I}$.

Next, note that, since the only pairs (ϕ,ψ)*, with* $\phi \neq \psi$*, such that* $\sigma^\flat_\Sigma[\phi,\psi] \leq \mathrm{Thm}(\mathcal{I})$ *are* $(0,1)$ *and* $(1,0)$ *and for neither of these is* $\phi \in \mathrm{Thm}_\Sigma(\mathcal{I})$*,* $I^\flat$ *has the global system modus ponens in* $\mathcal{I}$*.*

Finally, consider the set $\tau : \mathrm{SEN}^\flat \to (\mathrm{SEN}^\flat)^2$ *of natural transformations in* $N^\flat$*, given by* $\tau = \{\iota \approx \lambda^\flat\}$*, where* $\iota : \mathrm{SEN}^\flat \to \mathrm{SEN}^\flat$ *is the identity natural transformation. Since, for every* $\phi \in \mathrm{SEN}^\flat(\Sigma)$*, we have*

$$\phi \in \mathrm{Thm}_\Sigma(\mathcal{I}) \quad \textit{iff} \quad \overleftrightarrow{I}_\Sigma[\phi, \lambda^\flat_\Sigma(\phi)] \leq \mathrm{Thm}(\mathcal{I}),$$
